    Response was too big to send within one response packet.

enumerator EC_HOST_CMD_BUS_ERROR = 15
    Error on underlying communication bus.

enumerator EC_HOST_CMD_BUSY = 16
    System busy. Should retry later.

enumerator EC_HOST_CMD_INVALID_HEADER_VERSION = 17
    Header version invalid.

enumerator EC_HOST_CMD_INVALID_HEADER_CRC = 18
    Header CRC invalid.

enumerator EC_HOST_CMD_INVALID_DATA_CRC = 19
    Data CRC invalid.

enumerator EC_HOST_CMD_DUP_UNAVAILABLE = 20
    Can't resend response.

enumerator EC_HOST_CMD_MAX = UINT16_MAX

struct ec_host_cmd_handler_args
    #include <ec_host_cmd.h> Arguments passed into every installed host command handler.

Public Members

void *reserved
    Reserved for compatibility.

uint16_t command
    Command identifier.

const uint8_t version
    The version of the host command that is being requested. This will be a value that has
    been static registered as valid for the handler.
const void *const input_buf
The incoming data that can be cast to the handlers request type.

const uint16_t input_buf_size
The number of valid bytes that can be read from input_buf.

void *const output_buf
The data written to this buffer will be send to the host.

uint16_t output_buf_max
Maximum number of bytes that can be written to the output_buf.

uint16_t output_buf_size
Number of bytes of output_buf to send to the host.

struct ec_host_cmd_handler
#include <ec_host_cmd.h> Structure use for statically registering host command handlers.

Public Members

ec_host_cmd_handler_cb handler
Callback routine to process commands that match id.

uint16_t id
The numerical command id used as the lookup for commands.

uint16_t version_mask
The bitfield of all versions that the handler supports, where each bit value represents that
the handler supports that version. E.g. BIT(0) corresponds to version 0.

uint16_t min_rqt_size
The minimum input_buf_size enforced by the framework before passing to the handler.

uint16_t min_rsp_size
The minimum output_buf_size enforced by the framework before passing to the handler.

struct ec_host_cmd_request_header
#include <ec_host_cmd.h> Header for requests from host to embedded controller.
Represent the over-the-wire header in LE format for host command requests. This represent
version 3 of the host command header. The requests are always sent from host to embedded
controller.

Public Members

uint8_t prtcl_ver
Should be 3. The EC will return EC_HOST_CMD_INVALID_HEADER if it receives a header
with a version it doesn't know how to parse.
uint8_t checksum
    Checksum of response and data; sum of all bytes including checksum. Should total to 0.

uint16_t cmd_id
    Id of command that is being sent.

uint8_t cmd_ver
    Version of the specific cmd_id being requested. Valid versions start at 0.

uint8_t reserved
    Unused byte in current protocol version; set to 0.

uint16_t data_len
    Length of data which follows this header.

struct ec_host_cmd_response_header
    #include <ec_host_cmd.h> Header for responses from embedded controller to host.
    Represent the over-the-wire header in LE format for host command responses. This represent
    version 3 of the host command header. Responses are always sent from embedded controller
    to host.

Public Members

uint8_t prtcl_ver
    Should be 3.

uint8_t checksum
    Checksum of response and data; sum of all bytes including checksum. Should total to 0.

uint16_t result
    An ec_host_cmd_status response code for specific command.

uint16_t data_len
    Length of data which follows this header.

uint16_t reserved
    Unused bytes in current protocol version; set to 0.

7.3.11 Error Detection And Correction (EDAC)

API Reference

group edac
Enums

enum edac_error_type

EDAC error type.

Values:

enumerator EDAC_ERROR_TYPE_DRAM_COR = BIT(0)

Correctable error type

enumerator EDAC_ERROR_TYPE_DRAM_UC = BIT(1)

Uncorrectable error type

Functions

static inline int edac_inject_set_param1(const struct device *dev, uint64_t value)

Set injection parameter param1.

Set first error injection parameter value.

Parameters

• dev – Pointer to the device structure
• value – First injection parameter

Return values

• -ENOSYS – if the optional interface is not implemented
• 0 – on success, other error code otherwise

static inline int edac_inject_get_param1(const struct device *dev, uint64_t *value)

Get injection parameter param1.

Get first error injection parameter value.

Parameters

• dev – Pointer to the device structure
• value – Pointer to the first injection parameter

Return values

• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_inject_set_param2(const struct device *dev, uint64_t value)

Set injection parameter param2.

Set second error injection parameter value.

Parameters

• dev – Pointer to the device structure
• value – Second injection parameter

Return values

• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise
static inline int edac_inject_get_param2(const struct device *dev, uint64_t *value)
Get injection parameter param2.

Parameters
• dev – Pointer to the device structure
• value – Pointer to the second injection parameter

Return values
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_inject_set_error_type(const struct device *dev, uint32_t error_type)
Set error type value.

Set the value of error type to be injected

Parameters
• dev – Pointer to the device structure
• error_type – Error type value

Return values
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_inject_get_error_type(const struct device *dev, uint32_t *error_type)
Get error type value.

Get the value of error type to be injected

Parameters
• dev – Pointer to the device structure
• error_type – Pointer to error type value

Return values
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_inject_error_trigger(const struct device *dev)
Set injection control.

Trigger error injection.

Parameters
• dev – Pointer to the device structure

Return values
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_ecc_error_log_get(const struct device *dev, uint64_t *value)
Get ECC Error Log.

Read value of ECC Error Log.

Parameters
• dev – Pointer to the device structure
• value – Pointer to the ECC Error Log value
Return values

- 0 – on success, error code otherwise
- -ENOSYS – if the mandatory interface is not implemented

static inline int edac_ecc_error_log_clear(const struct device *dev)
Clear ECC Error Log.

Parameters

- dev – Pointer to the device structure

Return values

- 0 – on success, error code otherwise
- -ENOSYS – if the mandatory interface is not implemented

Get Parity Error Log.

Parameters

- dev – Pointer to the device structure
- value – Pointer to the parity Error Log value

Return values

- 0 – on success, error code otherwise
- -ENOSYS – if the mandatory interface is not implemented

Clear Parity Error Log.

Parameters

- dev – Pointer to the device structure

Get number of correctable errors.

Parameters

- dev – Pointer to the device structure

Return values

- num – Number of correctable errors
- -ENOSYS – if the mandatory interface is not implemented

Get number of uncorrectable errors.

Parameters

- dev – Pointer to the device structure

Return values
- **num** – Number of uncorrectable errors
- `-ENOSYS` – if the mandatory interface is not implemented

```c
static inline int edac_notify_callback_set(const struct device *dev, edac_notify_callback_f cb)
```

Register callback function for memory error exception

This callback runs in interrupt context

**Parameters**

- **dev** – EDAC driver device to install callback
- **cb** – Callback function pointer

**Return values**

- 0 – on success, error code otherwise
- `-ENOSYS` – if the mandatory interface is not implemented

```c
struct edac_driver_api
#include <edac.h> EDAC driver API.
```

This is the mandatory API any EDAC driver needs to expose.

### 7.3.12 EEPROM

**Overview**

The EEPROM API provides read and write access to Electrically Erasable Programmable Read-Only Memory (EEPROM) devices.

EEPROMs have an erase block size of 1 byte, a long lifetime, and allow overwriting data on byte-by-byte access.

**Configuration Options**

Related configuration options:

- `CONFIG_EEPROM`

**API Reference**

```c
typedef int (*eeprom_api_read)(const struct device *dev, off_t offset, void *data, size_t len)
```

```c
typedef int (*eeprom_api_write)(const struct device *dev, off_t offset, const void *data, size_t len)
```

```c
typedef size_t (*eeprom_api_size)(const struct device *dev)
```
Functions

int eeprom_read(const struct device *dev, off_t offset, void *data, size_t len)
Read data from EEPROM.

Parameters
• dev – EEPROM device
• offset – Address offset to read from.
• data – Buffer to store read data.
• len – Number of bytes to read.

Returns
0 on success, negative errno code on failure.

int eeprom_write(const struct device *dev, off_t offset, const void *data, size_t len)
Write data to EEPROM.

Parameters
• dev – EEPROM device
• offset – Address offset to write data to.
• data – Buffer with data to write.
• len – Number of bytes to write.

Returns
0 on success, negative errno code on failure.

size_t eeprom_get_size(const struct device *dev)
Get the size of the EEPROM in bytes.

Parameters
• dev – EEPROM device.

Returns
EEPROM size in bytes.

 struct eeprom_driver_api
    #include <eeprom.h>

7.3.13 Entropy

Overview

The entropy API provides functions to retrieve entropy values from entropy hardware present on the platform. The entropy APIs are provided for use by the random subsystem and cryptographic services. They are not suitable to be used as random number generation functions.

API Reference

group entropy_interface
    Entropy Interface.
Defines

ENTROPY_BUSYWAIT

typedef int (*entropy_get_entropy_t)(const struct device *dev, uint8_t *buffer, uint16_t length)
    Callback API to get entropy.
    See entropy_get_entropy() for argument description

typedef int (*entropy_get_entropy_isr_t)(const struct device *dev, uint8_t *buffer, uint16_t length, uint32_t flags)
    Callback API to get entropy from an ISR.
    See entropy_get_entropy_isr() for argument description

Functions

int entropy_get_entropy(const struct device *dev, uint8_t *buffer, uint16_t length)
    Fills a buffer with entropy. Blocks if required in order to generate the necessary random data.
    Parameters
    • dev – Pointer to the entropy device.
    • buffer – Buffer to fill with entropy.
    • length – Buffer length.
    Return values
    • 0 – on success.
    • -ERRNO – errno code on error.

static inline int entropy_get_entropy_isr(const struct device *dev, uint8_t *buffer, uint16_t length, uint32_t flags)
    Fills a buffer with entropy in a non-blocking or busy-wait manner. Callable from ISRs.
    Parameters
    • dev – Pointer to the device structure.
    • buffer – Buffer to fill with entropy.
    • length – Buffer length.
    • flags – Flags to modify the behavior of the call.
    Return values
    • number – of bytes filled with entropy or -error.

#include <entropy.h>
7.3.14 Flash

Overview

Flash offset concept

Offsets used by the user API are expressed in relation to the flash memory beginning address. This rule shall be applied to all flash controller regular memory that layout is accessible via API for retrieving the layout of pages (see `CONFIG_FLASH_PAGE_LAYOUT`).

An exception from the rule may be applied to a vendor-specific flash dedicated-purpose region (such a region obviously can’t be covered under API for retrieving the layout of pages).

User API Reference

`group flash_interface`

FLASH Interface.

**Typedefs**

```c
typedef bool (*flash_page_cb)(const struct flash_pages_info *info, void *data)
```

Callback type for iterating over flash pages present on a device.

The callback should return true to continue iterating, and false to halt.

**See also:**

`flash_page_foreach()`

**Param info**

Information for current page

**Param data**

Private data for callback

**Return**

True to continue iteration, false to halt iteration.

**Functions**

```c
int flash_read(const struct device *dev, off_t offset, void *data, size_t len)
```

Read data from flash.

All flash drivers support reads without alignment restrictions on the read offset, the read size, or the destination address.

**Parameters**

- `dev` – flash dev
- `offset` – Offset (byte aligned) to read
- `data` – Buffer to store read data
- `len` – Number of bytes to read.

**Returns**

0 on success, negative errno code on fail.
int flash_write(const struct device *dev, off_t offset, const void *data, size_t len)
  Write buffer into flash memory.

All flash drivers support a source buffer located either in RAM or SoC flash, without alignment restrictions on the source address. Write size and offset must be multiples of the minimum write block size supported by the driver.

Any necessary write protection management is performed by the driver write implementation itself.

Parameters

- dev – : flash device
- offset – : starting offset for the write
- data – : data to write
- len – : Number of bytes to write

Returns
0 on success, negative errno code on fail.

int flash_erase(const struct device *dev, off_t offset, size_t size)
  Erase part or all of a flash memory.

Acceptable values of erase size and offset are subject to hardware-specific multiples of page size and offset. Please check the API implemented by the underlying sub driver, for example by using flash_get_page_info_by_offs() if that is supported by your flash driver.

Any necessary erase protection management is performed by the driver erase implementation itself.

See also:
flash_get_page_info_by_offs()

See also:
flash_get_page_info_by_idx()

Parameters

- dev – : flash device
- offset – : erase area starting offset
- size – : size of area to be erased

Returns
0 on success, negative errno code on fail.

int flash_get_page_info_by_offs(const struct device *dev, off_t offset, struct flash_pages_info *info)
  Get the size and start offset of flash page at certain flash offset.

Parameters

- dev – flash device
- offset – Offset within the page
- info – Page Info structure to be filled

Returns
0 on success, -EINVAL if page of the offset doesn't exist.
Get the size and start offset of flash page of certain index.

**Parameters**
- `dev` – flash device
- `page_index` – Index of the page. Index are counted from 0.
- `info` – Page Info structure to be filled

**Returns**
- 0 on success, -EINVAL if page of the index doesn’t exist.

Get the total number of flash pages.

**Parameters**
- `dev` – flash device

**Returns**
- Number of flash pages.

Iterate over all flash pages on a device.

**Parameters**
- `dev` – Device whose pages to iterate over
- `cb` – Callback to invoke for each flash page
- `data` – Private data for callback function

Read data from Serial Flash Discoverable Parameters.

**Parameters**
- `dev` – device from which parameters will be read
- `offset` – address within the SFDP region containing data of interest
- `data` – where the data to be read will be placed
- `len` – the number of bytes of data to be read

**Return values**
- 0 – on success
- -ENOTSUP – if the flash driver does not support SFDP access
- negative – values for other errors.

Read the JEDEC ID from a compatible flash device.

**Parameters**
• dev – device from which id will be read
• id – pointer to a buffer of at least 3 bytes into which id will be stored

Return values
• 0 – on successful store of 3-byte JEDEC id
• -ENOTSUP – if flash driver doesn’t support this function
• negative – values for other errors

size_t flash_get_write_block_size(const struct device *dev)
Get the minimum write block size supported by the driver.

The write block size supported by the driver might differ from the write block size of memory used because the driver might implements write-modify algorithm.

Parameters
• dev – flash device

Returns
write block size in bytes.

const struct flash_parameters *flash_get_parameters(const struct device *dev)
Get pointer to flash_parameters structure.

Returned pointer points to a structure that should be considered constant through a runtime, regardless if it is defined in RAM or Flash. Developer is free to cache the structure pointer or copy its contents.

Returns
pointer to flash_parameters structure characteristic for the device.

struct flash_parameters

#include <flash.h> Flash memory parameters. Contents of this structure suppose to be filled in during flash device initialization and stay constant through a runtime.

struct flash_pages_info

#include <flash.h>

Implementation interface API Reference

group flash_internal_interface
FLASH internal Interface.

Typedefs

typedef int (*flash_api_read)(const struct device *dev, off_t offset, void *data, size_t len)

typedef int (*flash_api_write)(const struct device *dev, off_t offset, const void *data, size_t len)
Flash write implementation handler type.

Note: Any necessary write protection management must be performed by the driver, with the driver responsible for ensuring the “write-protect” after the operation completes (successfully or not) matches the write-protect state when the operation was started.
typedef int (*flash_api_erase)(const struct device *dev, off_t offset, size_t size)

Flash erase implementation handler type.

**Note:** Any necessary erase protection management must be performed by the driver, with the driver responsible for ensuring the “erase-protect” after the operation completes (successfully or not) matches the erase-protect state when the operation was started.

typedef const struct flash_parameters *(*flash_api_get_parameters)(const struct device *dev)

typedef void (*flash_api_pages_layout)(const struct device *dev, const struct flash_pages_layout **layout, size_t *layout_size)

Retrieve a flash device's layout.

A flash device layout is a run-length encoded description of the pages on the device. (Here, “page” means the smallest erasable area on the flash device.)

For flash memories which have uniform page sizes, this routine returns an array of length 1, which specifies the page size and number of pages in the memory.

Layouts for flash memories with nonuniform page sizes will be returned as an array with multiple elements, each of which describes a group of pages that all have the same size. In this case, the sequence of array elements specifies the order in which these groups occur on the device.

**Param dev**
Flash device whose layout to retrieve.

**Param layout**
The flash layout will be returned in this argument.

**Param layout_size**
The number of elements in the returned layout.

typedef int (*flash_api_sfdp_read)(const struct device *dev, off_t offset, void *data, size_t len)

typedef int (*flash_api_read_jedec_id)(const struct device *dev, uint8_t *id)

7.3.15 Fuel Gauges (Experimental API Stub Doc)

The fuel gauge subsystem exposes an API to uniformly access battery fuel gauge devices. Currently, only reading data is supported.

**Note:** This API is currently experimental and this doc will be significantly changed as new features are added to the API.
Basic Operation

Properties  Fundamentally, a property is a quantity that a fuel gauge device can measure.

Fuel gauges typically support multiple properties, such as temperature readings of the battery-pack or present-time current/voltage.

Properties are fetched using a client allocated array of `fuel_gauge_get_property`. This array is then populated by values as according to its `property_type` field.

Caching  The Fuel Gauge API explicitly provides no caching for its clients.

API Reference

group fuel_gauge_interface

Fuel Gauge Interface.

Defines

FUEL_GAUGE_AVG_CURRENT

Runtime Dynamic Battery Parameters Provide a 1 minute average of the current on the battery. Does not check for flags or whether those values are bad readings. See driver instance header for details on implementation and how the average is calculated. Units in uA negative=discharging

FUEL_GAUGE_CURRENT

Battery current (uA); negative=discharging

FUEL_GAUGE_CHARGE_CUTOFF

Whether the battery underlying the fuel-gauge is cut off from charge

FUEL_GAUGE_CYCLE_COUNT

Cycle count in 1/100ths (number of charge/discharge cycles)

FUEL_GAUGE_CONNECT_STATE

Connect state of battery

FUEL_GAUGE_FLAGS

General Error/Runtime Flags

FUEL_GAUGE_FULL_CHARGE_CAPACITY

Full Charge Capacity in uAh (might change in some implementations to determine wear)

FUEL_GAUGE_PRESENT_STATE

Is the battery physically present

FUEL_GAUGE_REMAINING_CAPACITY

Remaining capacity in uAh
FUEL_GAUGE_RUNTIME_TO_EMPTY
Remaining battery life time in minutes

FUEL_GAUGE_RUNTIME_TO_FULL
Remaining time in minutes until battery reaches full charge

FUEL_GAUGE_STATE_OF_CHARGE
Absolute state of charge (percent, 0-100) - expressed as % of design capacity

FUEL_GAUGE_TEMPERATURE
Temperature in 0.1 K

FUEL_GAUGE_VOLTAGE
Battery voltage (uV)

FUEL_GAUGE_COMMON_COUNT
Reserved to demark end of common fuel gauge properties

FUEL_GAUGE_CUSTOM_BEGIN
Reserved to demark downstream custom properties - use this value as the actual value may change over future versions of this API

FUEL_GAUGE_PROP_MAX
Reserved to demark end of valid enum properties

**Typedefs**

typedef int (*fuel_gauge_get_property_t)(const struct device *dev, struct fuel_gauge_get_property *props, size_t props_len)
Fetch a battery fuel-gauge property.

**Param dev**
Pointer to the battery fuel-gauge device

**Param props**
pointer to array of fuel_gauge_get_property struct where the property struct field is set by the caller to determine what property is read from the fuel gauge device into the fuel_gauge_get_property struct's value field.

**Param props_len**
number of properties in props array

**Return**
return=0 if successful, return < 0 if getting all properties failed, return > 0 if some properties failed where return=number of failing properties.

```c
#include <fuel_gauge.h>
```

**Public Members**

7.3. Peripherals
```c
#include <fuel_gauge.h>

union fuel_gauge_get_property.

struct battery_driver_api
    
#include <fuel_gauge.h>
```
7.3.16  GNA

Overview

The GNA API provides access to Intel's Gaussian Mixture Model and Neural Network Accelerator (GNA).

Configuration Options

Related configuration options:

* CONFIG_INTEL_GNA

API Reference

* group gna_interface

This file contains the driver APIs for Intel’s Gaussian Mixture Model and Neural Network Accelerator (GNA)

** Enums **

enum gna_result

Result of an inference operation

* Values: *

enumerator GNA_RESULT_INSTANCE_ERROR

enumerator GNA_RESULT_INFERENCE_COMPLETE

enumerator GNA_RESULT_OUTPUT_BUFFER_FULL_ERROR

enumerator GNA_RESULT_PARAM_OUT_OF_RANGE_ERROR

enumerator GNA_RESULT_SATURATION_OCCURRED

enumerator GNA_RESULT_GENERIC_ERROR

** Functions **

static inline int gna_configure(const struct device *dev, struct gna_config *cfg)

Configure the GNA device.

Configure the GNA device. The GNA device must be configured before registering a model or performing inference

* Parameters *

  * dev – Pointer to the device structure for the driver instance.
  * cfg – Device configuration information

* Return values *

  * 0 – If the configuration is successful
  * A – negative error code in case of a failure.
static inline int gna_register_model(const struct device *dev, struct gna_model_info *model, void **model_handle)

Register a neural network model.

Register a neural network model with the GNA device. A model needs to be registered before it can be used to perform inference.

Parameters
- dev – Pointer to the device structure for the driver instance.
- model – Information about the neural network model
- model_handle – Handle to the registered model if registration succeeds

Return values
- 0 – If registration of the model is successful.
- A – negative error code in case of a failure.

static inline int gna_deregister_model(const struct device *dev, void *model)

De-register a previously registered neural network model.

De-register a previously registered neural network model from the GNA device. De-registration may be done to free up memory for registering another model. Once de-registered, the model can no longer be used to perform inference.

Parameters
- dev – Pointer to the device structure for the driver instance.
- model – Model handle output by gna_register_model API

Return values
- 0 – If de-registration of the model is successful.
- A – negative error code in case of a failure.

static inline int gna_infer(const struct device *dev, struct gna_inference_req *req, gna_callback callback)

Perform inference on a model with input vectors.

Make an inference request on a previously registered model with an input data vector. A callback is provided for notification of inference completion.

Parameters
- dev – Pointer to the device structure for the driver instance.
- req – Information required to perform inference on a neural network
- callback – A callback function to notify inference completion

Return values
- 0 – If the request is accepted
- A – negative error code in case of a failure.

struct gna_config

#include <gna.h> GNA driver configuration structure. Currently empty.

struct gna_model_header

#include <gna.h> GNA Neural Network model header. Describes the key parameters of the neural network model.
struct gna_model_info
#include <gna.h>  GNA Neural Network model information to be provided by application
during model registration

struct gna_inference_req
#include <gna.h>  Request to perform inference on the given neural network model

struct gna_inference_stats
#include <gna.h>  Statistics of the inference operation returned after completion

struct gna_inference_resp
#include <gna.h>  Structure containing a response to the inference request

### 7.3.17 GPIO

#### Overview

#### Configuration Options

Related configuration options:
- CONFIG_GPIO

#### API Reference

**group gpio_interface**

GPIO Driver APIs.

**GPIO input/output configuration flags**

**GPIO_INPUT**

Enables pin as input.

**GPIO_OUTPUT**

Enables pin as output, no change to the output state.

**GPIO_DISCONNECTED**

Disables pin for both input and output.

**GPIO_OUTPUT_LOW**

Configures GPIO pin as output and initializes it to a low state.

**GPIO_OUTPUT_HIGH**

Configures GPIO pin as output and initializes it to a high state.

**GPIO_OUTPUT_INACTIVE**

Configures GPIO pin as output and initializes it to a logic 0.
GPIO_OUTPUT_ACTIVE

Configures GPIO pin as output and initializes it to a logic 1.

GPIO interrupt configuration flags

The GPIO_INT_* flags are used to specify how input GPIO pins will trigger interrupts. The interrupts can be sensitive to pin physical or logical level. Interrupts sensitive to pin logical level take into account GPIO_ACTIVE_LOW flag. If a pin was configured as Active Low, physical level low will be considered as logical level 1 (an active state), physical level high will be considered as logical level 0 (an inactive state).

GPIO_INT_DISABLE

Disables GPIO pin interrupt.

GPIO_INT_EDGE_RISING

Configures GPIO interrupt to be triggered on pin rising edge and enables it.

GPIO_INT_EDGE_FALLING

Configures GPIO interrupt to be triggered on pin falling edge and enables it.

GPIO_INT_EDGE_BOTH

Configures GPIO interrupt to be triggered on pin rising or falling edge and enables it.

GPIO_INT_LEVEL_LOW

Configures GPIO interrupt to be triggered on pin physical level low and enables it.

GPIO_INT_LEVEL_HIGH

Configures GPIO interrupt to be triggered on pin physical level high and enables it.

GPIO_INT_EDGE_TO_INACTIVE

Configures GPIO interrupt to be triggered on pin state change to logical level 0 and enables it.

GPIO_INT_EDGE_TO_ACTIVE

Configures GPIO interrupt to be triggered on pin state change to logical level 1 and enables it.

GPIO_INT_LEVEL_INACTIVE

Configures GPIO interrupt to be triggered on pin logical level 0 and enables it.

GPIO_INT_LEVEL_ACTIVE

Configures GPIO interrupt to be triggered on pin logical level 1 and enables it.

GPIO pin active level flags

GPIO_ACTIVE_LOW

GPIO pin is active (has logical value ‘1’) in low state.

GPIO_ACTIVE_HIGH

GPIO pin is active (has logical value ‘1’) in high state.
**GPIO pin drive flags**

**GPIO_OPEN_DRAIN**

Configures GPIO output in open drain mode (wired AND).

**Note:** ‘Open Drain’ mode also known as ‘Open Collector’ is an output configuration which behaves like a switch that is either connected to ground or disconnected.

**GPIO_OPEN_SOURCE**

Configures GPIO output in open source mode (wired OR).

**Note:** ‘Open Source’ is a term used by software engineers to describe output mode opposite to ‘Open Drain’. It behaves like a switch that is either connected to power supply or disconnected. There exist no corresponding hardware schematic and the term is generally unknown to hardware engineers.

**GPIO pin bias flags**

**GPIO_PULL_UP**

Enables GPIO pin pull-up.

**GPIO_PULL_DOWN**

Enable GPIO pin pull-down.

**Defines**

**GPIO_DT_SPEC_GET_BY_IDX(node_id, prop, idx)**

Static initializer for a `gpio_dt_spec`.

This returns a static initializer for a `gpio_dt_spec` structure given a devicetree node identifier, a property specifying a GPIO and an index.

Example devicetree fragment:

```plaintext
n: node {
    foo-gpios = <&gpio0 1 GPIO_ACTIVE_LOW>,
             <&gpio1 2 GPIO_ACTIVE_LOW>;
}
```

Example usage:

```c
const struct gpio_dt_spec spec = GPIO_DT_SPEC_GET_BY_IDX(DT_NODELABEL(n),
                                                      foo_gpios, 1);
// Initializes 'spec' to:
// {
//    .port = DEVICE_DT_GET(DT_NODELABEL(gpio1)),
//    .pin = 2,
//    .dt_flags = GPIO_ACTIVE_LOW
// }
```

7.3. Peripherals 2203
The ‘gpio’ field must still be checked for readiness, e.g. using \texttt{device\_is\_ready()}. It is an error to use this macro unless the node exists, has the given property, and that property specifies a GPIO controller, pin number, and flags as shown above.

**Parameters**
- \texttt{node\_id} – devicetree node identifier
- \texttt{prop} – lowercase-and-underscores property name
- \texttt{idx} – logical index into “prop”

**Returns**
static initializer for a struct \texttt{gpio\_dt\_spec} for the property

\texttt{GPI0\_DT\_SPEC\_GET\_BY\_IDX\_OR(node\_id, prop, idx, default\_value)}

Like \texttt{GPI0\_DT\_SPEC\_GET\_BY\_IDX()}, with a fallback to a default value.

If the devicetree node identifier ‘node\_id’ refers to a node with a property ‘prop’, this expands to \texttt{GPI0\_DT\_SPEC\_GET\_BY\_IDX(node\_id, prop, idx)}. The default\_value parameter is not expanded in this case.

Otherwise, this expands to default\_value.

**Parameters**
- \texttt{node\_id} – devicetree node identifier
- \texttt{prop} – lowercase-and-underscores property name
- \texttt{idx} – logical index into “prop”
- \texttt{default\_value} – fallback value to expand to

**Returns**
static initializer for a struct \texttt{gpio\_dt\_spec} for the property, or default\_value if the node or property do not exist

\texttt{GPI0\_DT\_SPEC\_GET(node\_id, prop)}

Equivalent to \texttt{GPI0\_DT\_SPEC\_GET\_BY\_IDX(node\_id, prop, 0)}.

**See also:**
\texttt{GPI0\_DT\_SPEC\_GET\_BY\_IDX()}

**Parameters**
- \texttt{node\_id} – devicetree node identifier
- \texttt{prop} – lowercase-and-underscores property name

**Returns**
static initializer for a struct \texttt{gpio\_dt\_spec} for the property

\texttt{GPI0\_DT\_SPEC\_GET\_OR(node\_id, prop, default\_value)}

Equivalent to \texttt{GPI0\_DT\_SPEC\_GET\_BY\_IDX\_OR(node\_id, prop, 0, default\_value)}.

**See also:**
\texttt{GPI0\_DT\_SPEC\_GET\_BY\_IDX\_OR()}

**Parameters**
- \texttt{node\_id} – devicetree node identifier
- \texttt{prop} – lowercase-and-underscores property name
• default_value – fallback value to expand to

Returns
static initializer for a struct gpio_dt_spec for the property

`GPIO_DT_SPEC_INST_GET_BY_IDX(inst, prop, idx)`
Static initializer for a gpio_dt_spec from a DT_DRV_COMPAT instance's GPIO property at an index.

See also:
`GPIO_DT_SPEC_GET_BY_IDX()`

Parameters
- inst – DT_DRV_COMPAT instance number
- prop – lowercase-and-underscores property name
- idx – logical index into “prop”

Returns
static initializer for a struct gpio_dt_spec for the property

`GPIO_DT_SPEC_INST_GET_BY_IDX_OR(inst, prop, idx, default_value)`
Static initializer for a gpio_dt_spec from a DT_DRV_COMPAT instance's GPIO property at an index, with fallback.

See also:
`GPIO_DT_SPEC_GET_BY_IDX()`

Parameters
- inst – DT_DRV_COMPAT instance number
- prop – lowercase-and-underscores property name
- idx – logical index into “prop”
- default_value – fallback value to expand to

Returns
static initializer for a struct gpio_dt_spec for the property

`GPIO_DT_SPEC_INST_GET(inst, prop)`
Equivalent to `GPIO_DT_SPEC_INST_GET_BY_IDX(inst, prop, 0)`.

See also:
`GPIO_DT_SPEC_INST_GET_BY_IDX()`

Parameters
- inst – DT_DRV_COMPAT instance number
- prop – lowercase-and-underscores property name

Returns
static initializer for a struct gpio_dt_spec for the property

**GPIO_DT_SPEC_INST_GET_OR**

```
inst, prop, default_value
```

Equivalent to **GPIO_DT_SPEC_INST_GET_BY_IDX_OR**

```
inst, prop, 0, default_value
```

See also:

**GPIO_DT_SPEC_INST_GET_BY_IDX()**

**Parameters**

- `inst` – DT_DRV_COMPAT instance number
- `prop` – lowercase-and-underscores property name
- `default_value` – fallback value to expand to

**Returns**

A static initializer for a struct `gpio_dt_spec` for the property

**GPIO_MAX_PINS_PER_PORT**

Maximum number of pins that are supported by `gpio_port_pins_t`.

**Typedefs**

```c
typedef uint32_t gpio_port_pins_t
```

Identifies a set of pins associated with a port.

The pin with index `n` is present in the set if and only if the bit identified by `(1U << n)` is set.

```c
typedef uint32_t gpio_port_value_t
```

Provides values for a set of pins associated with a port.

The value for a pin with index `n` is high (physical mode) or active (logical mode) if and only if the bit identified by `(1U << n)` is set. Otherwise the value for the pin is low (physical mode) or inactive (logical mode).

Values of this type are often paired with a `gpio_port_pins_t` value that specifies which encoded pin values are valid for the operation.

```c
typedef uint8_t gpio_pin_t
```

Provides a type to hold a GPIO pin index.

This reduced-size type is sufficient to record a pin number, e.g. from a devicetree GPIOS property.

```c
typedef uint16_t gpio_dt_flags_t
```

Provides a type to hold GPIO devicetree flags.

All GPIO flags that can be expressed in devicetree fit in the low 16 bits of the full flags field, so use a reduced-size type to record that part of a GPIOS property.

The lower 8 bits are used for standard flags. The upper 8 bits are reserved for SoC specific flags.

```c
typedef uint32_t gpio_flags_t
```

Provides a type to hold GPIO configuration flags.

This type is sufficient to hold all flags used to control GPIO configuration, whether pin or interrupt.
typedef void (*gpio_callback_handler_t)(const struct device *port, struct gpio_callback *cb, gpio_port_pins_t pins)

Define the application callback handler function signature.

Note: cb pointer can be used to retrieve private data through CONTAINER_OF() if original struct gpio_callback is stored in another private structure.

Param port
Device struct for the GPIO device.

Param cb
Original struct gpio_callback owning this handler

Param pins
Mask of pins that triggers the callback handler

Functions

static inline bool gpio_is_ready_dt(const struct gpio_dt_spec *spec)
Validate that GPIO port is ready.

Parameters
• spec – GPIO specification from devicetree

Return values
• true – if the GPIO spec is ready for use.
• false – if the GPIO spec is not ready for use.

int gpio_pin_interrupt_configure(const struct device *port, gpio_pin_t pin, gpio_flags_t flags)
Configure pin interrupt.

Note: This function can also be used to configure interrupts on pins not controlled directly by the GPIO module. That is, pins which are routed to other modules such as I2C, SPI, UART.

Parameters
• port – Pointer to device structure for the driver instance.
• pin – Pin number.
• flags – Interrupt configuration flags as defined by GPIO_INT_*. 

Return values
• 0 – If successful.
• -ENOTSUP – If any of the configuration options is not supported (unless otherwise directed by flag documentation).
• -EINVAL – Invalid argument.
• -EBUSY – Interrupt line required to configure pin interrupt is already in use.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.
static inline int gpio_pin_interrupt_configure_dt(const struct gpio_dt_spec *spec, gpio_flags_t flags)

Configure pin interrupts from a gpio_dt_spec.

This is equivalent to:

gpio_pin_interrupt_configure(spec->port, spec->pin, flags);

The spec->dt_flags value is not used.

**Parameters**

- spec – GPIO specification from devicetree
- flags – interrupt configuration flags

**Returns**

a value from gpio_pin_interrupt_configure()

int gpio_pin_configure(const struct device *port, gpio_pin_t pin, gpio_flags_t flags)

Configure a single pin.

**Parameters**

- port – Pointer to device structure for the driver instance.
- pin – Pin number to configure.
- flags – Flags for pin configuration: 'GPIO input/output configuration flags', 'GPIO pin drive flags', 'GPIO pin bias flags'.

**Return values**

- 0 – If successful.
- -ENOTSUP – if any of the configuration options is not supported (unless otherwise directed by flag documentation).
- -EINVAL – Invalid argument.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

static inline int gpio_pin_configure_dt(const struct gpio_dt_spec *spec, gpio_flags_t extra_flags)

Configure a single pin from a gpio_dt_spec and some extra flags.

This is equivalent to:

gpio_pin_configure(spec->port, spec->pin, spec->dt_flags | extra_flags);

**Parameters**

- spec – GPIO specification from devicetree
- extra_flags – additional flags

**Returns**

a value from gpio_pin_configure()
- `pin` – Pin number to query the direction of

**Return values**
- `1` – if `pin` is configured as `GPIO_INPUT`.
- `0` – if `pin` is not configured as `GPIO_INPUT`.
- `-ENOSYS` – if the underlying driver does not support this call.
- `-EIO` – I/O error when accessing an external GPIO chip.
- `-EWOULDBLOCK` – if operation would block.

```c
static inline int gpio_pin_is_output(const struct device *port, gpio_pin_t pin)
```
Check if `pin` is configured for output.

**Parameters**
- `port` – Pointer to device structure for the driver instance.
- `pin` – Pin number to query the direction of

**Return values**
- `1` – if `pin` is configured as `GPIO_OUTPUT`.
- `0` – if `pin` is not configured as `GPIO_OUTPUT`.
- `-ENOSYS` – if the underlying driver does not support this call.
- `-EIO` – I/O error when accessing an external GPIO chip.
- `-EWOULDBLOCK` – if operation would block.

```c
int gpio_pin_get_config(const struct device *port, gpio_pin_t pin, gpio_flags_t *flags)
```
Get a configuration of a single pin.

**Parameters**
- `port` – Pointer to device structure for the driver instance.
- `pin` – Pin number which configuration is get.
- `flags` – Pointer to variable in which the current configuration will be stored if function is successful.

**Return values**
- `0` – If successful.
- `-ENOSYS` – if getting current pin configuration is not implemented by the driver.
- `-EINVAL` – Invalid argument.
- `-EIO` – I/O error when accessing an external GPIO chip.
- `-EWOULDBLOCK` – if operation would block.

```c
static inline int gpio_pin_get_config_dt(const struct gpio_dt_spec *spec, gpio_flags_t *flags)
```
Get a configuration of a single pin from a `gpio_dt_spec`.

This is equivalent to:

```c
gpio_pin_get_config(spec->port, spec->pin, flags);
```

**Parameters**
- `spec` – GPIO specification from devicetree
- `flags` – Pointer to variable in which the current configuration will be stored if function is successful.
Returns

a value from `gpio_pin_configure()

```c
int gpio_port_get_raw(const struct device *port, gpio_port_value_t *value)
```

Get physical level of all input pins in a port.

A low physical level on the pin will be interpreted as value 0. A high physical level will be interpreted as value 1. This function ignores GPIO_ACTIVE_LOW flag.

Value of a pin with index n will be represented by bit n in the returned port value.

**Parameters**

- `port` – Pointer to the device structure for the driver instance.
- `value` – Pointer to a variable where pin values will be stored.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

```c
static inline int gpio_port_get(const struct device *port, gpio_port_value_t *value)
```

Get logical level of all input pins in a port.

Get logical level of an input pin taking into account GPIO_ACTIVE_LOW flag. If pin is configured as Active High, a low physical level will be interpreted as logical value 0. If pin is configured as Active Low, a low physical level will be interpreted as logical value 1.

Value of a pin with index n will be represented by bit n in the returned port value.

**Parameters**

- `port` – Pointer to the device structure for the driver instance.
- `value` – Pointer to a variable where pin values will be stored.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

```c
int gpio_port_set_masked_raw(const struct device *port, gpio_port_pins_t mask, gpio_port_value_t value)
```

Set physical level of output pins in a port.

Writing value 0 to the pin will set it to a low physical level. Writing value 1 will set it to a high physical level. This function ignores GPIO_ACTIVE_LOW flag.

Pin with index n is represented by bit n in mask and value parameter.

**Parameters**

- `port` – Pointer to the device structure for the driver instance.
- `mask` – Mask indicating which pins will be modified.
- `value` – Value assigned to the output pins.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.
static inline int gpio_port_set_masked(const struct device *port, gpio_port_pins_t mask, gpio_port_value_t value)

Set logical level of output pins in a port.

Set logical level of an output pin taking into account GPIO_ACTIVE_LOW flag. Value 0 sets the pin in logical 0 / inactive state. Value 1 sets the pin in logical 1 / active state. If pin is configured as Active High, the default, setting it in inactive state will force the pin to a low physical level. If pin is configured as Active Low, setting it in inactive state will force the pin to a high physical level.

Pin with index n is represented by bit n in mask and value parameter.

**Parameters**

- `port` – Pointer to the device structure for the driver instance.
- `mask` – Mask indicating which pins will be modified.
- `value` – Value assigned to the output pins.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

int gpio_port_set_bits_raw(const struct device *port, gpio_port_pins_t pins)

Set physical level of selected output pins to high.

**Parameters**

- `port` – Pointer to the device structure for the driver instance.
- `pins` – Value indicating which pins will be modified.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

static inline int gpio_port_set_bits(const struct device *port, gpio_port_pins_t pins)

Set logical level of selected output pins to active.

**Parameters**

- `port` – Pointer to the device structure for the driver instance.
- `pins` – Value indicating which pins will be modified.

**Return values**

- 0 – If successful.
- -EIO – I/O error when accessing an external GPIO chip.
- -EWOULDBLOCK – if operation would block.

int gpio_port_clear_bits_raw(const struct device *port, gpio_port_pins_t pins)

Set physical level of selected output pins to low.

**Parameters**

- `port` – Pointer to the device structure for the driver instance.
- `pins` – Value indicating which pins will be modified.

**Return values**

7.3. Peripherals
• 0 – If successful.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.

static inline int gpio_port_clear_bits(const struct device *port, gpio_port_pins_t pins)
Set logical level of selected output pins to inactive.

Parameters
• port – Pointer to the device structure for the driver instance.
• pins – Value indicating which pins will be modified.

Return values
• 0 – If successful.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.

int gpio_port_toggle_bits(const struct device *port, gpio_port_pins_t pins)
Toggle level of selected output pins.

Parameters
• port – Pointer to the device structure for the driver instance.
• pins – Value indicating which pins will be modified.

Return values
• 0 – If successful.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.

static inline int gpio_port_set_clr_bits_raw(const struct device *port, gpio_port_pins_t set_pins, gpio_port_pins_t clear_pins)
Set physical level of selected output pins.

Parameters
• port – Pointer to the device structure for the driver instance.
• set_pins – Value indicating which pins will be set to high.
• clear_pins – Value indicating which pins will be set to low.

Return values
• 0 – If successful.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.

static inline int gpio_port_set_clr_bits(const struct device *port, gpio_port_pins_t set_pins, gpio_port_pins_t clear_pins)
Set logical level of selected output pins.

Parameters
• port – Pointer to the device structure for the driver instance.
• set_pins – Value indicating which pins will be set to active.
• clear_pins – Value indicating which pins will be set to inactive.

Return values
static inline int gpio_pin_get_raw(const struct device *port, gpio_pin_t pin)
Get physical level of an input pin.
A low physical level on the pin will be interpreted as value 0. A high physical level will be interpreted as value 1. This function ignores GPIO_ACTIVE_LOW flag.

Parameters
• port – Pointer to the device structure for the driver instance.
• pin – Pin number.

Return values
• 1 – If pin physical level is high.
• 0 – If pin physical level is low.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.

static inline int gpio_pin_get(const struct device *port, gpio_pin_t pin)
Get logical level of an input pin.
Get logical level of an input pin taking into account GPIO_ACTIVE_LOW flag. If pin is configured as Active High, a low physical level will be interpreted as logical value 0. If pin is configured as Active Low, a low physical level will be interpreted as logical value 1.
Note: If pin is configured as Active High, the default, gpio_pin_get() function is equivalent to gpio_pin_get_raw().

Parameters
• port – Pointer to the device structure for the driver instance.
• pin – Pin number.

Return values
• 1 – If pin logical value is 1 / active.
• 0 – If pin logical value is 0 / inactive.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.

static inline int gpio_pin_get_dt(const struct gpio_dt_spec *spec)
Get logical level of an input pin from a gpio_dt_spec.
This is equivalent to:

gpio_pin_get(spec->port, spec->pin);

Parameters
• spec – GPIO specification from devicetree

Returns
a value from gpio_pin_get()
static inline int gpio_pin_set_raw(const struct device *port, gpio_pin_t pin, int value)
    Set physical level of an output pin.

    Writing value 0 to the pin will set it to a low physical level. Writing any value other than 0
    will set it to a high physical level. This function ignores GPIO_ACTIVE_LOW flag.

Parameters

• port – Pointer to the device structure for the driver instance.
• pin – Pin number.
• value – Value assigned to the pin.

Return values

• 0 – If successful.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.

static inline int gpio_pin_set(const struct device *port, gpio_pin_t pin, int value)
    Set logical level of an output pin.

    Set logical level of an output pin taking into account GPIO_ACTIVE_LOW flag. Value 0 sets
    the pin in logical 0 / inactive state. Any value other than 0 sets the pin in logical 1 / active
    state. If pin is configured as Active High, the default, setting it in inactive state will force
    the pin to a low physical level. If pin is configured as Active Low, setting it in inactive state will
    force the pin to a high physical level.

Note: If pin is configured as Active High, gpio_pin_set() function is equivalent to
    gpio_pin_set_raw().

Parameters

• port – Pointer to the device structure for the driver instance.
• pin – Pin number.
• value – Value assigned to the pin.

Return values

• 0 – If successful.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.

static inline int gpio_pin_set_dt(const struct gpio_dt_spec *spec, int value)
    Set logical level of a output pin from a gpio_dt_spec.

This is equivalent to:

    gpio_pin_set(spec->port, spec->pin, value);

Parameters

• spec – GPIO specification from devicetree
• value – Value assigned to the pin.

Returns

    a value from gpio_pin_set()
static inline int gpio_pin_toggle(const struct device *port, gpio_pin_t pin)
Toggle pin level.

Parameters
• port – Pointer to the device structure for the driver instance.
• pin – Pin number.

Return values
• 0 – If successful.
• -EIO – I/O error when accessing an external GPIO chip.
• -EWOULDBLOCK – if operation would block.

static inline int gpio_pin_toggle_dt(const struct gpio_dt_spec *spec)
Toggle pin level from a gpio_dt_spec.
This is equivalent to:
gpio_pin_toggle(spec->port, spec->pin);

Parameters
• spec – GPIO specification from devicetree

Returns
a value from gpio_pin_toggle()

static inline void gpio_init_callback(struct gpio_callback *callback, gpio_callback_handler_t handler, gpio_port_pins_t pin_mask)
Helper to initialize a struct gpio_callback properly.

Parameters
• callback – A valid Application’s callback structure pointer.
• handler – A valid handler function pointer.
• pin_mask – A bit mask of relevant pins for the handler

static inline int gpio_add_callback(const struct device *port, struct gpio_callback *callback)
Add an application callback.

Note: enables to add as many callback as needed on the same port.

Note: Callbacks may be added to the device from within a callback handler invocation, but whether they are invoked for the current GPIO event is not specified.

Parameters
• port – Pointer to the device structure for the driver instance.
• callback – A valid Application’s callback structure pointer.

Returns
0 if successful, negative errno code on failure.
static inline int gpio_remove_callback(const struct device *port, struct gpio_callback *callback)
Remove an application callback.

Note: enables to remove as many callbacks as added through gpio_add_callback().

Warning: It is explicitly permitted, within a callback handler, to remove the registration for the callback that is running, i.e. callback. Attempts to remove other registrations on the same device may result in undefined behavior, including failure to invoke callbacks that remain registered and unintended invocation of removed callbacks.

Parameters
• port – Pointer to the device structure for the driver instance.
• callback – A valid application’s callback structure pointer.

Returns
0 if successful, negative errno code on failure.

int gpio_get_pending_int(const struct device *dev)
Function to get pending interrupts.

The purpose of this function is to return the interrupt status register for the device. This is especially useful when waking up from low power states to check the wake up source.

Parameters
• dev – Pointer to the device structure for the driver instance.

Return values
• status – != 0 if at least one gpio interrupt is pending.
• 0 – if no gpio interrupt is pending.

struct gpio_dt_spec
#include <gpio.h> Container for GPIO pin information specified in devicetree.

This type contains a pointer to a GPIO device, pin number for a pin controlled by that device, and the subset of pin configuration flags which may be given in devicetree.

GPIO_DT_SPEC_GET
See also:
GPIO_DT_SPEC_GET_OR

Public Members
const struct device *port
  GPIO device controlling the pin

gpio_pin_t pin
  The pin's number on the device

gpio_dt_flags_t dt_flags
  The pin's configuration flags as specified in devicetree

struct gpio_driver_config
  #include <gpio.h> This structure is common to all GPIO drivers and is expected to be the first
  element in the object pointed to by the config field in the device structure.

struct gpio_driver_data
  #include <gpio.h> This structure is common to all GPIO drivers and is expected to be the first
  element in the driver's struct driver_data declaration.

struct gpio_callback
  #include <gpio.h> GPIO callback structure.

  Used to register a callback in the driver instance callback list. As many callbacks as needed
  can be added as long as each of them are unique pointers of struct gpio_callback. Beware such
  structure should not be allocated on stack.

  Note: To help setting it, see gpio_init_callback() below

Public Members

sys_snode_t node
  This is meant to be used in the driver and the user should not mess with it (see
  drivers/gpio/gpio_utils.h)

gpio_callback_handler_t handler
  Actual callback function being called when relevant.

gpio_port_pins_t pin_mask
  A mask of pins the callback is interested in, if 0 the callback will never be called. Such
  pin_mask can be modified whenever necessary by the owner, and thus will affect the
  handler being called or not. The selected pins must be configured to trigger an interrupt.

7.3.18 Hardware Information

Overview

The HW Info API provides access to hardware information such as device identifiers and reset cause
flags.

Reset cause flags can be used to determine why the device was reset; for example due to a watch-
dog timeout or due to power cycling. Different devices support different subset of flags. Use
hwinfo_get_supported_reset_cause() to retrieve the flags that are supported by that device.
Configuration Options

Related configuration options:
- CONFIG_HWINFO

API Reference

`group hwinfo_interface`

Hardware Information Interface.

**Defines**

- `RESET_PIN`

Functions

ssize_t hwinfo_get_device_id(uint8_t *buffer, size_t length)

Copy the device id to a buffer.

This routine copies “length” number of bytes of the device ID to the buffer. If the device ID is smaller then length, the rest of the buffer is left unchanged. The ID depends on the hardware and is not guaranteed unique.

Drivers are responsible for ensuring that the ID data structure is a sequence of bytes. The returned ID value is not supposed to be interpreted based on vendor-specific assumptions of byte order. It should express the identifier as a raw byte sequence, doing any endian conversion necessary so that a hex representation of the bytes produces the intended serial number.

Parameters

• buffer – Buffer to write the ID to.
• length – Max length of the buffer.

Return values

• size – of the device ID copied.
• -ENOSYS – if there is no implementation for the particular device.
• any – negative value on driver specific errors.

int hwinfo_get_reset_cause(uint32_t *cause)

Retrieve cause of device reset.

This routine retrieves the flags that indicate why the device was reset.

On some platforms the reset cause flags accumulate between successive resets and this routine may return multiple flags indicating all reset causes since the device was powered on. If you need to retrieve the cause only for the most recent reset call hwinfo_clear_reset_cause after calling this routine to clear the hardware flags before the next reset event.

Successive calls to this routine will return the same value, unless hwinfo_clear_reset_cause has been called.

Parameters

• cause – OR’d reset_cause flags

Return values

• zero – if successful.
• -ENOSYS – if there is no implementation for the particular device.
• any – negative value on driver specific errors.

int hwinfo_clear_reset_cause(void)

Clear cause of device reset.

Clears reset cause flags.

Return values

• zero – if successful.
• -ENOSYS – if there is no implementation for the particular device.
• any – negative value on driver specific errors.
```c
int hwinfo_get_supported_reset_cause(uint32_t *supported)

Get supported reset cause flags.

Retrieves all reset_cause flags that are supported by this device.

Parameters
• supported – OR'd reset_cause flags that are supported

Return values
• zero – if successful.
• -ENOSYS – if there is no implementation for the particular device.
• any – negative value on driver specific errors.
```

### 7.3.19 I2C EEPROM Target

#### Overview

#### API Reference

**group** i2c_eeprom_target_api

I2C EEPROM Target Driver API.

**Functions**

```c
int eeprom_target_program(const struct device *dev, const uint8_t *eeprom_data, unsigned int length)

Program memory of the virtual EEPROM.

Parameters
• dev – Pointer to the device structure for the driver instance.
• eeprom_data – Pointer of data to program into the virtual eeprom memory
• length – Length of data to program into the virtual eeprom memory

Return values
• 0 – If successful.
• -EINVAL – Invalid data size
```

```c
int eeprom_target_read(const struct device *dev, uint8_t *eeprom_data, unsigned int offset)

Read single byte of virtual EEPROM memory.

Parameters
• dev – Pointer to the device structure for the driver instance.
• eeprom_data – Pointer of byte where to store the virtual eeprom memory
• offset – Offset into EEPROM memory where to read the byte

Return values
• 0 – If successful.
• -EINVAL – Invalid data pointer or offset
```
7.3.20   I2C

Overview

Note: The terminology used in Zephyr I2C APIs follows that of the NXP I2C Bus Specification Rev 7.0. These changed from previous revisions as of its release October 1, 2021.

I2C (Inter-Integrated Circuit, pronounced “eye squared see”) is a commonly-used two-signal shared peripheral interface bus. Many system-on-chip solutions provide controllers that communicate on an I2C bus. Devices on the bus can operate in two roles: as a “controller” that initiates transactions and controls the clock, or as a “target” that responds to transaction commands. A I2C controller on a given SoC will generally support the controller role, and some will also support the target mode. Zephyr has API for both roles.

I2C Controller API  Zephyr’s I2C controller API is used when an I2C peripheral controls the bus, in particularly the start and stop conditions and the clock. This is the most common mode, used to interact with I2C devices like sensors and serial memory.

This API is supported in all in-tree I2C peripheral drivers and is considered stable.

I2C Target API  Zephyr’s I2C target API is used when an I2C peripheral responds to transactions initiated by a different controller on the bus. It might be used for a Zephyr application with transducer roles that are controlled by another device such as a host processor.

This API is supported in very few in-tree I2C peripheral drivers. The API is considered experimental, as it is not compatible with the capabilities of all I2C peripherals supported in controller mode.

Configuration Options

Related configuration options:
- CONFIG_I2C

API Reference

group i2c_interface
  I2C Interface.

Defines

I2C_SPEED_STANDARD
  I2C Standard Speed: 100 kHz

I2C_SPEED_FAST
  I2C Fast Speed: 400 kHz

I2C_SPEED_FAST_PLUS
  I2C Fast Plus Speed: 1 MHz
I2C_SPEED_HIGH
I2C High Speed: 3.4 MHz

I2C_SPEED_ULTRA
I2C Ultra Fast Speed: 5 MHz

I2C_SPEED_DT
Device Tree specified speed

I2C_SPEED_SHIFT
I2C_SPEED_SET(speed)

I2C_SPEED_MASK
I2C_SPEED_GET(cfg)

I2C_ADDR_10_BITS
Use 10-bit addressing. DEPRECATED - Use I2C_MSG_ADDR_10_BITS instead.

I2C_MODE_CONTROLLER
Peripheral to act as Controller.

I2C_MODE_MASTER
Deprecated:
Use I2C_MODE_CONTROLLER instead.

I2C_DT_SPEC_GET_ON_I3C(node_id)
Structure initializer for i2c_dt_spec from devicetree (on I3C bus)

This helper macro expands to a static initializer for a struct i2c_dt_spec by reading the relevant bus and address data from the devicetree.

Parameters
• node_id – Devicetree node identifier for the I2C device whose struct i2c_dt_spec to create an initializer for

I2C_DT_SPEC_GET_ON_I2C(node_id)
Structure initializer for i2c_dt_spec from devicetree (on I2C bus)

This helper macro expands to a static initializer for a struct i2c_dt_spec by reading the relevant bus and address data from the devicetree.

Parameters
• node_id – Devicetree node identifier for the I2C device whose struct i2c_dt_spec to create an initializer for

I2C_DT_SPEC_GET(node_id)
Structure initializer for i2c_dt_spec from devicetree.

This helper macro expands to a static initializer for a struct i2c_dt_spec by reading the relevant bus and address data from the devicetree.

Parameters
• node_id – Devicetree node identifier for the I2C device whose struct i2c_dt_spec to create an initializer for
I2C_DT_SPEC_INST_GET(inst)
Structure initializer for i2c_dt_spec from devicetree instance.
This is equivalent to I2C_DT_SPEC_GET(DT_DRV_INST(inst)).

Parameters
- inst – Devicetree instance number

I2C_MSG_WRITE
Write message to I2C bus.

I2C_MSG_READ
Read message from I2C bus.

I2C_MSG_STOP
Send STOP after this message.

I2C_MSG_RESTART
RESTART I2C transaction for this message.

**Note:** Not all I2C drivers have or require explicit support for this feature. Some drivers require this be present on a read message that follows a write, or vice-versa. Some drivers will merge adjacent fragments into a single transaction using this flag; some will not.

I2C_MSG_ADDR_10_BITS
Use 10-bit addressing for this message.

**Note:** Not all SoC I2C implementations support this feature.

I2C_TARGET_FLAGS_ADDR_10_BITS
Target device responds to 10-bit addressing.

I2C_DEVICE_DT_DEFINE(node_id, init_fn, pm, data, config, level, prio, api, ...)
Like DEVICE_DT_DEFINE() with I2C specifics.
Defines a device which implements the I2C API. May generate a custom device_state container struct and init_fn wrapper when needed depending on I2C CONFIG_I2C_STATS.

Parameters
- node_id – The devicetree node identifier.
- init_fn – Name of the init function of the driver.
- pm – PM device resources reference (NULL if device does not use PM).
- data – Pointer to the device’s private data.
- config – The address to the structure containing the configuration information for this instance of the driver.
- level – The initialization level. See SYS_INIT() for details.
- prio – Priority within the selected initialization level. See SYS_INIT() for details.
- api – Provides an initial pointer to the API function struct used by the driver. Can be NULL.
I2C_DEVICE_DT_INST_DEFINE(inst, ...)
Like I2C_DEVICE_DT_DEFINE() for an instance of a DT_DRV_COMPAT compatible.

Parameters
- inst – instance number. This is replaced by DT_DRV_COMPAT(inst) in the call to I2C_DEVICE_DT_DEFINE().
- ... – other parameters as expected by I2C_DEVICE_DT_DEFINE().

Typedefs

typedef void (*i2c_callback_t)(const struct device *dev, int result, void *data)
I2C callback for asynchronous transfer requests.

  Param dev
  I2C device which is notifying of transfer completion or error

  Param result
  Result code of the transfer request. 0 is success, -errno for failure.

  Param data
  Transfer requester supplied data which is passed along to the callback.

typedef int (*i2c_target_write_requested_cb_t)(struct i2c_target_config *config)
Function called when a write to the device is initiated.

  This function is invoked by the controller when the bus completes a start condition for a write
  operation to the address associated with a particular device.

  A success return shall cause the controller to ACK the next byte received. An error return shall
  cause the controller to NACK the next byte received.

  Param config
  the configuration structure associated with the device to which the operation is
  addressed.

  Return
  0 if the write is accepted, or a negative error code.

typedef int (*i2c_target_write_received_cb_t)(struct i2c_target_config *config, uint8_t val)
Function called when a write to the device is continued.

  This function is invoked by the controller when it completes reception of a byte of data in an
  ongoing write operation to the device.

  A success return shall cause the controller to ACK the next byte received. An error return shall
  cause the controller to NACK the next byte received.

  Param config
  the configuration structure associated with the device to which the operation is
  addressed.

  Param val
  the byte received by the controller.

  Return
  0 if more data can be accepted, or a negative error code.
typedef int (*i2c_target_read_requested_cb_t)(struct i2c_target_config *config, uint8_t *val)
Function called when a read from the device is initiated.
This function is invoked by the controller when the bus completes a start condition for a read
operation from the address associated with a particular device.
The value returned in *val will be transmitted. A success return shall cause the controller to
react to additional read operations. An error return shall cause the controller to ignore bus
operations until a new start condition is received.

Param config
the configuration structure associated with the device to which the operation is
addressed.

Param val
pointer to storage for the first byte of data to return for the read request.

Return
0 if more data can be requested, or a negative error code.

typedef int (*i2c_target_read_processed_cb_t)(struct i2c_target_config *config, uint8_t *val)
Function called when a read from the device is continued.
This function is invoked by the controller when the bus is ready to provide additional data for
a read operation from the address associated with the device device.
The value returned in *val will be transmitted. A success return shall cause the controller to
react to additional read operations. An error return shall cause the controller to ignore bus
operations until a new start condition is received.

Param config
the configuration structure associated with the device to which the operation is
addressed.

Param val
pointer to storage for the next byte of data to return for the read request.

Return
0 if data has been provided, or a negative error code.

typedef int (*i2c_target_stop_cb_t)(struct i2c_target_config *config)
Function called when a stop condition is observed after a start condition addressed to a par-
ticular device.
This function is invoked by the controller when the bus is ready to provide additional data
for a read operation from the address associated with the device device. After the function
returns the controller shall enter a state where it is ready to react to new start conditions.

Param config
the configuration structure associated with the device to which the operation is
addressed.

Return
Ignored.

Functions

static inline bool i2c_is_ready_dt(const struct i2c_dt_spec *spec)
Validate that I2C bus is ready.

Parameters

7.3. Peripherals
• spec – I2C specification from devicetree

**Return values**

• true – if the I2C bus is ready for use.
• false – if the I2C bus is not ready for use.

static inline void i2c_xfer_stats(const struct device *dev, struct i2c_msg *msgs, uint8_t num_msgs)

Updates the i2c stats for i2c transfers.

**Parameters**

• dev – I2C device to update stats for
• msgs – Array of struct i2c_msg
• num_msgs – Number of i2c_msgs

int i2c_configure(const struct device *dev, uint32_t dev_config)

Configure operation of a host controller.

**Parameters**

• dev – Pointer to the device structure for the driver instance.
• dev_config – Bit-packed 32-bit value to the device runtime configuration for the I2C controller.

**Return values**

• 0 – If successful.
• -EIO – General input / output error, failed to configure device.

int i2c_get_config(const struct device *dev, uint32_t *dev_config)

Get configuration of a host controller.

This routine provides a way to get current configuration. It is allowed to call the function before i2c_configure, because some I2C ports can be configured during init process. However, if the I2C port is not configured, i2c_get_config returns an error.

i2c_get_config can return cached config or probe hardware, but it has to be up to date with current configuration.

**Parameters**

• dev – Pointer to the device structure for the driver instance.
• dev_config – Pointer to return bit-packed 32-bit value of the I2C controller configuration.

**Return values**

• 0 – If successful.
• -EIO – General input / output error.
• -ERANGE – Configured I2C frequency is invalid.
• -ENOSYS – If get config is not implemented

int i2c_transfer(const struct device *dev, struct i2c_msg *msgs, uint8_t num_msgs, uint16_t addr)

Perform data transfer to another I2C device in controller mode.

This routine provides a generic interface to perform data transfer to another I2C device synchronously. Use i2c_read() / i2c_write() for simple read or write.

The array of message msgs must not be NULL. The number of message num_msgs may be zero, in which case no transfer occurs.
Note: Not all scatter/gather transactions can be supported by all drivers. As an example, a
gather write (multiple consecutive i2c_msg buffers all configured for I2C_MSG_WRITE) may
be packed into a single transaction by some drivers, but others may emit each fragment as a
distinct write transaction, which will not produce the same behavior. See the documentation
of struct i2c_msg for limitations on support for multi-message bus transactions.

Parameters
- dev – Pointer to the device structure for an I2C controller driver configured in
controller mode.
- msgs – Array of messages to transfer.
- num_msg – Number of messages to transfer.
- addr – Address of the I2C target device.

Return values
- 0 – If successful.
- -EIO – General input / output error.

static inline int i2c_transfer_dt(const struct i2c_dt_spec *spec, struct i2c_msg *msgs, uint8_t num_msgs)
Perform data transfer to another I2C device in controller mode.
This is equivalent to:

i2c_transfer(spec->bus, msgs, num_msg, spec->addr);

Parameters
- spec – I2C specification from devicetree.
- msgs – Array of messages to transfer.
- num_msg – Number of messages to transfer.

Returns
a value from i2c_transfer()

int i2c_recover_bus(const struct device *dev)
Recover the I2C bus.
Attempt to recover the I2C bus.

Parameters
- dev – Pointer to the device structure for an I2C controller driver configured in
controller mode.

Return values
- 0 – If successful
- -EBUSY – If bus is not clear after recovery attempt.
- -EIO – General input / output error.
- -ENOSYS – If bus recovery is not implemented

7.3. Peripherals
static inline int i2c_target_register(const struct device *dev, struct i2c_target_config *cfg)

Registers the provided config as Target device of a controller.

Enable I2C target mode for the 'dev' I2C bus driver using the provided 'config' struct containing the functions and parameters to send bus events. The I2C target will be registered at the address provided as ‘address’ struct member. Addressing mode - 7 or 10 bit - depends on the ‘flags’ struct member. Any I2C bus events related to the target mode will be passed onto I2C target device driver via a set of callback functions provided in the ‘callbacks’ struct member.

Most of the existing hardware allows simultaneous support for controller and target mode. This is however not guaranteed.

Parameters

- **dev** – Pointer to the device structure for an I2C controller driver configured in target mode.
- **cfg** – Config struct with functions and parameters used by the I2C driver to send bus events

Return values

- 0 – Is successful
- -EINVAL – If parameters are invalid
- -EIO – General input / output error.
- -ENOSYS – If target mode is not implemented

static inline int i2c_target_unregister(const struct device *dev, struct i2c_target_config *cfg)

Unregisters the provided config as Target device.

This routine disables I2C target mode for the 'dev' I2C bus driver using the provided 'config' struct containing the functions and parameters to send bus events.

Parameters

- **dev** – Pointer to the device structure for an I2C controller driver configured in target mode.
- **cfg** – Config struct with functions and parameters used by the I2C driver to send bus events

Return values

- 0 – Is successful
- -EINVAL – If parameters are invalid
- -ENOSYS – If target mode is not implemented

int i2c_target_driver_register(const struct device *dev)

Instructs the I2C Target device to register itself to the I2C Controller.

This routine instructs the I2C Target device to register itself to the I2C Controller via its parent controller's i2c_target_register() API.

Parameters

- **dev** – Pointer to the device structure for the I2C target device (not itself an I2C controller).

Return values

- 0 – Is successful
- -EINVAL – If parameters are invalid
- -EIO – General input / output error.
`i2c_target_driver_unregister(const struct device *dev)`
Instructs the I2C Target device to unregister itself from the I2C Controller.

This routine instructs the I2C Target device to unregister itself from the I2C Controller via its parent controller's `i2c_target_register()` API.

**Parameters**
- `dev` – Pointer to the device structure for the I2C target device (not itself an I2C controller).

**Return values**
- `0` – Is successful
- `-EINVAL` – If parameters are invalid

`static inline int i2c_write(const struct device *dev, const uint8_t *buf, uint32_t num_bytes, uint16_t addr)`
Write a set amount of data to an I2C device.

This routine writes a set amount of data synchronously.

**Parameters**
- `dev` – Pointer to the device structure for an I2C controller driver configured in controller mode.
- `buf` – Memory pool from which the data is transferred.
- `num_bytes` – Number of bytes to write.
- `addr` – Address to the target I2C device for writing.

**Return values**
- `0` – If successful.
- `-EIO` – General input / output error.

`static inline int i2c_write_dt(const struct i2c_dt_spec *spec, const uint8_t *buf, uint32_t num_bytes)`
Write a set amount of data to an I2C device.

This is equivalent to:
```
i2c_write(spec->bus, buf, num_bytes, spec->addr);
```

**Parameters**
- `spec` – I2C specification from devicetree.
- `buf` – Memory pool from which the data is transferred.
- `num_bytes` – Number of bytes to write.

**Returns**
A value from `i2c_write()`

`static inline int i2c_read(const struct device *dev, uint8_t *buf, uint32_t num_bytes, uint16_t addr)`
Read a set amount of data from an I2C device.

This routine reads a set amount of data synchronously.

**Parameters**
- `dev` – Pointer to the device structure for an I2C controller driver configured in controller mode.
• buf – Memory pool that stores the retrieved data.
• num_bytes – Number of bytes to read.
• addr – Address of the I2C device being read.

Return values
• 0 – If successful.
• -EIO – General input / output error.

static inline int i2c_read_dt(const struct i2c_dt_spec *spec, uint8_t *buf, uint32_t num_bytes)
Read a set amount of data from an I2C device.
This is equivalent to:

```c
i2c_read(spec->bus, buf, num_bytes, spec->addr);
```

Parameters
• spec – I2C specification from devicetree.
• buf – Memory pool that stores the retrieved data.
• num_bytes – Number of bytes to read.

Returns
a value from i2c_read()

static inline int i2c_write_read(const struct device *dev, uint16_t addr, const void *write_buf,
size_t num_write, void *read_buf, size_t num_read)
Write then read data from an I2C device.

This supports the common operation “this is what I want”, “now give
it to me” transaction pair through a combined write-then-read bus transaction.

Parameters
• dev – Pointer to the device structure for an I2C controller driver configured in
controller mode.
• addr – Address of the I2C device
• write_buf – Pointer to the data to be written
• num_write – Number of bytes to write
• read_buf – Pointer to storage for read data
• num_read – Number of bytes to read

Return values
• 0 – if successful
• negative – on error.

static inline int i2c_write_read_dt(const struct i2c_dt_spec *spec, const void *write_buf,
size_t num_write, void *read_buf, size_t num_read)
Write then read data from an I2C device.
This is equivalent to:
i2c_write_read(spec->bus, spec->addr, write_buf, num_write, read_buf, num_read);

Parameters

- **spec** – I2C specification from devicetree.
- **write_buf** – Pointer to the data to be written
- **num_write** – Number of bytes to write
- **read_buf** – Pointer to storage for read data
- **num_read** – Number of bytes to read

Returns

A value from `i2c_write_read()`

static inline int i2c_burst_read(const struct device *dev, uint16_t dev_addr, uint8_t start_addr, uint8_t *buf, uint32_t num_bytes)

Read multiple bytes from an internal address of an I2C device. This routine reads multiple bytes from an internal address of an I2C device synchronously. Instances of this may be replaced by `i2c_write_read()`.

Parameters

- **dev** – Pointer to the device structure for an I2C controller driver configured in controller mode.
- **dev_addr** – Address of the I2C device for reading.
- **start_addr** – Internal address from which the data is being read.
- **buf** – Memory pool that stores the retrieved data.
- **num_bytes** – Number of bytes being read.

Return values

- **0** – If successful.
- **-EIO** – General input / output error.

static inline int i2c_burst_read_dt(const struct i2c_dt_spec *spec, uint8_t start_addr, uint8_t *buf, uint32_t num_bytes)

Read multiple bytes from an internal address of an I2C device. This is equivalent to:

i2c_burst_read(spec->bus, spec->addr, start_addr, buf, num_bytes);

Parameters

- **spec** – I2C specification from devicetree.
- **start_addr** – Internal address from which the data is being read.
- **buf** – Memory pool that stores the retrieved data.
- **num_bytes** – Number of bytes to read.

Returns

A value from `i2c_burst_read()`
static inline int i2c_burst_write(const struct device *dev, uint16_t dev_addr, uint8_t start_addr, const uint8_t *buf, uint32_t num_bytes)

Write multiple bytes to an internal address of an I2C device.
This routine writes multiple bytes to an internal address of an I2C device synchronously.

Warning: The combined write synthesized by this API may not be supported on all I2C devices. Uses of this API may be made more portable by replacing them with calls to i2c_write() passing a buffer containing the combined address and data.

Parameters
- dev – Pointer to the device structure for an I2C controller driver configured in controller mode.
- dev_addr – Address of the I2C device for writing.
- start_addr – Internal address to which the data is being written.
- buf – Memory pool from which the data is transferred.
- num_bytes – Number of bytes being written.

Return values
- 0 – If successful.
- -EIO – General input / output error.

static inline int i2c_burst_write_dt(const struct i2c_dt_spec *spec, uint8_t start_addr, const uint8_t *buf, uint32_t num_bytes)

Write multiple bytes to an internal address of an I2C device.
This is equivalent to:

i2c_burst_write(spec->bus, spec->addr, start_addr, buf, num_bytes);

Parameters
- spec – I2C specification from devicetree.
- start_addr – Internal address to which the data is being written.
- buf – Memory pool from which the data is transferred.
- num_bytes – Number of bytes being written.

Returns
a value from i2c_burst_write()

static inline int i2c_reg_read_byte(const struct device *dev, uint16_t dev_addr, uint8_t reg_addr, uint8_t *value)

Read internal register of an I2C device.
This routine reads the value of an 8-bit internal register of an I2C device synchronously.

Parameters
- dev – Pointer to the device structure for an I2C controller driver configured in controller mode.
- dev_addr – Address of the I2C device for reading.
- reg_addr – Address of the internal register being read.
- value – Memory pool that stores the retrieved register value.
Return values

- 0 – If successful.
- -EIO – General input / output error.

static inline int i2c_reg_read_byte_dt(const struct i2c_dt_spec *spec, uint8_t reg_addr, uint8_t *value)

Read internal register of an I2C device.
This is equivalent to:

```c
i2c_reg_read_byte(spec->bus, spec->addr, reg_addr, value);
```

Parameters

- spec – I2C specification from devicetree.
- reg_addr – Address of the internal register being read.
- value – Memory pool that stores the retrieved register value.

Returns

a value from `i2c_reg_read_byte()`

static inline int i2c_reg_write_byte(const struct device *dev, uint16_t dev_addr, uint8_t reg_addr, uint8_t value)

Write internal register of an I2C device.
This routine writes a value to an 8-bit internal register of an I2C device synchronously.

Note:  This function internally combines the register and value into a single bus transaction.

Parameters

- dev – Pointer to the device structure for an I2C controller driver configured in controller mode.
- dev_addr – Address of the I2C device for writing.
- reg_addr – Address of the internal register being written.
- value – Value to be written to internal register.

Return values

- 0 – If successful.
- -EIO – General input / output error.

static inline int i2c_reg_write_byte_dt(const struct i2c_dt_spec *spec, uint8_t reg_addr, uint8_t *value)

Write internal register of an I2C device.
This is equivalent to:

```c
i2c_reg_write_byte(spec->bus, spec->addr, reg_addr, value);
```

Parameters

- spec – I2C specification from devicetree.
- reg_addr – Address of the internal register being written.
- value – Value to be written to internal register.
Returns

a value from `i2c_reg_write_byte()`

```
static inline int i2c_reg_update_byte(const struct device *dev, uint8_t dev_addr, uint8_t reg_addr, uint8_t mask, uint8_t value)
```

Update internal register of an I2C device.
This routine updates the value of a set of bits from an 8-bit internal register of an I2C device synchronously.

**Note:** If the calculated new register value matches the value that was read this function will not generate a write operation.

Parameters

- `dev` – Pointer to the device structure for an I2C controller driver configured in controller mode.
- `dev_addr` – Address of the I2C device for updating.
- `reg_addr` – Address of the internal register being updated.
- `mask` – Bitmask for updating internal register.
- `value` – Value for updating internal register.

Return values

- 0 – If successful.
- -EIO – General input / output error.

```
static inline int i2c_reg_update_byte_dt(const struct i2c_dt_spec *spec, uint8_t reg_addr, uint8_t mask, uint8_t value)
```

Update internal register of an I2C device.
This is equivalent to:
```
i2c_reg_update_byte(spec->bus, spec->addr, reg_addr, mask, value);
```

Parameters

- `spec` – I2C specification from devicetree.
- `reg_addr` – Address of the internal register being updated.
- `mask` – Bitmask for updating internal register.
- `value` – Value for updating internal register.

Returns

a value from `i2c_reg_write_byte()`

```
void i2c_dump_msgs(const char *name, const struct i2c_msg *msgs, uint8_t num_msgs, uint16_t addr)
```

Dump out an I2C message.
Dumps out a list of I2C messages. For any that are writes (W), the data is displayed in hex.
It looks something like this (with name “testing”):
D: I2C msg: testing, addr=56
D:     W len=01:
D: contents:
D:     06 |
D:     W len=0e:
D: contents:
D: 00 01 02 03 04 05 06 07 |........
D: 08 09 0a 0b 0c 0d |......

Parameters

• name – Name of this dump, displayed at the top.
• msgs – Array of messages to dump.
• num_msgs – Number of messages to dump.
• addr – Address of the I2C target device.

struct i2c_dt_spec
#include <i2c.h> Complete I2C DT information.

Param bus
is the I2C bus

Param addr
is the target address

struct i2c_msg
#include <i2c.h> One I2C Message.

This defines one I2C message to transact on the I2C bus.

Note: Some of the configurations supported by this API may not be supported by specific SoC I2C hardware implementations, in particular features related to bus transactions intended to read or write data from different buffers within a single transaction. Invocations of i2c_transfer() may not indicate an error when an unsupported configuration is encountered. In some cases drivers will generate separate transactions for each message fragment, with or without presence of I2C_MSG_RESTART in flags.

Public Members

uint8_t *buf
Data buffer in bytes

uint32_t len
Length of buffer in bytes

uint8_t flags
Flags for this message

struct i2c_target_callbacks
#include <i2c.h> Structure providing callbacks to be implemented for devices that supports the I2C target API.

7.3. Peripherals
This structure may be shared by multiple devices that implement the same API at different addresses on the bus.

```c
struct i2c_target_config
#include <i2c.h> Structure describing a device that supports the I2C target API.

Instances of this are passed to the `i2c_target_register()` and `i2c_target_unregister()` functions to indicate addition and removal of a target device, respective.

Fields other than `node` must be initialized by the module that implements the device behavior prior to passing the object reference to `i2c_target_register()`.

Public Members

```c
sys_snode_t node
Private, do not modify
```

```c
uint8_t flags
Flags for the target device defined by I2C_TARGET_FLAGS_* constants
```

```c
uint16_t address
Address for this target device
```

```c
const struct i2c_target_callbacks *callbacks
Callback functions
```

```c
struct i2c_device_state
#include <i2c.h> I2C specific device state which allows for i2c device class specific additions.
```

### 7.3.21 I3C

I3C (Improved Inter-Integrated Circuit) is a two-signal shared peripheral interface bus. Devices on the bus can operate in two roles: as a “controller” that initiates transactions and controls the clock, or as a “target” that responds to transaction commands.

Currently, the API is based on I3C Specification version 1.1.1.

  - Device Tree
  - Device Drivers for I3C Devices
  - I²C Devices under I3C Bus

- **Configuration Options**
- **API Reference**
I3C Controller API

Zephyr’s I3C controller API is used when an I3C controller controls the bus, in particular the start and stop conditions and the clock. This is the most common mode, used to interact with I3C target devices such as sensors.

Due to the nature of the I3C, there are devices on the bus where they may not have addresses when powered on. Therefore, an additional dynamic address assignment needs to be carried out by the I3C controller. Because of this, the controller needs to maintain separate structures to keep track of device status. This can be done at build time, for example, by creating arrays of device descriptors for both I3C and I2C devices:

```c
static struct i3c_device_desc i3c_device_array[] = I3C_DEVICE_ARRAY_DT_INST(inst);
static struct i3c_i2c_device_desc i2c_device_array[] = I3C_I2CDEVICE_ARRAY_DT_INST(inst);
```

The macros `I3C_DEVICE_ARRAY_DT_INST` and `I3C_I2CDEVICE_ARRAY_DT_INST` are helper macros to aid in creating arrays of device descriptors corresponding to the devicetree nodes under the I3C controller.

Here is a list of generic steps for initializing the I3C controller and the I3C bus inside the device driver initialization function:

1. Initialize the data structure of the I3C controller device driver instance. The usual device defining macros such as `DEVICE_DT_INST_DEFINE` can be used, and the initialization function provided as a parameter to the macro.
   - The `i3c_addr_slots` and `i3c_dev_list` are structures to aid in address assignments and device list management. If this is being used, this struct needs to be initialized by calling `i3c_addr_slots_init()`. These two structures can also be used with various helper functions.
   - Initialize the device descriptors if needed by the controller driver.

2. Initialize the hardware, including but not limited to:
   - Setup pin mux and directions.
   - Setup the clock for the controller.
   - Power on the hardware.
   - Configure the hardware (e.g. SCL clock frequency).

3. Perform bus initialization. There is a generic helper function, `i3c_bus_init()`, which performs the following steps. This function can be used if the controller does not require any special handling during bus initialization.
   1. Do `RSTDAA` to reset dynamic addresses of connected devices. If any connected devices have already been assigned an address, the bookkeeping data structures do not have records of these, for example, at power-on. So it is a good idea to reset and assign them new addresses.
   2. Do `DISEC` to disable any events from devices.
   3. Do `SETDASA` to use static addresses as dynamic address if so desired.
      - `SETAASA` may not be supported for all connected devices to assign static addresses as dynamic addresses.
      - BCR and DCR need to be obtained separately to populate the relevant fields in the I3C target device descriptor struct.
   4. Do `ENTDAA` to start dynamic address assignment, if there are still devices without addresses.
      - If there is a device waiting for address, it will send its Provisioned ID, BCR, and DCR back. Match the received Provisioned ID to the list of registered I3C devices.
      - If there is a match, assign an address (either from the stated static address if `SETDASA` has not been done, or use a free address).
Also, set the BCR and DCR fields in the device descriptor struct.

- If there is no match, depending on policy, it can be assigned a free address, or the device driver can stop the assignment process and errors out.
- Note that the I3C API requires device descriptor to function. A device without a device descriptor cannot be accessed through the API.

- This step can be skipped if there is no connected devices requiring DAA.

5. These are optional but highly recommended:

- Do GETMRL and GETMNL to get maximum read/write length.
- Do GETMXDS to get maximum read/write speed and maximum read turnaround time.
- The helper function, \texttt{i3c\_bus\_init()}, would retrieve basic device information such as BCR, DCR, MRL and MWL.

6. Do ENEC to re-enable events from devices.

- The helper function, \texttt{i3c\_bus\_init()}, only re-enables hot-join events. IBI event should only be enabled when enabling IBI of a device.

**In-Band Interrupt (IBI)** If a target device can generate In-Band Interrupt (IBI), the controller needs to be made aware of it.

- \texttt{i3c\_ibi\_enable()} to enable IBI of a target device.
  - Some controller hardware have IBI slots which need to be programmed so that the controller can recognize incoming IBIs from a particular target device.
    - If the hardware has IBI slots, \texttt{i3c\_ibi\_enable()} needs to program those IBI slots.
    - Note that there are usually limited IBI slots on the controller so this operation may fail.
  - The implementation in driver should also send the ENEC command to enable interrupt of this target device.
- \texttt{i3c\_ibi\_disable()} to disable IBI of a target device.
  - If controller hardware makes use of IBI slots, this will remove description of the target device from the slots.
  - The implementation in driver should also send the DISEC command to disable interrupt of this target device.

**Device Tree** Here is an example for defining a I3C controller in device tree:

```c
i3c0: i3c@10000 {
    compatible = "vendor,i3c";
    #address-cells = < 0x3 >;
    #size-cells = < 0x0 >;
    reg = < 0x10000 0x1000 >;
    interrupts = < 0x1F 0x0 >;
    pinctrl-0 = < &pinmux-i3c >;
    pinctrl-names = "default";
    i2c-scl-hz = < 400000 >;
    i3c-scl-hz = < 12000000 >;
}
```

(continues on next page)
I3C Devices
For I3C devices, the reg property has 3 elements:

- The first one is the static address of the device.
  - Can be zero if static address is not used. Address will be assigned during DAA (Dynamic Address Assignment).
  - If non-zero and property assigned-address is not set, this will be the address of the device after SETDASA (Set Dynamic Address from Static Address) is issued.

- Second element is the upper 16-bit of the Provisioned ID (PID) which contains the manufacturer ID left-shifted by 1. This is the bits 33-47 (zero-based) of the 48-bit Provisioned ID.

- Third element contains the lower 32-bit of the Provisioned ID which is a combination of the part ID (left-shifted by 16, bits 16-31 of the PID) and the instance ID (left-shifted by 12, bits 12-15 of the PID).

Note that the unit-address (the part after @) must match the reg property fully where each element is treated as 32-bit integer, combining to form a 96-bit integer. This is required for properly generating device tree macros.

I²C Devices
For I²C devices where the device driver has support for working under I3C bus, the device node can be described as a child of the I3C controller. If the device driver is written to only work with I²C controllers, define the node under the I²C virtual controller as described below. Otherwise, the reg property, similar to I3C devices, has 3 elements:

- The first one is the static address of the device. This must be a valid address as I²C devices do not support dynamic address assignment.

- Second element is always zero.
  - This is used by various helper macros to determine whether the device tree entry corresponds to a I²C device.

- Third element is the LVR (Legacy Virtual Register):
  - bit[31:8] are unused.
  - bit[7:5] are the I²C device index:
    * Index 0
I3C device has a 50 ns spike filter where it is not affected by high frequency on SCL.

Index 1

I2C device does not have a 50 ns spike filter but can work with high frequency on SCL.

Index 2

I3C device does not have a 50 ns spike filter and cannot work with high frequency on SCL.

– bit[4] is the I2C mode indicator:
  * 0 is FM+ mode.
  * 1 is FM mode.

Similar to I3C devices, the unit-address must match the reg property fully where each element is treated as 32-bit integer, combining to form a 96-bit integer.

**Device Drivers for I3C Devices**  All of the transfer functions of I3C controller API require the use of device descriptors, `i3c_device_desc`. This struct contains runtime information about a I3C device, such as, its dynamic address, BCR, DCR, MRL and MWL. Therefore, the device driver of a I3C device should grab a pointer to this device descriptor from the controller using `i3c_device_find()`. This function takes an ID parameter of type `i3c_device_id` for matching. The returned pointer can then be used in subsequent API calls to the controller.

**I2C Devices under I3C Bus**  Since I3C is backward compatible with I2C, the I3C controller API can accommodate I2C API calls without modifications if the controller device driver implements the I2C API. This has the advantage of using existing I2C devices without any modifications to their device drivers. However, since the I3C controller API works on device descriptors, any calls to I2C API will need to look up the corresponding device descriptor from the I2C device address. This adds a bit of processing cost to any I2C API calls.

On the other hand, a device driver can be extended to utilize native I2C device support via the I3C controller API. During device initialization, `i3c_i2c_device_find()` needs to be called to retrieve the pointer to the device descriptor. This pointer can be used in subsequent API calls.

Note that, with either methods mentioned above, the devicetree node of the I2C device must be declared according to I3C standard:

The I2C virtual controller device driver provides a way to interface I2C devices on the I3C bus where the associated device drivers can be used as-is without modifications. This requires adding an intermediate node in the device tree:

```plaintext
i3c0: i3c@10000 {
  <... I3C controller related properties ...>
  <... Nodes of I3C devices, if any ...

  i2c-dev0: i2c-dev0@420000000000000050 {
    compatible = "vendor-i2c-dev";
    reg = < 0x42 0x0 0x50 >;
    status = "okay";
  }
};
```

I3C_MSG_WRITE
Write message to I3C bus.

I3C_MSG_READ
Read message from I2C bus.

I3C_MSG_STOP
Send STOP after this message.

I3C_MSG_RESTART
RESTART I3C transaction for this message.

**Note:** Not all I3C drivers have or require explicit support for this feature. Some drivers require this be present on a read message that follows a write, or vice-versa. Some drivers will merge adjacent fragments into a single transaction using this flag; some will not.

I3C_DEVICE_ID(pid)
Structure initializer for i3c_device_id from PID.
This helper macro expands to a static initializer for a struct i3c_device_id by populating the PID (Provisioned ID) field.

**Parameters**
- pid – Provisioned ID.

**Enums**

enum i3c_bus_mode
I3C bus mode.

*Values:*

enumerator I3C_BUS_MODE_PURE
Only I3C devices are on the bus.

enumerator I3C_BUS_MODE_MIXED_FAST
Both I3C and legacy I2C devices are on the bus. The I2C devices have 50ns spike filter on SCL.

enumerator I3C_BUS_MODE_MIXED_LIMITED
Both I3C and legacy I2C devices are on the bus. The I2C devices do not have 50ns spike filter on SCL and can tolerate maximum SDR SCL clock frequency.

enumerator I3C_BUS_MODE_MIXED_SLOW
Both I3C and legacy I2C devices are on the bus. The I2C devices do not have 50ns spike filter on SCL but cannot tolerate maximum SDR SCL clock frequency.

enumerator I3C_BUS_MODE_MAX = I3C_BUS_MODE_MIXED_SLOW
enumerator I3C_BUS_MODE_INVALID

eenum i3c_i2c_speed_type
  I2C bus speed under I3C bus.
  Only FM and FM+ modes are supported for I2C devices under I3C bus.
  Values:
  
  enumerator I3C_I2C_SPEED_FM
    I2C FM mode
  
  enumerator I3C_I2C_SPEED_FMPLUS
    I2C FM+ mode
  
  enumerator I3C_I2C_SPEED_MAX = I3C_I2C_SPEED_FMPLUS

  enumerator I3C_I2C_SPEED_INVALID

eenum i3c_data_rate
  I3C data rate.
  I3C data transfer rate defined by the I3C specification.
  Values:
  
  enumerator I3C_DATA_RATE_SDR
    Single Data Rate messaging
  
  enumerator I3C_DATA_RATE_HDR_DDR
    High Data Rate - Double Data Rate messaging
  
  enumerator I3C_DATA_RATE_HDR_TSL
    High Data Rate - Ternary Symbol Legacy-inclusive-Bus
  
  enumerator I3C_DATA_RATE_HDR_TSP
    High Data Rate - Ternary Symbol for Pure Bus
  
  enumerator I3C_DATA_RATE_HDR_BT
    High Data Rate - Bulk Transport
  
  enumerator I3C_DATA_RATE_MAX = I3C_DATA_RATE_HDR_BT

  enumerator I3C_DATA_RATE_INVALID

eenum i3c_sdr_controller_error_codes
  I3C SDR Controller Error Codes.
  These are error codes defined by the I3C specification.
  I3C_ERROR_CE_UNKNOWN and I3C_ERROR_CE_NONE are not official error codes according to the specification. These are there simply to aid in error handling during interactions with the I3C drivers and subsystem.
Values:

enumerator I3C_ERROR_CE0
Transaction after sending CCC

enumerator I3C_ERROR_CE1
Monitoring Error

enumerator I3C_ERROR_CE2
No response to broadcast address (0x7E)

enumerator I3C_ERROR_CE3
Failed Controller Handoff

enumerator I3C_ERROR_CE_UNKNOWN
Unknown error (not official error code)

enumerator I3C_ERROR_CE_NONE
No error (not official error code)

enumerator I3C_ERROR_CE_MAX = I3C_ERROR_CE_UNKNOWN

enumerator I3C_ERROR_CE_INVALID

enum i3c_sdr_target_error_codes
I3C SDR Target Error Codes.
These are error codes defined by the I3C specification.
I3C_ERROR_TE_UNKNOWN and I3C_ERROR_TE_NONE are not official error codes according to the specification. These are there simply to aid in error handling during interactions with the I3C drivers and subsystem.

Values:

enumerator I3C_ERROR_TE0
Invalid Broadcast Address or Dynamic Address after DA assignment

enumerator I3C_ERROR_TE1
CCC Code

enumerator I3C_ERROR_TE2
Write Data

enumerator I3C_ERROR_TE3
Assigned Address during Dynamic Address Arbitration

enumerator I3C_ERROR_TE4
0x7E/R missing after RESTART during Dynamic Address Arbitration

enumerator I3C_ERROR_TE5
Transaction after detecting CCC
enumerator I3C_ERROR_TE6
    Monitoring Error

enumerator I3C_ERROR_DBR
    Dead Bus Recovery

enumerator I3C_ERROR_TE_UNKNOWN
    Unknown error (not official error code)

enumerator I3C_ERROR_TE_NONE
    No error (not official error code)

enumerator I3C_ERROR_TE_MAX = I3C_ERROR_TE_UNKNOWN

enumerator I3C_ERROR_TE_INVALID

enum i3c_config_type
    Type of configuration being passed to configure function.
    
    Values:
    
    enumerator I3C_CONFIG_CONTROLLER
    enumerator I3C_CONFIG_TARGET
    enumerator I3C_CONFIG_CUSTOM

Functions

struct i3c_device_desc *i3c_dev_list_find(const struct i3c_dev_list *dev_list, const struct i3c_device_id *id)

Find a I3C target device descriptor by ID.

This finds the I3C target device descriptor in the device list matching the provided ID struct (id).

Parameters

• dev_list – Pointer to the device list struct.
• id – Pointer to I3C device ID struct.

Returns

Pointer to the the I3C target device descriptor, or NULL if none is found.

struct i3c_device_desc *i3c_dev_list_i3c_addr_find(const struct i3c_dev_list *dev_list, uint8_t addr)

Find a I3C target device descriptor by dynamic address.

This finds the I3C target device descriptor in the device list matching the dynamic address (addr)

Parameters

• dev_list – Pointer to the device list struct.
• addr – Dynamic address to be matched.

Returns
Pointer the the I2C target device descriptor, or NULL if none is found.

struct i3c_i2c_device_desc *i3c_dev_list_i2c_addr_find(const struct i3c_dev_list *dev_list, uint16_t addr)

Find a I2C target device descriptor by address.

This finds the I2C target device descriptor in the device list matching the address (addr)

Parameters
• dev_list – Pointer to the device list struct.
• addr – Address to be matched.

Returns
Pointer the the I2C target device descriptor, or NULL if none is found.

int i3c_dev_list_daa_addr_helper(struct i3c_addr_slots *addr_slots, const struct i3c_dev_list *dev_list, uint64_t pid, bool must_match, bool assigned_okay, struct i3c_device_desc **target, uint8_t *addr)

Helper function to find a usable address during ENTDAA.

This is a helper function to find a usable address during Dynamic Address Assignment. Given the PID (pid), it will search through the device list for the matching device descriptor. If the device descriptor indicates that there is a preferred address (i.e. assigned-address in device tree),

If must_match is true, the PID (pid) must match one of the device in the device list.

See also:

i3c_device_desc::init_dynamic_addr), this preferred address will be returned if this address is still available. If it is not available, another free address will be returned.

If must_match is false, this will return an arbitrary address. This is useful when not all devices are described in device tree. Or else, the DAA process cannot proceed since there is no address to be assigned.

If assigned_okay is true, it will return the same address already assigned to the device (that

If assigned_okay is false, the device cannot have an address assigned already (that

See also:

i3c_device_desc::dynamic_addr). If no address has been assigned, it behaves as if assigned_okay is false. This is useful for assigning the same address to the same device (for example, hot-join after device coming back from suspend).

See also:

i3c_device_desc::dynamic_addr is not zero). This is mainly used during the initial DAA.

Parameters
• addr_slots – [in] Pointer to address slots struct.
• dev_list – [in] Pointer to the device list struct.
• pid – [in] Provisioned ID of device to be assigned address.
• must_match – [in] True if PID must match devices in the device list. False otherwise.
• assigned_okay – [in] True if it is okay to return the address already assigned to the target matching the PID (pid).
• **target** – [out] Store the pointer of the device descriptor if it matches the incoming PID (pid).

• **addr** – [out] Address to be assigned to target device.

**Return values**

• 0 – if successful.

• -ENODEV – if no device matches the PID (pid) in the device list and **must_match** is true.

• -EINVAL – if the device matching PID (pid) already has an address assigned or invalid function arguments.

static inline int i3c_configure(const struct device *dev, enum i3c_config_type type, void *config)

Configure the I3C hardware.

**Parameters**

• **dev** – Pointer to controller device driver instance.

• **type** – Type of configuration parameters being passed in **config**.

• **config** – Pointer to the configuration parameters.

**Return values**

• 0 – If successful.

• -EINVAL – If invalid configure parameters.

• -EIO – General Input/Output errors.

• -ENOSYS – If not implemented.

static inline int i3c_config_get(const struct device *dev, enum i3c_config_type type, void *config)

Get configuration of the I3C hardware.

This provides a way to get the current configuration of the I3C hardware.

This can return cached config or probed hardware parameters, but it has to be up to date with current configuration.

Note that if **type** is **I3C_CONFIG_CUSTOM**, **config** must contain the ID of the parameter to be retrieved.

**Parameters**

• **dev** – [in] Pointer to controller device driver instance.

• **type** – [in] Type of configuration parameters being passed in **config**.

• **config** – [inout] Pointer to the configuration parameters.

**Return values**

• 0 – If successful.

• -EIO – General Input/Output errors.

• -ENOSYS – If not implemented.

static inline int i3c_recover_bus(const struct device *dev)

Attempt bus recovery on the I3C bus.

This routine asks the controller to attempt bus recovery.
• 0 – If successful.
• -EBUSY – If bus recovery fails.
• -EIO – General input/output error.
• -ENOSYS – Bus recovery is not supported by the controller driver.

static inline int i3c_do_daa(const struct device *dev)

Perform Dynamic Address Assignment on the I3C bus.

This routine asks the controller to perform dynamic address assignment where the controller
belongs. Only the active controller of the bus should do this.

**Note:** For controller driver implementation, the controller should perform SETDASA to allow
static addresses to be the dynamic addresses before actually doing ENTDAA.

**Parameters**

- dev – Pointer to the device structure for the controller driver instance.

**Return values**

- 0 – If successful.
- -EBUSY – Bus is busy.
- -EIO – General input/output error.
- -ENODEV – If a provisioned ID does not match to any target devices in the
  registered device list.
- -ENOSPC – No more free addresses can be assigned to target.
- -ENOSYS – Dynamic address assignment is not supported by the controller
driver.

int i3c_do_ccc(const struct device *dev, struct i3c_ccc_payload *payload)

Send CCC to the bus.

**Parameters**

- dev – Pointer to the device structure for the controller driver instance.
- payload – Pointer to the structure describing the CCC payload.

**Return values**

- 0 – If successful.
- -EBUSY – Bus is busy.
- -EIO – General Input/output error.
- -EINVAL – Invalid valid set in the payload structure.
- -ENOSYS – Not implemented.

int i3c_transfer(struct i3c_device_desc *target, struct i3c_msg *msgs, uint8_t num_msgs)

Perform data transfer from the controller to a I3C target device.

This routine provides a generic interface to perform data transfer to a target device syn-
chronously. Use i3c_read()/i3c_write() for simple read or write.

The array of message msgs must not be NULL. The number of message num_msgs may be zero,
in which case no transfer occurs.
Note: Not all scatter/gather transactions can be supported by all drivers. As an example, a gather write (multiple consecutive `i3c_msg` buffers all configured for `I3C_MSG_WRITE`) may be packed into a single transaction by some drivers, but others may emit each fragment as a distinct write transaction, which will not produce the same behavior. See the documentation of `struct i3c_msg` for limitations on support for multi-message bus transactions.

Parameters
- `target` – I3C target device descriptor.
- `msgs` – Array of messages to transfer.
- `num_msgs` – Number of messages to transfer.

Return values
- `0` – If successful.
- `-EBUSY` – Bus is busy.
- `-EIO` – General input / output error.

```c
static inline struct i3c_device_desc *i3c_device_find(const struct device *dev, const struct i3c_device_id *id)
```

Find a registered I3C target device.

Controller only API.

This returns the I3C device descriptor of the I3C device matching the incoming `id`.

Parameters
- `dev` – Pointer to controller device driver instance.
- `id` – Pointer to I3C device ID.

Returns
Pointer to I3C device descriptor, or NULL if no I3C device found matching incoming `id`.

```c
static inline int i3c_ibi_raise(const struct device *dev, struct i3c_ibi *request)
```

Raise an In-Band Interrupt (IBI).

This raises an In-Band Interrupt (IBI) to the active controller.

Parameters
- `dev` – Pointer to controller device driver instance.
- `request` – Pointer to the IBI request struct.

Return values
- `0` – if operation is successful.
- `-EIO` – General input / output error.

```c
static inline int i3c_ibi_enable(struct i3c_device_desc *target)
```

Enable IBI of a target device.

This enables IBI of a target device where the IBI has already been request.

Parameters
- `target` – I3C target device descriptor.

Return values
- `0` – If successful.
• -EIO – General Input / output error.
• -ENOMEM – If there is no more empty entries in the controller's IBI table (if the controller uses such table).

static inline int i3c_ibi_disable(struct i3c_device_desc *target)

Disable IBI of a target device.
This enables IBI of a target device where the IBI has already been request.

Parameters
• target – I3C target device descriptor.

Return values
• 0 – If successful.
• -EIO – General Input / output error.
• -ENOMEM – If IBI is not previously enabled for target.

static inline int i3c_ibi_has_payload(struct i3c_device_desc *target)

Check if target's IBI has payload.
This reads the BCR from the device descriptor struct to determine whether IBI from device has payload.
Note that BCR must have been obtained from device and

See also:
i3c_device_desc::bcr must be set.

Returns
True if IBI has payload, false otherwise.

static inline int i3c_device_is_ibi_capable(struct i3c_device_desc *target)

Check if device is IBI capable.
This reads the BCR from the device descriptor struct to determine whether device is capable of IBI.
Note that BCR must have been obtained from device and

See also:
i3c_device_desc::bcr must be set.

Returns
True if IBI has payload, false otherwise.

static inline int i3c_write(struct i3c_device_desc *target, const uint8_t *buf, uint32_t num_bytes)

Write a set amount of data to an I3C target device.
This routine writes a set amount of data synchronously.

Parameters
• target – I3C target device descriptor.
• buf – Memory pool from which the data is transferred.
• num_bytes – Number of bytes to write.

Return values
• 0 – If successful.
• -EBUSY – Bus is busy.
• -EIO – General input / output error.

static inline int i3c_read(struct i3c_device_desc *target, uint8_t *buf, uint32_t num_bytes)
Read a set amount of data from an I3C target device.
This routine reads a set amount of data synchronously.

Parameters
• target – I3C target device descriptor.
• buf – Memory pool that stores the retrieved data.
• num_bytes – Number of bytes to read.

Return values
• 0 – If successful.
• -EBUSY – Bus is busy.
• -EIO – General input / output error.

static inline int i3c_write_read(struct i3c_device_desc *target, const void *write_buf, size_t num_write, void *read_buf, size_t num_read)
Write then read data from an I3C target device.

This supports the common operation “this is what I want”, “now give it to me” transaction pair through a combined write-then-read bus transaction.

Parameters
• target – I3C target device descriptor.
• write_buf – Pointer to the data to be written
• num_write – Number of bytes to write
• read_buf – Pointer to storage for read data
• num_read – Number of bytes to read

Return values
• 0 – if successful
• -EBUSY – Bus is busy.
• -EIO – General input / output error.

static inline int i3c_burst_read(struct i3c_device_desc *target, uint8_t start_addr, uint8_t *buf, uint32_t num_bytes)
Read multiple bytes from an internal address of an I3C target device.
This routine reads multiple bytes from an internal address of an I3C target device synchronously.
Instances of this may be replaced by i3c_write_read().

Parameters
• target – I3C target device descriptor,
• start_addr – Internal address from which the data is being read.
• buf – Memory pool that stores the retrieved data.
• num_bytes – Number of bytes being read.

Return values
static inline int i3c_burst_write(struct i3c_device_desc *target, uint8_t start_addr, const uint8_t *buf, uint32_t num_bytes)

Write multiple bytes to an internal address of an I3C target device.

This routine writes multiple bytes to an internal address of an I3C target device synchronously.

**Warning:** The combined write synthesized by this API may not be supported on all I3C devices. Uses of this API may be made more portable by replacing them with calls to `i3c_write()` passing a buffer containing the combined address and data.

**Parameters**

- `target` – I3C target device descriptor.
- `start_addr` – Internal address to which the data is being written.
- `buf` – Memory pool from which the data is transferred.
- `num_bytes` – Number of bytes being written.

**Return values**

- 0 – If successful.
- -EBUSY – Bus is busy.
- -EIO – General input / output error.

static inline int i3c_reg_read_byte(struct i3c_device_desc *target, uint8_t reg_addr, uint8_t *value)

Read internal register of an I3C target device.

This routine reads the value of an 8-bit internal register of an I3C target device synchronously.

**Parameters**

- `target` – I3C target device descriptor.
- `reg_addr` – Address of the internal register being read.
- `value` – Memory pool that stores the retrieved register value.

**Return values**

- 0 – If successful.
- -EBUSY – Bus is busy.
- -EIO – General input / output error.

static inline int i3c_reg_write_byte(struct i3c_device_desc *target, uint8_t reg_addr, uint8_t value)

Write internal register of an I3C target device.

This routine writes a value to an 8-bit internal register of an I3C target device synchronously.

**Note:** This function internally combines the register and value into a single bus transaction.
• target – I3C target device descriptor.
• reg_addr – Address of the internal register being written.
• value – Value to be written to internal register.

Return values
• 0 – If successful.
• -EBUSY – Bus is busy.
• -EIO – General input / output error.

static inline int i3c_reg_update_byte(struct i3c_device_desc *target, uint8_t reg_addr, uint8_t mask, uint8_t value)

Update internal register of an I3C target device.
This routine updates the value of a set of bits from an 8-bit internal register of an I3C target device synchronously.

Note: If the calculated new register value matches the value that was read this function will not generate a write operation.

Parameters
• target – I3C target device descriptor.
• reg_addr – Address of the internal register being updated.
• mask – Bitmask for updating internal register.
• value – Value for updating internal register.

Return values
• 0 – If successful.
• -EBUSY – Bus is busy.
• -EIO – General input / output error.

void i3c_dump_msgs(const char *name, const struct i3c_msg *msgs, uint8_t num_msgs, struct i3c_device_desc *target)

Dump out an I3C message.
Dumps out a list of I3C messages. For any that are writes (W), the data is displayed in hex.
It looks something like this (with name “testing”):

```
D: I3C msg: testing, addr=56
D:   W len=01:
D: contents:
D:   06 | .
D:   W len=0e:
D: contents:
D: 00 01 02 03 04 05 06 07 | . . . . . .
D: 08 09 0a 0b 0c 0d | . . . . . .
```

Parameters
• name – Name of this dump, displayed at the top.
• msgs – Array of messages to dump.
• num_msgs – Number of messages to dump.
• target – I3C target device descriptor.

int i3c_bus_init(const struct device *dev, const struct i3c_dev_list *i3c_dev_list)
Generic helper function to perform bus initialization.

Parameters
• dev – Pointer to controller device driver instance.
• i3c_dev_list – Pointer to I3C device list.

Return values
• 0 – If successful.
• -EBUSY – Bus is busy.
• -EIO – General input / output error.
• -ENOMEM – If a provisioned ID does not match to any target devices in the registered device list.
• -ENOSPC – No more free addresses can be assigned to target.
• -ENOSYS – Dynamic address assignment is not supported by the controller driver.

int i3c_device_basic_info_get(struct i3c_device_desc *target)
Get basic information from device and update device descriptor.

This retrieves some basic information:
• Bus Characteristics Register (GETBCR)
• Device Characteristics Register (GETDCR)
• Max Read Length (GETMRL)
• Max Write Length (GETMWL) from the device and update the corresponding fields of the device descriptor.

This only updates the field(s) in device descriptor only if CCC operations succeed.

Parameters
• target – [inout] I3C target device descriptor.

Return values
• 0 – if successful.
• -EIO – General Input/Output error.

struct i3c_msg
#include <i3c.h> One I3C Message.

This defines one I3C message to transact on the I3C bus.

Note: Some of the configurations supported by this API may not be supported by specific SoC I3C hardware implementations, in particular features related to bus transactions intended to read or write data from different buffers within a single transaction. Invocations of i3c_transfer() may not indicate an error when an unsupported configuration is encountered. In some cases drivers will generate separate transactions for each message fragment, with or without presence of I3C_MSG_RESTART in flags.
Public Members

uint8_t *buf
   Data buffer in bytes

uint32_t len
   Length of buffer in bytes

uint8_t flags
   Flags for this message

uint8_t hdr_mode
   HDR mode (I3C_MSG_HDR_MODE*) for transfer if any I3C_MSG_HDR_* is set in flags.
   Use SDR mode if none is set.

struct i3c_config_controller
   #include <i3c.h> Configuration parameters for I3C hardware to act as controller.

Public Members

bool is_primary
   True if the controller is to be the primary controller of the bus. False to be the secondary controller.

uint32_t i3c
   SCL frequency (in Hz) for I3C transfers.

uint32_t i2c
   SCL frequency (in Hz) for I2C transfers.

uint8_t supported_hdr
   Bit mask of supported HDR modes (0 - 7).
   This can be used to enable or disable HDR mode supported by the hardware at runtime.

struct i3c_config_custom
   #include <i3c.h> Custom I3C configuration parameters.

This can be used to configure the I3C hardware on parameters not covered by

See also:
i3c_config_controller or

See also:
i3c_config_target. Mostly used to configure vendor specific parameters of the I3C hardware.

Public Members
**Public Members**

```c
const uint64_t pid
Device Provisioned ID
```

```c
const struct device *const bus
I3C bus to which this target device is attached
```

```c
const struct device *const dev
Device driver instance of the I3C device
```

```c
const uint64_t pid
Device Provisioned ID
```

```c
const uint8_t static_addr
Static address for this target device.
0 if static address is not being used, and only dynamic address is used. This means that the target device must go through ENTDAA (Dynamic Address Assignment) to get
```
a dynamic address before it can communicate with the controller. This means SETAASA and SETDASA CCC cannot be used to set dynamic address on the target device (as both are to tell target device to use static address as dynamic address).

const uint8_t init_dynamic_addr
Initial dynamic address.
This is specified in the device tree property “assigned-address” to indicate the desired dynamic address during address assignment (SETDASA and ENTDAA).
0 if there is no preference.

uint8_t dynamic_addr
Dynamic Address for this target device used for communication.
This is to be set by the controller driver in one of the following situations:
- During Dynamic Address Assignment (during ENTDAA)
- Reset Dynamic Address Assignment (RSTDAA)
- Set All Addresses to Static Addresses (SETAASA)
- Set New Dynamic Address (SETNEWDA)
- Set Dynamic Address from Static Address (SETDASA)
0 if address has not been assigned.

uint8_t group_addr
Group address for this target device. Set during:
- Reset Group Address(es) (RSTGRPA)
- Set Group Address (SETGRPA)
0 if group address has not been assigned.

uint8_t bcr
Bus Characteristic Register (BCR)
- BCR[7:6]: Device Role
  - 0: I3C Target
  - 1: I3C Controller capable
  - 2: Reserved
  - 3: Reserved
- BCR[5]: Advanced Capabilities
  - 0: Does not support optional advanced capabilities.
  - 1: Supports optional advanced capabilities which can be viewed via GETCAPS CCC.
- BCR[4]: Virtual Target Support
  - 0: Is not a virtual target.
  - 1: Is a virtual target.
- BCR[3]: Offline Capable
  - 0: Will always response to I3C commands.
  - 1: Will not always response to I3C commands.
- BCR[2]: IBI Payload
  - 0: No data bytes following the accepted IBI.
  - 1: One data byte (MDB, Mandatory Data Byte) follows the accepted IBI. Additional data bytes may also follows.
- BCR[1]: IBI Request Capable
  - 0: Not capable
  - 1: Capable
- BCR[0]: Max Data Speed Limitation
  - 0: No Limitation
  - 1: Limitation obtained via GETMXDS CCC.

uint8_t dcr
Device Characteristic Register (DCR)
Describes the type of device. Refer to official documentation on what this number means.

`uint8_t maxrd`
Maximum Read Speed

`uint8_t maxwr`
Maximum Write Speed

`uint32_t max_read_turnaround`
Maximum Read turnaround time in microseconds.

`uint16_t mrl`
Maximum Read Length

`uint16_t mwl`
Maximum Write Length

`uint8_t max_ibi`
Maximum IBI Payload Size. Valid only if BCR[2] is 1.

`void *controller_priv`
Private data by the controller to aid in transactions. Do not modify.

`i3c_target_ibi_cb_t ibi_cb`
In-Band Interrupt (IBI) callback.

`struct i3c_i2c_device_desc`
#include <i3c.h> Structure describing a I2C device on I3C bus.
Instances of this are passed to the I3C controller device APIs, for example: () i3c_i2c_device_register() to tell the controller of an I2C device. () i3c_i2c_transfers() to initiate data transfers between controller and I2C device.
Fields other than node must be initialized by the module that implements the device behavior prior to passing the object reference to I3C controller device APIs.

**Public Members**

`sys_snodet_t node`
Private, do not modify

`const struct device *bus`
I3C bus to which this I2C device is attached

`const uint16_t addr`
Static address for this I2C device.
const uint8_t lvr

Legacy Virtual Register (LVR)
• LVR[7:5]: I2C device index:
  – 0: I2C device has a 50 ns spike filter where it is not affected by high frequency on SCL.
  – 1: I2C device does not have a 50 ns spike filter but can work with high frequency on SCL.
  – 2: I2C device does not have a 50 ns spike filter and cannot work with high frequency on SCL.
• LVR[4]: I2C mode indicator:
  – 0: FM+ mode
  – 1: FM mode
• LVR[3:0]: Reserved.

void *controller_priv

Private data by the controller to aid in transactions. Do not modify.

struct i3c_dev_list

#include <i3c.h> Structure for describing attached devices for a controller.
This contains arrays of attached I3C and I2C devices.
This is a helper struct that can be used by controller device driver to aid in device management.

Public Members

struct i3c_device_desc *const i3c
Pointer to array of attached I3C devices.

struct i3c_i2c_device_desc *const i2c
Pointer to array of attached I2C devices.

const uint8_t num_i3c
Number of I3C devices in array.

const uint8_t num_i2c
Number of I2C devices in array.

group i3c_ccc
I3C Common Command Codes.

Defines

I3C_CCC_BROADCAST_MAX_ID
Maximum CCC ID for broadcast

I3C_CCC_ENEC(broadcast)
Enable Events Command

Parameters
• broadcast – True if broadcast, false if direct.
I3C_CCC_DISEC(broadcast)
Disable Events Command

Parameters
- broadcast – True if broadcast, false if direct.

I3C_CCC_ENTAS(as, broadcast)
Enter Activity State

Parameters
- as – Desired activity state
- broadcast – True if broadcast, false if direct.

I3C_CCC_ENTAS0(broadcast)
Enter Activity State 0

Parameters
- broadcast – True if broadcast, false if direct.

I3C_CCC_ENTAS1(broadcast)
Enter Activity State 1

Parameters
- broadcast – True if broadcast, false if direct.

I3C_CCC_ENTAS2(broadcast)
Enter Activity State 2

Parameters
- broadcast – True if broadcast, false if direct.

I3C_CCC_ENTAS3(broadcast)
Enter Activity State 3

Parameters
- broadcast – True if broadcast, false if direct.

I3C_CCC_RSTDAA
Reset Dynamic Address Assignment (Broadcast)

I3C_CCC_ENTDAA
Enter Dynamic Address Assignment (Broadcast)

I3C_CCC_DEFTGTS
Define List of Targets (Broadcast)

I3C_CCC_SETMWL(broadcast)
Set Max Write Length (Broadcast or Direct)

Parameters
- broadcast – True if broadcast, false if direct.

I3C_CCC_SETMRL(broadcast)
Set Max Read Length (Broadcast or Direct)

Parameters
- broadcast – True if broadcast, false if direct.
I3C_CCC_ENTTM  
Enter Test Mode (Broadcast)

I3C_CCC_SETBUSCON  
Set Bus Context (Broadcast)

I3C_CCC_ENDXFER(broadcast)  
Data Transfer Ending Procedure Control

**Parameters**  
- broadcast – True if broadcast, false if direct.

I3C_CCC_ENTHDR(x)  
Enter HDR Mode (HDR-DDR) (Broadcast)

I3C_CCC_ENTHDR0  
Enter HDR Mode 0 (HDR-DDR) (Broadcast)

I3C_CCC_ENTHDR1  
Enter HDR Mode 1 (HDR-TSP) (Broadcast)

I3C_CCC_ENTHDR2  
Enter HDR Mode 2 (HDR-TSL) (Broadcast)

I3C_CCC_ENTHDR3  
Enter HDR Mode 3 (HDR-BT) (Broadcast)

I3C_CCC_ENTHDR4  
Enter HDR Mode 4 (Broadcast)

I3C_CCC_ENTHDR5  
Enter HDR Mode 5 (Broadcast)

I3C_CCC_ENTHDR6  
Enter HDR Mode 6 (Broadcast)

I3C_CCC_ENTHDR7  
Enter HDR Mode 7 (Broadcast)

I3C_CCC_SETXTIME(broadcast)  
Exchange Timing Information (Broadcast or Direct)

**Parameters**  
- broadcast – True if broadcast, false if direct.

I3C_CCC_SETAASA  
Set All Addresses to Static Addresses (Broadcast)

I3C_CCC_RSTACT(broadcast)  
Target Reset Action

**Parameters**  
- broadcast – True if broadcast, false if direct.
I3C_CCC_DEFGRPA
- Define List of Group Address (Broadcast)

I3C_CCC_RSTGRPA(broadcast)
- Reset Group Address

**Parameters**
- broadcast – True if broadcast, false if direct.

I3C_CCC_MLANE(broadcast)
- Multi-Lane Data Transfer Control (Broadcast)

I3C_CCC_VENDOR(broadcast, id)
- Vendor/Standard Extension

**Parameters**
- broadcast – True if broadcast, false if direct.
- id – Extension ID.

I3C_CCC_SETDASA
- Set Dynamic Address from Static Address (Direct)

I3C_CCC_SETNEWDA
- Set New Dynamic Address (Direct)

I3C_CCC_GETMWL
- Get Max Write Length (Direct)

I3C_CCC_GETMRL
- Get Max Read Length (Direct)

I3C_CCC_GETPID
- Get Provisioned ID (Direct)

I3C_CCC_GETBCR
- Get Bus Characteristics Register (Direct)

I3C_CCC_GETDCR
- Get Device Characteristics Register (Direct)

I3C_CCC_GETSTATUS
- Get Device Status (Direct)

I3C_CCC_GETACCCR
- Get Accept Controller Role (Direct)

I3C_CCC_SETBRGTGT
- Set Bridge Targets (Direct)

I3C_CCC_GETMXDS
- Get Max Data Speed (Direct)

7.3. Peripherals
I3C_CCC_GETCAPS
Get Optional Feature Capabilities (Direct)

I3C_CCC_SETROUTE
Set Route (Direct)

I3C_CCC_D2DXFER
Device to Device(s) Tunneling Control (Direct)

I3C_CCC_GETXTIME
Get Exchange Timing Information (Direct)

I3C_CCC_SETGRP
Set Group Address (Direct)

I3C_CCC_ENEC_EVT_ENINTR

I3C_CCC_ENEC_EVT_ENCR

I3C_CCC_ENEC_EVT_ENHJ

I3C_CCC_ENEC_EVT_ALL

I3C_CCC_DISEC_EVT_DISINTR

I3C_CCC_DISEC_EVT_DISCR

I3C_CCC_DISEC_EVT_DISHJ

I3C_CCC_DISEC_EVT_ALL

I3C_CCC_EVT_INTR

I3C_CCC_EVT_CR

I3C_CCC_EVT_HJ

I3C_CCC_EVT_ALL

I3C_CCC_GETSTATUS_PROTOCOL_ERR

I3C_CCC_GETSTATUS_ACTIVITY_MODE_SHIFT

I3C_CCC_GETSTATUS_ACTIVITY_MODE_MASK

I3C_CCC_GETSTATUS_ACTIVITY_MODE(status)
I3C_CCC_GETMXDS_MAXRD_MAX_SDR_FSCL_SHIFT
I3C_CCC_GETMXDS_MAXRD_MAX_SDR_FSCL_MASK
I3C_CCC_GETMXDS_MAXRD_MAX_SDR_FSCL(maxrd)
I3C_CCC_GETMXDS_CRDHLY1_SET_BUS_ACT_STATE
I3C_CCC_GETMXDS_CRDHLY1_CTRL_HANDOFF_ACT_STATE_SHIFT
I3C_CCC_GETMXDS_CRDHLY1_CTRL_HANDOFF_ACT_STATE_MASK
I3C_CCC_GETMXDS_CRDHLY1_CTRL_HANDOFF_ACT_STATE(crhdly1)
I3C_CCC_GETCAPS1_HDR_DDR
I3C_CCC_GETCAPS1_HDR_BT
I3C_CCC_GETCAPS1_HDR_MODE(x)
I3C_CCC_GETCAPS1_HDR_MODE0
I3C_CCC_GETCAPS1_HDR_MODE1
I3C_CCC_GETCAPS1_HDR_MODE2
I3C_CCC_GETCAPS1_HDR_MODE3
I3C_CCC_GETCAPS1_HDR_MODE4
I3C_CCC_GETCAPS1_HDR_MODE5
I3C_CCC_GETCAPS1_HDR_MODE6
I3C_CCC_GETCAPS1_HDR_MODE7
I3C_CCC_GETCAPS2_HDRDDR_WRITE_ABORT
I3C_CCC_GETCAPS2_HDRDDR_ABORT_CRC
I3C_CCC_GETCAPS2_GRPADDR_CAP_SHIFT
I3C_CCC_GETCAPS2_GRPADDR_CAP_MASK
I3C_CCC_GETCAPS2_GRPADDR_CAP(getcaps2)
I3C_CCC_GETCAPS2_SPEC_VER_SHIFT
I3C_CCC_GETCAPS2_SPEC_VER_MASK
I3C_CCC_GETCAPS2_SPEC_VER(getcaps2)

I3C_CCC_GETCAPS3_HDRBT_CRC32_SUPPORT
I3C_CCC_GETCAPS3_IBI_MDR_PENDING_READ_NOTIFICATION

Enums

enum i3c_ccc_getstatus_fmt
   Indicate which format of GETSTATUS to use.
   Values:

   enumerator GETSTATUS_FORMAT_1
   enumerator GETSTATUS_FORMAT_2

enum i3c_ccc_getstatus_defbyte
   Values:

   enumerator GETSTATUS_FORMAT_2_TGTSTAT = 0x00U
   enumerator GETSTATUS_FORMAT_2_PRECR = 0x91U
   enumerator GETSTATUS_FORMAT_2_INVALID = 0x100U

enum i3c_ccc_rstact_defining_byte
   Values:

   enumerator I3C_CCC_RSTACT_NO_RESET = 0x00U
   enumerator I3C_CCC_RSTACT_PERIPHERAL_ONLY = 0x01U
   enumerator I3C_CCC_RSTACT_RESET_WHOLE_TARGET = 0x02U

7.3. Peripherals
enumerator I3C_CCC_RSTACT_DEBUG_NETWORK_ADAPTER = 0x03U

enumerator I3C_CCC_RSTACT_VIRTUAL_TARGET_DETECT = 0x04U

Functions

static inline bool i3c_ccc_is_payload_broadcast(const struct i3c_ccc_payload *payload)
    Test if I3C CCC payload is for broadcast.
    This tests if the CCC payload is for broadcast.

    Parameters
    • payload – [in] Pointer to the CCC payload.

    Return values
    • true – if payload target is broadcast
    • false – if payload target is direct

int i3c_ccc_do_getbcr(struct i3c_device_desc *target, struct i3c_ccc_getbcr *bcr)
    Get BCR from a target.
    Helper function to get BCR (Bus Characteristic Register) from target device.

See also:
    i3c_do_ccc

    Parameters
    • target – [in] Pointer to the target device descriptor.
    • bcr – [out] Pointer to the BCR payload structure.

    Returns

int i3c_ccc_do_getdcr(struct i3c_device_desc *target, struct i3c_ccc_getdcr *dcr)
    Get DCR from a target.
    Helper function to get DCR (Device Characteristic Register) from target device.

See also:
    i3c_do_ccc

    Parameters
    • target – [in] Pointer to the target device descriptor.
    • dcr – [out] Pointer to the DCR payload structure.

    Returns

int i3c_ccc_do_getpid(struct i3c_device_desc *target, struct i3c_ccc_getpid *pid)
    Get PID from a target.
    Helper function to get PID (Provisioned ID) from target device.
See also:

i3c_do_ccc

Parameters

- pid – [out] Pointer to the PID payload structure.

Returns

int i3c_ccc_do_rstact_all(const struct device *controller, enum i3c_ccc_rstact_defining_byte action)

Broadcast RSTACT to reset I3C Peripheral.
Helper function to broadcast Target Reset Action (RSTACT) to all connected targets to Reset the I3C Peripheral Only (0x01).

See also:

i3c_do_ccc

Parameters

- controller – [in] Pointer to the controller device driver instance.

Returns

int i3c_ccc_do_rstdaa_all(const struct device *controller)

Broadcast RSTDAA to reset dynamic addresses for all targets.
Helper function to reset dynamic addresses of all connected targets.

See also:

i3c_do_ccc

Parameters

- controller – [in] Pointer to the controller device driver instance.

Returns

int i3c_ccc_do_setdasa(const struct i3c_device_desc *target)

Set Dynamic Address from Static Address for a target.
Helper function to do SETDASA (Set Dynamic Address from Static Address) for a particular target.
Note this does not update target with the new dynamic address.

See also:

i3c_do_ccc

Parameters

- target – [in] Pointer to the target device descriptor where the device is configured with a static address.
Returns

int i3c_ccc_do_events_all_set(const struct device *controller, bool enable, struct i3c_ccc_events *events)

Broadcast ENEC/DISEC to enable/disable target events.
Helper function to broadcast Target Events Command to enable or disable target events (ENEC/DISEC).

See also:
i3c_do_ccc

Parameters
• controller – [in] Pointer to the controller device driver instance.
• enable – [in] ENEC if true, DISEC if false.
• events – [in] Pointer to the event struct.

Returns

int i3c_ccc_do_events_set(struct i3c_device_desc *target, bool enable, struct i3c_ccc_events *events)

Direct CCC ENEC/DISEC to enable/disable target events.
Helper function to send Target Events Command to enable or disable target events (ENEC/DISEC) on a single target.

See also:
i3c_do_ccc

Parameters
• target – [in] Pointer to the target device descriptor.
• enable – [in] ENEC if true, DISEC if false.
• events – [in] Pointer to the event struct.

Returns

int i3c_ccc_do_setmwl_all(const struct device *controller, const struct i3c_ccc_mwl *mwl)

Broadcast SETMWL to Set Maximum Write Length.
Helper function to do SETMWL (Set Maximum Write Length) to all connected targets.

See also:
i3c_do_ccc

Parameters
• controller – [in] Pointer to the controller device driver instance.
• mwl – [in] Pointer to SETMWL payload.

Returns
int i3c_ccc_do_setmwl(const struct i3c_device_desc *target, const struct i3c_ccc_mwl *mwl)
Single target SETMWL to Set Maximum Write Length.
Helper function to do SETMWL (Set Maximum Write Length) to one target.

See also:
i3c_do_ccc

Parameters
• target – [in] Pointer to the target device descriptor.
• mwl – [in] Pointer to SETMWL payload.

Returns

int i3c_ccc_do_getmwl(const struct i3c_device_desc *target, struct i3c_ccc_mwl *mwl)
Single target GETMWL to Get Maximum Write Length.
Helper function to do GETMWL (Get Maximum Write Length) of one target.

See also:
i3c_do_ccc

Parameters
• target – [in] Pointer to the target device descriptor.
• mwl – [out] Pointer to GETMWL payload.

Returns

int i3c_ccc_do_setmrl_all(const struct device *controller, const struct i3c_ccc_mrl *mrl, bool has_ibi_size)
Broadcast SETMRL to Set Maximum Read Length.
Helper function to do SETMRL (Set Maximum Read Length) to all connected targets.

See also:
i3c_do_ccc

Parameters
• controller – [in] Pointer to the controller device driver instance.
• mrl – [in] Pointer to SETMRL payload.
• has_ibi_size – [in] True if also sending the optional IBI payload size. False if not sending.

Returns

int i3c_ccc_do_setmrl(const struct i3c_device_desc *target, const struct i3c_ccc_mrl *mrl)
Single target SETMRL to Set Maximum Read Length.
Helper function to do SETMRL (Set Maximum Read Length) to one target.
Note this uses the BCR of the target to determine whether to send the optional IBI payload size.
See also:

*i3c_do_ccc*

### Parameters

### Returns

**int i3c_ccc_do_getmrl(const struct i3c_device_desc \*target, struct i3c_ccc_mrl \*mrl)**

Single target GETMRL to Get Maximum Read Length.

Helper function to do GETMRL (Get Maximum Read Length) of one target.

Note this uses the BCR of the target to determine whether to send the optional IBI payload size.

See also:

*i3c_do_ccc*

### Parameters

- mrl – [out] Pointer to GETMRL payload.

### Returns

**int i3c_ccc_do_getstatus(const struct i3c_device_desc \*target, union i3c_ccc_getstatus \*status, enum i3c_ccc_getstatus_fmt fmt, enum i3c_ccc_getstatus_defbyte defbyte)**

Single target GETSTATUS to Get Target Status.

Helper function to do GETSTATUS (Get Target Status) of one target.

Note this uses the BCR of the target to determine whether to send the optional IBI payload size.

See also:

*i3c_do_ccc*

### Parameters

- status – [out] Pointer to GETSTATUS payload.

### Returns

**static inline int i3c_ccc_do_getstatus_fmt1(const struct i3c_device_desc \*target, union i3c_ccc_getstatus \*status)**

Single target GETSTATUS to Get Target Status (Format 1).

Helper function to do GETSTATUS (Get Target Status, format 1) of one target.
See also:

\texttt{i3c\_do\_ccc}

**Parameters**

- **target** – [in] Pointer to the target device descriptor.
- **status** – [out] Pointer to GETSTATUS payload.

**Returns**

\footnotesize{\begin{verbatim}
static inline int i3c_ccc_do_getstatus_fmt2(const struct i3c_device_desc *target, union i3c_ccc_getstatus *status, enum i3c_ccc_getstatus_defbyte defbyte)
\end{verbatim}}

Single target GETSTATUS to Get Target Status (Format 2).

Helper function to do GETSTATUS (Get Target Status, format 2) of one target.

See also:

\texttt{i3c\_do\_ccc}

**Parameters**

- **target** – [in] Pointer to the target device descriptor.
- **status** – [out] Pointer to GETSTATUS payload.

**Returns**

\footnotesize{\begin{verbatim}
struct i3c_ccc_target_payload
\end{verbatim}}

\texttt{#include <ccc.h>} Payload structure for Direct CCC to one target.

**Public Members**

\begin{verbatim}
uint8_t addr
    Target address

uint8_t trnw
    0 for Write, 1 for Read

uint8_t *data
    • For Write CCC, pointer to the byte array of data to be sent, which may contain the Sub-Command Byte and additional data.
    • For Read CCC, pointer to the byte buffer for data to be read into.

size_t data_len
    Length in bytes for data.
\end{verbatim}

\footnotesize{\begin{verbatim}
struct i3c_ccc_payload
\end{verbatim}}

\texttt{#include <ccc.h>} Payload structure for one CCC transaction.
Public Members

uint8_t id
The CCC ID (I3C_CCC_*)

uint8_t *data
Pointer to byte array of data for this CCC.
This is the bytes following the CCC command in CCC frame. Set to NULL if no associated data.

size_t data_len
Length in bytes for optional data array.

struct i3c_ccc_target_payload *payloads
Array of struct i3c_ccc_target_payload.
Each element describes the target and associated payloads for this CCC.
Use with Direct CCC.

size_t num_targets
Number of targets

struct i3c_ccc_events
#include <ccc.h> Payload for ENEC/DISEC CCC (Target Events Command).

Public Members

uint8_t events
Event byte:
• Bit[0]: ENINT/DISINT:
  – Target Interrupt Requests
• Bit[1]: ENCR/DISCR:
  – Controller Role Requests
• Bit[3]: ENHJ/DISHJ:
  – Hot-Join Event

struct i3c_ccc_mwl
#include <ccc.h> Payload for SETMWL/GETMWL CCC (Set/Get Maximum Write Length).

Note: For drivers and help functions, the raw data coming back from target device is in big endian. This needs to be translated back to CPU endianness before passing back to function caller.

Public Members

uint16_t len
Maximum Write Length
struct i3c_ccc_mrl
#include <ccc.h> Payload for SETMRL/GETMRL CCC (Set/Get Maximum Read Length).

**Note:** For drivers and help functions, the raw data coming back from target device is in big endian. This needs to be translated back to CPU endianness before passing back to function caller.

**Public Members**

- uint16_t len
  Maximum Read Length

- uint8_t ibi_len
  Optional IBI Payload Size

struct i3c_ccc_deftgts_active_controller
#include <ccc.h> The active controller part of payload for DEFTGTS CCC.
This is used by DEFTGTS (Define List of Targets) CCC to describe the active controller on the I3C bus.

**Public Members**

- uint8_t addr
  Dynamic Address of Active Controller

- uint8_t dcr
  Device Characteristic Register of Active Controller

- uint8_t bcr
  Bus Characteristic Register of Active Controller

- uint8_t static_addr
  Static Address of Active Controller

struct i3c_ccc_deftgts_target
#include <ccc.h> The target device part of payload for DEFTGTS CCC.
This is used by DEFTGTS (Define List of Targets) CCC to describe the existing target devices on the I3C bus.

**Public Members**

- uint8_t addr
  Dynamic Address of a target device, or a group address

7.3. Peripherals
urban st_dcr
   Device Characteristic Register of a I3C target device or a group.

urban st_lvr
   Legacy Virtual Register for legacy I2C device.

urban st_bcr
   Bus Characteristic Register of a target device or a group

urban st_static_addr
   Static Address of a target device or a group

struct i3c_ccc_deftgts
   #include <ccc.h> Payload for DEFTGTS CCC (Define List of Targets).

Note:  i3c_ccc_deftgts_target is an array of targets, where the number of elements is dependent on the number of I3C targets on the bus. Please have enough space for both read and write of this CCC.

Public Members

struct i3c_ccc_deftgts_active_controller active_controller
   Data describing the active controller

struct i3c_ccc_deftgts_target targets[]
   Data describing the target(s) on the bus

struct i3c_ccc_address
   #include <ccc.h> Payload for a single device address.

This is used for:
   • SETDASA (Set Dynamic Address from Static Address)
   • SETNEWDA (Set New Dynamic Address)
   • SETGRPA (Set Group Address)
   • GETACCCCR (Get Accept Controller Role)

Note that the target address is encoded within struct i3c_ccc_target_payload instead of being encoded in this payload.

Public Members

uint8_t addr
   • For SETDASA, Static Address to be assigned as Dynamic Address.
   • For SETNEWDA, new Dynamic Address to be assigned.
   • For SETGRPA, new Group Address to be set.
   • For GETACCCCR, the correct address of Secondary Controller.
Note: For SETDATA, SETNEWDA and SETGRAP, the address is left-shift by 1, and bit[0] is always 0.

Note: For SETGETACCCR, the address is left-shift by 1, and bit[0] is the calculated odd parity bit.

```c
struct i3c_ccc_getpid
#include <ccc.h> Payload for GETPID CCC (Get Provisioned ID).

Public Members

uint8_t pid[6]
48-bit Provisioned ID.

Note: Data is big-endian where first byte is MSB.
```

```c
struct i3c_ccc_getbcr
#include <ccc.h> Payload for GETBCR CCC (Get Bus Characteristics Register).

Public Members

uint8_t bcr
Bus Characteristics Register

struct i3c_ccc_getdcr
#include <ccc.h> Payload for GETDCR CCC (Get Device Characteristics Register).

Public Members

uint8_t dcr
Device Characteristics Register

union i3c_ccc_getstatus
#include <ccc.h> Payload for GETSTATUS CCC (Get Device Status).

Public Members

uint16_t status
Device Status
• Bit[15:8]: Reserved.
• Bit[7:6]: Activity Mode.
• Bit[5]: Protocol Error.
• Bit[4]: Reserved.
```

7.3. Peripherals
• Bit[3:0]: Number of Pending Interrupts.

**Note:** For drivers and help functions, the raw data coming back from target device is in big endian. This needs to be translated back to CPU endianness before passing back to function caller.

```c
struct i3c_ccc_getstatus.[anonymous] fmt1

uint16_t tgtstat
    Defining Byte 0x00: TGTSTAT

**See also:**

i3c_ccc_getstatus::fmt1::status

uint16_t precr
    Defining Byte 0x91: PRECR
    • Bit[15:8]: Vendor Reserved
    • Bit[7:2]: Reserved
    • Bit[1]: Handoff Delay NACK
    • Bit[0]: Deep Sleep Detected

**Note:** For drivers and help functions, the raw data coming back from target device is in big endian. This needs to be translated back to CPU endianness before passing back to function caller.

uint16_t raw_u16

union i3c_ccc_getstatus.[anonymous] fmt2

struct i3c_ccc_setbrgtgt_tgt
    #include <ccc.h> One Bridged Target for SETBRGTGT payload.

**Public Members**

uint8_t addr
    Dynamic address of the bridged target.

**Note:** The address is left-shift by 1, and bit[0] is always 0.

uint16_t id
    16-bit ID for the bridged target.

**Note:** For drivers and help functions, the raw data coming back from target device is in big endian. This needs to be translated back to CPU endianness before passing back to function caller.
struct i3c_ccc_setbrgtgt

#include <ccc.h> Payload for SETBRGTGT CCC (Set Bridge Targets).

Note that the bridge target address is encoded within struct i3c_ccc_target_payload instead of being encoded in this payload.

Public Members

uint8_t count
    Number of bridged targets

struct i3c_ccc_setbrgtgt_tgt targets[]
    Array of bridged targets

union i3c_ccc_getmxds

#include <ccc.h> Payload for GETMXDS CCC (Get Max Data Speed).

Note: This is only for GETMXDS Format 1 and Format 2.

Public Members

uint8_t maxwr
    maxWr

uint8_t maxrd
    maxRd

struct i3c_ccc_getmxds.[anonymous] fmt1

uint8_t maxrdturn[3]
    Maximum Read Turnaround Time in microsecond.
    This is in little-endian where first byte is LSB.

struct i3c_ccc_getmxds.[anonymous] fmt2

uint8_t wrrdturn
    Defining Byte 0x00: WRRDTURN

    See also: i3c_ccc_getmxds::fmt2

uint8_t crhdly1
    Defining Byte 0x91: CRHDLY
    • Bit[2]: Set Bus Activity State
    • Bit[1:0]: Controller Handoff Activity State
struct i3c_ccc_getmxds.[anonymous] fmt3

struct i3c_ccc_getcaps

#include <ccc.h> Payload for GETCAPS CCC (Get Optional Feature Capabilities).

Note: Only support GETCAPS Format 1.

Public Members

uint8_t getcaps[4]

group i3c_addresses

I3C Address-related Helper Code.

Defines

I3C_BROADCAST_ADDR

I3C_MAX_ADDR

 Enums

denum i3c_addr_slot_status

Values:

enumerator I3C_ADDR_SLOT_STATUS_FREE = 0U

enumerator I3C_ADDR_SLOT_STATUS_RSVD

enumerator I3C_ADDR_SLOT_STATUS_I3C_DEV

enumerator I3C_ADDR_SLOT_STATUS_I2C_DEV

enumerator I3C_ADDR_SLOT_STATUS_MASK = 0x03U

Functions

int i3c_addr_slots_init(struct i3c_addr_slots *slots, const struct i3c_dev_list *dev_list)

Initialize the I3C address slots struct.

This clears out the assigned address bits, and set the reserved address bits according to the I3C specification.

Parameters
• slots – Pointer to address slots struct.
• dev_list – Pointer to device list struct.

Return values
• 0 – if successful.
• -EINVAL – if duplicate addresses.

void i3c_addr_slots_set(struct i3c_addr_slots *slots, uint8_t dev_addr, enum i3c_addr_slot_status status)

Set the address status of a device.

Parameters
• slots – Pointer to the address slots structure.
• dev_addr – Device address.
• status – New status for the address dev_addr.

enum i3c_addr_slot_status i3c_addr_slots_status(struct i3c_addr_slots *slots, uint8_t dev_addr)

Get the address status of a device.

Parameters
• slots – Pointer to the address slots structure.
• dev_addr – Device address.

Returns
Address status for the address dev_addr.

bool i3c_addr_slots_is_free(struct i3c_addr_slots *slots, uint8_t dev_addr)

Check if the address is free.

Parameters
• slots – Pointer to the address slots structure.
• dev_addr – Device address.

Return values
• true – if address is free.
• false – if address is not free.

uint8_t i3c_addr_slots_next_free_find(struct i3c_addr_slots *slots)

Find the next free address.

This can be used to find the next free address that can be assigned to a new device.

Parameters
• slots – Pointer to the address slots structure.

Returns
The next free address, or 0 if none found.

static inline void i3c_addr_slots_mark_free(struct i3c_addr_slots *addr_slots, uint8_t addr)

Mark the address as free (not used) in device list.

Parameters
• addr_slots – Pointer to the address slots struct.
• addr – Device address.
static inline void i3c_addr_slots_mark_rsvd(struct i3c_addr_slots *addr_slots, uint8_t addr)
Mark the address as reserved in device list.

Parameters
• addr_slots – Pointer to the address slots struct.
• addr – Device address.

static inline void i3c_addr_slots_mark_i3c(struct i3c_addr_slots *addr_slots, uint8_t addr)
Mark the address as I3C device in device list.

Parameters
• addr_slots – Pointer to the address slots struct.
• addr – Device address.

static inline void i3c_addr_slots_mark_i2c(struct i3c_addr_slots *addr_slots, uint8_t addr)
Mark the address as I2C device in device list.

Parameters
• addr_slots – Pointer to the address slots struct.
• addr – Device address.

struct i3c_addr_slots

#include <addresses.h> Structure to keep track of addresses on I3C bus.

7.3.22 IPM

Overview

API Reference

Enum ipm_interface

IPM Interface.

Typedefs

typedef void (*ipm_callback_t)(const struct device *ipmdev, void *user_data, uint32_t id,
volatile void *data)

Callback API for incoming IPM messages.

These callbacks execute in interrupt context. Therefore, use only interrupt-safe APIs. Registration of callbacks is done via ipm_register_callback

Param ipmdev
Driver instance

Param user_data
Pointer to some private data provided at registration time.

Param id
Message type identifier.

Param data
Message data pointer. The correct amount of data to read out must be inferred using the message id/upper level protocol.
typedef int (*ipm_send_t)(const struct device *ipmdev, int wait, uint32_t id, const void *data, int size)

Callback API to send IPM messages.
See ipm_send() for argument definitions.

typedef int (*ipm_max_data_size_get_t)(const struct device *ipmdev)

Callback API to get maximum data size.
See ipm_max_data_size_get() for argument definitions.

typedef uint32_t (*ipm_max_id_val_get_t)(const struct device *ipmdev)

Callback API to get the ID's maximum value.
See ipm_max_id_val_get() for argument definitions.

typedef void (*ipm_register_callback_t)(const struct device *port, ipm_callback_t cb, void *user_data)

Callback API upon registration.
See ipm_register_callback() for argument definitions.

typedef int (*ipm_set_enabled_t)(const struct device *ipmdev, int enable)

Callback API upon enablement of interrupts.
See ipm_set_enabled() for argument definitions.

typedef void (*ipm_complete_t)(const struct device *ipmdev)

Callback API upon command completion.
See ipm_complete() for argument definitions.

Functions

int ipm_send(const struct device *ipmdev, int wait, uint32_t id, const void *data, int size)

Try to send a message over the IPM device.

A message is considered consumed once the remote interrupt handler finishes. If there is deferred processing on the remote side, or if outgoing messages must be queued and wait on an event/semaphore, a high-level driver can implement that.

There are constraints on how much data can be sent or the maximum value of id. Use the ipm_max_data_size_get and ipm_max_id_val_get routines to determine them.

The size parameter is used only on the sending side to determine the amount of data to put in the message registers. It is not passed along to the receiving side. The upper-level protocol dictates the amount of data read back.

Parameters

- ipmdev – Driver instance
- wait – If nonzero, busy-wait for remote to consume the message. The message is considered consumed once the remote interrupt handler finishes. If there is deferred processing on the remote side, or you would like to queue outgoing messages and wait on an event/semaphore, you can implement that in a high-level driver
- id – Message identifier. Values are constrained by ipm_max_data_size_get since many boards only allow for a subset of bits in a 32-bit register to store the ID.
- data – Pointer to the data sent in the message.
- size – Size of the data.

**Return values**
- -EBUSY – If the remote hasn’t yet read the last data sent.
- -EMSGSIZE – If the supplied data size is unsupported by the driver.
- -EINVAL – If there was a bad parameter, such as: too-large id value. or the device isn’t an outbound IPM channel.
- 0 – On success.

```c
static inline void ipm_register_callback(const struct device *ipmdev, ipm_callback_t cb, void *user_data)
```

Register a callback function for incoming messages.

**Parameters**
- ipmdev – Driver instance pointer.
- cb – Callback function to execute on incoming message interrupts.
- user_data – Application-specific data pointer which will be passed to the callback function when executed.

```c
int ipm_max_data_size_get(const struct device *ipmdev)
```

Return the maximum number of bytes possible in an outbound message.

IPM implementations vary on the amount of data that can be sent in a single message since the data payload is typically stored in registers.

**Parameters**
- ipmdev – Driver instance pointer.

**Returns**
Maximum possible size of a message in bytes.

```c
uint32_t ipm_max_id_val_get(const struct device *ipmdev)
```

Return the maximum id value possible in an outbound message.

Many IPM implementations store the message’s ID in a register with some bits reserved for other uses.

**Parameters**
- ipmdev – Driver instance pointer.

**Returns**
Maximum possible value of a message ID.

```c
int ipm_set_enabled(const struct device *ipmdev, int enable)
```

Enable interrupts and callbacks for inbound channels.

**Parameters**
- ipmdev – Driver instance pointer.
- enable – Set to 0 to disable and to nonzero to enable.

**Return values**
- 0 – On success.
- -EINVAL – If it isn’t an inbound channel.
void ipm_complete(const struct device *ipmdev)

Signal asynchronous command completion.

Some IPM backends have an ability to deliver a command asynchronously. The callback will be invoked in interrupt context, but the message (including the provided data pointer) will stay “active” and unacknowledged until later code (presumably in thread mode) calls `ipm_complete()`.

This function is, obviously, a noop on drivers without async support.

**Parameters**

- ipmdev – Driver instance pointer.

```c
struct ipm_driver_api
#include <ipm.h>
```

### 7.3.23 KSCAN

#### Overview

The kscan driver (keyboard scan matrix) is used for detecting a key press in a connected matrix keyboard or any device with buttons such as joysticks. Typically, matrix keyboards are implemented using a two-dimensional configuration in order to sense several keys. This allows interfacing to many keys through fewer physical pins. Keyboard matrix drivers read the rows while applying power through the columns one at a time with the purpose of detecting key events. There is no correlation between the physical and electrical layout of keys. For example, the physical layout may be one array of 16 or fewer keys, which may be electrically connected to a 4 x 4 array. In addition, key values are defined by a keymap provided by the keyboard manufacturer.

#### Configuration Options

Related configuration options:

- `CONFIG_KSCAN`

#### API Reference

```c
group kscan_interface

KSCAN APIs.
```

#### Typedefs

```c
typedef void (*kscan_callback_t)(const struct device *dev, uint32_t row, uint32_t column, bool pressed)

Keyboard scan callback called when user press/release a key on a matrix keyboard.
```

**Param dev**

Pointer to the device structure for the driver instance.

**Param row**

Describes row change.

**Param column**

Describes column change.
**Param pressed**
Describes the kind of key event.

**Functions**

```c
int kscan_config(const struct device *dev, kscan_callback_t callback)
```
Configure a Keyboard scan instance.

**Parameters**
- `dev` – Pointer to the device structure for the driver instance.
- `callback` – called when keyboard devices reply to a keyboard event such as key pressed/released.

**Return values**
- 0 – If successful.
- Negative – errno code if failure.

```c
int kscan_enable_callback(const struct device *dev)
```
Enables callback.

**Parameters**
- `dev` – Pointer to the device structure for the driver instance.

**Return values**
- 0 – If successful.
- Negative – errno code if failure.

```c
int kscan_disable_callback(const struct device *dev)
```
Disables callback.

**Parameters**
- `dev` – Pointer to the device structure for the driver instance.

**Return values**
- 0 – If successful.
- Negative – errno code if failure.

### 7.3.24 LED

**Overview**
The LED API provides access to Light Emitting Diodes, both in individual and strip form.

**Configuration Options**
Related configuration options:
- `CONFIG_LED`
- `CONFIG_LED_STRIP`
API Reference

LED

\texttt{group\ led_interface}

LED Interface.

\textbf{Typedefs}

typedef int (*\texttt{led_api_blink})(const \texttt{device} *dev, \texttt{uint32_t} led, \texttt{uint32_t} delay_on, \texttt{uint32_t} delay_off)

Callback API for blinking an LED.

\textbf{See also:}

\texttt{led_blink()} for argument descriptions.

typedef int (*\texttt{led_api_get_info})(const \texttt{device} *dev, \texttt{uint32_t} led, const \texttt{struct led_info} **info)

Optional API callback to get LED information.

\textbf{See also:}

\texttt{led_get_info()} for argument descriptions.

typedef int (*\texttt{led_api_set_brightness})(const \texttt{device} *dev, \texttt{uint32_t} led, \texttt{uint8_t} value)

Callback API for setting brightness of an LED.

\textbf{See also:}

\texttt{led_set_brightness()} for argument descriptions.

typedef int (*\texttt{led_api_set_color})(const \texttt{device} *dev, \texttt{uint32_t} led, \texttt{uint8_t} num_colors, const \texttt{uint8_t} *color)

Optional API callback to set the colors of a LED.

\textbf{See also:}

\texttt{led_set_color()} for argument descriptions.

typedef int (*\texttt{led_api_on})(const \texttt{device} *dev, \texttt{uint32_t} led)

Callback API for turning on an LED.

\textbf{See also:}

\texttt{led_on()} for argument descriptions.

typedef int (*\texttt{led_api_off})(const \texttt{device} *dev, \texttt{uint32_t} led)

Callback API for turning off an LED.
typedef int (*led_api_write_channels)(const struct device *dev, uint32_t start_channel, uint32_t num_channels, const uint8_t *buf)

Callback API for writing a strip of LED channels.

See also:
led_api_write_channels() for arguments descriptions.

Functions

int led_blink(const struct device *dev, uint32_t led, uint32_t delay_on, uint32_t delay_off)

Blink an LED.

This optional routine starts blinking a LED forever with the given time period.

Parameters

• dev – LED device
• led – LED number
• delay_on – Time period (in milliseconds) an LED should be ON
• delay_off – Time period (in milliseconds) an LED should be OFF

Returns

0 on success, negative on error

int led_get_info(const struct device *dev, uint32_t led, const struct led_info **info)

Get LED information.

This optional routine provides information about a LED.

Parameters

• dev – LED device
• led – LED number
• info – Pointer to a pointer filled with LED information

Returns

0 on success, negative on error

int led_set_brightness(const struct device *dev, uint32_t led, uint8_t value)

Set LED brightness.

This optional routine sets the brightness of a LED to the given value. Calling this function after led_blink() won't affect blinking.

LEDs which can only be turned on or off may provide this function. These should simply turn the LED on if value is nonzero, and off if value is zero.

Parameters

• dev – LED device
• led – LED number
• value – Brightness value to set in percent

Returns

0 on success, negative on error
int led_write_channels(const struct device *dev, uint32_t start_channel, uint32_t num_channels, const uint8_t *buf)

Write/update a strip of LED channels.

This optional routine writes a strip of LED channels to the given array of levels. Therefore it can be used to configure several LEDs at the same time.

Calling this function after led_blink() won’t affect blinking.

**Parameters**

- **dev** – LED device
- **start_channel** – Absolute number (i.e. not relative to a LED) of the first channel to update.
- **num_channels** – The number of channels to write/update.
- **buf** – array of values to configure the channels with. num_channels entries must be provided.

**Returns**

0 on success, negative on error

int led_set_channel(const struct device *dev, uint32_t channel, uint8_t value)

Set a single LED channel.

This optional routine sets a single LED channel to the given value.

Calling this function after led_blink() won’t affect blinking.

**Parameters**

- **dev** – LED device
- **channel** – Absolute channel number (i.e. not relative to a LED)
- **value** – Value to configure the channel with

**Returns**

0 on success, negative on error

int led_set_color(const struct device *dev, uint32_t led, uint8_t num_colors, const uint8_t *color)

Set LED color.

This routine configures all the color channels of a LED with the given color array.

Calling this function after led_blink() won’t affect blinking.

**Parameters**

- **dev** – LED device
- **led** – LED number
- **num_colors** – Number of colors in the array.
- **color** – Array of colors. It must be ordered following the color mapping of the LED controller. See the the color_mapping member in struct led_info.

**Returns**

0 on success, negative on error

int led_on(const struct device *dev, uint32_t led)

Turn on an LED.

This routine turns on an LED

**Parameters**

7.3. Peripherals
• dev – LED device
• led – LED number

**Returns**
0 on success, negative on error

```c
int led_off(const struct device *dev, uint32_t led)
```

Turn off an LED.

This routine turns off an LED

**Parameters**

• dev – LED device
• led – LED number

**Returns**
0 on success, negative on error

```c
struct led_info
```

```c
#include <led.h> LED information structure.
```

This structure gathers useful information about LED controller.

**Param label**
LED label.

**Param num_colors**
Number of colors per LED.

**Param index**
Index of the LED on the controller.

**Param color_mapping**
Mapping of the LED colors.

```c
struct led_driver_api
```

```c
#include <led.h> LED driver API.
```

**LED Strip**

**group led_strip_interface**
LED Strip Interface.

**Typedefs**

```c
typedef int (*led_api_update_rgb)(const struct device *dev, struct led_rgb *pixels, size_t num_pixels)
```

Callback API for updating an RGB LED strip.

**See also:**

`led_strip_update_rgb()` for argument descriptions.

```c
typedef int (*led_api_update_channels)(const struct device *dev, uint8_t *channels, size_t num_channels)
```

Callback API for updating channels without an RGB interpretation.

See also:
led_strip_update_channels() for argument descriptions.

Functions

static inline int led_strip_update_rgb(const struct device *dev, struct led_rgb *pixels, size_t num_pixels)

Update an LED strip made of RGB pixels.
Important: This routine may overwrite pixels.
This routine immediately updates the strip display according to the given pixels array.

Warning: May overwrite pixels

Parameters
• dev – LED strip device
• pixels – Array of pixel data
• num_pixels – Length of pixels array

Returns
0 on success, negative on error

static inline int led_strip_update_channels(const struct device *dev, uint8_t *channels, size_t num_channels)

Update an LED strip on a per-channel basis.
Important: This routine may overwrite channels.
This routine immediately updates the strip display according to the given channels array. Each channel byte corresponds to an individually addressable color channel or LED. Channels are updated linearly in strip order.

Warning: May overwrite channels

Parameters
• dev – LED strip device
• channels – Array of per-channel data
• num_channels – Length of channels array

Returns
0 on success, negative on error

struct led_rgb

#include <led_strip.h> Color value for a single RGB LED.

Individual strip drivers may ignore lower-order bits if their resolution in any channel is less than a full byte.
Public Members

uint8_t r
Red channel

uint8_t g
Green channel

uint8_t b
Blue channel

struct led_strip_driver_api

#include <led_strip.h> LED strip driver API.
This is the mandatory API any LED strip driver needs to expose.

7.3.25 MBOX

Overview

An MBOX device is a peripheral capable of passing signals (and data depending on the peripheral) between CPUs and clusters in the system. Each MBOX instance is providing one or more channels, each one targeting one other CPU cluster (multiple channels can target the same cluster).

API Reference

group mbox_interface
MBOX Interface.

An MBOX device is a peripheral capable of passing signals (and data depending on the peripheral) between CPUs and clusters in the system. Each MBOX instance is providing one or more channels, each one targeting one other CPU cluster (multiple channels can target the same cluster).
For example in the plot the device ‘dev A’ is using the TX channel 9 to signal (or send data to) the CPU #2 and it’s expecting data or signals on the RX channel 8. Thus it can send the message through the channel 9, and it can register a callback on the channel 8 of the MBOX device.

This API supports two modes: signalling mode and data transfer mode.

In signalling mode:
- `mbox_mtu_get()` must return 0
- `mbox_send()` must have (msg == NULL)
- the callback must be called with (data == NULL)

In data transfer mode:
- `mbox_mtu_get()` must return a (value != 0)
- `mbox_send()` must have (msg != NULL)
- the callback must be called with (data != NULL)
- The msg content must be the same between sender and receiver

Defines

`MBOX_DT_CHANNEL_GET(node_id, name)`
Structure initializer for `mbox_channel` from devicetree.

This helper macro expands to a static initializer for a `mbox_channel` by reading the relevant device controller and channel number from the devicetree.

Example devicetree fragment:

```plaintext
mbox1: mbox-controller@... { ...);

n: node {
    mboxes = <&mbox1 8>,
          <&mbox1 9>;
    mbox-names = "tx", "rx";
};
```

Example usage:

```plaintext
const struct mbox_channel channel = MBOX_DT_CHANNEL_GET(DT_NODELABEL(n), tx);
```

Parameters
- `node_id` – Devicetree node identifier for the MBOX device
- `name` – lowercase-and-underscores name of the mboxes element

Typedefs

```plaintext
typedef void (*mbox_callback_t)(const struct device *dev, uint32_t channel, void *user_data, struct mbox_msg *data)
```

Callback API for incoming MBOX messages.

These callbacks execute in interrupt context. Therefore, use only interrupt-safe APIs. Registration of callbacks is done via `mbox_register_callback()`

The data parameter must be NULL in signalling mode.

7.3. Peripherals
typedef int (*mbox_send_t)(const struct device *dev, uint32_t channel, const struct mbox_msg *msg)

Callback API to send MBOX messages.
See \texttt{mbox\_send()} for function description

**Param dev**
Driver instance

**Param channel**
Channel ID

**Param msg**
Message struct

**Return**
See return values for \texttt{mbox\_send()}

typedef int (*mbox_mtu_get_t)(const struct device *dev)

Callback API to get maximum data size.
See \texttt{mbox\_mtu\_get()} for argument definitions.

typedef int (*mbox_register_callback_t)(const struct device *dev, uint32_t channel, mbox_callback_t cb, void *user_data)

Callback API upon registration.
See \texttt{mbox\_register\_callback()} for function description

**Param dev**
Driver instance

**Param channel**
Channel ID

**Param cb**
Callback function to execute on incoming message interrupts.

**Param user\_data**
Application-specific data pointer which will be passed to the callback function when executed.

**Return**
See return values for \texttt{mbox\_register\_callback()}

typedef int (*mbox_set_enabled_t)(const struct device *dev, uint32_t channel, bool enable)

Callback API upon enablement of interrupts.
See \texttt{mbox\_set\_enabled()} for function description

**Param dev**
Driver instance
**Param channel**
Channel ID

**Param enable**
Set to 0 to disable and to nonzero to enable.

**Return**
See return values for `mbox_set_enabled()`

typedef uint32_t (*mbox_max_channels_get_t)(const struct device *dev)

Callback API to get maximum number of channels.

See `mbox_max_channels_get()` for argument definitions.

**Functions**

static inline void mbox_init_channel(struct mbox_channel *channel, const struct device *dev, uint32_t ch_id)

Initialize a channel struct.

Initialize an `mbox_channel` passed by the user with a provided MBOX device and channel ID. This function is needed when the information about the device and the channel ID is not in the DT. In the DT case `MBOX_DT_CHANNEL_GET()` must be used instead.

**Parameters**
- `channel` – Pointer to the channel struct
- `dev` – Driver instance
- `ch_id` – Channel ID

int mbox_send(const struct mbox_channel *channel, const struct mbox_msg *msg)

Try to send a message over the MBOX device.

Send a message over an `mbox_channel`. The `msg` parameter must be NULL when the driver is used for signalling.

If the `msg` parameter is not NULL, this data is expected to be delivered on the receiving side using the data parameter of the receiving callback.

**Parameters**
- `channel` – Channel instance pointer
- `msg` – Pointer to the message struct

**Return values**
- `-EBUSY` – If the remote hasn’t yet read the last data sent.
- `-EMSGSIZE` – If the supplied data size is unsupported by the driver.
- `-EINVAL` – If there was a bad parameter, such as: too-large channel descriptor or the device isn’t an outbound MBOX channel.
- `0` – On success, negative value on error.

static inline int mbox_register_callback(const struct mbox_channel *channel, mbox_callback_t cb, void *user_data)

Register a callback function on a channel for incoming messages.

This function doesn’t assume anything concerning the status of the interrupts. Use `mbox_set_enabled()` to enable or to disable the interrupts if needed.

**Parameters**
• channel – Channel instance pointer.
• cb – Callback function to execute on incoming message interrupts.
• user_data – Application-specific data pointer which will be passed to the callback function when executed.

Return values
0 – On success, negative value on error.

int mbox_mtu_get (const struct device *dev)
Return the maximum number of bytes possible in an outbound message.
Returns the actual number of bytes that it is possible to send through an outgoing channel.
This number can be 0 when the driver only supports signalling or when on the receiving side the content and size of the message must be retrieved in an indirect way (i.e. probing some other peripheral, reading memory regions, etc. . . ).
If this function returns 0, the msg parameter in mbox_send() is expected to be NULL.

Parameters
• dev – Driver instance pointer.

Returns
Maximum possible size of a message in bytes, 0 for signalling, negative value on error.

int mbox_set_enabled (const struct mbox_channel *channel, bool enable)
Enable (disable) interrupts and callbacks for inbound channels.
Enable interrupt for the channel when the parameter 'enable' is set to true. Disable it otherwise.
Immediately after calling this function with 'enable' set to true, the channel is considered enabled and ready to receive signal and messages (even already pending), so the user must take care of installing a proper callback (if needed) using mbox_register_callback() on the channel before enabling it. For this reason it is recommended that all the channels are disabled at probe time.
Enabling a channel for which there is no installed callback is considered undefined behavior (in general the driver must take care of gracefully handling spurious interrupts with no installed callback).

Parameters
• channel – Channel instance pointer.
• enable – Set to 0 to disable and to nonzero to enable.

Return values
• 0 – On success.
• -EINVAL – If it isn’t an inbound channel.

uint32_t mbox_max_channels_get (const struct device *dev)
Return the maximum number of channels.

Parameters
• dev – Driver instance pointer.

Returns
Maximum possible number of supported channels on success, negative value on error.
\texttt{struct mbox\_msg}

\texttt{#include <mbox.h> Message struct (to hold data and its size).}

**Public Members**

\texttt{const void *data}

Pointer to the data sent in the message.

\texttt{size\_t size}

Size of the data.

\texttt{struct mbox\_channel}

\texttt{#include <mbox.h> Provides a type to hold an MBOX channel.}

Struct type to hold an MBOX device pointer and the channel ID.

**Public Members**

\texttt{const struct device *dev}

MBOX device pointer.

\texttt{uint32\_t id}

Channel ID.

\texttt{struct mbox\_driver\_api}

\texttt{#include <mbox.h>}

### 7.3.26 Pinmux

**Overview**

**API Reference**

\texttt{group pinmux\_interface}

Pinmux Interface.

**Defines**

\texttt{PINMUX\_FUNC\_A}

\texttt{PINMUX\_FUNC\_B}

\texttt{PINMUX\_FUNC\_C}

\texttt{PINMUX\_FUNC\_D}
typedef int (*pmux_set)(const struct device *dev, uint32_t pin, uint32_t func)
    Callback API upon setting a PIN's function See pinmux_pin_set() for argument description.

typedef int (*pmux_get)(const struct device *dev, uint32_t pin, uint32_t *func)
    Callback API upon getting a PIN's function See pinmux_pin_get() for argument description.

typedef int (*pmux_pullup)(const struct device *dev, uint32_t pin, uint8_t func)
    Callback API upon setting a PIN's pullup See pinmux_pin_pullup() for argument description.

typedef int (*pmux_input)(const struct device *dev, uint32_t pin, uint8_t func)
    Callback API upon setting a PIN’s input function See pinmux_input() for argument description.
**Functions**

static inline int pinmux_pin_set(const struct device *dev, uint32_t pin, uint32_t func)
static inline int pinmux_pin_get(const struct device *dev, uint32_t pin, uint32_t *func)
static inline int pinmux_pin_pullup(const struct device *dev, uint32_t pin, uint8_t *func)
static inline int pinmux_pin_input_enable(const struct device *dev, uint32_t pin, uint8_t *func)

struct pinmux_driver_api
   #include <pinmux.h>

7.3.27 PWM

Overview

API Reference

*group pwm_interface*
   
   PWM Interface.

**PWM capture configuration flags**

**PWM_CAPTURE_TYPE_PERIOD**
   
   PWM pin capture captures period.

**PWM_CAPTURE_TYPE_PULSE**
   
   PWM pin capture captures pulse width.

**PWM_CAPTURE_TYPE_BOTH**
   
   PWM pin capture captures both period and pulse width.

**PWM_CAPTURE_MODE_SINGLE**
   
   PWM pin capture captures a single period/pulse width.

**PWM_CAPTURE_MODE_CONTINUOUS**
   
   PWM pin capture captures period/pulse width continuously.

**PWM period set helpers**

The period cell in the PWM specifier needs to be provided in nanoseconds. However, in some applications it is more convenient to use another scale.

**PWM_NSEC(x)**
   
   Specify PWM period in nanoseconds

**PWM_USEC(x)**
   
   Specify PWM period in microseconds
PWM_MSEC(x)
   Specify PWM period in milliseconds

PWM_SEC(x)
   Specify PWM period in seconds

PWM_HZ(x)
   Specify PWM frequency in hertz

PWM_KHZ(x)
   Specify PWM frequency in kilohertz

**PWM polarity flags**

The PWM POLARITY_* flags are used with `pwm_set_cycles()`, `pwm_set()` or `pwm_configure_capture()` to specify the polarity of a PWM channel.

The flags are on the lower 8 bits of the `pwm_flags_t`.

- **PWM_POLARITY_NORMAL**
  - PWM pin normal polarity (active-high pulse).

- **PWM_POLARITY_INVERTED**
  - PWM pin inverted polarity (active-low pulse).

**Defines**

- **PWM_DT_SPEC_GET_BY_NAME(node_id, name)**
  - Static initializer for a struct `pwm_dt_spec`.

  This returns a static initializer for a struct `pwm_dt_spec` given a devicetree node identifier and an index.

  Example devicetree fragment:

  ```
  n: node {
    pwms = <&pwm1 1 1000 PWM_POLARITY_NORMAL>,
           <&pwm2 3 2000 PWM_POLARITY_INVERTED>;
    pwm-names = "alpha", "beta";
  };
  ```

  Example usage:

  ```
  const struct pwm_dt_spec spec =
      PWM_DT_SPEC_GET_BY_NAME(DT_NODELABEL(n), alpha);
  // Initializes 'spec' to:
  // { 
  //   .dev = DEVICE_DT_GET(DT_NODELABEL(pwm1)),
  //   .channel = 1,
  //   .period = 1000,
  //   .flags = PWM_POLARITY_NORMAL,
  // }
The device (dev) must still be checked for readiness, e.g. using `device_is_ready()`. It is an error to use this macro unless the node exists, has the `pwms` property, and that `pwms` property specifies a PWM controller, a channel, a period in nanoseconds and optionally flags.

See also:

`PWM_DT_SPEC_INST_GET_BY_NAME`

**Parameters**

- `node_id` – Devicetree node identifier.
- `name` – Lowercase-and-underscores name of a pwms element as defined by the node's pwm-names property.

**Returns**

Static initializer for a struct `pwm_dt_spec` for the property.

`PWM_DT_SPEC_INST_GET_BY_NAME_INST(node_id, name)`  
Static initializer for a struct `pwm_dt_spec` from a DT_DRV_COMPAT instance.

See also:

`PWM_DT_SPEC_GET_BY_NAME`

**Parameters**

- `inst` – DT_DRV_COMPAT instance number
- `name` – Lowercase-and-underscores name of a pwms element as defined by the node's pwm-names property.

**Returns**

Static initializer for a struct `pwm_dt_spec` for the property.

`PWM_DT_SPEC_GET_BY_NAME_INST(node_id, name, default_value)`  
Like `PWM_DT_SPEC_GET_BY_NAME()`, with a fallback to a default value.

If the devicetree node identifier `node_id` refers to a node with a property `pwms`, this expands to `PWM_DT_SPEC_GET_BY_NAME(node_id, name)`. The `default_value` parameter is not expanded in this case. Otherwise, this expands to `default_value`.

See also:

`PWM_DT_SPEC_INST_GET_BY_NAME_OR`

**Parameters**

- `node_id` – Devicetree node identifier.
- `name` – Lowercase-and-underscores name of a pwms element as defined by the node's pwm-names property
- `default_value` – Fallback value to expand to.

**Returns**

Static initializer for a struct `pwm_dt_spec` for the property, or `default_value` if the node or property do not exist.
PWM_DT_SPEC_INST_GET_BY_NAME_OR(inst, name, default_value)

Like `PWM_DT_SPEC_INST_GET_BY_NAME()`, with a fallback to a default value.

**See also:**

`PWM_DT_SPEC_INST_GET_BY_NAME_OR`

**Parameters**

- `inst` – DT_DRV_COMPAT instance number
- `name` – Lowercase-and-underscores name of a pwms element as defined by the node’s `pwm-names` property.
- `default_value` – Fallback value to expand to.

**Returns**

Static initializer for a struct `pwm_dt_spec` for the property, or `default_value` if the node or property do not exist.

PWM_DT_SPEC_GET_BYIDX(node_id, idx)

Static initializer for a struct `pwm_dt_spec`.

This returns a static initializer for a struct `pwm_dt_spec` given a devicetree node identifier and an index.

Example devicetree fragment:

```plaintext
n: node {
    pwms = <&pwm1 1 1000 PWM_POLARITY_NORMAL>,
          <&pwm2 3 2000 PWM_POLARITY_INVERTED>;
};
```

Example usage:

```c
const struct pwm_dt_spec spec =
    PWM_DT_SPEC_GET_BY_IDX(DT_NODELABEL(n), 1);

// Initializes 'spec' to:
// {
//   .dev = DEVICE_DT_GET(DT_NODELABEL(pwm2)),
//   .channel = 3,
//   .period = 2000,
//   .flags = PWM_POLARITY_INVERTED,
// }
```

The device (dev) must still be checked for readiness, e.g. using `device_is_ready()`. It is an error to use this macro unless the node exists, has the ‘pwms’ property, and that ‘pwms’ property specifies a PWM controller, a channel, a period in nanoseconds and optionally flags.

**See also:**

`PWM_DT_SPEC_INST_GET_BY_IDX`

**Parameters**

- `node_id` – Devicetree node identifier.
• idx – Logical index into ‘pwms’ property.

Returns
Static initializer for a struct `pwm_dt_spec` for the property.

PWM_DT_SPEC_INST_GET_BY_IDX(inst, idx)
Static initializer for a struct `pwm_dt_spec` from a DT_DRV_COMPAT instance.

See also:
`PWM_DT_SPEC_GET_BY_IDX`

Parameters
• inst – DT_DRV_COMPAT instance number
• idx – Logical index into ‘pwms’ property.

Returns
Static initializer for a struct `pwm_dt_spec` for the property.

PWM_DT_SPEC_GET_BY_IDX_OR(node_id, idx, default_value)
Like `PWM_DT_SPEC_GET_BY_IDX()`, with a fallback to a default value.

If the devicetree node identifier 'node_id' refers to a node with a property ‘pwms’, this expands to `PWM_DT_SPEC_GET_BY_IDX(node_id, idx)`. The default_value parameter is not expanded in this case. Otherwise, this expands to default_value.

See also:
`PWM_DT_SPEC_INST_GET_BY_IDX_OR`

Parameters
• node_id – Devicetree node identifier.
• idx – Logical index into ‘pwms’ property.
• default_value – Fallback value to expand to.

Returns
Static initializer for a struct `pwm_dt_spec` for the property, or default_value if the node or property do not exist.

PWM_DT_SPEC_INST_GET_BY_IDX_OR(inst, idx, default_value)
Like `PWM_DT_SPEC_INST_GET_BY_IDX()`, with a fallback to a default value.

See also:
`PWM_DT_SPEC_GET_BY_IDX_OR`

Parameters
• inst – DT_DRV_COMPAT instance number
• idx – Logical index into ‘pwms’ property.
• default_value – Fallback value to expand to.

Returns
Static initializer for a struct `pwm_dt_spec` for the property, or default_value if the node or property do not exist.
PWM_DT_SPEC_GET(node_id)
   Equivalent to PWM_DT_SPEC_GET_BY_IDX(node_id, 0).

See also:
PWM_DT_SPEC_GET_BY_IDX

See also:
PWM_DT_SPEC_INST_GET

Parameters
   • node_id – Devicetree node identifier.

Returns
   Static initializer for a struct pwm_dt_spec for the property.

PWM_DT_SPEC_INST_GET(inst)
   Equivalent to PWM_DT_SPEC_INST_GET_BY_IDX(inst, 0).

See also:
PWM_DT_SPEC_INST_GET_BY_IDX

See also:
PWM_DT_SPEC_GET

Parameters
   • inst – DT_DRV_COMPAT instance number

Returns
   Static initializer for a struct pwm_dt_spec for the property.

PWM_DT_SPEC_GET_OR(node_id, default_value)
   Equivalent to PWM_DT_SPEC_GET_BY_IDX_OR(node_id, 0, default_value).

See also:
PWM_DT_SPEC_GET_BY_IDX_OR

See also:
PWM_DT_SPEC_INST_GET_OR

Parameters
   • node_id – Devicetree node identifier.
   • default_value – Fallback value to expand to.

Returns
   Static initializer for a struct pwm_dt_spec for the property.

PWM_DT_SPEC_INST_GET_OR(inst, default_value)
   Equivalent to PWM_DT_SPEC_INST_GET_BY_IDX_OR(inst, 0, default_value).

See also:
PWM_DT_SPEC_INST_GET_BY_IDX_OR
See also:

`PWM_DT_SPEC_GET_OR`

**Parameters**

- `inst` – DT_DRV_COMPAT instance number
- `default_value` – Fallback value to expand to.

**Returns**

Static initializer for a struct `pwm_dt_spec` for the property.

**Typedefs**

typedef uint16_t `pwm_flags_t`

Provides a type to hold PWM configuration flags.

The lower 8 bits are used for standard flags. The upper 8 bits are reserved for SoC specific flags.

See also:

`PWM_CAPTURE_FLAGS`.

typedef void (\*`pwm_capture_callback_handler_t`) (const struct device *dev, uint32_t channel, uint32_t period_cycles, uint32_t pulse_cycles, int status, void *user_data)

PWM capture callback handler function signature.

---

**Note:** The callback handler will be called in interrupt context.

---

**Note:** CONFIG_PWM_CAPTURE must be selected to enable PWM capture support.

**Param dev**

[in] PWM device instance.

**Param channel**

PWM channel.

**Param period_cycles**

Captured PWM period width (in clock cycles). HW specific.

**Param pulse_cycles**

Captured PWM pulse width (in clock cycles). HW specific.

**Param status**

Status for the PWM capture (0 if no error, negative errno otherwise. See `pwm_capture_cycles()` return value descriptions for details).

**Param user_data**

User data passed to `pwm_configure_capture()`

**Functions**
int pwm_set_cycles(
    const struct device *dev, uint32_t channel, uint32_t period, uint32_t pulse,
    pwm_flags_t flags)

Set the period and pulse width for a single PWM output.
The PWM period and pulse width will synchronously be set to the new values without glitches
in the PWM signal, but the call will not block for the change to take effect.

Passing 0 as pulse will cause the pin to be driven to a constant inactive level. Passing a
non-zero pulse equal to period will cause the pin to be driven to a constant active level.

Note: Not all PWM controllers support synchronous, glitch-free updates of the PWM period
and pulse width. Depending on the hardware, changing the PWM period and/or pulse width
may cause a glitch in the generated PWM signal.

Note: Some multi-channel PWM controllers share the PWM period across all channels. De-
pending on the hardware, changing the PWM period for one channel may affect the PWM
period for the other channels of the same PWM controller.

Parameters
- channel – PWM channel.
- period – Period (in clock cycles) set to the PWM. HW specific.
- pulse – Pulse width (in clock cycles) set to the PWM. HW specific.
- flags – Flags for pin configuration.

Return values
- 0 – If successful.
- -EINVAL – If pulse > period.
- -errno – Negative errno code on failure.

int pwm_get_cycles_per_sec(
    const struct device *dev, uint32_t channel, uint64_t *cycles)

Get the clock rate (cycles per second) for a single PWM output.

Parameters
- channel – PWM channel.
- cycles – [out] Pointer to the memory to store clock rate (cycles per sec). HW
  specific.

Return values
- 0 – If successful.
- -errno – Negative errno code on failure.

static inline int pwm_set(
    const struct device *dev, uint32_t channel, uint32_t period, uint32_t pulse,
    pwm_flags_t flags)

Set the period and pulse width in nanoseconds for a single PWM output.
Note: Utility macros such as `PWM_MSEC()` can be used to convert from other scales or units to nanoseconds, the units used by this function.

**Parameters**
- `channel` – PWM channel.
- `period` – Period (in nanoseconds) set to the PWM.
- `pulse` – Pulse width (in nanoseconds) set to the PWM.
- `flags` – Flags for pin configuration (polarity).

**Return values**
- 0 – If successful.
- -ENOTSUP – If requested period or pulse cycles are not supported.
- -errno – Other negative errno code on failure.

```c
static inline int pwm_set_dt(const struct pwm_dt_spec *spec, uint32_t period, uint32_t pulse)
```

Set the period and pulse width in nanoseconds from a struct `pwm_dt_spec` (with custom period).

This is equivalent to:

```c
pwm_set(spec->dev, spec->channel, period, pulse, spec->flags)
```

The period specified in `spec` is ignored. This API call can be used when the period specified in Devicetree needs to be changed at runtime.

**See also:**
`pwm_set_pulse_dt()`

**Parameters**
- `period` – Period (in nanoseconds) set to the PWM.
- `pulse` – Pulse width (in nanoseconds) set to the PWM.

**Returns**
A value from `pwm_set()`.

```c
static inline int pwm_set_pulse_dt(const struct pwm_dt_spec *spec, uint32_t pulse)
```

Set the period and pulse width in nanoseconds from a struct `pwm_dt_spec`.

This is equivalent to:

```c
pwm_set(spec->dev, spec->channel, spec->period, pulse, spec->flags)
```

**See also:**
`pwm_set_pulse_dt()`
Returns
A value from `pwm_set()`.

```
static inline int pwm_cycles_to_usec(const struct device *dev, uint32_t channel, uint32_t cycles, uint64_t *usec)
```

Convert from PWM cycles to microseconds.

Parameters
- `channel` – PWM channel.
- `cycles` – Cycles to be converted.
- `usec` – [out] Pointer to the memory to store calculated usec.

Return values
- 0 – If successful.
- -ERANGE – If result is too large.
- -errno – Other negative errno code on failure.

```
static inline int pwm_cycles_to_nsec(const struct device *dev, uint32_t channel, uint32_t cycles, uint64_t *nsec)
```

Convert from PWM cycles to nanoseconds.

Parameters
- `channel` – PWM channel.
- `cycles` – Cycles to be converted.
- `nsec` – [out] Pointer to the memory to store the calculated nsec.

Return values
- 0 – If successful.
- -ERANGE – If result is too large.
- -errno – Other negative errno code on failure.

```
static inline int pwm_configure_capture(const struct device *dev, uint32_t channel, pwm_flags_t flags, pwm_capture_callback_handler_t cb, void *user_data)
```

Configure PWM period/pulse width capture for a single PWM input.

After configuring PWM capture using this function, the capture can be enabled/disabled using `pwm_enable_capture()` and `pwm_disable_capture()`.

**Note:** This API function cannot be invoked from user space due to the use of a function callback. In user space, one of the simpler API functions (`pwm_capture_cycles()`, `pwm_capture_usec()`, or `pwm_capture_nsec()`) can be used instead.

**Note:** `CONFIG_PWM_CAPTURE` must be selected for this function to be available.

Parameters
- `channel` – PWM channel.
• flags – PWM capture flags
• cb – [in] Application callback handler function to be called upon capture
• user_data – [in] User data to pass to the application callback handler function

Return values
• -EINVAL – if invalid function parameters were given
• -ENOSYS – if PWM capture is not supported or the given flags are not supported
• -EIO – if IO error occurred while configuring
• -EBUSY – if PWM capture is already in progress

int pwm_enable_capture(const struct device *dev, uint32_t channel)
Enable PWM period/pulse width capture for a single PWM input.
The PWM pin must be configured using pwm_configure_capture() prior to calling this function.

Note: CONFIG_PWM_CAPTURE must be selected for this function to be available.

Parameters
• dev – [in] PWM device instance.
• channel – PWM channel.

Return values
• 0 – If successful.
• -EINVAL – if invalid function parameters were given
• -ENOSYS – if PWM capture is not supported
• -EIO – if IO error occurred while enabling PWM capture
• -EBUSY – if PWM capture is already in progress

int pwm_disable_capture(const struct device *dev, uint32_t channel)
Disable PWM period/pulse width capture for a single PWM input.

Note: CONFIG_PWM_CAPTURE must be selected for this function to be available.

Parameters
• dev – [in] PWM device instance.
• channel – PWM channel.

Return values
• 0 – If successful.
• -EINVAL – if invalid function parameters were given
• -ENOSYS – if PWM capture is not supported
• -EIO – if IO error occurred while disabling PWM capture
int pwm_capture_cycles(const struct device *dev, uint32_t channel, pwm_flags_t flags, uint32_t *period, uint32_t *pulse, k_timeout_t timeout)

Capture a single PWM period/pulse width in clock cycles for a single PWM input. This API function wraps calls to pwm_configure_capture(), pwm_enable_capture(), and pwm_disable_capture() and passes the capture result to the caller. The function is blocking until either the PWM capture is completed or a timeout occurs.

**Note:** CONFIG_PWM_CAPTURE must be selected for this function to be available.

**Parameters**

- **dev** – [in] PWM device instance.
- **channel** – PWM channel.
- **flags** – PWM capture flags.
- **period** – [out] Pointer to the memory to store the captured PWM period width (in clock cycles). HW specific.
- **pulse** – [out] Pointer to the memory to store the captured PWM pulse width (in clock cycles). HW specific.
- **timeout** – Waiting period for the capture to complete.

**Return values**

- 0 – If successful.
- -EBUSY – PWM capture already in progress.
- -EAGAIN – Waiting period timed out.
- -EIO – IO error while capturing.
- -ERANGE – If result is too large.

static inline int pwm_capture_usec(const struct device *dev, uint32_t channel, pwm_flags_t flags, uint64_t *period, uint64_t *pulse, k_timeout_t timeout)

Capture a single PWM period/pulse width in microseconds for a single PWM input. This API function wraps calls to pwm_capture_cycles() and pwm_cycles_to_usec() and passes the capture result to the caller. The function is blocking until either the PWM capture is completed or a timeout occurs.

**Note:** CONFIG_PWM_CAPTURE must be selected for this function to be available.

**Parameters**

- **dev** – [in] PWM device instance.
- **channel** – PWM channel.
- **flags** – PWM capture flags.
- **period** – [out] Pointer to the memory to store the captured PWM period width (in usec).
- **pulse** – [out] Pointer to the memory to store the captured PWM pulse width (in usec).
- **timeout** – Waiting period for the capture to complete.

**Return values**
• 0 – If successful.
• -EBUSY – PWM capture already in progress.
• -EAGAIN – Waiting period timed out.
• -EIO – IO error while capturing.
• -ERANGE – If result is too large.
• -errno – Other negative errno code on failure.

static inline int pwm_capture_nsec(const struct device *dev, uint32_t channel, pwm_flags_t flags, uint64_t *period, uint64_t *pulse, k_timeout_t timeout)

Capture a single PWM period/pulse width in nanoseconds for a single PWM input.

This API function wraps calls to pwm_capture_cycles() and pwm_cycles_to_nsec() and passes the capture result to the caller. The function is blocking until either the PWM capture is completed or a timeout occurs.

**Note:** CONFIG_PWM_CAPTURE must be selected for this function to be available.

**Parameters**

- channel – PWM channel.
- flags – PWM capture flags.
- period – [out] Pointer to the memory to store the captured PWM period width (in nsec).
- pulse – [out] Pointer to the memory to store the captured PWM pulse width (in nsec).
- timeout – Waiting period for the capture to complete.

**Return values**

- 0 – If successful.
- -EBUSY – PWM capture already in progress.
- -EAGAIN – Waiting period timed out.
- -EIO – IO error while capturing.
- -ERANGE – If result is too large.
- -errno – Other negative errno code on failure.

struct pwm_dt_spec

#include <pwm.h> Container for PWM information specified in devicetree.

This type contains a pointer to a PWM device, channel number (controlled by the PWM device), the PWM signal period in nanoseconds and the flags applicable to the channel. Note that not all PWM drivers support flags. In such case, flags will be set to 0.

Flags.

7.3.28 PS/2

Overview

The PS/2 connector first hit the market in 1987 on IBM’s desktop PC line of the same name before becoming an industry-wide standard for mouse and keyboard connections. Starting around 2007, USB superseded PS/2 and is the modern peripheral device connection standard. For legacy support on boards with a PS/2 connector, Zephyr provides these PS/2 driver APIs.

Configuration Options

Related configuration options:

• CONFIG_PS2

API Reference

group ps2_interface

PS/2 Driver APIs.
typedef void (*ps2_callback_t)(const struct device *dev, uint8_t data)

PS/2 callback called when user types or click a mouse.

**Param dev**
Pointer to the device structure for the driver instance.

**Param data**
Data byte passed pack to the user.

### Functions

**int ps2_config(const struct device *dev, ps2_callback_t callback_isr)**

Configure a ps2 instance.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance.
- **callback_isr** – called when PS/2 devices reply to a configuration command or when a mouse/keyboard send data to the client application.

**Return values**

- 0 – If successful.
- Negative – errno code if failure.

**int ps2_write(const struct device *dev, uint8_t value)**

Write to PS/2 device.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance.
- **value** – Data for the PS2 device.

**Return values**

- 0 – If successful.
- Negative – errno code if failure.

**int ps2_read(const struct device *dev, uint8_t *value)**

Read slave-to-host values from PS/2 device.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance.
- **value** – Pointer used for reading the PS2 device.

**Return values**

- 0 – If successful.
- Negative – errno code if failure.

**int ps2_enable_callback(const struct device *dev)**

Enables callback.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance.

**Return values**

- 0 – If successful.
int ps2_disable_callback(const struct device *dev)
Disables callback.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.

**Return values**

- **0** – If successful.
- **Negative** – errno code if failure.

### 7.3.29 PECI

#### Overview

The Platform Environment Control Interface, abbreviated as PECI, is a thermal management standard introduced in 2006 with the Intel Core 2 Duo Microprocessors. The PECI interface allows external devices to read processor temperature, perform processor manageability functions, and manage processor interface tuning and diagnostics. The PECI bus driver APIs enable the interaction between Embedded Microcontrollers and CPUs.

Functions

int peci_config(const struct device *dev, uint32_t bitrate)

Configures the PECI interface.

Parameters
• dev – Pointer to the device structure for the driver instance.
• bitrate – the selected expressed in Kbps. command or when an event needs to be sent to the client application.

Return values
• 0 – If successful.
• Negative – errno code if failure.

int peci_enable(const struct device *dev)

Enable PECI interface.

Parameters
• dev – Pointer to the device structure for the driver instance.

Return values
• 0 – If successful.
• Negative – errno code if failure.

int peci_disable(const struct device *dev)

Disable PECI interface.

Parameters
• dev – Pointer to the device structure for the driver instance.

Return values
• 0 – If successful.
• Negative – errno code if failure.

int peci_transfer(const struct device *dev, struct peci_msg *msg)

Performs a PECI transaction.

Parameters
• dev – Pointer to the device structure for the driver instance.
• msg – Structure representing a PECI transaction.

Return values
• 0 – If successful.
• Negative – errno code if failure.
struct peci_buf
#include <peci.h> PECI buffer structure.

Note: Frame check sequence byte is added into rx buffer, need to allocate an additional byte for this in rx buffer.

  **Param buf**
  is a valid pointer on a data buffer, or NULL otherwise.

  **Param len**
  is the length of the data buffer expected to received without considering the frame check sequence byte.

struct peci_msg
#include <peci.h> PECI transaction packet format.

**Public Members**

  uint8_t addr
  Client address

  enum peci_command_code cmd_code
  Command code

  struct peci_buf tx_buffer
  Pointer to buffer of write data

  struct peci_buf rx_buffer
  Pointer to buffer of read data

  uint8_t tflags
  PECI msg flags

7.3.30  Regulators

This subsystem provides control of voltage and current regulators. A common example is a GPIO that controls a transistor that supplies current to a device that is not always needed.

Conceptually regulators have two modes: off and on. A transition between modes may involve a time delay, so operations on regulators are inherently asynchronous. To maximize flexibility the On-Off Manager infrastructure is used in the generic API for the regulator subsystem. Nodes with a devicetree compatible of regulator-fixed are the most common flexible regulators.

The vin-supply devicetree property is used to identify the regulator(s) that a devicetree node directly depends on. Within the driver for the node the regulator API is used to issue requests for power when the device is to be active, and release the power request when the device shuts down.

The simplest case where a regulator is needed is one where there is only one client. For those situations the cost of using even the optimized synchronous regulator device infrastructure is not justified, and the supply-gpios devicetree property should be used. There is no device interface to these regulators as they are entirely controlled within the driver for the corresponding node, e.g. a sensor.
API Reference

`group regulator_interface`

Regulator Interface.

**Functions**

**int regulator_enable(const struct device *dev)**

Enable a regulator.

Reference-counted request that a regulator be turned on. A regulator is considered “on” when it has reached a stable/usable state.

**Parameters**

- `dev` – Regulator device instance

**Return values**

- 0 – If regulator has been successfully enabled.
- -errno – Negative errno in case of failure.

**int regulator_disable(const struct device *dev)**

Disable a regulator.

Release a regulator after a previous `regulator_enable()` completed successfully.

If the release removes the last dependency on the regulator it will begin a transition to its “off” state. There is currently no mechanism to notify when the regulator has completely turned off.

This must be invoked at most once for each successful `regulator_enable()`.

**Parameters**

- `dev` – Regulator device instance.

**Return values**

- 0 – If regulator has been successfully disabled.
- -errno – Negative errno in case of failure.

**static inline int regulator_count_voltages(const struct device *dev)**

Obtain the number of supported voltage levels.

Selectors are numbered starting at zero, and typically correspond to bitfields in hardware registers.

**Parameters**

- `dev` – Regulator device instance.

**Return values**

- selectors – Number of selectors, if successful.
- -ENOSYS – If function is not implemented.
- -errno – In case of any other error.

**static inline int regulator_count_modes(const struct device *dev)**

Obtain the number of supported modes.
See also:

`regulator_set_mode()`

**Parameters**

- `dev` – Regulator device instance.

**Returns**

Number of supported modes.

```c
static inline int32_t regulator_list_voltages(const struct device *dev, unsigned int selector)
```

Obtain supported voltages.

**Parameters**

- `dev` – Regulator device instance.
- `selector` – Voltage selector.

**Return values**

- `0` – If selector code can’t be used.

**Returns**

Voltage level in microvolts.

```c
static inline int regulator_is_supported_voltage(const struct device *dev, int32_t min_uv, int32_t max_uv)
```

Check if a voltage range is supported.

**Parameters**

- `dev` – Regulator device instance.
- `min_uv` – Minimum voltage in microvolts.
- `max_uv` – Maximum voltage in microvolts.

**Return values**

- `0` – If successful.
- `-ENOSYS` – If function is not implemented.
- `-errno` – In case of any other error.

```c
static inline int regulator_set_voltage(const struct device *dev, int32_t min_uv, int32_t max_uv)
```

Set output voltage.

---

**Note:** The output voltage will be configured to the closest supported output voltage. `regulator_get_voltage()` can be used to obtain the actual configured voltage.

**Parameters**

- `dev` – Regulator device instance.
- `min_uv` – Minimum acceptable voltage in microvolts.
- `max_uv` – Maximum acceptable voltage in microvolts.

**Return values**

- `0` – If successful.
- `-ENOSYS` – If function is not implemented.
- `-errno` – In case of any other error.
static inline int32_t regulator_get_voltage(const struct device *dev)
    Obtain output voltage.

Parameters
• dev – Regulator device instance.

Returns
Voltage level in microvolts.

static inline int regulator_set_current_limit(const struct device *dev, int32_t min_ua, int32_t max_ua)
Set output current limit.

Parameters
• dev – Regulator device instance.
• min_ua – Minimum acceptable current limit in microamps.
• max_ua – Maximum acceptable current limit in microamps.

Return values
• 0 – If successful.
• -ENOSYS – If function is not implemented.
• -errno – In case of any other error.

static inline int32_t regulator_get_current_limit(const struct device *dev)
Get output current limit.

Parameters
• dev – Regulator device instance.

Return values
• current – Current limit in microamperes
• -ENOSYS – If function is not implemented.
• -errno – In case of any other error.

static inline int regulator_set_mode(const struct device *dev, uint32_t mode)
Set mode.

Regulators can support multiple modes in order to permit different voltage configuration or
better power savings. This API will apply a mode for the regulator.

Parameters
• dev – Regulator device instance.
• mode – Mode to select for this regulator. Only modes present in the
  regulator-allowed-modes devicetree property are permitted.

Return values
• 0 – If successful.
• -ENOSYS – If function is not implemented.
• -errno – In case of any other error.

static inline int regulator_set_mode_voltage(const struct device *dev, uint32_t mode, int32_t min_uv, int32_t max_uv)
Set target voltage for a regulator mode.
Note: Mode does not need to be the active mode. The regulator can be switched to that mode with `regulator_set_mode()`.

### Parameters
- **dev** – Regulator device instance.
- **mode** – Regulator mode.
- **min_uv** – Minimum acceptable voltage in microvolts.
- **max_uv** – Maximum acceptable voltage in microvolts.

### Return values
- **0** – If successful.
- **-ENOSYS** – If function is not implemented.
- **-errno** – In case of any other error.

```c
static inline int32_t regulator_get_mode_voltage(const struct device *dev, uint32_t mode)
```

Get target voltage for a regulator mode.

This API can be used to read voltages from a regulator mode other than the default. The given mode does not need to be active.

### Parameters
- **dev** – Regulator device instance.
- **mode** – Regulator mode.

### Returns
Voltage level in microvolts.

```c
static inline int regulator_mode_disable(const struct device *dev, uint32_t mode)
```

Disable regulator for a given mode.

### Parameters
- **dev** – Regulator device instance.
- **mode** – Regulator mode.

### Return values
- **0** – If successful.
- **-ENOSYS** – If function is not implemented.
- **-errno** – In case of any other error.

```c
static inline int regulator_mode_enable(const struct device *dev, uint32_t mode)
```

Enable regulator for a given mode.

### Parameters
- **dev** – Regulator device instance.
- **mode** – Regulator mode.

### Return values
- **0** – If successful.
- **-ENOSYS** – If function is not implemented.
- **-errno** – In case of any other error.
7.3.31 Reset Controller

Overview

Reset controllers are units that control the reset signals to multiple peripherals. The reset controller API allows peripheral drivers to request control over their reset input signals, including the ability to assert, deassert and toggle those signals. Also, the reset status of the reset input signal can be checked.

Mainly, the line_assert and line_deassert API functions are optional because in most cases we want to toggle the reset signals.

Configuration Options

Related configuration options:
- CONFIG_RESET

API Reference

**group reset_controller_interface**

Reset Controller Interface.

**Defines**

`RESET_DT_SPEC_GET_BY_IDX(node_id, idx)`

Static initializer for a `reset_dt_spec`.

This returns a static initializer for a `reset_dt_spec` structure given a devicetree node identifier, a property specifying a Reset Controller and an index.

Example devicetree fragment:

```c
n: node {
    resets = <&reset 10>;
}
```

Example usage:

```c
const struct reset_dt_spec spec = RESET_DT_SPEC_GET_BY_IDX(DT_NODELABEL(n), 0);
// Initializes 'spec' to:
// {
//     .dev = DEVICE_DT_GET(DT_NODELABEL(reset)),
//     .id = 10
// }
```

The ‘reset’ field must still be checked for readiness, e.g. using `device_is_ready()`. It is an error to use this macro unless the node exists, has the given property, and that property specifies a reset controller reset line id as shown above.

**Parameters**

- `node_id` – devicetree node identifier
- `idx` – logical index into “resets”

**Returns**

static initializer for a struct `reset_dt_spec` for the property
RESET_DT_SPEC_GET(node_id)
   Equivalent to RESET_DT_SPEC_GET_BY_IDX(node_id, 0).

See also:
   RESET_DT_SPEC_GET_BY_IDX()

Parameters
   • node_id – devicetree node identifier

Returns
   static initializer for a struct reset_dt_spec for the property

RESET_DT_SPEC_INST_GET_BY_IDX(inst, idx)
   Static initializer for a reset_dt_spec from a DT_DRV_COMPAT instance's Reset Controller property at an index.

See also:
   RESET_DT_SPEC_GET_BY_IDX()

Parameters
   • inst – DT_DRV_COMPAT instance number
   • idx – logical index into “resets”

Returns
   static initializer for a struct reset_dt_spec for the property

RESET_DT_SPEC_INST_GET(inst)
   Equivalent to RESET_DT_SPEC_INST_GET_BY_IDX(inst, 0).

See also:
   RESET_DT_SPEC_INST_GET_BY_IDX()

Parameters
   • inst – DT_DRV_COMPAT instance number

Returns
   static initializer for a struct reset_dt_spec for the property

Functions

int reset_status(const struct device *dev, uint32_t id, uint8_t *status)
   Get the reset status.

This function returns the reset status of the device.

Parameters
   • dev – Reset controller device.
   • id – Reset line.
   • status – Where to write the reset status.

Return values
Zephyr Project Documentation, Release 3.2.99

- 0 – On success.
- -ENOMEM – If the functionality is not implemented by the driver.
- -errno – Other negative errno in case of failure.

static inline int reset_status_dt(const struct reset_dt_spec *spec, uint8_t *status)
Get the reset status from a reset_dt_spec.
This is equivalent to:
reset_status(spec->dev, spec->id, status);

Parameters
• spec – Reset controller specification from devicetree
• status – Where to write the reset status.

Returns
a value from reset_status()

int reset_line_assert(const struct device *dev, uint32_t id)
Put the device in reset state.
This function sets/clears the reset bits of the device, depending on the logic level (active-high/active-low).

Parameters
• dev – Reset controller device.
• id – Reset line.

Return values
• 0 – On success.
• -ENOMEM – If the functionality is not implemented by the driver.
• -errno – Other negative errno in case of failure.

static inline int reset_line_assert_dt(const struct reset_dt_spec *spec)
Assert the reset state from a reset_dt_spec.
This is equivalent to:
reset_line_assert(spec->dev, spec->id);

Parameters
• spec – Reset controller specification from devicetree

Returns
a value from reset_line_assert()

int reset_line_deassert(const struct device *dev, uint32_t id)
Take out the device from reset state.
This function sets/clears the reset bits of the device, depending on the logic level (active-low/active-high).

Parameters
• dev – Reset controller device.
• id – Reset line.

Return values
• 0 – On success.

7.3. Peripherals
• -ENOSYS – If the functionality is not implemented by the driver.
• -errno – Other negative errno in case of failure.

static inline int reset_line_deassert_dt(const struct reset_dt_spec *spec)
Deassert the reset state from a reset_dt_spec.
This is equivalent to:

reset_line_deassert(spec->dev, spec->id)

Parameters
• spec – Reset controller specification from devicetree

Returns
a value from reset_line_deassert()

int reset_line_toggle(const struct device *dev, uint32_t id)
Reset the device.
This function performs reset for a device (assert + deassert).

Parameters
• dev – Reset controller device.
• id – Reset line.

Return values
• 0 – On success.
• -ENOSYS – If the functionality is not implemented by the driver.
• -errno – Other negative errno in case of failure.

static inline int reset_line_toggle_dt(const struct reset_dt_spec *spec)
Reset the device from a reset_dt_spec.
This is equivalent to:

reset_line_toggle(spec->dev, spec->id)

Parameters
• spec – Reset controller specification from devicetree

Returns
a value from reset_line_toggle()

struct reset_dt_spec
#include <reset.h> Reset controller device configuration.

Public Members

const struct device *dev
Reset controller device.

uint32_t id
Reset line.
7.3.32 RTC

Overview

This is a placeholder for API specific to real-time clocks. Currently all RTC peripherals are implemented through Counter with device-specific API for counters with real-time support.

API Reference

```c
typedef void (*maxim_ds3231_alarm_callback_handler_t)(const struct device *dev, uint8_t id, uint32_t syncclock, void *user_data)
```

Signature for DS3231 alarm callbacks.

The alarm callback is invoked from the system work queue thread. At the point the callback is invoked the corresponding alarm flags will have been cleared from the device status register. The callback is permitted to invoke operations on the device.

**Param dev**
the device from which the callback originated

**Param id**
the alarm id

**Param syncclock**
the value from `maxim_ds3231_read_syncclock()` at the time the alarm interrupt was processed.

**Param user_data**
the corresponding parameter from `maxim_ds3231_alarm::user_data`.

```c
typedef void (*maxim_ds3231_notify_callback)(const struct device *dev, struct sys_notify *notify, int res)
```

Signature used to notify a user of the DS3231 that an asynchronous operation has completed.

Functions compatible with this type are subject to all the constraints of `sys_notify_generic_callback`.

**Param dev**
the DS3231 device pointer

**Param notify**
the notification structure provided in the call

**Param res**
the result of the operation.

Functions
static inline uint32_t maxim_ds3231_read_syncclock(const struct device *dev)
{
    Read the local synchronization clock.
    Synchronization aligns the DS3231 real-time clock with a stable monotonic local clock which
should have a frequency between 1 kHz and 1 MHz and be itself synchronized with the primary
system time clock. The accuracy of the alignment and the maximum time between
synchronization updates is affected by the resolution of this clock.

    On some systems the hardware clock from k_cycles_get_32() is suitable, but on others
    that clock advances too quickly. The frequency of the target-specific clock is provided by
    maxim_ds3231_syncclock_frequency().

    At this time the value is captured from k_uptime_get_32(); future kernel extensions may
    make a higher-resolution clock available.

    Note: This function is isr-ok.
}

struct

Parameters
    • dev – the DS3231 device pointer

Returns
    the current value of the synchronization clock.

static inline uint32_t maxim_ds3231_syncclock_frequency(const struct device *dev)
{
    Get the frequency of the synchronization clock.
    Provides the frequency of the clock used in maxim_ds3231_read_syncclock().

    Parameters
        • dev – the DS3231 device pointer

    Returns
        the frequency of the selected synchronization clock.

int maxim_ds3231_ctrl_update(const struct device *dev, uint8_t set_bits, uint8_t clear_bits)
{
    Set and clear specific bits in the control register.

    Note: This function assumes the device register cache is valid. It will not read the register
value, and it will write to the device only if the value changes as a result of applying the set
and clear changes.

    Note: Unlike maxim_ds3231_stat_update() the return value from this function indicates the
register value after changes were made. That return value is cached for use in subsequent
operations.

    Note: This function is supervisor.

    Returns
        the non-negative updated value of the register, or a negative error code from an
        I2C transaction.
int maxim_ds3231_stat_update(const struct device *dev, uint8_t set_bits, uint8_t clear_bits)
Read the ctrl_stat register then set and clear bits in it.

The content of the ctrl_stat register will be read, then the set and clear bits applied and the
result written back to the device (regardless of whether there appears to be a change in value).
OSF, A1F, and A2F will be written with 1s if the corresponding bits do not appear in either
set_bits or clear_bits. This ensures that if any flag becomes set between the read and the
write that indicator will not be cleared.

**Note:** Unlike `maxim_ds3231_ctrl_update()` the return value from this function indicates the
register value before any changes were made.

**Note:** This function is *supervisor*.

### Parameters

- `dev` – the DS3231 device pointer
- `set_bits` – bits to be set when writing back. Setting bits other than
  MAXIM_DS3231_REG_STAT_EN32kHz will have no effect.
- `clear_bits` – bits to be cleared when writing back. Include the bits for the
  status flags you want to clear.

### Returns

the non-negative register value as originally read (disregarding the effect of clears
and sets), or a negative error code from an I2C transaction.

int maxim_ds3231_get_alarm(const struct device *dev, uint8_t id, struct maxim_ds3231_alarm *
cfg)
Read a DS3231 alarm configuration.

The alarm configuration data is read from the device and reconstructed into the output pa-
rameter.

**Note:** This function is *supervisor*.

### Parameters

- `dev` – the DS3231 device pointer.
- `id` – the alarm index, which must be 0 (for the 1 s resolution alarm) or 1 (for
  the 1 min resolution alarm).
- `cfg` – a pointer to a structure into which the configured alarm data will be
  stored.

### Returns

a non-negative value indicating successful conversion, or a negative error code from
an I2C transaction or invalid parameter.

int maxim_ds3231_set_alarm(const struct device *dev, uint8_t id, const struct
maxim_ds3231_alarm *cfg)
Configure a DS3231 alarm.

The alarm configuration is validated and stored into the device.

To cancel an alarm use `counter_cancel_channel_alarm()`.
Note: This function is supervisor.

Parameters

- **dev** – the DS3231 device pointer.
- **id** – 0 Analog to counter index. ALARM1 is 0 and has 1 s resolution, ALARM2 is 1 and has 1 minute resolution.
- **cfg** – a pointer to the desired alarm configuration. Both alarms are configured; if only one is to change the application must supply the existing configuration for the other.

Returns

- a non-negative value on success, or a negative error code from an I2C transaction or an invalid parameter.

```c
int maxim_ds3231_synchronize(const struct device *dev, struct sys_notify *notify)
```

Synchronize the RTC against the local clock.

The RTC advances one tick per second with no access to sub-second precision. Synchronizing clocks at sub-second resolution requires enabling a 1pps signal then capturing the system clocks in a GPIO callback. This function provides that operation.

Synchronization is performed in asynchronously, and may take as long as 1 s to complete; notification of completion is provided through the `notify` parameter.

Applications should use `maxim_ds3231_get_syncpoint()` to retrieve the synchronization data collected by this operation.

Note: This function is supervisor.

Parameters

- **dev** – the DS3231 device pointer.
- **notify** – pointer to the object used to specify asynchronous function behavior and store completion information.

Return values

- **non-negative** – on success
- -EBUSY – if a synchronization or set is currently in progress
- -EINVAL – if notify is not provided
- -ENOTSUP – if the required interrupt is not configured

```c
int maxim_ds3231_req_syncpoint(const struct device *dev, struct k_poll_signal *signal)
```

Request to update the synchronization point.

This is a variant of `maxim_ds3231_synchronize()` for use from user threads.

Parameters

- **dev** – the DS3231 device pointer.
- **signal** – pointer to a valid and ready-to-be-signalled `k_poll_signal`. May be NULL to request a synchronization point be collected without notifying when it has been updated.

Return values
Retrieve the most recent synchronization point.

This function returns the synchronization data last captured using `maxim_ds3231_synchronize()`.

Parameters

- `dev` – the DS3231 device pointer.
- `syncpoint` – where to store the synchronization data.

Return values

- non-negative – on success
- -EBUSY – if a synchronization or set is currently in progress
- -ENOTSUP – if the required interrupt is not configured

Set the RTC to a time consistent with the provided synchronization.

The RTC advances one tick per second with no access to sub-second precision, and setting the clock resets the internal countdown chain. This function implements the magic necessary to set the clock while retaining as much sub-second accuracy as possible. It requires a synchronization point that pairs sub-second resolution civil time with a local synchronization clock captured at the same instant. The set operation may take as long as 1 second to complete; notification of completion is provided through the `notify` parameter.

Note: This function is `supervisor`.

Parameters

- `dev` – the DS3231 device pointer.
- `syncpoint` – the structure providing the synchronization point.
- `notify` – pointer to the object used to specify asynchronous function behavior and store completion information.

Return values

- non-negative – on success
- -EINVAL – if syncpoint or notify are null
- -ENOTSUP – if the required interrupt signal is not configured
- -EBUSY – if a synchronization or set is currently in progress

Check for and clear flags indicating that an alarm has fired.

Returns a mask indicating alarms that are marked as having fired, and clears from stat the flags that it found set. Alarms that have been configured with a callback are not represented in the return value.

This API may be used when a persistent alarm has been programmed.
Note: This function is supervisor.

Parameters

- dev – the DS3231 device pointer.

Returns

a non-negative value that may have MAXIM_DS3231_ALARM1 and/or MAXIM_DS3231_ALARM2 set, or a negative error code.

struct maxim_ds3231_alarm

#include <maxim_ds3231.h> Information defining the alarm configuration.

DS3231 alarms can be set to fire at specific times or at the rollover of minute, hour, day, or day of week.

When an alarm is configured with a handler an interrupt will be generated and the handler called from the system work queue.

When an alarm is configured without a handler, or a persisted alarm is present, alarms can be read using maxim_ds3231_check_alarms().

Public Members

time_t time

Time specification for an RTC alarm.

Though specified as a UNIX time, the alarm parameters are determined by converting to civil time and interpreting the component hours, minutes, seconds, day-of-week, and day-of-month fields, mediated by the corresponding flags.

The year and month are ignored, but be aware that gmtime() determines day-of-week based on calendar date. Decoded alarm times will fall within 1978-01 since 1978-01-01 (first of month) was a Sunday (first of week).

maxim_ds3231_alarm_callback_handler_t handler

Handler to be invoked when alarms are signalled.

If this is null the alarm will not be triggered by the INTn/SQW GPIO. This is a “persisted” alarm from its role in using the DS3231 to trigger a wake from deep sleep. The application should use maxim_ds3231_check_alarms() to determine whether such an alarm has been triggered.

If this is not null the driver will monitor the ISW GPIO for alarm signals and will invoke the handler with a parameter carrying the value returned by maxim_ds3231_check_alarms(). The corresponding status flags will be cleared in the device before the handler is invoked.

The handler will be invoked from the system work queue.

void *user_data

User-provided pointer passed to alarm callback.

uint8_t flags

Flags controlling configuration of the alarm alarm.

See MAXIM_DS3231_ALARM_FLAGS_IGNSE and related constants.
Note that as described the alarm mask fields require that if a unit is not ignored, higher-precision units must also not be ignored. For example, if match on hours is enabled, match on minutes and seconds must also be enabled. Failure to comply with this requirement will cause `maxim_ds3231_set_alarm()` to return an error, leaving the alarm configuration unchanged.

```c
struct maxim_ds3231_syncpoint
    #include <maxim_ds3231.h> Register the RTC clock against system clocks.
    This captures the same instant in both the RTC time scale and a stable system clock scale, allowing conversion between those scales.

Public Members

struct timespec rtc
    Time from the DS3231.
    This maybe in UTC, TAI, or local offset depending on how the RTC is maintained.

uint32_t syncclock
    Value of a local clock at the same instant as rtc.
    This is captured from a stable monotonic system clock running at between 1 kHz and 1 MHz, allowing for microsecond to millisecond accuracy in synchronization.

7.3.33 SDHC

The SDHC api offers a generic interface for interacting with an SD host controller device. It is used by the SD subsystem, and is not intended to be directly used by the application

Basic Operation

SD Host Controller An SD host controller is a device capable of sending SD commands to an attached SD card. These commands can be sent using the native SD protocol, or over SPI. the SDHC api is designed to provide a generic way to send commands to and interact with attached SD devices.

Requests The core of the SDHC api is the `sdhc_request()` api. Requests contain a `sdhc_command` command structure, and an optional `sdhc_data` data structure. The caller may check the return code, or the response field of the SD command structure to determine if the SDHC request succeeded. The data structure allows the caller to specify a number of blocks to transfer, and a buffer location to read or write them from. Whether the provided buffer is used for sending or reading data depends on the command opcode provided.

Host Controller I/O The `sdhc_set_io()` api allows the user to change I/O settings of the SD host controller, such as clock frequency, I/O voltage, and card power. Not all controllers will support applying all I/O settings. For example, SPI mode controllers typically cannot toggle power to the SD card.

Related configuration options:

- `CONFIG_SDHC`

group sdhc_interface
  SDHC interface.

SD command timeouts

SDHC_TIMEOUT_FOREVER

Defines

SDHC_NATIVE_RESPONSE_MASK

SDHC_SPI_RESPONSE_TYPE_MASK

Enums

enum sdhc_bus_mode
  SD bus mode.
  Most controllers will use push/pull, including spi, but SDHC controllers that implement SD host specification can support open drain mode
  Values:

  enumerator SDHC_BUSMODE_OPENDRAIN = 1

  enumerator SDHC_BUSMODE_PUSHPULL = 2

enum sdhc_power
  SD host controller power.
  Many host controllers can control power to attached SD cards. This enum allows applications to request the host controller power off the SD card.
  Values:

  enumerator SDHC_POWER_OFF = 1

  enumerator SDHC_POWER_ON = 2

enum sdhc_bus_width
  SD host controller bus width.
  Only relevant in SD mode, SPI does not support bus width. UHS cards will use 4 bit data bus, all cards start in 1 bit mode
  Values:

  enumerator SDHC_BUS_WIDTH1BIT = 1U
enumerator SDHC_BUS_WIDTH4BIT = 4U

enumerator SDHC_BUS_WIDTH8BIT = 8U

denum sdhc_timing_mode
    SD host controller timing mode.
    Used by SD host controller to determine the timing of the cards attached to the bus. Cards start with legacy timing, but UHS-II cards can go up to SDR104.
    Values:
        enumerator SDHC_TIMING_LEGACY = 1U
            Legacy 3.3V Mode
        enumerator SDHC_TIMING_HS = 2U
            Legacy High speed mode (3.3V)
        enumerator SDHC_TIMING_SDR12 = 3U
            Identification mode & SDR12
        enumerator SDHC_TIMING_SDR25 = 4U
            High speed mode & SDR25
        enumerator SDHC_TIMING_SDR50 = 5U
            SDR49 mode
        enumerator SDHC_TIMING_SDR104 = 6U
            SDR104 mode
        enumerator SDHC_TIMING_DDR50 = 7U
            DDR50 mode
        enumerator SDHC_TIMING_DDR52 = 8U
            DDR52 mode
        enumerator SDHC_TIMING_HS200 = 9U
            HS200 mode
        enumerator SDHC_TIMING_HS400 = 10U
            HS400 mode

denum sd_voltage
    SD voltage.
    UHS cards can run with 1.8V signalling for improved power consumption. Legacy cards may support 3.0V signalling, and all cards start at 3.3V. Only relevant for SD controllers, not SPI ones.
    Values:
enumerator SD_VOL_3_3_V = 1U
    card operation voltage around 3.3v
enumerator SD_VOL_3_0_V = 2U
    card operation voltage around 3.0v
enumerator SD_VOL_1_8_V = 3U
    card operation voltage around 1.8v
enumerator SD_VOL_1_2_V = 4U
    card operation voltage around 1.2v

Functions

int sdhc_hw_reset(const struct device *dev)
    reset SDHC controller state
    Used when the SDHC has encountered an error. Resetting the SDHC controller should clear
    all errors on the SDHC, but does not necessarily reset I/O settings to boot (this can be done
    with sdhc_set_io)
    Parameters
    • dev – SD host controller device
Return values
    • 0 – reset succeeded
    • -ETIMEDOUT – controller reset timed out
    • -EIO – reset failed

int sdhc_request(const struct device *dev, struct sdhc_command *cmd, struct sdhc_data *data)
    Send command to SDHC.
    Sends a command to the SD host controller, which will send this command to attached SD
    cards.
    Parameters
    • dev – SDHC device
    • cmd – SDHC command
    • data – SDHC data. Leave NULL to send SD command without data.
Return values
    • 0 – command was sent successfully
    • -ETIMEDOUT – command timed out while sending
    • -ENOTSUP – host controller does not support command
    • -EIO – I/O error

int sdhc_set_io(const struct device *dev, struct sdhc_io *io)
    set I/O properties of SDHC
    I/O properties should be reconfigured when the card has been sent a command to change its
    own SD settings. This function can also be used to toggle power to the SD card.
    Parameters
• dev – SDHC device
• io – I/O properties

Returns
0 I/O was configured correctly

Returns
-ENOTSUP controller does not support these I/O settings

Returns
-ESIO controller could not configure I/O settings

int sdhc_card_present(const struct device *dev)
check for SDHC card presence

Checks if card is present on the SD bus. Note that if a controller requires cards be powered up to detect presence, it should do so in this function.

Parameters
• dev – SDHC device

Return values
• 1 – card is present
• 0 – card is not present
• -EIO – I/O error

int sdhc_execute_tuning(const struct device *dev)
run SDHC tuning

SD cards require signal tuning for UHS modes SDR104 and SDR50. This function allows an application to request the SD host controller to tune the card.

Parameters
• dev – SDHC device

Return values
• 0 – tuning succeeded, card is ready for commands
• -ETIMEDOUT – tuning failed after timeout
• -ENOTSUP – controller does not support tuning
• -EIO – I/O error while tuning

int sdhc_card_busy(const struct device *dev)
check if SD card is busy

This check should generally be implemented as checking the line level of the DAT[0:3] lines of the SD bus. No SD commands need to be sent, the controller simply needs to report the status of the SD bus.

Parameters
• dev – SDHC device

Return values
• 0 – card is not busy
• 1 – card is busy
• -EIO – I/O error
int sdhc_get_host_props(const struct device *dev, struct sdhc_host_props *props)

Get SD host controller properties.

Gets host properties from the host controller. Host controller should initialize all values in the sdhc_host_props structure provided.

**Parameters**

- `dev` – SDHC device
- `props` – property structure to be filled by sdhc driver

**Return values**

- 0 – function succeeded.
- -ENOTSUP – host controller does not support this call

```c
struct sdhc_command
#include <sdhc.h> SD host controller command structure.

This command structure is used to send command requests to an SD host controller, which will be sent to SD devices.

**Public Members**

- `uint32_t opcode`
  SD Host specification CMD index

- `uint32_t arg`
  SD host specification argument

- `uint32_t response[4]`
  SD card response field

- `uint32_t response_type`
  Expected SD response type

- `unsigned int retries`
  Max number of retries

- `int timeout_ms`
  Command timeout in milliseconds

```c
struct sdhc_data
#include <sdhc.h> SD host controller data structure.

This command structure is used to send data transfer requests to an SD host controller, which will be sent to SD devices.

**Public Members**

- `unsigned int block_addr`
  Block to start read from
unsigned int block_size
    Block size

unsigned int blocks
    Number of blocks

unsigned int bytes_xfered
    populated with number of bytes sent by SDHC

void *data
    Data to transfer or receive

int timeout_ms
    data timeout in milliseconds

struct sdhc_host_caps
    #include <sdhc.h> SD host controller capabilities.
    SD host controller capability flags. These flags should be set by the SDHC driver, using the sdhc_get_host_props api.

struct sdhc_io
    #include <sdhc.h> SD host controller I/O control structure.
    Controls I/O settings for the SDHC. Note that only a subset of these settings apply to host controllers in SPI mode. Populate this struct, then call sdhc_set_io to apply I/O settings

Public Members

datatype sdhc_clock_speed clock
    Clock rate

datatype sdhc_bus_mode bus_mode
    command output mode

datatype sdhc_power power_mode
    SD power supply mode

datatype sdhc_bus_width bus_width
    SD bus width

datatype sdhc_timing_mode timing
    SD bus timing

datatype sd_driver_type driver_type
    SD driver type

datatype sd_voltge signal_voltage
    IO signalling voltage (usually 1.8 or 3.3V)
struct sdhc_host_props

#include <sdhc.h> SD host controller properties.
Populated by the host controller using sdhc_get_host_props api.

Public Members

unsigned int f_max
Max bus frequency

unsigned int f_min
Min bus frequency

unsigned int power_delay
Delay to allow SD to power up or down (in ms)

struct sdhc_host_caps host_caps
Host capability bitfield

uint32_t max_current_330
Max current (in mA) at 3.3V

uint32_t max_current_300
Max current (in mA) at 3.0V

uint32_t max_current_180
Max current (in mA) at 1.8V

bool is_spi
Is the host using SPI mode

struct sdhc_driver_api
#include <sdhc.h>

7.3.34 Sensors

The sensor subsystem exposes an API to uniformly access sensor devices. Common operations are:
reading data and executing code when specific conditions are met.

Basic Operation

Channels Fundamentally, a channel is a quantity that a sensor device can measure.

Sensors can have multiple channels, either to represent different axes of the same physical property (e.g.
acceleration); or because they can measure different properties altogether (ambient temperature, pressure
and humidity). Complex sensors cover both cases, so a single device can expose three acceleration
channels and a temperature one.

It is imperative that all sensors that support a given channel express results in the same unit of mea-
urement. Consult the API Reference for all supported channels, along with their description and units of
measurement:
Values  Sensor devices return results as sensor_value. This representation avoids use of floating point values as they may not be supported on certain setups.

Fetching Values  Getting a reading from a sensor requires two operations. First, an application instructs the driver to fetch a sample of all its channels. Then, individual channels may be read. In the case of channels with multiple axes, they can be read in a single operation by supplying the corresponding _XYZ channel type and a buffer of 3 sensor_value objects. This approach ensures consistency of channels between reads and efficiency of communication by issuing a single transaction on the underlying bus.

Below is an example illustrating the usage of the BME280 sensor, which measures ambient temperature and atmospheric pressure. Note that sensor_sample_fetch() is only called once, as it reads and compensates data for both channels.

```
/*
 * Get a device structure from a devicetree node with compatible
 * "bosch,bme280". (If there are multiple, just pick one.) */
static const struct device *get_bme280_device(void)
{
    const struct device *const dev = DEVICE_DT_GET_ANY(bosch_bme280);

    if (dev == NULL) {
        /* No such node, or the node does not have status "okay". */
        printk("Error: no device found.
");
        return NULL;
    }

    if (!device_is_ready(dev)) {
        printk("Error: Device "%s" is not ready; "
                "check the driver initialization logs for errors.
", dev->name);
        return NULL;
    }

    printk("Found device "%s", getting sensor data
", dev->name);
    return dev;
}

void main(void)
{
    const struct device *dev = get_bme280_device();

}

Configuration and Attributes

Setting the communication bus and address is considered the most basic configuration for sensor devices. This setting is done at compile time, via the configuration menu. If the sensor supports interrupts, the interrupt lines and triggering parameters described below are also configured at compile time.

Alongside these communication parameters, sensor chips typically expose multiple parameters that control the accuracy and frequency of measurement. In compliance with Zephyr's design goals, most of these values are statically configured at compile time.

However, certain parameters could require runtime configuration, for example, threshold values for interrupts. These values are configured via attributes. The example in the following section showcases a sensor with an interrupt line that is triggered when the temperature crosses a threshold. The threshold is configured at runtime using an attribute.

Triggers

Triggers in Zephyr refer to the interrupt lines of the sensor chips. Many sensor chips support one or more triggers. Some examples of triggers include: new data is ready for reading, a channel value has crossed a threshold, or the device has sensed motion.

To configure a trigger, an application needs to supply a `sensor_trigger` and a handler function. The structure contains the trigger type and the channel on which the trigger must be configured.

Because most sensors are connected via SPI or I2C buses, it is not possible to communicate with them from the interrupt execution context. The execution of the trigger handler is deferred to a thread, so that data fetching operations are possible. A driver can spawn its own thread to fetch data, thus ensuring minimum latency. Alternatively, multiple sensor drivers can share a system-wide thread. The shared thread approach increases the latency of handling interrupts but uses less memory. You can configure which approach to follow for each driver. Most drivers can entirely disable triggers resulting in a smaller footprint.

The following example contains a trigger fired whenever temperature crosses the 26 degree Celsius threshold. It also samples the temperature every second. A real application would ideally disable periodic sampling in the interest of saving power. Since the application has direct access to the kernel config symbols, no trigger is registered when triggering was disabled by the driver's configuration.

API Reference

**group sensor_interface**

Sensor Interface.

**Defines**

**SENSOR_G**

The value of gravitational constant in micro m/s^2.

**SENSOR_PI**

The value of constant PI in micros.

**SENSOR_INFO_DEFINE(name, ...)**

**SENSOR_INFO_DT_DEFINE(node_id)**

**SENSOR_DEVICE_DT_DEFINE(node_id, init_fn, pm_device, data_ptr, cfg_ptr, level, prio, api_ptr, ...)**

Like **DEVICE_DT_DEFINE()** with sensor specifics.

Defines a device which implements the sensor API. May define an element in the sensor info iterable section used to enumerate all sensor devices.

**Parameters**

- **node_id** – The devicetree node identifier.
- **init_fn** – Name of the init function of the driver.
- **pm_device** – PM device resources reference (NULL if device does not use PM).
- **data_ptr** – Pointer to the device’s private data.
- **cfg_ptr** – The address to the structure containing the configuration information for this instance of the driver.
- **level** – The initialization level. See SYS_INIT() for details.
• prio — Priority within the selected initialization level. See SYS_INIT() for details.
• api_ptr — Provides an initial pointer to the API function struct used by the driver. Can be NULL.

SENSOR_DEVICE_DT_INST_DEFINE(inst, ...)
Like SENSOR_DEVICE_DT_DEFINE() for an instance of a DT_DRV_COMPAT compatible.

Parameters
• inst — instance number. This is replaced by DT_DRV_COMPAT(inst) in the call to SENSOR_DEVICE_DT_DEFINE().
• ... — other parameters as expected by SENSOR_DEVICE_DT_DEFINE().

Typedefs

typedef void (*sensor_trigger_handler_t)(const struct device *dev, const struct sensor_trigger *trigger)
Callback API upon firing of a trigger.

    Param dev
    Pointer to the sensor device

    Param trigger
    The trigger

typedef int (*sensor_attr_set_t)(const struct device *dev, enum sensor_channel chan, enum sensor_attribute attr, const struct sensor_value *val)
Callback API upon setting a sensor's attributes.
See sensor_attr_set() for argument description

typedef int (*sensor_attr_get_t)(const struct device *dev, enum sensor_channel chan, enum sensor_attribute attr, struct sensor_value *val)
Callback API upon getting a sensor's attributes.
See sensor_attr_get() for argument description

typedef int (*sensor_trigger_set_t)(const struct device *dev, const struct sensor_trigger *trig, sensor_trigger_handler_t handler)
Callback API for setting a sensor's trigger and handler.
See sensor_trigger_set() for argument description

typedef int (*sensor_sample_fetch_t)(const struct device *dev, enum sensor_channel chan)
Callback API for fetching data from a sensor.
See sensor_sample_fetch() for argument description

typedef int (*sensor_channel_get_t)(const struct device *dev, enum sensor_channel chan, struct sensor_value *val)
Callback API for getting a reading from a sensor.
See sensor_channel_get() for argument description
Enums

```c
enum sensor_channel

    Sensor channels.

    Values:

    enumerator SENSOR_CHAN_ACCEL_X  
        Acceleration on the X axis, in m/s^2.

    enumerator SENSOR_CHAN_ACCEL_Y  
        Acceleration on the Y axis, in m/s^2.

    enumerator SENSOR_CHAN_ACCEL_Z  
        Acceleration on the Z axis, in m/s^2.

    enumerator SENSOR_CHAN_ACCEL_XYZ  
        Acceleration on the X, Y and Z axes.

    enumerator SENSOR_CHAN_GYRO_X  
        Angular velocity around the X axis, in radians/s.

    enumerator SENSOR_CHAN_GYRO_Y  
        Angular velocity around the Y axis, in radians/s.

    enumerator SENSOR_CHAN_GYRO_Z  
        Angular velocity around the Z axis, in radians/s.

    enumerator SENSOR_CHAN_GYRO_XYZ  
        Angular velocity around the X, Y and Z axes.

    enumerator SENSOR_CHAN_MAGN_X  
        Magnetic field on the X axis, in Gauss.

    enumerator SENSOR_CHAN_MAGN_Y  
        Magnetic field on the Y axis, in Gauss.

    enumerator SENSOR_CHAN_MAGN_Z  
        Magnetic field on the Z axis, in Gauss.

    enumerator SENSOR_CHAN_MAGN_XYZ  
        Magnetic field on the X, Y and Z axes.

    enumerator SENSOR_CHAN_DIE_TEMP  
        Device die temperature in degrees Celsius.

    enumerator SENSOR_CHAN_AMBIENT_TEMP  
        Ambient temperature in degrees Celsius.
```
enumerator SENSOR_CHAN_PRESS
    Pressure in kilopascal.

enumerator SENSOR_CHAN_PROX
    Proximity. Adimensional. A value of 1 indicates that an object is close.

enumerator SENSOR_CHAN_HUMIDITY
    Humidity, in percent.

enumerator SENSOR_CHAN_LIGHT
    Illuminance in visible spectrum, in lux.

enumerator SENSOR_CHAN_IR
    Illuminance in infra-red spectrum, in lux.

enumerator SENSOR_CHAN_RED
    Illuminance in red spectrum, in lux.

enumerator SENSOR_CHAN_GREEN
    Illuminance in green spectrum, in lux.

enumerator SENSOR_CHAN_BLUE
    Illuminance in blue spectrum, in lux.

enumerator SENSOR_CHAN_ALTITUDE
    Altitude, in meters

enumerator SENSOR_CHAN_PM_1_0
    1.0 micro-meters Particulate Matter, in ug/m^3

enumerator SENSOR_CHAN_PM_2_5
    2.5 micro-meters Particulate Matter, in ug/m^3

enumerator SENSOR_CHAN_PM_10
    10 micro-meters Particulate Matter, in ug/m^3

enumerator SENSOR_CHAN_DISTANCE
    Distance. From sensor to target, in meters

enumerator SENSOR_CHAN_CO2
    CO2 level, in parts per million (ppm)

enumerator SENSOR_CHAN_VOC
    VOC level, in parts per billion (ppb)

enumerator SENSOR_CHAN_GAS_RES
    Gas sensor resistance in ohms.
enumerator SENSOR_CHAN_VOLTAGE
    Voltage, in volts
enumerator SENSOR_CHAN_CURRENT
    Current, in amps
enumerator SENSOR_CHAN_POWER
    Power in watts
enumerator SENSOR_CHAN_RESISTANCE
    Resistance, in Ohm
enumerator SENSOR_CHAN_ROTATION
    Angular rotation, in degrees
enumerator SENSOR_CHAN_POS_DX
    Position change on the X axis, in points.
enumerator SENSOR_CHAN_POS_DY
    Position change on the Y axis, in points.
enumerator SENSOR_CHAN_POS_DZ
    Position change on the Z axis, in points.
enumerator SENSOR_CHAN_RPM
    Revolutions per minute, in RPM.
enumerator SENSOR_CHAN_GAUGE_VOLTAGE
    Voltage, in volts
enumerator SENSOR_CHAN_GAUGE_AVG_CURRENT
    Average current, in amps
enumerator SENSOR_CHAN_GAUGE_STDBY_CURRENT
    Standby current, in amps
enumerator SENSOR_CHAN_GAUGE_MAX_LOAD_CURRENT
    Max load current, in amps
enumerator SENSOR_CHAN_GAUGE_TEMP
    Gauge temperature
enumerator SENSOR_CHAN_GAUGE_STATE_OF_CHARGE
    State of charge measurement in %
enumerator SENSOR_CHAN_GAUGE_FULL_CHARGE_CAPACITY
    Full Charge Capacity in mAh
enumerator SENSOR_CHAN_GAUGE_REMAINING_CHARGE_CAPACITY
    Remaining Charge Capacity in mAh
enumerator SENSOR_CHAN_GAUGE_NOM_AVAIL_CAPACITY
    Nominal Available Capacity in mAh
enumerator SENSOR_CHAN_GAUGE_FULL_AVAIL_CAPACITY
    Full Available Capacity in mAh
enumerator SENSOR_CHAN_GAUGE_AVG_POWER
    Average power in mW
enumerator SENSOR_CHAN_GAUGE_STATE_OF_HEALTH
    State of health measurement in %
enumerator SENSOR_CHAN_GAUGE_TIME_TO_EMPTY
    Time to empty in minutes
enumerator SENSOR_CHAN_GAUGE_TIME_TO_FULL
    Time to full in minutes
enumerator SENSOR_CHAN_GAUGE_CYCLE_COUNT
    Cycle count (total number of charge/discharge cycles)
enumerator SENSOR_CHAN_GAUGE_DESIGN_VOLTAGE
    Design voltage of cell in V (max voltage)
enumerator SENSOR_CHAN_GAUGE_DESIRED_VOLTAGE
    Desired voltage of cell in V (nominal voltage)
enumerator SENSOR_CHAN_GAUGE_DESIRED_CHARGING_CURRENT
    Desired charging current in mA
enumerator SENSOR_CHAN_ALL
    All channels.
enumerator SENSOR_CHAN_COMMON_COUNT
    Number of all common sensor channels.
enumerator SENSOR_CHAN_PRIV_START = SENSOR_CHAN_COMMON_COUNT
    This and higher values are sensor specific. Refer to the sensor header file.
enumerator SENSOR_CHAN_MAX = INT16_MAX
    Maximum value describing a sensor channel type.

defined sensor_trigger_type
    Sensor trigger types.
    Values:
enumerator SENSOR_TRIG_TIMER
    Timer-based trigger, useful when the sensor does not have an interrupt line.

denumerator SENSOR_TRIG_DATA_READY
    Trigger fires whenever new data is ready.

denumerator SENSOR_TRIG_DELTA
    Trigger fires when the selected channel varies significantly. This includes any-motion
detection when the channel is acceleration or gyro. If detection is based on slope
to successive channel readings, the slope threshold is configured via the SENSOR_ATTR_SLOPE_TH
and SENSOR_ATTR_SLOPE_DUR attributes.

enumerator SENSOR_TRIG_NEAR_FAR
    Trigger fires when a near/far event is detected.

denumerator SENSOR_TRIG_THRESHOLD
    Trigger fires when channel reading transitions configured thresholds. The thresholds are
configured via the SENSOR_ATTR_LOWER_THRESH, SENSOR_ATTR_UPPER_THRESH,
and SENSOR_ATTR_HYSTERESIS attributes.

denumerator SENSOR_TRIG_TAP
    Trigger fires when a single tap is detected.

denumerator SENSOR_TRIG_DOUBLE_TAP
    Trigger fires when a double tap is detected.

denumerator SENSOR_TRIG_FREEFALL
    Trigger fires when a free fall is detected.

denumerator SENSOR_TRIG_MOTION
    Trigger fires when motion is detected.

denumerator SENSOR_TRIG_STATIONARY
    Trigger fires when no motion has been detected for a while.

denumerator SENSOR_TRIG_COMMON_COUNT
    Number of all common sensor triggers.

denumerator SENSOR_TRIG_PRIV_START = SENSOR_TRIG_COMMON_COUNT
    This and higher values are sensor specific. Refer to the sensor header file.

denumerator SENSOR_TRIG_MAX = INT16_MAX
    Maximum value describing a sensor trigger type.

enum sensor_attribute
    Sensor attribute types.
    Values:
enumerator SENSOR_ATTR_SAMPLING_FREQUENCY
  Sensor sampling frequency, i.e. how many times a second the sensor takes a measure-
  ment.

enumerator SENSOR_ATTR_LOWER_THRESH
  Lower threshold for trigger.

enumerator SENSOR_ATTR_UPPER_THRESH
  Upper threshold for trigger.

enumerator SENSOR_ATTR_SLOPE_TH
  Threshold for any-motion (slope) trigger.

enumerator SENSOR_ATTR_SLOPE_DUR
  Duration for which the slope values needs to be outside the threshold for the trigger to
  fire.

enumerator SENSOR_ATTR_HYSTERESIS

denumerator SENSOR_ATTR_OVERSAMPLING
  Oversampling factor

enumerator SENSOR_ATTR_FULL_SCALE
  Sensor range, in SI units.

enumerator SENSOR_ATTR_OFFSET
  The sensor value returned will be altered by the amount indicated by offset: final_value
  = sensor_value + offset.

enumerator SENSOR_ATTR_CALIB_TARGET
  Calibration target. This will be used by the internal chip's algorithms to calibrate itself on
  a certain axis, or all of them.

enumerator SENSOR_ATTR_CONFIGURATION
  Configure the operating modes of a sensor.

enumerator SENSOR_ATTR_CALIBRATION
  Set a calibration value needed by a sensor.

enumerator SENSOR_ATTR_FEATURE_MASK
  Enable/disable sensor features

enumerator SENSOR_ATTR_ALERT
  Alert threshold or alert enable/disable

enumerator SENSOR_ATTR_FF_DUR
  Free-fall duration represented in milliseconds. If the sampling frequency is changed dur-
  ing runtime, this attribute should be set to adjust freefall duration to the new sampling
  frequency.
enumerator SENSOR_ATTR_COMMON_COUNT
Number of all common sensor attributes.

enumerator SENSOR_ATTR_PRIV_START = SENSOR_ATTR_COMMON_COUNT
This and higher values are sensor specific. Refer to the sensor header file.

enumerator SENSOR_ATTR_MAX = INT16_MAX
Maximum value describing a sensor attribute type.

Functions

int sensor_attr_set(const struct device *dev, enum sensor_channel chan, enum sensor_attribute attr, const struct sensor_value *val)
Set an attribute for a sensor.

Parameters
• dev – Pointer to the sensor device
• chan – The channel the attribute belongs to, if any. Some attributes may only be set for all channels of a device, depending on device capabilities.
• attr – The attribute to set
• val – The value to set the attribute to

Returns
0 if successful, negative errno code if failure.

int sensor_attr_get(const struct device *dev, enum sensor_channel chan, enum sensor_attribute attr, struct sensor_value *val)
Get an attribute for a sensor.

Parameters
• dev – Pointer to the sensor device
• chan – The channel the attribute belongs to, if any. Some attributes may only be set for all channels of a device, depending on device capabilities.
• attr – The attribute to get
• val – Pointer to where to store the attribute

Returns
0 if successful, negative errno code if failure.

static inline int sensor_trigger_set(const struct device *dev, const struct sensor_trigger *trig, sensor_trigger_handler_t handler)
Activate a sensor’s trigger and set the trigger handler.

The handler will be called from a thread, so I2C or SPI operations are safe. However, the thread’s stack is limited and defined by the driver. It is currently up to the caller to ensure that the handler does not overflow the stack.

Function properties (list may not be complete)

supervisor

Parameters
• dev – Pointer to the sensor device
• **trig** – The trigger to activate
• **handler** – The function that should be called when the trigger fires

**Returns**
0 if successful, negative errno code if failure.

```c
int sensor_sample_fetch(const struct device *dev)
```
Fetch a sample from the sensor and store it in an internal driver buffer.

Read all of a sensor's active channels and, if necessary, perform any additional operations necessary to make the values useful. The user may then get individual channel values by calling `sensor_channel_get`.

Since the function communicates with the sensor device, it is unsafe to call it in an ISR if the device is connected via I2C or SPI.

**Parameters**
- `dev` – Pointer to the sensor device

**Returns**
0 if successful, negative errno code if failure.

```c
int sensor_sample_fetch_chan(const struct device *dev, enum sensor_channel type)
```
Fetch a sample from the sensor and store it in an internal driver buffer.

Read and compute compensation for one type of sensor data (magnetometer, accelerometer, etc). The user may then get individual channel values by calling `sensor_channel_get`.

This is mostly implemented by multi function devices enabling reading at different sampling rates.

Since the function communicates with the sensor device, it is unsafe to call it in an ISR if the device is connected via I2C or SPI.

**Parameters**
- `dev` – Pointer to the sensor device
- `type` – The channel that needs updated

**Returns**
0 if successful, negative errno code if failure.

```c
int sensor_channel_get(const struct device *dev, enum sensor_channel chan, struct sensor_value *val)
```
Get a reading from a sensor device.

Return a useful value for a particular channel, from the driver's internal data. Before calling this function, a sample must be obtained by calling `sensor_sample_fetch` or `sensor_sample_fetch_chan`. It is guaranteed that two subsequent calls of this function for the same channels will yield the same value, if `sensor_sample_fetch` or `sensor_sample_fetch_chan` has not been called in the meantime.

For vectorial data samples you can request all axes in just one call by passing the specific channel with _XYZ suffix. The sample will be returned at val[0], val[1] and val[2] (X, Y and Z in that order).

**Parameters**
- `dev` – Pointer to the sensor device
- `chan` – The channel to read
- `val` – Where to store the value

**Returns**
0 if successful, negative errno code if failure.
static inline int32_t sensor_ms2_to_g(const struct sensor_value *ms2)
    Helper function to convert acceleration from m/s^2 to Gs.

    **Parameters**
    • ms2 – A pointer to a `sensor_value` struct holding the acceleration, in m/s^2.

    **Returns**
    The converted value, in Gs.

static inline void sensor_g_to_ms2(int32_t g, struct sensor_value *ms2)
    Helper function to convert acceleration from Gs to m/s^2.

    **Parameters**
    • g – The G value to be converted.
    • ms2 – A pointer to a `sensor_value` struct, where the result is stored.

static inline int32_t sensor_rad_to_degrees(const struct sensor_value *rad)
    Helper function for converting radians to degrees.

    **Parameters**
    • rad – A pointer to a `sensor_value` struct, holding the value in radians.

    **Returns**
    The converted value, in degrees.

static inline void sensor_degrees_to_rad(int32_t d, struct sensor_value *rad)
    Helper function for converting degrees to radians.

    **Parameters**
    • d – The value (in degrees) to be converted.
    • rad – A pointer to a `sensor_value` struct, where the result is stored.

static inline double sensor_value_to_double(const struct sensor_value *val)
    Helper function for converting struct `sensor_value` to double.

    **Parameters**
    • val – A pointer to a `sensor_value` struct.

    **Returns**
    The converted value.

static inline int sensor_value_from_double(struct sensor_value *val, double inp)
    Helper function for converting double to struct `sensor_value`.

    **Parameters**
    • val – A pointer to a `sensor_value` struct.
    • inp – The converted value.

    **Returns**
    0 if successful, negative errno code if failure.

**struct sensor_value**

```c
#include <sensor.h> Representation of a sensor readout value.
```

The value is represented as having an integer and a fractional part, and can be obtained using the formula \( \text{val1} + \text{val2} \times 10^{-6} \). Negative values also adhere to the above formula, but may need special attention. Here are some examples of the value representation:
0.5: \( \text{val1} = 0, \text{val2} = 500000 \)
-0.5: \( \text{val1} = 0, \text{val2} = -500000 \)
-1.0: \( \text{val1} = -1, \text{val2} = 0 \)
-1.5: \( \text{val1} = -1, \text{val2} = -500000 \)

**Public Members**

```c
int32_t val1
```

Integer part of the value.

```c
int32_t val2
```

Fractional part of the value (in one-millionth parts).

```c
struct sensor_trigger
```

```
#include <sensor.h> Sensor trigger spec.
```

**Public Members**

```c
enum sensor_trigger_type type
```

Trigger type.

```c
enum sensor_channel chan
```

Channel the trigger is set on.

```c
struct sensor_driver_api
```

```
#include <sensor.h>
```

### 7.3.35 SPI

**Overview**

**API Reference**

```c
#define group spi_interface
```

SPI Interface.

#### SPI operational mode

```

```c
SPI_OP_MODE_MASK
```

```c
SPI_OP_MODE_GET(_operation_)
```
**SPI Polarity & Phase Modes**

**SPI_MODE_CPOL**
- Clock Polarity: if set, clock idle state will be 1 and active state will be 0. If untouched, the inverse will be true which is the default.

**SPI_MODE_CPHA**
- Clock Phase: this dictates when is the data captured, and depends clock's polarity. When SPI_MODE_CPOL is set and this bit as well, capture will occur on low to high transition and high to low if this bit is not set (default). This is fully reversed if CPOL is not set.

**SPI_MODE_LOOP**
- Whatever data is transmitted is looped-back to the receiving buffer of the controller. This is fully controller dependent as some may not support this, and can be used for testing purposes only.

**SPI_MODE_MASK**

**SPI_MODE_GET(_mode_)**

**SPI Transfer modes (host controller dependent)**

**SPI_TRANSFER_MSB**

**SPI_TRANSFER_LSB**

**SPI word size**

**SPI_WORD_SIZE_SHIFT**

**SPI_WORD_SIZE_MASK**

**SPI_WORD_SIZE_GET(_operation_)**

**SPI_WORD_SET(_word_size_)**

**Specific SPI devices control bits**

**SPI_HOLD_ON_CS**

**SPI_LOCK_ON**

**SPI_CS_ACTIVE_HIGH**
SPI MISO lines (if `<code>CONFIG_SPI_EXTENDED_MODES</code>` enabled)

Some controllers support dual, quad or octal MISO lines connected to slaves. Default is single, which is the case most of the time. Without `CONFIG_SPI_EXTENDED_MODES` being enabled, single is the only supported one.

```
SPI_LINES_SINGLE
SPI_LINES_DUAL
SPI_LINES_QUAD
SPI_LINES_OCTAL
SPI_LINES_MASK
```

SPI duplex mode

Some controllers support half duplex transfer, which results in 3-wire usage. By default, full duplex will prevail.

```
SPI_FULL_DUPLEX
SPI_HALF_DUPLEX
```

SPI Frame Format

2 frame formats are exposed: Motorola and TI. The main difference is the behavior of the CS line. In Motorola it stays active the whole transfer. In TI, it’s active only one serial clock period prior to actually make the transfer, it is thus inactive during the transfer, which ends when the clocks ends as well. By default, as it is the most commonly used, the Motorola frame format will prevail.

```
SPI_FRAME_FORMAT_MOTOROLA
SPI_FRAME_FORMAT_TI
```

Defines

```
SPI_CS_GPIOS_DT_SPEC_GET(spi_dev)
    Get a struct `gpio_dt_spec` for a SPI device's chip select pin.
    Example devicetree fragment:
    
    gpio1: gpio@abcd0001 { ... };
    gpio2: gpio@abcd0002 { ... };
```

(continues on next page)
spi@abcd0003 {
    compatible = "vnd.spi";
    cs-gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
              <&gpio2 20 GPIO_ACTIVE_LOW>;

    a: spi-dev-a@0 {
        reg = <0>;
    };

    b: spi-dev-b@1 {
        reg = <1>;
    };
};

Example usage:

```
SPI_CS_GPIOS_DT_SPEC_GET(DT_NODELABEL(a)) \ 
    // { DEVICE_DT_GET(DT_NODELABEL(gpio1)), 10, GPIO_ACTIVE_LOW }
SPI_CS_GPIOS_DT_SPEC_GET(DT_NODELABEL(b)) \ 
    // { DEVICE_DT_GET(DT_NODELABEL(gpio2)), 20, GPIO_ACTIVE_LOW }
```

**Parameters**

- spi_dev – a SPI device node identifier

**Returns**

`gpio_dt_spec` struct corresponding with spi_dev's chip select

SPI_CS_GPIOS_DT_SPEC_INST_GET(inst)

Get a struct `gpio_dt_spec` for a SPI device's chip select pin.

This is equivalent to `SPI_CS_GPIOS_DT_SPEC_GET(DT_DRV_INST(inst))`.

**Parameters**

- inst – Devicetree instance number

**Returns**

`gpio_dt_spec` struct corresponding with spi_dev's chip select

SPI_CS_CONTROL_PTR_DT(node_id, delay_)

Initialize and get a pointer to a `spi_cs_control` from a devicetree node identifier.

This helper is useful for initializing a device on a SPI bus. It initializes a struct `spi_cs_control` and returns a pointer to it. Here, `node_id` is a node identifier for a SPI device, not a SPI controller.

Example devicetree fragment:

```
spi@... {
    cs-gpios = <&gpio0 1 GPIO_ACTIVE_LOW>;
    spidev: spi-device@0 { ... };
};
```

Assume that gpio0 follows the standard convention for specifying GPIOs, i.e. it has the following in its binding:
gpio-cells:
- pin
- flags

Example usage:

```c
struct spi_cs_control *ctrl =
    SPI_CS_CONTROL_PTR_DT(DT_NODELABEL(spidev), 2);
```

This example is equivalent to:

```c
struct spi_cs_control *ctrl =
    &struct spi_cs_control {
        .gpio_dev = DEVICE_DT_GET(DT_NODELABEL(gpio0)),
        .delay = 2,
        .gpio_pin = 1,
        .gpio_dt_flags = GPIO_ACTIVE_LOW
    };
```

This macro is not available in C++.

Parameters

- **node_id** – Devicetree node identifier for a device on a SPI bus
- **delay_** – The delay field to set in the `spi_cs_control`

Returns

a pointer to the `spi_cs_control` structure

SPI_CS_CONTROL_PTR_DT_INST(inst, delay_)

Get a pointer to a `spi_cs_control` from a devicetree node.

This is equivalent to `SPI_CS_CONTROL_PTR_DT(DT_DRV_INST(inst), delay)`

Therefore, `DT_DRV_COMPAT` must already be defined before using this macro.

This macro is not available in C++.

Parameters

- **inst** – Devicetree node instance number
- **delay_** – The delay field to set in the `spi_cs_control`

Returns

a pointer to the `spi_cs_control` structure

SPI_CONFIG_DT(node_id, operation_, delay_)

Structure initializer for `spi_config` from devicetree.

This helper macro expands to a static initializer for a struct `spi_config` by reading the relevant frequency, slave, and cs data from the devicetree.

Important: the cs field is initialized using `SPI_CS_CONTROL_PTR_DT()`. The gpio_dev value pointed to by this structure must be checked using `device_is_ready()` before use.

This macro is not available in C++.

Parameters

- **node_id** – Devicetree node identifier for the SPI device whose struct `spi_config` to create an initializer for
- **operation_** – the desired operation field in the struct `spi_config`
- **delay_** – the desired delay field in the struct `spi_config`'s `spi_cs_control`, if there is one
SPI_CONFIG_DT_INST(inst, operation_, delay_)
Structure initializer for spi_config from devicetree instance.

This is equivalent to SPI_CONFIG_DT(DT_DRV_INST(inst), operation_, delay_).

This macro is not available in C++.

Parameters

• inst – Devicetree instance number
• operation_ – the desired operation field in the struct spi_config
• delay_ – the desired delay field in the struct spi_config's spi_cs_control, if there is one

SPI_DT_SPEC_GET(node_id, operation_, delay_)
Structure initializer for spi_dt_spec from devicetree.

This helper macro expands to a static initializer for a struct spi_dt_spec by reading the relevant bus, frequency, slave, and cs data from the devicetree.

Important: multiple fields are automatically constructed by this macro which must be checked before use. spi_is_ready performs the required device_is_ready checks.

Deprecated:
Use spi_is_ready_dt instead.

This macro is not available in C++.

Parameters

• node_id – Devicetree node identifier for the SPI device whose struct spi_dt_spec to create an initializer for
• operation_ – the desired operation field in the struct spi_config
• delay_ – the desired delay field in the struct spi_config's spi_cs_control, if there is one

SPI_DT_SPEC_INST_GET(inst, operation_, delay_)
Structure initializer for spi_dt_spec from devicetree instance.

This is equivalent to SPI_DT_SPEC_GET(DT_DRV_INST(inst), operation_, delay_).

This macro is not available in C++.

Parameters

• inst – Devicetree instance number
• operation_ – the desired operation field in the struct spi_config
• delay_ – the desired delay field in the struct spi_config's spi_cs_control, if there is one

Typedefs

typedef int (*spi_api_io)(const struct device *dev, const struct spi_config *config, const struct spi_buf_set *tx_bufs, const struct spi_buf_set *rx_bufs)

Callback API for I/O See spi_transceive() for argument descriptions.

Callback API for asynchronous I/O See spi_transceive_async() for argument descriptions.
typedef void (*spi_callback_t)(const struct device *dev, int result, void *data)

SPI callback for asynchronous transfer requests.

**Param dev**
SPI device which is notifying of transfer completion or error

**Param result**
Result code of the transfer request. 0 is success, -errno for failure.

**Param data**
Transfer requester supplied data which is passed along to the callback.

typedef int (*spi_api_io_async)(const struct device *dev, const struct spi_config *config, const struct spi_buf_set *tx_bufs, const struct spi_buf_set *rx_bufs, spi_callback_t cb, void *userdata)

typedef int (*spi_api_release)(const struct device *dev, const struct spi_config *config)

Callback API for unlocking SPI device. See *spi_release()* for argument descriptions.

**Functions**

static inline bool spi_is_ready(const struct spi_dt_spec *spec)

Validate that SPI bus is ready.

**Parameters**

- **spec** – SPI specification from devicetree

**Return values**

- **true** – if the SPI bus is ready for use.
- **false** – if the SPI bus is not ready for use.

static inline bool spi_is_ready_dt(const struct spi_dt_spec *spec)

Validate that SPI bus (and CS gpio if defined) is ready.

**Parameters**

- **spec** – SPI specification from devicetree

**Return values**

- **true** – if the SPI bus is ready for use.
- **false** – if the SPI bus (or the CS gpio defined) is not ready for use.

int spi_transceive(const struct device *dev, const struct spi_config *config, const struct spi_buf_set *tx_bufs, const struct spi_buf_set *rx_bufs)

Read/write the specified amount of data from the SPI driver.

**Note:** This function is synchronous.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance
- **config** – Pointer to a valid *spi_config* structure instance. Pointer-comparison may be used to detect changes from previous operations.
- **tx_bufs** – Buffer array where data to be sent originates from, or NULL if none.
- **rx_bufs** – Buffer array where data to be read will be written to, or NULL if none.
Return values

- frames – Positive number of frames received in slave mode.
- 0 – If successful in master mode.
- -errno – Negative errno code on failure.

static inline int spi_transceive_dt(const struct spi_dt_spec *spec, const struct spi_buf_set *tx_bufs, const struct spi_buf_set *rx_bufs)

Read/write data from an SPI bus specified in spi_dt_spec.
This is equivalent to:

spi_transceive(spec->bus, &spec->config, tx_bufs, rx_bufs);

Parameters

- spec – SPI specification from devicetree
- tx_bufs – Buffer array where data to be sent originates from, or NULL if none.
- rx_bufs – Buffer array where data to be read will be written to, or NULL if none.

Returns

a value from spi_transceive().

static inline int spi_read_dt(const struct spi_dt_spec *spec, const struct spi_buf_set *rx_bufs)

Read data from a SPI bus specified in spi_dt_spec.
This is equivalent to:

spi_read(spec->bus, &spec->config, rx_bufs);

Parameters

- spec – SPI specification from devicetree
- tx_bufs – Buffer array where data to be sent originates from, or NULL if none.
- rx_bufs – Buffer array where data to be read will be written to, or NULL if none.

Returns

a value from spi_transceive().

Note: This function is an helper function calling spi_transceive.
• **rx_bufs** – Buffer array where data to be read will be written to.

**Returns**

a value from `spi_read()`.

static inline int spi_write(const struct device *dev, const struct spi_config *config, const struct spi_buf_set *tx_bufs)

Write the specified amount of data from the SPI driver.

**Note:** This function is synchronous.

**Note:** This function is an helper function calling `spi_transceive`.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance
- **config** – Pointer to a valid `spi_config` structure instance. Pointer-comparison may be used to detect changes from previous operations.
- **tx_bufs** – Buffer array where data to be sent originates from.

**Return values**

- 0 – If successful.
- -errno – Negative errno code on failure.

static inline int spi_write_dt(const struct spi_dt_spec *spec, const struct spi_buf_set *tx_bufs)

Write data to a SPI bus specified in `spi_dt_spec`.

This is equivalent to:

`spi_write(spec->bus, &spec->config, tx_bufs);`

**Parameters**

- **spec** – SPI specification from devicetree
- **tx_bufs** – Buffer array where data to be sent originates from.

**Returns**

a value from `spi_write()`.

static inline int spi_transceive_cb(const struct device *dev, const struct spi_config *config, const struct spi_buf_set *tx_bufs, const struct spi_buf_set *rx_bufs, spi_callback_t callback, void *userdata)

Read/write the specified amount of data from the SPI driver.

**Note:** This function is asynchronous.

**Note:** This function is available only if `CONFIG_SPI_ASYNC` is selected.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance
• **config** – Pointer to a valid *spi_config* structure instance. Pointer-comparison may be used to detect changes from previous operations.

• **tx_bufs** – Buffer array where data to be sent originates from, or NULL if none.

• **rx_bufs** – Buffer array where data to be read will be written to, or NULL if none.

• **callback** – Function pointer to completion callback. (Note: if NULL this function will not notify the end of the transaction, and whether it went successfully or not).

• **userdata** – Userdata passed to callback

**Return values**

• **frames** – Positive number of frames received in slave mode.

• **0** – If successful in master mode.

• **-errno** – Negative errno code on failure.

```c
int spi_release(const struct device *dev, const struct spi_config *config)
```

Release the SPI device locked on and/or the CS by the current config.

Note: This synchronous function is used to release either the lock on the SPI device and/or the CS line that was kept if, and if only, given config parameter was the last one to be used (in any of the above functions) and if it has the SPI_LOCK_ON bit set and/or the SPI_HOLD_ON_CS bit set into its operation bits field. This can be used if the caller needs to keep its hand on the SPI device for consecutive transactions and/or if it needs the device to stay selected. Usually both bits will be used along each other, so the the device is locked and stays on until another operation is necessary or until it gets released with the present function.

**Parameters**

• **dev** – Pointer to the device structure for the driver instance

• **config** – Pointer to a valid *spi_config* structure instance.

**Return values**

• **0** – If successful.

• **-errno** – Negative errno code on failure.

```c
static inline int spi_release_dt(const struct spi_dt_spec *spec)
```

Release the SPI device specified in *spi_dt_spec*.

This is equivalent to:

```c
spi_release(spec->bus, &spec->config);
```

**Parameters**

• **spec** – SPI specification from devicetree

**Returns**

a value from *spi_release()*.

```c
struct spi_cs_control
```

`#include <spi.h>` SPI Chip Select control structure.

This can be used to control a CS line via a GPIO line, instead of using the controller inner CS logic.
Public Members

struct *gpio_dt_spec* gpio

GPIO devicetree specification of CS GPIO. The device pointer can be set to NULL to fully inhibit CS control if necessary. The GPIO flags GPIO_ACTIVE_LOW/GPIO_ACTIVE_HIGH should be equivalent to SPI_CS_ACTIVE_HIGH/SPI_CS_ACTIVE_LOW options in struct *spi_config*.

`uint32_t delay`

Delay in microseconds to wait before starting the transmission and before releasing the CS line.

struct *spi_config*

`#include <spi.h>`  SPI controller configuration structure.

**Warning:** Most drivers use pointer comparison to determine whether a passed configuration is different from one used in a previous transaction. Changes to fields in the structure may not be detected.

**Param frequency**

is the bus frequency in Hertz

**Param operation**

is a bit field with the following parts:

<table>
<thead>
<tr>
<th>Field</th>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operational mode</td>
<td>[ 0 ]</td>
<td>master or slave.</td>
</tr>
<tr>
<td>mode</td>
<td>[ 1 : 3 ]</td>
<td>Polarity, phase and loop mode.</td>
</tr>
<tr>
<td>transfer</td>
<td>[ 4 ]</td>
<td>LSB or MSB first.</td>
</tr>
<tr>
<td>word_size</td>
<td>[ 5 : 10 ]</td>
<td>Size of a data frame in bits.</td>
</tr>
<tr>
<td>cs_hold</td>
<td>[ 12 ]</td>
<td>Hold on the CS line if possible.</td>
</tr>
<tr>
<td>cs_active_high</td>
<td>[ 14 ]</td>
<td>Active high CS logic.</td>
</tr>
<tr>
<td>format</td>
<td>[ 15 ]</td>
<td>Motorola or TI frame format.</td>
</tr>
<tr>
<td>---(optional)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Param slave**

is the slave number from 0 to host controller slave limit.

**Param cs**

is a valid pointer on a struct *spi_cs_control* is CS line is emulated through a gpio line, or NULL otherwise.

struct *spi_dt_spec*

`#include <spi.h>`  Complete SPI DT information.

**Param bus**

is the SPI bus

**Param config**

is the slave specific configuration
struct spi_buf

    #include <spi.h> SPI buffer structure.

    **Param buf**
    
    is a valid pointer on a data buffer, or NULL otherwise.

    **Param len**
    
    is the length of the buffer or, if buf is NULL, will be the length which as to be sent as dummy bytes (as TX buffer) or the length of bytes that should be skipped (as RX buffer).

struct spi_buf_set

    #include <spi.h> SPI buffer array structure.

    **Param buffers**
    
    is a valid pointer on an array of *spi_buf*, or NULL.

    **Param count**
    
    is the length of the array pointed by buffers.

struct spi_driver_api

    #include <spi.h> SPI driver API This is the mandatory API any SPI driver needs to expose.

7.3.36 TCPC

**Overview**

TCPC (USB Type-C Port Controller) The TCPC is a device used to simplify the implementation of a USB-C system by providing the following three function:

- VBUS and VCONN control **USB Type-C**: The TCPC may provide a Source device, the mechanism to control VBUS sourcing, and a Sink device, the mechanism to control VBUS sinking. A similar mechanism is provided for the control of VCONN.

- CC control and sensing: The TCPC implements logic for controlling the CC pin pull-up and pull-down resistors. It also provides a way to sense and report what resistors are present on the CC pin.

- Power Delivery message reception and transmission **USB Power Delivery**: The TCPC sends and receives messages constructed in the TCPM and places them on the CC lines.

**TCPC API** The TCPC device driver functions as the liaison between the TCPC device and the application software; this is accomplished by the Zephyr’s API provided by the device driver that’s used to communicate with and control the TCPC device.

**Configuration Options**

Related configuration options:

- `CONFIG_USBC_TCPC_DRIVER`

**API Reference**

*group* usb_type_c

USB Type-C.
Defines

TC_V_SINK_DISCONNECT_MIN_MV
VBUS minimum for a sink disconnect detection. See Table 4-3 VBUS Sink Characteristics.

TC_V_SINK_DISCONNECT_MAX_MV
VBUS maximum for a sink disconnect detection. See Table 4-3 VBUS Sink Characteristics.

TC_T_VBUS_ON_MAX_MS
From entry to Attached.SRC until VBUS reaches the minimum vSafe5V threshold as measured at the source's receptacle. See Table 4-29 VBUS and VCONN Timing Parameters.

TC_T_VBUS_OFF_MAX_MS
From the time the Sink is detached until the Source removes VUSB and reaches vSafe0V (See USB PD). See Table 4-29 VBUS and VCONN Timing Parameters.

TC_T_VCONN_ON_MAX_MS
From the time the Source supplied VUSB in the Attached.SRC state. See Table 4-29 VBUS and VCONN Timing Parameters.

TC_T_VCONN_ON_PA_MAX_MS
From the time a Sink with accessory support enters the PoweredAccessory state until the Sink sources minimum VCONN voltage. See Table 4-5. See Table 4-29 VBUS and VCONN Timing Parameters.

TC_T_VCONN_OFF_MAX_MS
From the time that a Sink is detached or as directed until the VCONN supply is disconnected. See Table 4-29 VBUS and VCONN Timing Parameters.

TC_T_SINK_ADJ_MAX_MS
Response time for a Sink to adjust its current consumption to be in the specified range due to a change in USB Type-C Current advertisement. See Table 4-29 VBUS and VCONN Timing Parameters.

TC_T_DRP_MIN_MS
The minimum period a DRP shall complete a Source to Sink and back advertisement. See Table 4-30 DRP Timing Parameters.

TC_T_DRP_MAX_MS
The maximum period a DRP shall complete a Source to Sink and back advertisement. See Table 4-30 DRP Timing Parameters.

TC_T_DRP_TRANSITION_MIN_MS
The minimum time a DRP shall complete transitions between Source and Sink roles during role resolution. See Table 4-30 DRP Timing Parameters.

TC_T_DRP_TRANSITION_MAX_MS
The maximum time a DRP shall complete transitions between Source and Sink roles during role resolution. See Table 4-30 DRP Timing Parameters.
TC_T_DRP_TRY_MIN_MS
Minimum wait time associated with the Try.SRC state. See Table 4-30 DRP Timing Parameters.

TC_T_DRP_TRY_MAX_MS
Maximum wait time associated with the Try.SRC state. See Table 4-30 DRP Timing Parameters.

TC_T_DRP_TRY_WAIT_MIN_MS
Minimum wait time associated with the Try.SNK state. See Table 4-30 DRP Timing Parameters.

TC_T_DRP_TRY_WAIT_MAX_MS
Maximum wait time associated with the Try.SNK state. See Table 4-30 DRP Timing Parameters.

TC_T_TRY_TIMEOUT_MIN_MS
Minimum timeout for transition from Try.SRC to TryWait.SNK. See Table 4-30 DRP Timing Parameters.

TC_T_TRY_TIMEOUT_MAX_MS
Maximum timeout for transition from Try.SRC to TryWait.SNK. See Table 4-30 DRP Timing Parameters.

TC_T_VPD_DETACH_MIN_MS
Minimum Time for a DRP to detect that the connected Charge-Through VCONNPowered USB Device has been detached, after VBUS has been removed. See Table 4-30 DRP Timing Parameters.

TC_T_VPD_DETACH_MAX_MS
Maximum Time for a DRP to detect that the connected Charge-Through VCONNPowered USB Device has been detached, after VBUS has been removed. See Table 4-30 DRP Timing Parameters.

TC_T_CC_DEBOUNCE_MIN_MS
Minimum time a port shall wait before it can determine it is attached See Table 4-31 CC Timing.

TC_T_CC_DEBOUNCE_MAX_MS
Maximum time a port shall wait before it can determine it is attached See Table 4-31 CC Timing.

TC_T_PD_DEBOUNCE_MIN_MS
Minimum time a Sink port shall wait before it can determine it is detached due to the potential for USB PD signaling on CC as described in the state definitions. See Table 4-31 CC Timing.

TC_T_PD_DEBOUNCE_MAX_MS
Maximum time a Sink port shall wait before it can determine it is detached due to the potential for USB PD signaling on CC as described in the state definitions. See Table 4-31 CC Timing.

TC_T_TRY_CC_DEBOUNCE_MIN_MS
Minimum Time a port shall wait before it can determine it is re-attached during the try-wait process. See Table 4-31 CC Timing.
TC_T_TRY_CC_DEBOUNCE_MAX_MS
Maximum Time a port shall wait before it can determine it is re-attached during the try-wait process. See Table 4-31 CC Timing.

TC_T_ERROR_RECOVERY_SELF_POWERS_MIN_MS
Minimum time a self-powered port shall remain in the ErrorRecovery state. See Table 4-31 CC Timing.

TC_T_ERROR_RECOVERY_SOURCE_MIN_MS
Minimum time a source shall remain in the ErrorRecovery state if it was sourcing VCONN in the previous state. See Table 4-31 CC Timing.

TC_T_RP_VALUE_CHANGE_MIN_MS
Minimum time a Sink port shall wait before it can determine there has been a change in Rp where CC is not BMC Idle or the port is unable to detect BMC Idle. See Table 4-31 CC Timing.

TC_T_RP_VALUE_CHANGE_MAX_MS
Maximum time a Sink port shall wait before it can determine there has been a change in Rp where CC is not BMC Idle or the port is unable to detect BMC Idle. See Table 4-31 CC Timing.

TC_T_SRC_DISCONNECT_MIN_MS
Minimum time a Source shall detect the SRC.Open state. The Source should detect the SRC.Open state as quickly as practical. See Table 4-31 CC Timing.

TC_T_SRC_DISCONNECT_MAX_MS
Maximum time a Source shall detect the SRC.Open state. The Source should detect the SRC.Open state as quickly as practical. See Table 4-31 CC Timing.

TC_T_NO_TOGGLE_CONNECT_MIN_MS
Minimum time to detect connection when neither Port Partner is toggling. See Table 4-31 CC Timing.

TC_T_NO_TOGGLE_CONNECT_MAX_MS
Maximum time to detect connection when neither Port Partner is toggling. See Table 4-31 CC Timing.

TC_T_ONE_PORT_TOGGLE_CONNECT_MIN_MS
Minimum time to detect connection when one Port Partner is toggling (0ms ... dcSRC.DRP max * tDRP max + 2 * tNoToggleConnect). See Table 4-31 CC Timing.

TC_T_ONE_PORT_TOGGLE_CONNECT_MAX_MS
Maximum time to detect connection when one Port Partner is toggling (0ms ... dcSRC.DRP max * tDRP max + 2 * tNoToggleConnect). See Table 4-31 CC Timing.

TC_T_TWO_PORT_TOGGLE_CONNECT_MIN_MS
Minimum time to detect connection when both Port Partners are toggling (0ms ... 5 * tDRP max + 2 * tNoToggleConnect). See Table 4-31 CC Timing.

TC_T_TWO_PORT_TOGGLE_CONNECT_MAX_MS
Maximum time to detect connection when both Port Partners are toggling (0ms ... 5 * tDRP max + 2 * tNoToggleConnect). See Table 4-31 CC Timing.
TC_T_VPDCTDD_MIN_US
Minimum time for a Charge-Through VCONN-Powered USB Device to detect that the Charge-Through source has disconnected from CC after VBUS has been removed, transition to CTUnattached.VPD, and re-apply its Rp termination advertising 3.0 A on the host port CC. See Table 4-31 CC Timing.

TC_T_VPDCTDD_MAX_MS
Maximum time for a Charge-Through VCONN-Powered USB Device to detect that the Charge-Through source has disconnected from CC after VBUS has been removed, transition to CTUnattached.VPD, and re-apply its Rp termination advertising 3.0 A on the host port CC. See Table 4-31 CC Timing.

TC_T_VPDISABLE_MIN_MS
Minimum time for a Charge-Through VCONN-Powered USB Device shall remain in CTDisabled.VPD state. See Table 4-31 CC Timing.

Enums

enum tc_cc_voltage_state
CC Voltage status.
Values:

enumerator TC_CC_VOLT_OPEN = 0
No port partner connection

tenumerator TC_CC_VOLT_RA = 1
Port partner is applying Ra

tenumerator TC_CC_VOLT_RD = 2
Port partner is applying Rd

tenumerator TC_CC_VOLT_RP_DEF = 5
Port partner is applying Rp (0.5A)

tenumerator TC_CC_VOLT_RP_1A5 = 6

enumerator TC_CC_VOLT_RP_3A0 = 7
Port partner is applying Rp (3.0A)

enum tc_vbus_level
VBUS level voltages.
Values:

enumerator TC_VBUS_SAFE0V = 0
VBUS is less than vSafe0V max

enumerator TC_VBUS_PRESENT = 1
VBUS is at least vSafe5V min
enumerator TC_VBUS_REMOVED = 2
    VBUS is less than vSinkDisconnect max

enum tc_rp_value
    Pull-Up resistor values.
    Values:

    enumerator TC_RP_USB = 0
        Pull-Up resistor for a current of 900mA

    enumerator TC_RP_1A5 = 1
        Pull-Up resistor for a current of 1.5A

    enumerator TC_RP_3A0 = 2
        Pull-Up resistor for a current of 3.0A

    enumerator TC_RP_RESERVED = 3
        No Pull-Up resistor is applied

enum tc_cc_pull
    CC pull resistors.
    Values:

    enumerator TC_CC_RA = 0
        Ra Pull-Down resistor

    enumerator TC_CC_RP = 1
        Rp Pull-Up resistor

    enumerator TC_CC_RD = 2
        Rd Pull-Down resistor

    enumerator TC_CC_OPEN = 3
        No CC resistor

    enumerator TC_RA_RD = 4
        Ra and Rd Pull-Down resistor

enum tc_cable_plug
    Cable plug. See 6.2.1.1.7 Cable Plug. Only applies to SOP' and SOP". Replaced by pd_power_role for SOP packets.
    Values:

    enumerator PD_PLUG_FROM_DFP_UFP = 0

    enumerator PD_PLUG_FROM_CABLE_VPD = 1
enum tc_power_role
  Power Delivery Power Role.
  
  Values:
  
enumerator TC_ROLE_SINK = 0
  Power role is a sink

enumerator TC_ROLE_SOURCE = 1
  Power role is a source

enum tc_data_role
  Power Delivery Data Role.
  
  Values:
  
enumerator TC_ROLE_UFP = 0
  Data role is an Upstream Facing Port

enumerator TC_ROLE_DFP = 1
  Data role is a Downstream Facing Port

enumerator TC_ROLE_DISCONNECTED = 2
  Port is disconnected

enum tc_cc_polarity
  Polarity of the CC lines.
  
  Values:
  
enumerator TC_POLARITY_CC1 = 0
  Use CC1 IO for Power Delivery communication

enumerator TC_POLARITY_CC2 = 1
  Use CC2 IO for Power Delivery communication

enum tc_cc_states
  Possible port partner connections based on CC line states.
  
  Values:
  
enumerator TC_CC_NONE = 0
  No port partner attached

enumerator TC_CC_UFP_NONE = 1
  From DFP perspective No UFP accessory connected

enumerator TC_CC_UFP_AUDIO_ACC = 2
  UFP Audio accessory connected

enumerator TC_CC_UFP_DEBUG_ACC = 3
  UFP Debug accessory connected

7.3. Peripherals
enumerator TC_CC_UFP_ATTACHED = 4
  Plain UFP attached
enumerator TC_CC_DFP_ATTACHED = 5
  From UFP perspective Plain DFP attached
enumerator TC_CC_DFP_DEBUG_ACC = 6
  DFP debug accessory connected

**group** usb_type_c_port_controller_api
  USB Type-C Port Controller API.

**Typedefs**

typedef int (*tcpc_vconn_control_cb_t)(const struct device *dev, bool enable)

typedef void (*tcpc_alert_handler_cb_t)(const struct device *dev, void *data, enum tcpc_alert alert)

**Enums**

enum tcpc_alert
  TCPC Alert bits.
  Values:
  
  enumerator TCPC_ALERT_CC_STATUS
    CC status changed
  enumerator TCPC_ALERT_POWER_STATUS
    Power status changed
  enumerator TCPC_ALERT_MSG_STATUS
    Receive Buffer register changed
  enumerator TCPC_ALERT_HARD_RESET_RECEIVED
    Received Hard Reset message
  enumerator TCPC_ALERT_TRANSMIT_MSG_FAILED
    SOP* message transmission not successful
  enumerator TCPC_ALERT_TRANSMIT_MSG_DISCARDED
    Reset or SOP* message transmission not sent due to an incoming receive message
  enumerator TCPC_ALERT_TRANSMIT_MSG_SUCCESS
    Reset or SOP* message transmission successful
enumerator TCPC_ALERT_VBUS_ALARM_HI
   A high-voltage alarm has occurred

enumerator TCPC_ALERT_VBUS_ALARM_LO
   A low-voltage alarm has occurred

enumerator TCPC_ALERT_FAULT_STATUS
   A fault has occurred. Read the FAULT_STATUS register

enumerator TCPC_ALERT_RX_BUFFER_OVERFLOW
   TCPC RX buffer has overflowed

enumerator TCPC_ALERT_VBUS_SNK_DISCONNECT
   The TCPC in Attached.SNK state has detected a sink disconnect

enumerator TCPC_ALERT_BEGINNING_MSG_STATUS
   Receive buffer register changed

enumerator TCPC_ALERT_EXTENDED_STATUS
   Extended status changed

enumerator TCPC_ALERT_EXTENDED
   An extended interrupt event has occurred. Read the alert_extended register

enumerator TCPC_ALERT_VENDOR_DEFINED
   A vendor defined alert has been detected

enum tcpc_status_reg
   TCPC Status register.
   Values:

   enumerator TCPC_CC_STATUS
      The CC Status register

   enumerator TCPC_POWER_STATUS
      The Power Status register

   enumerator TCPC_FAULT_STATUS
      The Fault Status register

   enumerator TCPC_EXTENDED_STATUS
      The Extended Status register

   enumerator TCPC_EXTENDED_ALERT_STATUS
      The Extended Alert Status register

   enumerator TCPC_VENDOR_DEFINED_STATUS
      The Vendor Defined Status register

7.3. Peripherals 2377
Functions

static inline int tcpc_is_cc_rp(enum tc_cc_voltage_state cc)
Returns whether the sink has detected a Rp resistor on the other side.

static inline int tcpc_is_cc_open(enum tc_cc_voltage_state cc1, enum tc_cc_voltage_state cc2)
Returns true if both CC lines are completely open.

static inline int tcpc_is_cc_snk_dbg_acc(enum tc_cc_voltage_state cc1, enum tc_cc_voltage_state cc2)
Returns true if we detect the port partner is a snk debug accessory.

static inline int tcpc_is_cc_src_dbg_acc(enum tc_cc_voltage_state cc1, enum tc_cc_voltage_state cc2)
Returns true if we detect the port partner is a src debug accessory.

static inline int tcpc_is_cc_audio_acc(enum tc_cc_voltage_state cc1, enum tc_cc_voltage_state cc2)
Returns true if the port partner is an audio accessory.

static inline int tcpc_is_cc_at_least_one_rd(enum tc_cc_voltage_state cc1, enum tc_cc_voltage_state cc2)
Returns true if the port partner is presenting at least one Rd.

static inline int tcpc_is_cc_only_one_rd(enum tc_cc_voltage_state cc1, enum tc_cc_voltage_state cc2)
Returns true if the port partner is presenting Rd on only one CC line.

static inline int tcpc_init(const struct device *dev)
Initializes the TCPC.

Parameters

• dev – Runtime device structure

Return values

• 0 – on success
• -EIO – on failure

static inline int tcpc_get_cc(const struct device *dev, enum tc_cc_voltage_state *cc1, enum tc_cc_voltage_state *cc2)
Reads the status of the CC lines.

Parameters

• dev – Runtime device structure
• cc1 – A pointer where the CC1 status is written
• cc2 – A pointer where the CC2 status is written

Return values

• 0 – on success
• -EIO – on failure
• -ENOSYS – if not implemented

static inline int tcpc_select_rp_value(const struct device *dev, enum tc_rp_value rp)
Sets the value of CC pull up resistor used when operating as a Source.

Parameters

• dev – Runtime device structure
• \texttt{rp} – Value of the Pull-Up Resistor.

**Return values**

• 0 – on success
• -ENOSYS –
• -EIO – on failure

static inline int tcpc_get_rp_value(const struct device *dev, enum tc rp_value *rp)

Gets the value of the CC pull up resistor used when operating as a Source.

**Parameters**

• dev – Runtime device structure
• rp – pointer where the value of the Pull-Up Resistor is stored

**Return values**

• 0 – on success
• -ENOSYS –
• -EIO – on failure

static inline int tcpc_set_cc(const struct device *dev, enum tc cc_pull pull)

Sets the CC pull resistor and sets the role as either Source or Sink.

**Parameters**

• dev – Runtime device structure
• pull – The pull resistor to set

**Return values**

• 0 – on success
• -EIO – on failure

static inline void tcpc_set_vconn_cb(const struct device *dev, tcpc_vconn_control_cb_t vconn_cb)

Sets a callback that can enable or disable VCONN if the TCPC is unable to or the system is configured in a way that does not use the VCONN control capabilities of the TCPC.

The callback is called in the tcpc_set_vconn function if vconn_cb isn’t NULL.

**Parameters**

• dev – Runtime device structure
• vconn_cb – pointer to the callback function that controls vconn

static inline int tcpc_set_vconn(const struct device *dev, bool enable)

Enables or disables VCONN.

This function uses the TCPC to measure VCONN if possible or calls the callback function set by tcpc_set_vconn_cb

**Parameters**

• dev – Runtime device structure
• enable – VCONN is enabled when true, it’s disabled

**Return values**

• 0 – on success
• -EIO – on failure
• -ENOSYS – if not implemented

7.3. Peripherals 2379
static inline int tcpc_set_roles(const struct device *dev, enum tc_power_role power_role, enum tc_data_role data_role)

Sets the Power and Data Role of the PD message header.

This function only needs to be called once per data / power role change

Parameters

- dev – Runtime device structure
- power_role – current power role
- data_role – current data role

Return values

- 0 – on success
- -EIO – on failure
- -ENOSYS – if not implemented

static inline bool tcpc_is_rx_pending_msg(const struct device *dev, enum pd_packet_type *type)

Tests if a received Power Delivery message is pending.

Parameters

- dev – Runtime device structure
- type – pointer to where message type is written. Can be NULL

Return values

- true – if message is pending, else false
- -EIO – on failure
- -ENOSYS – if not implemented

static inline int tcpc_receive_data(const struct device *dev, struct pd_msg *buf)

Retrieves the Power Delivery message from the TCPC.

Parameters

- dev – Runtime device structure
- buf – pointer where the pd_buf pointer is written

Return values

- Greater – or equal to 0 is the number of bytes received
- -EIO – on failure
- -EFAULT – on buf being NULL
- -ENOSYS – if not implemented

static inline int tcpc_set_rx_enable(const struct device *dev, bool enable)

Enables the reception of SOP* message types.

Parameters

- dev – Runtime device structure
- enable – Enable Power Delivery when true, else it’s disabled

Return values

- 0 – on success
- -EIO – on failure
- -ENOSYS – if not implemented
static inline int tcpc_set_cc_polarity(const struct device *dev, enum tc_cc_polarity polarity)
Sets the polarity of the CC lines.

Parameters
- dev – Runtime device structure
- polarity – Polarity of the cc line

Return values
- 0 – on success
- -EIO – on failure

static inline int tcpc_transmit_data(const struct device *dev, struct pd_msg *msg)
Transmits a Power Delivery message.

Parameters
- dev – Runtime device structure
- msg – Power Delivery message to transmit

Return values
- 0 – on success
- -EIO – on failure
- -ENOSYS – if not implemented

static inline int tcpc_dump_std_reg(const struct device *dev)
Dump a set of TCPC registers.

Parameters
- dev – Runtime device structure

Return values
- 0 – on success
- -EIO – on failure
- -ENOSYS – if not implemented

static inline int tcpc_set_alert_handler_cb(const struct device *dev, tcpc_alert_handler_cb_t handler, void *data)
Sets the alert function that’s called when an interrupt is triggered due to an alert bit.
Calling this function enables the particular alert bit

Parameters
- dev – Runtime device structure
- handler – The callback function called when the bit is set
- data – user data passed to the callback

Return values
- 0 – on success
- -EINVAL – on failure

static inline int tcpc_get_status_register(const struct device *dev, enum tcpc_status_reg reg, int32_t *status)
Gets a status register.

Parameters
• dev – Runtime device structure
• reg – The status register to read
• status – Pointer where the status is stored

**Return values**

• 0 – on success
• -EIO – on failure
• -ENOSYS – if not implemented

```c
static inline int tcpc_clear_status_register(const struct device *dev, enum tcpc_status_reg reg, uint32_t mask)
```

Clears a TCPC status register.

**Parameters**

• dev – Runtime device structure
• reg – The status register to read
• mask – A bit mask of the status register to clear. A status bit is cleared when it’s set to 1.

**Return values**

• 0 – on success
• -EIO – on failure
• -ENOSYS – if not implemented

```c
static inline int tcpc_mask_status_register(const struct device *dev, enum tcpc_status_reg reg, uint32_t mask)
```

Sets the mask of a TCPC status register.

**Parameters**

• dev – Runtime device structure
• reg – The status register to read
• mask – A bit mask of the status register to mask. The status bit is masked if it’s 0, else it’s unmasked.

**Return values**

• 0 – on success
• -EIO – on failure
• -ENOSYS – if not implemented

```c
static inline int tcpc_set_debug_accessory(const struct device *dev, bool enable)
```

Manual control of TCPC DebugAccessory control.

**Parameters**

• dev – Runtime device structure
• enable – Enable Debug Accessory when true, else it’s disabled

**Return values**

• 0 – on success
• -EIO – on failure
• -ENOSYS – if not implemented
static inline int tcpc_set_debug_detach(const struct device *dev)
  Detach from a debug connection.

  Parameters
  • dev – Runtime device structure

  Return values
  • 0 – on success
  • -EIO – on failure
  • -ENOSYS – if not implemented

static inline int tcpc_set_drp_toggle(const struct device *dev, bool enable)
  Enable TCPC auto dual role toggle.

  Parameters
  • dev – Runtime device structure
  • enable – Auto dual role toggle is active when true, else it's disabled

  Return values
  • 0 – on success
  • -EIO – on failure
  • -ENOSYS – if not implemented

static inline bool tcpc_get_snk_ctrl(const struct device *dev)
  Queries the current sinking state of the TCPC.

  Parameters
  • dev – Runtime device structure

  Return values
  • true – if sinking power
  • false – if not sinking power
  • -ENOSYS – if not implemented

static inline bool tcpc_get_src_ctrl(const struct device *dev)
  Queries the current sourcing state of the TCPC.

  Parameters
  • dev – Runtime device structure

  Return values
  • true – if sourcing power
  • false – if not sourcing power
  • -ENOSYS – if not implemented

static inline int tcpc_set_bist_test_mode(const struct device *dev, bool enable)
  Controls the BIST Mode of the TCPC. It disables RX alerts while the mode is active.

  Parameters
  • dev – Runtime device structure
  • enable – The TCPC enters BIST TEST Mode when true

  Return values
  • 0 – on success
static inline int tcpc_get_chip_info(const struct device *dev, struct tcpc_chip_info *chip_info)
Gets the TCPC firmware version.

Parameters

- dev – Runtime device structure
- chip_info – Pointer to TCPC chip info where the version is stored

Return values

- 0 – on success
- -EIO – on failure
- -ENOSYS – if not implemented

static inline int tcpc_set_low_power_mode(const struct device *dev, bool enable)
Instructs the TCPC to enter or exit low power mode.

Parameters

- dev – Runtime device structure
- enable – The TCPC enters low power mode when true, else it exits it

Return values

- 0 – on success
- -EIO – on failure
- -ENOSYS – if not implemented

static inline int tcpc_sop_prime_enable(const struct device *dev, bool enable)
Enables the reception of SOP Prime messages.

Parameters

- dev – Runtime device structure
- enable – Can receive SOP Prime messages when true, else it can not

Return values

- 0 – on success
- -EIO – on failure
- -ENOSYS – if not implemented

struct tcpc_chip_info
#include <usbc_tcpc.h> TCPC Chip Information.

Public Members

uint16_t vendor_id
Vendor Id

uint16_t product_id
Product Id
uint16_t device_id
    Device Id

uint64_t fw_version_number
    Firmware version number

uint8_t min_req_fw_version_string[8]
    Minimum Required firmware version string

uint64_t min_req_fw_version_number
    Minimum Required firmware version number

    USB Power Delivery.

Defines

PD_MAX_EXTENDED_MSG_LEGACY_LEN
    Maximum length of a non-Extended Message in bytes. See Table 6-75 Value Parameters Parameter Name: MaxExtendedMsgLegacyLen.

PD_MAX_EXTENDED_MSG_LEN
    Maximum length of an Extended Message in bytes. See Table 6-75 Value Parameters Parameter Name: MaxExtendedMsgLen.

PD_MAX_EXTENDED_MSG_CHUNK_LEN
    Maximum length of a Chunked Message in bytes. When one of both Port Partners do not support Extended Messages of Data Size greater than PD_MAX_EXTENDED_MSG_LEGACY_LEN then the Protocol Layer supports a Chunking mechanism to break larger Messages into smaller Chunks of size PD_MAX_EXTENDED_MSG_CHUNK_LEN. See Table 6-75 Value Parameters Parameter Name: MaxExtendedMsgChunkLen.

PD_T_TYPEC_SINK_WAIT_CAP_MIN_MS
    Minimum time a sink shall wait for a Source_Capabilities message before sending a Hard Reset See Table 6-61 Time Values Parameter Name: tTypeCSinkWaitCap.

PD_T_TYPEC_SINK_WAIT_CAP_MAX_MS
    Minimum time a sink shall wait for a Source_Capabilities message before sending a Hard Reset See Table 6-61 Time Values Parameter Name: tTypeCSinkWaitCap.

PD_V_SAFE_0V_MAX_MV
    VBUS maximum safe operating voltage at “zero volts”. See Table 7-24 Common Source/Sink Electrical Parameters Parameter Name: vSafe0V.

PD_V_SAFE_5V_MIN_MV
    VBUS minimum safe operating voltage at 5V. See Table 7-24 Common Source/Sink Electrical Parameters Parameter Name: vSafe5V.
**PD_T_SAFE_0V_MAX_MS**
Time to reach PD_V_SAFE_0V_MV max in milliseconds. See Table 7-24 Common Source/Sink Electrical Parameters Parameter Name: tSafe0V.

**PD_T_SAFE_5V_MAX_MS**
Time to reach PD_V_SAFE_5V_MV max in milliseconds. See Table 7-24 Common Source/Sink Electrical Parameters Parameter Name: tSafe5V.

**PD_T_TX_TIMEOUT_MS**
Time to wait for TCPC to complete transmit.

**PD_T_HARD_RESET_COMPLETE_MIN_MS**
Minimum time a Hard Reset must complete. See Table 6-68 Time Values.

**PD_T_HARD_RESET_COMPLETE_MAX_MS**
Maximum time a Hard Reset must complete. See Table 6-68 Time Values.

**PD_T_SENDER_RESPONSE_MIN_MS**
Minimum time a response must be sent from a Port Partner See Table 6-68 Time Values.

**PD_T_SENDER_RESPONSE_NOM_MS**
Nominal time a response must be sent from a Port Partner See Table 6-68 Time Values.

**PD_T_SENDER_RESPONSE_MAX_MS**
Maximum time a response must be sent from a Port Partner See Table 6-68 Time Values.

**PD_T_SPR_PS_TRANSITION_MIN_MS**
Minimum SPR Mode time for a power supply to transition to a new level See Table 6-68 Time Values.

**PD_T_SPR_PS_TRANSITION_NOM_MS**
Nominal SPR Mode time for a power supply to transition to a new level See Table 6-68 Time Values.

**PD_T_SPR_PS_TRANSITION_MAX_MS**
Maximum SPR Mode time for a power supply to transition to a new level See Table 6-68 Time Values.

**PD_T_EPR_PS_TRANSITION_MIN_MS**
Minimum EPR Mode time for a power supply to transition to a new level See Table 6-68 Time Values.

**PD_T_EPR_PS_TRANSITION_NOM_MS**
Nominal EPR Mode time for a power supply to transition to a new level See Table 6-68 Time Values.

**PD_T_EPR_PS_TRANSITION_MAX_MS**
Maximum EPR Mode time for a power supply to transition to a new level See Table 6-68 Time Values.
PD_T_SINK_REQUEST_MIN_MS
Minimum time to wait before sending another request after receiving a Wait message. See Table 6-68 Time Values.

PD_T_CHUNKING_NOT_SUPPORTED_MIN_MS
Minimum time to wait before sending a Not_Supported message after receiving a Chunked message. See Table 6-68 Time Values.

PD_T_CHUNKING_NOT_SUPPORTED_NOM_MS
Nominal time to wait before sending a Not_Supported message after receiving a Chunked message. See Table 6-68 Time Values.

PD_T_CHUNKING_NOT_SUPPORTED_MAX_MS
Maximum time to wait before sending a Not_Supported message after receiving a Chunked message. See Table 6-68 Time Values.

PD_CONVERT_BYTES_TO_PD_HEADER_COUNT(c)
Convert bytes to PD Header data object count, where a data object is 4-bytes.

Parameters
• c – number of bytes to convert

PD_CONVERT_PD_HEADER_COUNT_TO_BYTES(c)
Convert PD Header data object count to bytes.

Parameters
• c – number of PD Header data objects

SINK_TX_OK
Collision avoidance Rp values in REV 3.0 Sink Transmit “OK”.

SINK_TX_NG
Collision avoidance Rp values in REV 3.0 Sink Transmit “NO GO”.

PD_GET_EXT_HEADER(c)
Used to get extended header from the first 32-bit word of the message.

Parameters
• c – first 32-bit word of the message

PDO_MAX_DATA_OBJECTS
Maximum number of 32-bit data objects sent in a single request.

PDO - Power Data Object RDO - Request Data Object

PD_CONVERT_MA_TO_FIXED_PDO_CURRENT(c)
Convert milliamps to Fixed PDO Current in 10mA units.

Parameters
• c – Current in milliamps

PD_CONVERT_MV_TO_FIXED_PDO_VOLTAGE(v)
Convert millivolts to Fixed PDO Voltage in 50mV units.

Parameters
• v – Voltage in millivolts
PD_CONVERT_FIXED_PDO_CURRENT_TO_MA(c)
Convert a Fixed PDO Current from 10mA units to milliamps.

Parameters
• c – Fixed PDO current in 10mA units.

PD_CONVERT_FIXED_PDO_VOLTAGE_TO_MV(v)
Convert a Fixed PDO Voltage from 50mV units to millivolts. Used for converting
pd_fixed_supply_pdo_source.voltage and pd_fixed_supply_pdo_sink.voltage.

Parameters
• v – Fixed PDO voltage in 50mV units.

PD_CONVERT_MA_TO_VARIABLE_PDO_CURRENT(c)
Convert milliamps to Variable PDO Current in 10ma units.

Parameters
• c – Current in milliamps

PD_CONVERT_MV_TO_VARIABLE_PDO_VOLTAGE(v)
Convert millivolts to Variable PDO Voltage in 50mV units.

Parameters
• v – Voltage in millivolts

PD_CONVERT_VARIABLE_PDO_CURRENT_TO_MA(c)
Convert a Variable PDO Current from 10mA units to milliamps.

Parameters
• c – Variable PDO current in 10mA units.

PD_CONVERT_VARIABLE_PDO_VOLTAGE_TO_MV(v)
Convert a Variable PDO Voltage from 50mV units to millivolts.

Parameters
• v – Variable PDO voltage in 50mV units.

PD_CONVERT_MW_TO_BATTERY_PDO_POWER(c)
Convert milliwatts to Battery PDO Power in 250mW units.

Parameters
• c – Power in milliwatts

PD_CONVERT_MV_TO_BATTERY_PDO_VOLTAGE(v)
Convert milliwatts to Battery PDO Voltage in 50mV units.

Parameters
• v – Voltage in millivolts

PD_CONVERT_BATTERY_PDO_POWER_TO_MW(c)
Convert a Battery PDO Power from 250mW units to milliwatts.

Parameters
• c – Power in 250mW units.

PD_CONVERT_BATTERY_PDO_VOLTAGE_TO_MV(v)
Convert a Battery PDO Voltage from 50mV units to millivolts.

Parameters
• v – Voltage in 50mV units.
PD_CONVERT_MA_TO_AUGMENTED_PDO_CURRENT\( (c) \)
Convert milliamps to Augmented PDO Current in 50mA units.

**Parameters**
- \( c \) – Current in milliamps

PD_CONVERT_MV_TO_AUGMENTED_PDO_VOLTAGE\( (v) \)
Convert millivolts to Augmented PDO Voltage in 100mV units.

**Parameters**
- \( v \) – Voltage in millivolts

PD_CONVERT_AUGMENTED_PDO_CURRENT_TO_MA\( (c) \)
Convert an Augmented PDO Current from 50mA units to milliamps.

**Parameters**
- \( c \) – Augmented PDO current in 50mA units.

PD_CONVERT_AUGMENTED_PDO_VOLTAGE_TO_MV\( (v) \)
Convert an Augmented PDO Voltage from 100mV units to millivolts.

**Parameters**
- \( v \) – Augmented PDO voltage in 100mV units.

NUM_SOP_STAR_TYPES
Number of valid Transmit Types.

** Enums**

```c
enum pdo_type
{ PDO_FIXED = 0, /**< Fixed supply (Vmin = Vmax) */
  PDO_BATTERY = 1, /**< Battery */
  PDO_VARIABLE = 2, /**< Variable Supply (non-Battery) */
  PDO_AUGMENTED = 3, /**< Augmented Power Data Object (APDO) */
};
```

```java
enum pd_frs_type
{ FRS_NOT_SUPPORTED = 0, /**< Fast Swap not supported */
};
```

7.3. Peripherals
enumerator FRS_DEFAULT_USB_POWER
    Default USB Power

enumerator FRS_1P5A_5V
    1.5A @ 5V

enumerator FRS_3P0A_5V
    3.0A @ 5V

enum pd_rev_type
    Protocol revision.
    
    Values:
    
    enumerator PD_REV10 = 0
        PD revision 1.0
    
    enumerator PD_REV20 = 1
        PD revision 2.0
    
    enumerator PD_REV30 = 2
        PD revision 3.0

enum pd_packet_type
    Power Delivery packet type See USB Type-C Port Controller Interface Specification, Revision 2.0, Version 1.2, Table 4-38 TRANSMIT Register Definition.
    
    Values:
    
    enumerator PD_PACKET_SOP = 0
        Port Partner message
    
    enumerator PD_PACKET_SOP_PRIME = 1
        Cable Plug message
    
    enumerator PD_PACKET_PRIME_PRIME = 2
        Cable Plug message far end
    
    enumerator PD_PACKET_DEBUG_PRIME = 3
        Currently undefined in the PD specification
    
    enumerator PD_PACKET_DEBUG_PRIME_PRIME = 4
        Currently undefined in the PD specification
    
    enumerator PD_PACKET_TX_HARD_RESET = 5
        Hard Reset message to the Port Partner
    
    enumerator PD_PACKET_CABLE_RESET = 6
        Cable Reset message to the Cable
enumerator PD_PACKET_TX_BIST_MODE_2 = 7
    BIST_MODE_2 message to the Port Partner

enumerator PD_PACKET_MSG_INVALID = 0xf
    USED ONLY FOR RECEPTION OF UNKNOWN MSG TYPES

c enum pd_ctrl_msg_type
    Control Message type See Table 6-5 Control Message Types.

    Values:

7.3.37 UART

Overview

Zephyr provides three different ways to access the UART peripheral. Depending on the method, different API functions are used according to below sections:

1. Polling API
2. Interrupt-driven API
3. Asynchronous API using DMA

Polling is the most basic method to access the UART peripheral. The reading function, uart_poll_in, is a non-blocking function and returns a character or -1 when no valid data is available. The writing function, uart_poll_out, is a blocking function and the thread waits until the given character is sent.

With the Interrupt-driven API, possibly slow communication can happen in the background while the thread continues with other tasks. The Kernel's Data Passing features can be used to communicate between the thread and the UART driver.

The Asynchronous API allows to read and write data in the background using DMA without interrupting the MCU at all. However, the setup is more complex than the other methods.
Configuration Options

Most importantly, the Kconfig options define whether the polling API (default), the interrupt-driven API or the asynchronous API can be used. Only enable the features you need in order to minimize memory footprint.

Related configuration options:
- CONFIG_SERIAL
- CONFIG_UART_INTERRUPT_DRIVEN
- CONFIG_UART_ASYNC_API
- CONFIG_UART_WIDE_DATA
- CONFIG_UART_USE_RUNTIME_CONFIGURE
- CONFIG_UART_LINE_CTRL
- CONFIG_UART_DRV_CMD

API Reference

group uart_interface
  UART Interface.

Enums

enum uart_line_ctrl
  Line control signals.
  Values:
  
  enumerator UART_LINE_CTRL_BAUD_RATE = BIT(0)

  enumerator UART_LINE_CTRL_RTS = BIT(1)

  enumerator UART_LINE_CTRL_DTR = BIT(2)

  enumerator UART_LINE_CTRL_DCD = BIT(3)

  enumerator UART_LINE_CTRL_DSR = BIT(4)

enum uart_rx_stop_reason
  Reception stop reasons.
  Values that correspond to events or errors responsible for stopping receiving.
  Values:

  enumerator UART_ERROR_OVERRUN = (1 << 0)

  Overrun error.
enumerator UART_ERROR_PARITY = (1 << 1)
    Parity error.

enumerator UART_ERROR_FRAMING = (1 << 2)
    Framing error.

enumerator UART_BREAK = (1 << 3)
    Break interrupt.
    A break interrupt was received. This happens when the serial input is held at a logic ‘0’ state for longer than the sum of start time + data bits + parity + stop bits.

enumerator UART_ERROR_COLLISION = (1 << 4)
    Collision error.
    This error is raised when transmitted data does not match received data. Typically this is useful in scenarios where the TX and RX lines maybe connected together such as RS-485 half-duplex. This error is only valid on UARTs that support collision checking.

enum uart_config_parity
    Parity modes.
    Values:

    enumerator UART_CFG_PARITY_NONE
    enumerator UART_CFG_PARITY_ODD
    enumerator UART_CFG_PARITY_EVEN
    enumerator UART_CFG_PARITY_MARK
    enumerator UART_CFG_PARITY_SPACE

enum uart_config_stop_bits
    Number of stop bits.
    Values:

    enumerator UART_CFG_STOP_BITS_0_5
    enumerator UART_CFG_STOP_BITS_1
    enumerator UART_CFG_STOP_BITS_1_5
    enumerator UART_CFG_STOP_BITS_2

enum uart_config_data_bits
    Number of data bits.
    Values:
enumerator UART_CFG_DATA_BITS_5
enumerator UART_CFG_DATA_BITS_6
enumerator UART_CFG_DATA_BITS_7
enumerator UART_CFG_DATA_BITS_8
enumerator UART_CFG_DATA_BITS_9

e num uart_config_flow_control
   Hardware flow control options.
   With flow control set to none, any operations related to flow control signals can be managed by user with uart_line_ctrl functions. In other cases, flow control is managed by hardware/driver.
   Values:

   enumerator UART_CFG_FLOW_CTRL_NONE
   enumerator UART_CFG_FLOW_CTRL_RTS_CTS
   enumerator UART_CFG_FLOW_CTRL_DTR_DSR
   enumerator UART_CFG_FLOW_CTRL_RS485

Functions

int uart_err_check(const struct device *dev)
   Check whether an error was detected.

   Parameters
      • dev – UART device instance.

   Return values
      • 0 – If no error was detected.
      • err – Error flags as defined in uart_rx_stop_reason
      • -ENOSYS – If not implemented.

int uart_configure(const struct device *dev, const struct uart_config *cfg)
   Set UART configuration.
   Sets UART configuration using data from *cfg.

   Parameters
      • dev – UART device instance.
      • cfg – UART configuration structure.

   Return values
      • 0 – If successful.
• -errno – Negative errno code in case of failure.
• -ENOSYS – If configuration is not supported by device or driver does not support setting configuration in runtime.

int uart_config_get(const struct device *dev, struct uart_config *cfg)
Get UART configuration.
Stores current UART configuration to *cfg, can be used to retrieve initial configuration after device was initialized using data from DTS.

Parameters
• dev – UART device instance.
• cfg – UART configuration structure.

Return values
• 0 – If successful.
• -errno – Negative errno code in case of failure.
• -ENOSYS – If driver does not support getting current configuration.

int uart_line_ctrl_set(const struct device *dev, uint32_t ctrl, uint32_t val)
Manipulate line control for UART.

Parameters
• dev – UART device instance.
• ctrl – The line control to manipulate (see enum uart_line_ctrl).
• val – Value to set to the line control.

Return values
• 0 – If successful.
• -ENOSYS – If this function is not implemented.
• -ENOTSUP – If API is not enabled.
• -errno – Other negative errno value in case of failure.

int uart_line_ctrl_get(const struct device *dev, uint32_t ctrl, uint32_t *val)
Retrieve line control for UART.

Parameters
• dev – UART device instance.
• ctrl – The line control to retrieve (see enum uart_line_ctrl).
• val – Pointer to variable where to store the line control value.

Return values
• 0 – If successful.
• -ENOSYS – If this function is not implemented.
• -ENOTSUP – If API is not enabled.
• -errno – Other negative errno value in case of failure.

int uart_drv_cmd(const struct device *dev, uint32_t cmd, uint32_t p)
Send extra command to driver.
Implementation and accepted commands are driver specific. Refer to the drivers for more information.

Parameters
• dev – UART device instance.
• cmd – Command to driver.
• p – Parameter to the command.

Return values
• 0 – If successful.
• -ENOSYS – If this function is not implemented.
• -ENOTSUP – If API is not enabled.
• -errno – Other negative errno value in case of failure.

struct uart_config
#include <uart.h> UART controller configuration structure.

Param baudrate
   Baudrate setting in bps

Param parity
   Parity bit, use uart_configparity

Param stop_bits
   Stop bits, use uart_config_stop_bits

Param data_bits
   Data bits, use uart_config_data_bits

Param flow_ctrl
   Flow control setting, use uart_config_flow_control

Polling API

group uart_polling

Functions

int uart_poll_in(const struct device *dev, unsigned char *p_char)
Read a character from the device for input.

This routine checks if the receiver has valid data. When the receiver has valid data, it reads a character from the device, stores to the location pointed to by p_char, and returns 0 to the calling thread. It returns -1, otherwise. This function is a non-blocking call.

Parameters
• dev – UART device instance.
• p_char – Pointer to character.

Return values
• 0 – If a character arrived.
• -1 – If no character was available to read (i.e. the UART input buffer was empty).
• -ENOSYS – If the operation is not implemented.
• -EBUSY – If async reception was enabled using uart_rx_enable
int uart_poll_in_u16(const struct device *dev, uint16_t *p_u16)
    Read a 16-bit datum from the device for input.
    This routine checks if the receiver has valid data. When the receiver has valid data, it reads a
    16-bit datum from the device, stores to the location pointed to by p_u16, and returns 0 to the
    calling thread. It returns -1, otherwise. This function is a non-blocking call.

    Parameters
    • dev – UART device instance.
    • p_u16 – Pointer to 16-bit data.

    Return values
    • 0 – If data arrived.
    • -1 – If no data was available to read (i.e., the UART input buffer was empty).
    • -ENOTSUP – If API is not enabled.
    • -ENOSYS – If the function is not implemented.
    • -EBUSY – If async reception was enabled using uart_rx_enable

void uart_poll_out(const struct device *dev, unsigned char out_char)
    Write a character to the device for output.
    This routine checks if the transmitter is full. When the transmitter is not full, it writes a
    character to the data register. It waits and blocks the calling thread, otherwise. This function
    is a blocking call.
    To send a character when hardware flow control is enabled, the handshake signal CTS must
    be asserted.

    Parameters
    • dev – UART device instance.
    • out_char – Character to send.

void uart_poll_out_u16(const struct device *dev, uint16_t out_u16)
    Write a 16-bit datum to the device for output.
    This routine checks if the transmitter is full. When the transmitter is not full, it writes a 16-bit
datum to the data register. It waits and blocks the calling thread, otherwise. This function is
a blocking call.
    To send a datum when hardware flow control is enabled, the handshake signal CTS must be
asserted.

    Parameters
    • dev – UART device instance.
    • out_u16 – Wide data to send.

Interrupt-driven API

group uart_interrupt

Typedefs
typedef void (*uart_irq_callback_user_data_t)(const struct device *dev, void *user_data)

Define the application callback function signature for uart_irq_callback_user_data_set() function.

**Param dev**
UART device instance.

**Param user_data**
Arbitrary user data.

typedef void (*uart_irq_config_func_t)(const struct device *dev)

For configuring IRQ on each individual UART device.

**Param dev**
UART device instance.

**Functions**

static inline int uart_fifo_fill(const struct device *dev, const uint8_t *tx_data, int size)

Fill FIFO with data.

This function is expected to be called from UART interrupt handler (ISR), if uart_irq_tx_ready() returns true. Result of calling this function not from an ISR is undefined (hardware-dependent). Likewise, not calling this function from an ISR if uart_irq_tx_ready() returns true may lead to undefined behavior, e.g. infinite interrupt loops. It’s mandatory to test return value of this function, as different hardware has different FIFO depth (oftentimes just 1).

**Parameters**
- dev – UART device instance.
- tx_data – Data to transmit.
- size – Number of bytes to send.

**Return values**
- -ENOSYS – if this function is not supported
- -ENOTSUP – If API is not enabled.

**Returns**
Number of bytes sent.

static inline int uart_fifo_fill_u16(const struct device *dev, const uint16_t *tx_data, int size)

Fill FIFO with wide data.

This function is expected to be called from UART interrupt handler (ISR), if uart_irq_tx_ready() returns true. Result of calling this function not from an ISR is undefined (hardware-dependent). Likewise, not calling this function from an ISR if uart_irq_tx_ready() returns true may lead to undefined behavior, e.g. infinite interrupt loops. It’s mandatory to test return value of this function, as different hardware has different FIFO depth (oftentimes just 1).

**Parameters**
- dev – UART device instance.
- tx_data – Wide data to transmit.
- size – Number of datum to send.

**Return values**
static inline int uart_fifo_read(const struct device *dev, uint8_t *rx_data, const int size)
Read data from FIFO.

This function is expected to be called from UART interrupt handler (ISR), if
uart_irq_rx_ready() returns true. Result of calling this function not from an ISR is unde-

fined (hardware-dependent). It's unspecified whether “RX ready” condition as returned by
uart_irq_rx_ready() is level- or edge- triggered. That means that once uart_irq_rx_ready() is
detected, uart_fifo_read() must be called until it reads all available data in the FIFO (i.e. until
it returns less data than was requested).

Note that the calling context only applies to physical UARTs and no to the virtual ones found
in USB CDC ACM code.

Parameters
- dev – UART device instance.
- rx_data – Data container.
- size – Container size.

Return values
- -ENOSYS – If this function is not implemented.
- -ENOTSUP – If API is not enabled.

Returns
Number of bytes read.

static inline int uart_fifo_read_u16(const struct device *dev, uint16_t *rx_data, const int size)
Read wide data from FIFO.

This function is expected to be called from UART interrupt handler (ISR), if
uart_irq_rx_ready() returns true. Result of calling this function not from an ISR is unde-

fined (hardware-dependent). It's unspecified whether “RX ready” condition as returned by
uart_irq_rx_ready() is level- or edge- triggered. That means that once uart_irq_rx_ready() is
detected, uart_fifo_read() must be called until it reads all available data in the FIFO (i.e. until
it returns less data than was requested).

Note that the calling context only applies to physical UARTs and no to the virtual ones found
in USB CDC ACM code.

Parameters
- dev – UART device instance.
- rx_data – Wide data container.
- size – Container size.

Return values
- -ENOSYS – If this function is not implemented.
- -ENOTSUP – If API is not enabled.

Returns
Number of datum read.

void uart_irq_tx_enable(const struct device *dev)
Enable TX interrupt in IER.
Parameters

- `dev` – UART device instance.

```c
void uart_irq_tx_disable(const struct device *dev)
```

Disable TX interrupt in IER.

Parameters

- `dev` – UART device instance.

```c
static inline int uart_irq_tx_ready(const struct device *dev)
```

Check if UART TX buffer can accept a new char.

Check if UART TX buffer can accept at least one character for transmission (i.e. `uart_fifo_fill()` will succeed and return non-zero). This function must be called in a UART interrupt handler, or its result is undefined. Before calling this function in the interrupt handler, `uart_irq_update()` must be called once per the handler invocation.

Parameters

- `dev` – UART device instance.

Return values

- `1` – If TX interrupt is enabled and at least one char can be written to UART.
- `0` – If device is not ready to write a new byte.
- `-ENOSYS` – If this function is not implemented.
- `-ENOTSUP` – If API is not enabled.

```
void uart_irq_rx_enable(const struct device *dev)
```

Enable RX interrupt.

Parameters

- `dev` – UART device instance.

```
void uart_irq_rx_disable(const struct device *dev)
```

Disable RX interrupt.

Parameters

- `dev` – UART device instance.

```
static inline int uart_irq_tx_complete(const struct device *dev)
```

Check if UART TX block finished transmission.

Check if any outgoing data buffered in UART TX block was fully transmitted and TX block is idle. When this condition is true, UART device (or whole system) can be power off. Note that this function is *not* useful to check if UART TX can accept more data, use `uart_irq_tx_ready()` for that. This function must be called in a UART interrupt handler, or its result is undefined. Before calling this function in the interrupt handler, `uart_irq_update()` must be called once per the handler invocation.

Parameters

- `dev` – UART device instance.

Return values

- `1` – If nothing remains to be transmitted.
- `0` – If transmission is not completed.
- `-ENOSYS` – If this function is not implemented.
- `-ENOTSUP` – If API is not enabled.
static inline int uart_irq_rx_ready(const struct device *dev)

Check if UART RX buffer has a received char.

Check if UART RX buffer has at least one pending character (i.e. \texttt{uart_fifo_read()} will succeed and return non-zero). This function must be called in a UART interrupt handler, or its result is undefined. Before calling this function in the interrupt handler, \texttt{uart_irq_update()} must be called once per the handler invocation. It's unspecified whether condition as returned by this function is level- or edge-triggered (i.e. if this function returns true when RX FIFO is non-empty, or when a new char was received since last call to it). See description of \texttt{uart_fifo_read()} for implication of this.

**Parameters**

- \texttt{dev} – UART device instance.

**Return values**

- 1 – If a received char is ready.
- 0 – If a received char is not ready.
- -ENOSYS – If this function is not implemented.
- -ENOTSUP – If API is not enabled.

\textbf{void uart irq err enable(const struct device *dev)}

Enable error interrupt.

**Parameters**

- \texttt{dev} – UART device instance.

\textbf{void uart irq err disable(const struct device *dev)}

Disable error interrupt.

**Parameters**

- \texttt{dev} – UART device instance.

\textbf{int uart irq is pending(const struct device *dev)}

Check if any IRQs is pending.

**Parameters**

- \texttt{dev} – UART device instance.

**Return values**

- 1 – If an IRQ is pending.
- 0 – If an IRQ is not pending.
- -ENOSYS – If this function is not implemented.
- -ENOTSUP – If API is not enabled.

\textbf{int uart irq update(const struct device *dev)}

Start processing interrupts in ISR.

This function should be called the first thing in the ISR. Calling \texttt{uart_irq_rx_ready()}, \texttt{uart_irq_tx_ready()}, \texttt{uart_irq_tx_complete()} allowed only after this.

The purpose of this function is:

- For devices with auto-acknowledge of interrupt status on register read to cache the value of this register (rx_ready, etc. then use this case).
- For devices with explicit acknowledgment of interrupts, to ack any pending interrupts and likewise to cache the original value.
For devices with implicit acknowledgment, this function will be empty. But the ISR must perform the actions needed to ack the interrupts (usually, call `uart_fifo_read()` on rx_ready, and `uart_fifo_fill()` on tx_ready).

**Parameters**
- dev – UART device instance.

**Return values**
- 1 – On success.
- -ENOSYS – If this function is not implemented.
- -ENOTSUP – If API is not enabled.

```c
static inline void uart_irq_callback_user_data_set(const struct device *dev,
                                                 uart_irq_callback_user_data_t cb, void *
                                                 user_data)
```

Set the IRQ callback function pointer.
This sets up the callback for IRQ. When an IRQ is triggered, the specified function will be called with specified user data. See description of `uart_irq_update()` for the requirements on ISR.

**Parameters**
- dev – UART device instance.
- cb – Pointer to the callback function.
- user_data – Data to pass to callback function.

```c
static inline void uart_irq_callback_set(const struct device *dev,
                                        uart_irq_callback_user_data_t cb)
```

Set the IRQ callback function pointer (legacy).
This sets up the callback for IRQ. When an IRQ is triggered, the specified function will be called with the device pointer.

**Parameters**
- dev – UART device instance.
- cb – Pointer to the callback function.

### Asynchronous API

**group** uart_async

### Typedefs

```c
typedef void (*uart_callback_t)(const struct device *dev, struct uart_event *evt, void *user_data)
```

Define the application callback function signature for `uart_callback_set()` function.

**Param dev**
- UART device instance.

**Param evt**
- Pointer to `uart_event` instance.

**Param user_data**
- Pointer to data specified by user.
Enums

enum uart_event_type

Types of events passed to callback in UART_ASYNC_API.

Receiving:

a. To start receiving, uart_rx_enable has to be called with first buffer
b. When receiving starts to current buffer, UART_RX_BUF_REQUEST will be generated, in response to that user can either:
   • Provide second buffer using uart_rx_buf_rsp, when first buffer is filled, receiving will automatically start to second buffer.
   • Ignore the event, this way when current buffer is filled UART_RX_RDY event will be generated and receiving will be stopped.
c. If some data was received and timeout occurred UART_RX_RDY event will be generated. It can happen multiples times for the same buffer. RX timeout is counted from last byte received i.e. if no data was received, there won't be any timeout event.
d. After buffer is filled UART_RX_RDY will be generated, immediately followed by UART_RX_BUF_RELEASED indicating that current buffer is no longer used.
e. If there was second buffer provided, it will become current buffer and we start again at point 2. If no second buffer was specified receiving is stopped and UART_RX_DISABLED event is generated. After that whole process can be repeated.

Any time during reception UART_RX_STOPPED event can occur. if there is any data received, UART_RX_RDY event will be generated. It will be followed by UART_RX_BUF_RELEASED event for every buffer currently passed to driver and finally UART_RX_DISABLED event.

Receiving can be disabled using uart_rx_disable, after calling that function, if there is any data received, UART_RX_RDY event will be generated. UART_RX_BUF_RELEASED event will be generated for every buffer currently passed to driver and finally UART_RX_DISABLED event will occur.

 Transmitting:

a. Transmitting starts by uart_tx function.
b. If whole buffer was transmitted UART_TX_DONE is generated. If timeout occurred UART_TX_ABORTED will be generated.

Transmitting can be aborted using uart_tx_abort, after calling that function UART_TX_ABORTED event will be generated.

Values:

enumerator UART_TX_DONE
    Whole TX buffer was transmitted.

enumerator UART_TX_ABORTED
    Transmitting aborted due to timeout or uart_tx_abort call.

When flow control is enabled, there is a possibility that TX transfer won't finish in the allotted time. Some data may have been transferred, information about it can be found in event data.

enumerator UART_RX_RDY
    Received data is ready for processing.

This event is generated in the following cases:
• When RX timeout occurred, and data was stored in provided buffer. This can happen multiple times in the same buffer.
• When provided buffer is full.
• After `uart_rx_disable()`.
• After stopping due to external event (`UART_RX_STOPPED`).

enumerator UART_RX_BUF_REQUEST
Driver requests next buffer for continuous reception.
This event is triggered when receiving has started for a new buffer, i.e. it’s time to provide a next buffer for a seamless switchover to it. For continuous reliable receiving, user should provide another RX buffer in response to this event, using `uart_rx_buf_rsp` function.
If `uart_rx_buf_rsp` is not called before current buffer is filled up, receiving will stop.

enumerator UART_RX_BUF_RELEASED
Buffer is no longer used by UART driver.

enumerator UART_RX_DISABLED
RX has been disabled and can be reenabled.
This event is generated whenever receiver has been stopped, disabled or finished its operation and can be enabled again using `uart_rx_enable`.

enumerator UART_RX_STOPPED
RX has stopped due to external event.
Reason is one of `uart_rx_stop_reason`.

Functions

static inline int uart_callback_set(const struct device *dev, uart_callback_t callback, void *user_data)
Set event handler function.
Since it is mandatory to set callback to use other asynchronous functions, it can be used to detect if the device supports asynchronous API. Remaining API does not have that detection.

Parameters
• dev – UART device instance.
• callback – Event handler.
• user_data – Data to pass to event handler function.

Return values
• 0 – If successful.
• -ENOSYS – If not supported by the device.
• -ENOTSUP – If API not enabled.

int uart_tx(const struct device *dev, const uint8_t *buf, size_t len, int32_t timeout)
Send given number of bytes from buffer through UART.
Function returns immediately and event handler, set using `uart_callback_set`, is called after transfer is finished.

Parameters
• dev – UART device instance.
• buf – Pointer to transmit buffer.
• len – Length of transmit buffer.
• timeout – Timeout in microseconds. Valid only if flow control is enabled.
  SYS_FOREVER_US disables timeout.

Return values
• 0 – If successful.
• -ENOTSUP – If API is not enabled.
• -EBUSY – If there is already an ongoing transfer.
• -errno – Other negative errno value in case of failure.

```c
int uart_tx_u16(const struct device *dev, const uint16_t *buf, size_t len, int32_t timeout)
```
Send given number of datum from buffer through UART.

Function returns immediately and event handler, set using `uart_callback_set`, is called after
transfer is finished.

Parameters
• dev – UART device instance.
• buf – Pointer to wide data transmit buffer.
• len – Length of wide data transmit buffer.
• timeout – Timeout in milliseconds. Valid only if flow control is enabled.
  SYS_FOREVER_MS disables timeout.

Return values
• 0 – If successful.
• -ENOTSUP – If API is not enabled.
• -EBUSY – If there is already an ongoing transfer.
• -errno – Other negative errno value in case of failure.

```c
int uart_tx_abort(const struct device *dev)
```
Abort current TX transmission.

`UART TX DONE` event will be generated with amount of data sent.

Parameters
• dev – UART device instance.

Return values
• 0 – If successful.
• -ENOTSUP – If API is not enabled.
• -EFAULT – There is no active transmission.
• -errno – Other negative errno value in case of failure.

```c
int uart_rx_enable(const struct device *dev, uint8_t *buf, size_t len, int32_t timeout)
```
Start receiving data through UART.

Function sets given buffer as first buffer for receiving and returns immediately. After that event
handler, set using `uart_callback_set`, is called with `UART_RX_RDY` or `UART_RX_BUF_REQUEST`
events.

Parameters
• dev – UART device instance.
• buf – Pointer to receive buffer.
• len – Buffer length.
• timeout – Inactivity period after receiving at least a byte which triggers \texttt{UART\_RX\_RDY} event. Given in microseconds. SYS\_FOREVER\_US disables timeout. See \texttt{uart\_event\_type} for details.

\textbf{Return values}

• 0 – If successful.
• -ENOTSUP – If API is not enabled.
• -EBUSY – RX already in progress.
• -errno – Other negative errno value in case of failure.

\begin{verbatim}
int uart_rx_enable_u16(const struct device *dev, uint16_t *buf, size_t len, int timeout)
\end{verbatim}

Start receiving wide data through UART.

Function sets given buffer as first buffer for receiving and returns immediately. After that event handler, set using \texttt{uart\_callback\_set}, is called with \texttt{UART\_RX\_RDY} or \texttt{UART\_RX\_BUF\_REQUEST} events.

\textbf{Parameters}

• dev – UART device instance.
• buf – Pointer to wide data receive buffer.
• len – Buffer length.
• timeout – Inactivity period after receiving at least a byte which triggers \texttt{UART\_RX\_RDY} event. Given in milliseconds. SYS\_FOREVER\_MS disables timeout. See \texttt{uart\_event\_type} for details.

\textbf{Return values}

• 0 – If successful.
• -ENOTSUP – If API is not enabled.
• -EBUSY – RX already in progress.
• -errno – Other negative errno value in case of failure.

\begin{verbatim}
static inline int uart_rx_buf_rsp(const struct device *dev, uint8_t *buf, size_t len)
\end{verbatim}

Provide receive buffer in response to \texttt{UART\_RX\_BUF\_REQUEST} event.

Provide pointer to RX buffer, which will be used when current buffer is filled.

\textbf{Note:} Providing buffer that is already in usage by driver leads to undefined behavior. Buffer can be reused when it has been released by driver.

\begin{verbatim}
Parameters
\end{verbatim}

• dev – UART device instance.
• buf – Pointer to receive buffer.
• len – Buffer length.

\textbf{Return values}

• 0 – If successful.
• -ENOTSUP – If API is not enabled.
• -EBUSY – Next buffer already set.
• -EACCES – Receiver is already disabled (function called too late?).
• -errno – Other negative errno value in case of failure.

static inline int uart_rx_buf_rsp_u16(const struct device *dev, uint16_t *buf, size_t len)

Provide wide data receive buffer in response to UART_RX_BUF_REQUEST event.

Provide pointer to RX buffer, which will be used when current buffer is filled.

**Note:** Providing buffer that is already in usage by driver leads to undefined behavior. Buffer can be reused when it has been released by driver.

**Parameters**

- `dev` – UART device instance.
- `buf` – Pointer to wide data receive buffer.
- `len` – Buffer length.

**Return values**

- 0 – If successful.
- -ENOTSUP – If API is not enabled
- -EBUSY – Next buffer already set.
- -EACCES – Receiver is already disabled (function called too late?).
- -errno – Other negative errno value in case of failure.

int uart_rx_disable(const struct device *dev)

Disable RX.

UART_RX_BUF_RELEASED event will be generated for every buffer scheduled, after that UART_RX_DISABLED event will be generated. Additionally, if there is any pending received data, the UART_RX_RDY event for that data will be generated before the UART_RX_BUF_RELEASED events.

**Parameters**

- `dev` – UART device instance.

**Return values**

- 0 – If successful.
- -ENOTSUP – If API is not enabled.
- -EFAULT – There is no active reception.
- -errno – Other negative errno value in case of failure.

struct uart_event_tx

#include <uart.h> UART TX event data.

**Public Members**

- const uint8_t *buf
  Pointer to current buffer.
size_t len
   Number of bytes sent.

struct uart_event_rx
   #include <uart.h> UART RX event data.
   The data represented by the event is stored in rx.buf[rx.offset] to rx.buf[rx.offset+rx.len].
   That is, the length is relative to the offset.

Public Members

uint8_t *buf
   Pointer to current buffer.

size_t offset
   Currently received data offset in bytes.

size_t len
   Number of new bytes received.

struct uart_event_rx_buf
   #include <uart.h> UART RX buffer released event data.

struct uart_event_rx_stop
   #include <uart.h> UART RX stopped data.

Public Members

enum uart_rx_stop_reason reason
   Reason why receiving stopped.

struct uart_event_rx data
   Last received data.

struct uart_event
   #include <uart.h> Structure containing information about current event.

Public Members

enum uart_event_type type
   Type of event.

union uart_event_data
   #include <uart.h> Event data.
Public Members

struct uart_event_tx tx
    UART_TX_DONE and UART_TX_ABORTED events data.

struct uart_event_rx rx
    UART_RX_RDY event data.

struct uart_event_rx_buf rx_buf
    UART_RX_BUF_RELEASED event data.

struct uart_event_rx_stop rx_stop
    UART_RX_STOPPED event data.

7.3.38 USB-C VBUS

Overview

USB-C VBUS is the line in a USB Type-C connection that delivers power from a Source to a Sink device.

USB-C VBUS API The USB-C VBUS device driver presents an API that’s used to control and measure VBUS.

Configuration Options

Related configuration options:
- CONFIG_USBC_VBUS_DRIVER

API Reference

group usbc_vbus_api
    USB-C VBUS API.

Functions

static inline bool usbc_vbus_check_level(const struct device *dev, enum tc_vbus_level level)
    Checks if VBUS is at a particular level.

Parameters
- dev – Runtime device structure
- level – The level voltage to check against

Return values
- true – if VBUS is at the level voltage
- false – if VBUS is not at that level voltage
static inline int usbc_vbus_measure(const struct device *dev, int *meas)
    Reads and returns VBUS measured in mV.

    **Parameters**
    - `dev` – Runtime device structure
    - `meas` – pointer where the measured VBUS voltage is stored

    **Return values**
    - `0` – on success
    - `-EIO` – on failure

static inline int usbc_vbus_discharge(const struct device *dev, bool enable)
    Controls a pin that discharges VBUS.

    **Parameters**
    - `dev` – Runtime device structure
    - `enable` – Discharge VBUS when true

    **Return values**
    - `0` – on success
    - `-EIO` – on failure
    - `-ENOENT` – if discharge pin isn’t defined

static inline int usbc_vbus_enable(const struct device *dev, bool enable)
    Controls a pin that enables VBUS measurements.

    **Parameters**
    - `dev` – Runtime device structure
    - `enable` – enable VBUS measurements when true

    **Return values**
    - `0` – on success
    - `-EIO` – on failure
    - `-ENOENT` – if enable pin isn’t defined

struct usbc_vbus_driver_api
    #include <usbc_vbus.h>

### 7.3.39 MDIO

**Overview**

MDIO is a bus that is commonly used to communicate with ethernet PHY devices. Many ethernet MAC controllers also provide hardware to communicate over MDIO bus with a peripheral device.

This API is intended to be used primarily by PHY drivers but can also be used by user firmware.

**API Reference**

`group mdio_interface`

MDIO Interface.
Functions

void mdio_bus_enable(const struct device *dev)
Enable MDIO bus.

Parameters
  • dev – [in] Pointer to the device structure for the controller

void mdio_bus_disable(const struct device *dev)
Disable MDIO bus and tri-state drivers.

Parameters
  • dev – [in] Pointer to the device structure for the controller

int mdio_read(const struct device *dev, uint8_t prtad, uint8_t devad, uint16_t *data)
Read from MDIO Bus.
This routine provides a generic interface to perform a read on the MDIO bus.

Parameters
  • dev – [in] Pointer to the device structure for the controller
  • prtad – [in] Port address
  • devad – [in] Device address
  • data – Pointer to receive read data

Return values
  • 0 – If successful.
  • -EIO – General input / output error.
  • -ETIMEDOUT – If transaction timedout on the bus

int mdio_write(const struct device *dev, uint8_t prtad, uint8_t devad, uint16_t data)
Write to MDIO bus.
This routine provides a generic interface to perform a write on the MDIO bus.

Parameters
  • dev – [in] Pointer to the device structure for the controller
  • prtad – [in] Port address
  • devad – [in] Device address
  • data – [in] Data to write

Return values
  • 0 – If successful.
  • -EIO – General input / output error.
  • -ETIMEDOUT – If transaction timedout on the bus

7.3.40 Watchdog

Overview

API Reference
group watchdog_interface
  Watchdog Interface.

Watchdog options

WDT_OPT_PAUSE_IN_SLEEP
  Pause watchdog timer when CPU is in sleep state.

WDT_OPT_PAUSE_HALTED_BY_DBG
  Pause watchdog timer when CPU is halted by the debugger.

Watchdog behavior flags

WDT_FLAG_RESET_NONE
  Reset: none

WDT_FLAG_RESET_CPU_CORE
  Reset: CPU core

WDT_FLAG_RESET_SOC
  Reset: SoC

Typedefs

typedef void (*wdt_callback_t)(const struct device *dev, int channel_id)
  Watchdog callback.

  Param dev
    Watchdog device instance.

  Param channel_id
    Channel identifier.

Functions

int wdt_setup(const struct device *dev, uint8_t options)
  Set up watchdog instance.

  This function is used for configuring global watchdog settings that affect all timeouts. It
  should be called after installing timeouts. After successful return, all installed timeouts are
  valid and must be serviced periodically by calling wdt_feed().

  Parameters
    • dev – Watchdog device instance.
    • options – Configuration options (see WDT_OPT).

  Return values
int wdt_disable(const struct device *dev)

Disable watchdog instance.

This function disables the watchdog instance and automatically uninstalls all timeouts. To set up a new watchdog, install timeouts and call `wdt_setup()` again. Not all watchdogs can be restarted after they are disabled.

**Parameters**

- `dev` – Watchdog device instance.

**Return values**

- 0 – If successful.
- -EFAULT – If watchdog instance is not enabled.
- -EPERM – If watchdog can not be disabled directly by application code.
- -errno – In case of any other failure.

static inline int wdt_install_timeout(const struct device *dev, const struct wdt_timeout_cfg *cfg)

Install a new timeout.

**Note:** This function must be used before `wdt_setup()`. Changes applied here have no effects until `wdt_setup()` is called.

**Parameters**

- `dev` – Watchdog device instance.

**Return values**

- `channel_id` – If successful, a non-negative value indicating the index of the channel to which the timeout was assigned. This value is supposed to be used as the parameter in calls to `wdt_feed()`.
- -EBUSY – If timeout can not be installed while watchdog has already been setup.
- -ENOMEM – If no more timeouts can be installed.
- -ENOTSUP – If any of the set flags is not supported.
- -EINVAL – If any of the window timeout value is out of possible range. This value is also returned if watchdog supports only one timeout value for all timeouts and the supplied timeout window differs from windows for alarms installed so far.
- -errno – In case of any other failure.

int wdt_feed(const struct device *dev, int channel_id)

Feed specified watchdog timeout.

**Parameters**

- `dev` – Watchdog device instance.
• channel_id – Channel index.

**Return values**

• 0 – If successful.
• -EAGAIN – If completing the feed operation would stall the caller, for example due to an in-progress watchdog operation such as a previous `wdt_feed()` call.
• -EINVAL – If there is no installed timeout for supplied channel.
• -errno – In case of any other failure.

```c
struct wdt_window
#include <watchdog.h> Watchdog timeout window.
```

Each installed timeout needs feeding within the specified time window, otherwise the watchdog will trigger. If the watchdog instance does not support window timeouts then min value must be equal to 0.

**Note:** If specified values can not be precisely set they are always rounded up.

### Public Members

- `uint32_t min`
  - Lower limit of watchdog feed timeout in milliseconds.

- `uint32_t max`
  - Upper limit of watchdog feed timeout in milliseconds.

```c
struct wdt_timeout_cfg
#include <watchdog.h> Watchdog timeout configuration.
```

### Public Members

- `struct wdt_window window`
  - Timing parameters of watchdog timeout.

- `wdt_callback_t callback`
  - Timeout callback (can be `NULL`).

- `struct wdt_timeout_cfg *next`
  - Pointer to the next timeout configuration.

  This field is only available if `CONFIG_WDT_MULTISTAGE` is enabled (watchdogs with staged timeouts functionality). Value must be `NULL` for single stage timeout.

- `uint8_t flags`
  - Flags (see `WDT_FLAGS`).

### 7.3.41 Video

The video driver API offers a generic interface to video devices.
Basic Operation

**Video Device**  A video device is the abstraction of a hardware or software video function, which can produce, process, consume or transform video data. The video API is designed to offer flexible way to create, handle and combine various video devices.

**Endpoint**  Each video device can have one or more endpoints. Output endpoints configure video output function and generate data. Input endpoints configure video input function and consume data.

**Video Buffer**  A video buffer provides the transport mechanism for the data. There is no particular requirement on the content. The requirement for the content is defined by the endpoint format. A video buffer can be queued to a device endpoint for filling (input ep) or consuming (output ep) operation, once the operation is achieved, buffer can be dequeued for post-processing, release or reuse.

**Controls**  A video control is accessed and identified by a CID (control identifier). It represents a video control property. Different devices will have different controls available which can be generic, related to a device class or vendor specific. The set/get control functions provide a generic scalable interface to handle and create controls.

**Configuration Options**

Related configuration options:

- `CONFIG_VIDEO`

**API Reference**

```
group video_interface

Video Interface.

Defines

video_fourcc(a, b, c, d)

VIDEO_PIX_FMT_BGGR8
VIDEO_PIX_FMT_GBRG8
VIDEO_PIX_FMT_GRBG8
VIDEO_PIX_FMT_RGGB8
VIDEO_PIX_FMT_RGB565
VIDEO_PIX_FMT_JPEG
```
### Typedefs

typedef int (*video_api_set_format_t)(const struct device *dev, enum video_endpoint_id ep, struct video_format *fmt)

Set video format See `video_set_format()` for argument descriptions.

typedef int (*video_api_get_format_t)(const struct device *dev, enum video_endpoint_id ep, struct video_format *fmt)

get current video format See `video_get_format()` for argument descriptions.

typedef int (*video_api_enqueue_t)(const struct device *dev, enum video_endpoint_id ep, struct video_buffer *buf)

Enqueue a buffer in the driver’s incoming queue. See `video_enqueue()` for argument descriptions.

typedef int (*video_api_dequeue_t)(const struct device *dev, enum video_endpoint_id ep, struct video_buffer **buf, k_timeout_t timeout)

Dequeue a buffer from the driver’s outgoing queue. See `video_dequeue()` for argument descriptions.

typedef int (*video_api_flush_t)(const struct device *dev, enum video_endpoint_id ep, bool cancel)

Flush endpoint buffers, buffer are moved from incoming queue to outgoing queue. See `video_flush()` for argument descriptions.

typedef int (*video_api_stream_start_t)(const struct device *dev)

Start the capture or output process. See `video_stream_start()` for argument descriptions.

typedef int (*video_api_stream_stop_t)(const struct device *dev)

Stop the capture or output process. See `video_stream_stop()` for argument descriptions.

typedef int (*video_api_set_ctrl_t)(const struct device *dev, unsigned int cid, void *value)

set a video control value. See `video_set_ctrl()` for argument descriptions.

typedef int (*video_api_get_ctrl_t)(const struct device *dev, unsigned int cid, void *value)

get a video control value. See `video_get_ctrl()` for argument descriptions.

typedef int (*video_api_get_caps_t)(const struct device *dev, enum video_endpoint_id ep, struct video_caps *caps)

Get capabilities of a video endpoint. See `video_get_caps()` for argument descriptions.

typedef int (*video_api_set_signal_t)(const struct device *dev, enum video_endpoint_id ep, struct k_poll_signal *signal)

Register/Unregister poll signal for buffer events. See `video_set_signal()` for argument descriptions.

### Enums

enum video_endpoint_id

video_endpoint_id enum Identify the video device endpoint.

Values:
enumerator VIDEO_EP_NONE
enumerator VIDEO_EP_ANY
enumerator VIDEO_EP_IN
enumerator VIDEO_EP_OUT

enum video_signal_result
    video_event enum Identify video event.
    Values:
    enumerator VIDEO_BUF_DONE
    enumerator VIDEO_BUF_ABORTED
    enumerator VIDEO_BUF_ERROR

Functions

static inline int video_set_format(const struct device *dev, enum video_endpoint_id ep, struct video_format *fmt)

Set video format.
Configure video device with a specific format.

Parameters
    • dev – Pointer to the device structure for the driver instance.
    • ep – Endpoint ID.
    • fmt – Pointer to a video format struct.

Return values
    • 0 – Is successful.
    • -EINVAL – If parameters are invalid.
    • -ENOTSUP – If format is not supported.
    • -EIO – General input / output error.

static inline int video_get_format(const struct device *dev, enum video_endpoint_id ep, struct video_format *fmt)

Get video format.
Get video device current video format.

Parameters
    • dev – Pointer to the device structure for the driver instance.
    • ep – Endpoint ID.
    • fmt – Pointer to video format struct.

Return values
    pointer – to video format
static inline int video_enqueue(const struct device *dev, enum video_endpoint_id ep, struct video_buffer *buf)

Enqueue a video buffer.

Enqueue an empty (capturing) or filled (output) video buffer in the driver's endpoint incoming queue.

Parameters
- `dev` – Pointer to the device structure for the driver instance.
- `ep` – Endpoint ID.
- `buf` – Pointer to the video buffer.

Return values
- 0 – Is successful.
- -EINVAL – If parameters are invalid.
- -EIO – General input / output error.

static inline int video_dequeue(const struct device *dev, enum video_endpoint_id ep, struct video_buffer **buf, k_timeout_t timeout)

Dequeue a video buffer.

Dequeue a filled (capturing) or displayed (output) buffer from the driver's endpoint outgoing queue.

Parameters
- `dev` – Pointer to the device structure for the driver instance.
- `ep` – Endpoint ID.
- `buf` – Pointer to a video buffer pointer.
- `timeout` – Timeout

Return values
- 0 – Is successful.
- -EINVAL – If parameters are invalid.
- -EIO – General input / output error.

static inline int video_flush(const struct device *dev, enum video_endpoint_id ep, bool cancel)

Flush endpoint buffers.

A call to flush finishes when all endpoint buffers have been moved from incoming queue to outgoing queue. Either because canceled or fully processed through the video function.

Parameters
- `dev` – Pointer to the device structure for the driver instance.
- `ep` – Endpoint ID.
- `cancel` – If true, cancel buffer processing instead of waiting for completion.

Return values
- 0 – Is successful, -ERRNO code otherwise.

static inline int video_stream_start(const struct device *dev)

Start the video device function.

video_stream_start is called to enter 'streaming' state (capture, output...). The driver may receive buffers with video_enqueue() before video_stream_start is called. If driver/device needs a minimum number of buffers before being able to start streaming, then driver set the min_vbuf_count to the related endpoint capabilities.
Return values

- 0 – Is successful.
- -EIO – General input / output error.

static inline int video_stream_stop(const struct device *dev)
Stop the video device function.

On video_stream_stop, driver must stop any transactions or wait until they finish.

Return values

- 0 – Is successful.
- -EIO – General input / output error.

static inline int video_get_caps(const struct device *dev, enum video_endpoint_id ep, struct video_caps *caps)
Get the capabilities of a video endpoint.

Parameters

- dev – Pointer to the device structure for the driver instance.
- ep – Endpoint ID.
- caps – Pointer to the video_caps struct to fill.

Return values

0 – Is successful, -ERRNO code otherwise.

static inline int video_set_ctrl(const struct device *dev, unsigned int cid, void *value)
Set the value of a control.

This set the value of a video control, value type depends on control ID, and must be interpreted accordingly.

Parameters

- dev – Pointer to the device structure for the driver instance.
- cid – Control ID.
- value – Pointer to the control value.

Return values

- 0 – Is successful.
- -EINVAL – If parameters are invalid.
- -ENOTSUP – If format is not supported.
- -EIO – General input / output error.

static inline int video_get_ctrl(const struct device *dev, unsigned int cid, void *value)
Get the current value of a control.

This retrieve the value of a video control, value type depends on control ID, and must be interpreted accordingly.

Parameters

- dev – Pointer to the device structure for the driver instance.
- cid – Control ID.
- value – Pointer to the control value.

Return values

- 0 – Is successful.
-EINVAL – If parameters are invalid.
-ENOTSUP – If format is not supported.
-EIO – General input / output error.

static inline int video_set_signal(const struct device *dev, enum video_endpoint_id ep, struct k_poll_signal *signal)

Register/Unregister k_poll signal for a video endpoint.

Register a poll signal to the endpoint, which will be signaled on frame completion (done, aborted, error). Registering a NULL poll signal unregisters any previously registered signal.

Parameters
• dev – Pointer to the device structure for the driver instance.
• ep – Endpoint ID.
• signal – Pointer to k_poll_signal

Return values
0 – Is successful, -ERRNO code otherwise.

struct video_buffer *video_buffer_alloc(size_t size)

Allocate video buffer.

Parameters
• size – Size of the video buffer.

Return values
pointer – to allocated video buffer

void video_buffer_release(struct video_buffer *buf)

Release a video buffer.

Parameters
• buf – Pointer to the video buffer to release.

struct video_format
#include <video.h> video format structure

Used to configure frame format.

Param pixelformat
is the fourcc pixel format value.

Param width
is the frame width in pixels.

Param height
is the frame height in pixels.

Param pitch
is the line stride, the number of bytes that needs to be added to the address in the first pixel of a row in order to go to the address of the first pixel of the next row (>=width).

struct video_format_cap
#include <video.h> video format capability

Used to describe a video endpoint format capability.

Param pixelformat
is a list of supported pixel formats (0 terminated).
**Param width_min**
is the minimum supported frame width.

**Param width_max**
is the maximum supported frame width.

**Param height_min**
is the minimum supported frame width.

**Param height_max**
is the maximum supported frame width.

**Param width_step**
is the width step size.

**Param height_step**
is the height step size.

```
struct video_caps
    #include <video.h> video capabilities
    Used to describe video endpoint capabilities.
    **Param format_caps**
    is a list of video format capabilities (zero terminated).
    **Param min_vbuf_count**
    is the minimal count of video buffers to enqueue before being able to start the stream.
```

```
struct video_buffer
    #include <video.h> video buffer structure
    Represent a video frame.
    **Param driver_data**
    is a pointer to driver specific data.
    **Param buffer**
    is a pointer to the start of the buffer.
    **Param size**
    is the size in bytes of the buffer.
    **Param bytesused**
    is the number of bytes occupied by the valid data in the buffer.
    **Param timestamp**
    is a time reference in milliseconds at which the last data byte was actually received for input endpoints or to be consumed for output endpoints.
```

```
struct video_driver_api
    #include <video.h>
```

**group video_controls**

Video controls.

**Defines**

```
VIDEO_CTRL_CLASS_GENERIC
```
The eSPI (enhanced serial peripheral interface) is a serial bus that is based on SPI. It also features a four-wire interface (receive, transmit, clock and slave select) and three configurations: single IO, dual IO and quad IO.

The technical advancements include lower voltage signal levels (1.8V vs. 3.3V), lower pin count, and the frequency is twice as fast (66MHz vs. 33MHz) Because of its enhancements, the eSPI is used to replace the LPC (lower pin count) interface, SPI, SMBus and sideband signals.

See eSPI interface specification for additional details.
group espi_interface

  eSPI SAF Driver APIs

Defines

HOST_KBC_EVT_IBF

HOST_KBC_EVT_OBE

Typedefs

typedef void (*espi_callback_handler_t)(const struct device *dev, struct espi_callback *cb, struct espi_event espi_evt)

Define the application callback handler function signature.

Param dev
  Device struct for the eSPI device.

Param cb
  Original struct espi_callback owning this handler.

Param espi_evt
  event details that trigger the callback handler.

Enums

class espi_io_mode
  eSPI I/O mode capabilities

Values:

enumerator ESPI_IO_MODE_SINGLE_LINE = BIT(0)
enumerator ESPI_IO_MODE_DUAL_LINES = BIT(1)
enumerator ESPI_IO_MODE_QUAD_LINES = BIT(2)

enum espi_channel
  eSPI channel.
Identifies each eSPI logical channel supported by eSPI controller. Each channel allows independent traffic, but the assignment of channel type to channel number is fixed.

Note that generic commands are not associated with any channel, so traffic over eSPI can occur if all channels are disabled or not ready.

Values:

enumerator ESPI_CHANNEL_PERIPHERAL = BIT(0)

enumerator ESPI_CHANNEL_VWIRE = BIT(1)

enumerator ESPI_CHANNEL_OOB = BIT(2)

enumerator ESPI_CHANNEL_FLASH = BIT(3)
eSPI bus event.
eSPI bus event to indicate events for which user can register callbacks

Values:

enumerator ESPI_BUS_RESET = BIT(0)

enumerator ESPI_BUS_EVENT_CHANNEL_READY = BIT(1)

enumerator ESPI_BUS_EVENT_VWIRE_RECEIVED = BIT(2)

enumerator ESPI_BUS_EVENT_OOB_RECEIVED = BIT(3)

enumerator ESPI_BUS_PERIPHERAL_NOTIFICATION = BIT(4)

enumerator ESPI_BUS_SA_FNOTIFICATION = BIT(5)

enum espi_pc_event
eSPI peripheral channel events.
eSPI peripheral channel event types to indicate users.

Values:

enumerator ESPI_PC_EVT_BUS_CHANNEL_READY = BIT(0)

enumerator ESPI_PC_EVT_BUS_MASTER_ENABLE = BIT(1)

denum espi_virtual_peripheral
eSPI peripheral notification type.
eSPI peripheral notification event details to indicate which peripheral trigger the eSPI callback

Values:

enumerator ESPI_PERIPHERAL_UART

enumerator ESPI_PERIPHERAL_8042_KBC

enumerator ESPI_PERIPHERAL_HOST_IO

enumerator ESPI_PERIPHERAL_DEBUG_PORT80

enumerator ESPI_PERIPHERAL_HOST_IO_PVT

enum espi_cycle_type
eSPI cycle types supported over eSPI peripheral channel

Values:
enumerator ESPI_CYCLE_MEMORY_READ32
enumerator ESPI_CYCLE_MEMORY_READ64
enumerator ESPI_CYCLE_MEMORY_WRITE32
enumerator ESPI_CYCLE_MEMORY_WRITE64
enumerator ESPI_CYCLE_MESSAGE_NODATA

Functions

int espi_config(const struct device *dev, struct espi_cfg *cfg)
Configure operation of a eSPI controller.

This routine provides a generic interface to override eSPI controller capabilities.

If this eSPI controller is acting as slave, the values set here will be discovered as part through
the GET_CONFIGURATION command issued by the eSPI master during initialization.

If this eSPI controller is acting as master, the values set here will be used by eSPI master to de-
termine minimum common capabilities with eSPI slave then send via SET_CONFIGURATION
command.

Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `cfg` – the device runtime configuration for the eSPI controller.

Return values

- 0 – If successful.
- -EIO – General input / output error, failed to configure device.
- -EINVAL – invalid capabilities, failed to configure device.
- -ENOTSUP – capability not supported by eSPI slave.

bool espi_get_channel_status(const struct device *dev, enum espi_channel ch)
Query to see if it a channel is ready.

This routine allows to check if logical channel is ready before use. Note that queries for
channels not supported will always return false.

Parameters
• dev – Pointer to the device structure for the driver instance.
• ch – the eSPI channel for which status is to be retrieved.

Return values
• true – If eSPI channel is ready.
• false – otherwise.

int espi_read_request(const struct device *dev, struct espi_request_packet *req)
Sends memory, I/O or message read request over eSPI.
This routines provides a generic interface to send a read request packet.

Parameters
• dev – Pointer to the device structure for the driver instance.
• req – Address of structure representing a memory, I/O or message read request.

Return values
• 0 – If successful.
• -ENOTSUP – if eSPI controller doesn’t support raw packets and instead low memory transactions are handled by controller hardware directly.
• -EIO – General input / output error, failed to send over the bus.

int espi_write_request(const struct device *dev, struct espi_request_packet *req)
Sends memory, I/O or message write request over eSPI.
This routines provides a generic interface to send a write request packet.

Parameters
• dev – Pointer to the device structure for the driver instance.
• req – Address of structure representing a memory, I/O or message write request.

Return values
• 0 – If successful.
• -ENOTSUP – if eSPI controller doesn’t support raw packets and instead low memory transactions are handled by controller hardware directly.
• -EINVAL – General input / output error, failed to send over the bus.

int espi_read_lpc_request(const struct device *dev, enum lpc_peripheral_opcode op, uint32_t *data)
Reads SOC data from a LPC peripheral with information updated over eSPI.
This routine provides a generic interface to read a block whose information was updated by an eSPI transaction. Reading may trigger a transaction. The eSPI packet is assembled by the HW block.

Parameters
• dev – Pointer to the device structure for the driver instance.
• op – Enum representing opcode for peripheral type and read request.
• data – Parameter to be read from to the LPC peripheral.

Return values
• 0 – If successful.
• -ENOTSUP – if eSPI peripheral is off or not supported.
int espi_write_lpc_request(const struct device *dev, enum lpc_peripheral_opcode op, uint32_t *data)

Writes data to a LPC peripheral which generates an eSPI transaction.
This routine provides a generic interface to write data to a block which triggers an eSPI transaction. The eSPI packet is assembled by the HW block.

Parameters

- dev – Pointer to the device structure for the driver instance.
- op – Enum representing an opcode for peripheral type and write request.
- data – Represents the parameter passed to the LPC peripheral.

Return values

- 0 – If successful.
- -ENOTSUP – if eSPI peripheral is off or not supported.
- -EINVAL – for unimplemented lpc opcode, but in range.

int espi_send_vwire(const struct device *dev, enum espi_vwire_signal signal, uint8_t level)

Sends system/platform signal as a virtual wire packet.
This routines provides a generic interface to send a virtual wire packet from slave to master.

Parameters

- dev – Pointer to the device structure for the driver instance.
- signal – The signal to be send to eSPI master.
- level – The level of signal requested LOW or HIGH.

Return values

- 0 – If successful.
- -EIO – General input / output error, failed to send over the bus.

int espi_receive_vwire(const struct device *dev, enum espi_vwire_signal signal, uint8_t *level)

Retrieves level status for a signal encapsulated in a virtual wire.
This routines provides a generic interface to request a virtual wire packet from eSPI master and retrieve the signal level.

Parameters

- dev – Pointer to the device structure for the driver instance.
- signal – the signal to be requested from eSPI master.
- level – the level of signal requested 0b LOW, 1b HIGH.

Return values

- -EIO – General input / output error, failed request to master.

int espi_send_oob(const struct device *dev, struct espi_oob_packet *pckt)

Sends SMBus transaction (out-of-band) packet over eSPI bus.
This routines provides an interface to encapsulate a SMBus transaction and send into packet over eSPI bus.

Parameters

- dev – Pointer to the device structure for the driver instance.
- pckt – Address of the packet representation of SMBus transaction.
Return values
- EIO – General input / output error, failed request to master.

```c
int espi_receive_oob(const struct device *dev, struct espi_oob_packet *pckt)
```

Receives SMBus transaction (out-of-band) packet from eSPI bus.

This routines provides an interface to receive and decoded a SMBus transaction from eSPI bus.

Parameters
- `dev` – Pointer to the device structure for the driver instance.
- `pckt` – Address of the packet representation of SMBus transaction.

Return values
- EIO – General input / output error, failed request to master.

```c
int espi_read_flash(const struct device *dev, struct espi_flash_packet *pckt)
```

Sends a read request packet for shared flash.

This routines provides an interface to send a request to read the flash component shared between the eSPI master and eSPI slaves.

Parameters
- `dev` – Pointer to the device structure for the driver instance.
- `pckt` – Address of the representation of read flash transaction.

Return values
- ENOTSUP – eSPI flash logical channel transactions not supported.
- EBUSY – eSPI flash channel is not ready or disabled by master.
- EIO – General input / output error, failed request to master.

```c
int espi_write_flash(const struct device *dev, struct espi_flash_packet *pckt)
```

Sends a write request packet for shared flash.

This routines provides an interface to send a request to write to the flash components shared between the eSPI master and eSPI slaves.

Parameters
- `dev` – Pointer to the device structure for the driver instance.
- `pckt` – Address of the representation of write flash transaction.

Return values
- ENOTSUP – eSPI flash logical channel transactions not supported.
- EBUSY – eSPI flash channel is not ready or disabled by master.
- EIO – General input / output error, failed request to master.

```c
int espi_flash_erase(const struct device *dev, struct espi_flash_packet *pckt)
```

Sends a write request packet for shared flash.

This routines provides an interface to send a request to write to the flash components shared between the eSPI master and eSPI slaves.

Parameters
- `dev` – Pointer to the device structure for the driver instance.
- `pckt` – Address of the representation of write flash transaction.

Return values
- ENOTSUP – eSPI flash logical channel transactions not supported.
- **EBUSY** – eSPI flash channel is not ready or disabled by master.
- **EIO** – General input / output error, failed request to master.

```c
static inline void espi_init_callback(
    struct espi_callback *callback,
    espi_callback_handler_t handler, enum espi_bus_event evt_type)
```

Helper to initialize a struct espi_callback properly.

Callback model

```plaintext
+-------+ +-------------+ +------+
| App | eSPI driver | HW | eSPI Host |
+---+---+ +-------+-----+ +---+--+ +----+----+
|   | | | |
|   | | |
| espi_init_callback | | |
| +----------------------------> | | |
| espi_add_callback | |
+----------------------------->+ |
| IRQ +<------------+ resets the bus |
| Processed within the driver |
| VW CH ready | eSPI host enables VW channel |
| IRQ +<---------+ |
| Processed within the driver |
| Memory I/O | Peripheral event |
+<-----------------------------+ callback |
| Report peripheral event and data for the event |
+<-----------------------------+ callback |
| App enables/configures discrete regulator |
| espi_send_vwire_signal |
+----------------------------->| |
| HOST_RST | eSPI host send VWire |
+<-----------------------------+ callback |
| App reset host-related |
(continues on next page)
```
### Parameters

- **callback** – A valid Application's callback structure pointer.
- **handler** – A valid handler function pointer.
- **evt_type** – indicates the eSPI event relevant for the handler. For VWIRE_RECEIVED event the data will indicate the new level asserted.

```c
static inline int espi_add_callback(const struct device *dev, struct espi_callback *callback)
Add an application callback.
```

**Note:** Enables to add as many callbacks as needed on the same device.

### Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **callback** – A valid Application's callback structure pointer.

```c
static inline int espi_remove_callback(const struct device *dev, struct espi_callback *callback)
Remove an application callback.
```

**Note:** Enables to remove as many callbacks as added through `espi_add_callback()`.

**Warning:** It is explicitly permitted, within a callback handler, to remove the registration for the callback that is running, i.e. `callback`. Attempts to remove other registrations on the same device may result in undefined behavior, including failure to invoke callbacks that remain registered and unintended invocation of removed callbacks.

### Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **callback** – A valid application's callback structure pointer.

```c
static inline int espi_free_callback(const struct device *dev, struct espi_callback *callback)
Free an application callback.
```

**Note:** Enables to free as many callbacks as added through `espi_add_callback()`.

**Warning:** It is explicitly permitted, within a callback handler, to free the registration for the callback that is running, i.e. `callback`. Attempts to free other registrations on the same device may result in undefined behavior, including failure to invoke callbacks that remain registered and unintended invocation of removed callbacks.
Configure operation of an eSPI controller.

This routine provides a generic interface to override eSPI controller capabilities.

If this eSPI controller is acting as slave, the values set here will be discovered as part through the GET_CONFIGURATION command issued by the eSPI master during initialization.

If this eSPI controller is acting as master, the values set here will be used by eSPI master to determine minimum common capabilities with eSPI slave then send via SET_CONFIGURATION command.

Parameters
- `dev` – Pointer to the device structure for the driver instance.
- `cfg` – the device runtime configuration for the eSPI controller.

Return values
- `0` – If successful.
- `-EIO` – General input / output error, failed to configure device.
- `-EINVAL` – invalid capabilities, failed to configure device.
- `-ENOTSUP` – capability not supported by eSPI slave.

Set one or more SAF protection regions.

Parameters
- `dev` – Pointer to the device structure for the driver instance.
• pr – Pointer to the SAF protection region structure.

Return values
• 0 – If successful.
• -EIO – General input / output error, failed to configure device.
• -EINVAL – invalid capabilities, failed to configure device.
• -ENOTSUP – capability not supported by eSPI slave.

int espi_saf_activate(const struct device *dev)

Activate SAF block.

This routine activates the SAF block and should only be called after SAF has been configured and the eSPI Master has enabled the Flash Channel.

Parameters
• dev – Pointer to the device structure for the driver instance.

Return values
• 0 – If successful
• -EINVAL – if failed to activate SAF.

bool espi_saf_get_channel_status(const struct device *dev)

Query to see if SAF is ready.

This routine allows to check if SAF is ready before use.

Parameters
• dev – Pointer to the device structure for the driver instance.

Return values
• true – If eSPI SAF is ready.
• false – otherwise.

int espi_saf_flash_read(const struct device *dev, struct espi_saf_packet *pckt)

Sends a read request packet for slave attached flash.

This routines provides an interface to send a request to read the flash component shared between the eSPI master and eSPI slaves.

Parameters
• dev – Pointer to the device structure for the driver instance.
• pckt – Address of the representation of read flash transaction.

Return values
• -ENOTSUP – eSPI flash logical channel transactions not supported.
• -EBUSY – eSPI flash channel is not ready or disabled by master.
• -EIO – General input / output error, failed request to master.

int espi_saf_flash_write(const struct device *dev, struct espi_saf_packet *pckt)

Sends a write request packet for slave attached flash.

This routines provides an interface to send a request to write to the flash components shared between the eSPI master and eSPI slaves.

Parameters
• dev – Pointer to the device structure for the driver instance.
• pckt – Address of the representation of write flash transaction.
Return values

- **-ENOTSUP** – eSPI flash logical channel transactions not supported.
- **-EBUSY** – eSPI flash channel is not ready or disabled by master.
- **-EIO** – General input / output error, failed request to master.

```c
int espi_saf_flash_erase(const struct device *dev, struct espi_saf_packet *pckt)
```

Sends a write request packet for slave attached flash.

This routine provides an interface to send a request to write to the flash components shared between the eSPI master and eSPI slaves.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `pckt` – Address of the representation of erase flash transaction.

**Return values**

- **-ENOTSUP** – eSPI flash logical channel transactions not supported.
- **-EBUSY** – eSPI flash channel is not ready or disabled by master.
- **-EIO** – General input / output error, failed request to master.

```c
static inline void espi_saf_init_callback(struct espi_callback *callback,
                                         espi_callback_handler_t handler,
                                         enum espi_bus_event evt_type)
```

Helper to initialize a struct `espi_callback` properly.

**Callback model**

(continues on next page)
Parameters

- **callback** – A valid Application’s callback structure pointer.
- **handler** – A valid handler function pointer.
- **evt_type** – indicates the eSPI event relevant for the handler. for VWIRE_RECEIVED event the data will indicate the new level asserted

```c
static inline int espisaf_add_callback(const struct device *dev, struct espi_callback *callback)
```

Add an application callback.

**Note:** enables to add as many callback as needed on the same device.

---

**Note:** Callbacks may be added to the device from within a callback handler invocation, but whether they are invoked for the current eSPI event is not specified.

---

Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **callback** – A valid Application’s callback structure pointer.

Returns

0 if successful, negative errno code on failure.
static inline int espi_saf_remove_callback(const struct device *dev, struct espi_callback *callback)

Remove an application callback.

Note: enables to remove as many callbacks as added through espi_add_callback().

Warning: It is explicitly permitted, within a callback handler, to remove the registration for the callback that is running, i.e. callback. Attempts to remove other registrations on the same device may result in undefined behavior, including failure to invoke callbacks that remain registered and unintended invocation of removed callbacks.

Parameters

• dev – Pointer to the device structure for the driver instance.
• callback – A valid application’s callback structure pointer.

Returns

0 if successful, negative errno code on failure.

struct espi_evt_data_kbc

#include <espi.h> Bit field definition of evt_data in struct espi_event for KBC.

**Functions**

```c
static inline int mipi_dsi_attach(const struct device *dev, uint8_t channel, const struct mipi_dsi_device *mdev)
{
    Attach a new device to the MIPI-DSI bus.
    
    Parameters
    • dev – MIPI-DSI host device.
    • channel – Device channel (VID).
    • mdev – MIPI-DSI device description.
    
    Returns
    0 on success, negative on error
}
```

```c
static inline ssize_t mipi_dsi_transfer(const struct device *dev, uint8_t channel, struct mipi_dsi_msg *msg)
{
    Transfer data to/from a device attached to the MIPI-DSI bus.
    
    Parameters
    • dev – MIPI-DSI device.
    • channel – Device channel (VID).
    • msg – Message.
    
    Returns
    Size of the transferred data on success, negative on error.
}
```

```c
ssize_t mipi_dsi_generic_read(const struct device *dev, uint8_t channel, const void *params, size_t nparams, void *buf, size_t len)
{
    MIPI-DSI generic read.
    
    Parameters
    • dev – MIPI-DSI host device.
    • channel – Device channel (VID).
    • params – Buffer containing request parameters.
    • nparams – Number of parameters.
    • buf – Buffer where read data will be stored.
    • len – Length of the reception buffer.
}
```
Returns
Size of the read data on success, negative on error.

ssize_t mipi_dsi_generic_write(const struct device *dev, uint8_t channel, const void *buf, size_t len)

MIPI-DSI generic write.

Parameters
- dev – MIPI-DSI host device.
- channel – Device channel (VID).
- buf – Transmission buffer.
- len – Length of the transmission buffer

Returns
Size of the written data on success, negative on error.

ssize_t mipi_dsi_dcs_read(const struct device *dev, uint8_t channel, uint8_t cmd, void *buf, size_t len)

MIPI-DSI DCS read.

Parameters
- dev – MIPI-DSI host device.
- channel – Device channel (VID).
- cmd – DCS command.
- buf – Buffer where read data will be stored.
- len – Length of the reception buffer.

Returns
Size of the read data on success, negative on error.

ssize_t mipi_dsi_dcs_write(const struct device *dev, uint8_t channel, uint8_t cmd, const void *buf, size_t len)

MIPI-DSI DCS write.

Parameters
- dev – MIPI-DSI host device.
- channel – Device channel (VID).
- cmd – DCS command.
- buf – Transmission buffer.
- len – Length of the transmission buffer

Returns
Size of the written data on success, negative on error.

    #include <mipi_dsi.h> MIPI-DSI host driver API.

7.3.44 W1: Dallas 1-Wire Interface

Overview

1-Wire is a low speed half-duplex serial bus using only a single wire plus ground for both data transmission and device power supply. Similarly to I2C, 1-Wire uses a bidirectional open-collector data line, and is a single master multidrop bus. This means one master initiates all data exchanges with the slave devices. The 1-Wire bus supports longer bus lines than I2C, while it reaches speeds of up to 15.4 kbps in standard mode and up to 125 kbps in overdrive mode. Reliable communication in standard speed configuration is possible with 10 nodes over a bus length of 100 meters. Using overdrive speed, 3 nodes on a bus of 10 meters length are expected to work solid. Optimized timing parameters and fewer nodes on the bus may allow to reach larger bus extents.

The implementation details are specified in the BOOK OF IBUTTON STANDARDS.

![Fig. 7.1: A typical 1-Wire bus topology](image)
**W1 Master API**  Zephyr’s 1-Wire Master API is used to interact with 1-Wire slave devices like temperature sensors and serial memories.

In Zephyr this API is split into the following layers.

- The link layer handles basic communication functions such as bus reset, presence detect and bit transfer operations. It is the only hardware-dependent layer in Zephyr. This layer is supported by a driver using the Zephyr UART interface, which should work on most Zephyr platforms. In the future, a GPIO/Timer based driver and hardware specific drivers might be added.

- The 1-Wire network layer handles all means for slave identification and bus arbitration. This includes ROM commands like Match ROM, or Search ROM.
  - All slave devices have a unique 64-bit identification number, which includes a 8-bit 1-Wire Family Code and a 8-bit CRC.
  - In order to find slaves on the bus, the standard specifies an search algorithm which successively detects all slaves on the bus. This algorithm is described in detail by Maxim’s Applicationnote 187.

- Transport layer and Presentation layer functions are not implemented in the generic 1-Wire driver and therefore must be handled in individual slave drivers.

The 1-Wire API is considered experimental.

**Configuration Options**

Related configuration options:

- `CONFIG_W1`
- `CONFIG_W1_NET`

**API Reference**

**1-Wire data link layer**

*group w1_data_link*

1-Wire data link layer

**Functions**

```c
int w1_reset_bus(const struct device *dev)
```

Reset the 1-Wire bus to prepare slaves for communication.

This routine resets all 1-Wire bus slaves such that they are ready to receive a command. Connected slaves answer with a presence pulse once they are ready to receive data.

In case the driver supports both standard speed and overdrive speed, the reset routine takes care of sendig either a short or a long reset pulse depending on the current state. The speed can be changed using `w1_configure()`.

**Parameters**

- `dev` – *[in]* Pointer to the device structure for the driver instance.

**Return values**

- 0 – If no slaves answer with a present pulse.
- 1 – If at least one slave answers with a present pulse.
- `-errno` – Negative error code on error.
int w1_read_bit(const struct device *dev)
Read a single bit from the 1-Wire bus.

Parameters
• dev – [in] Pointer to the device structure for the driver instance.

Return values
• rx_bit – The read bit value on success.
• -errno – Negative error code on error.

int w1_write_bit(const struct device *dev, const bool bit)
Write a single bit to the 1-Wire bus.

Parameters
• dev – [in] Pointer to the device structure for the driver instance.
• bit – Transmitting bit value 1 or 0.

Return values
• 0 – If successful.
• -errno – Negative error code on error.

int w1_read_byte(const struct device *dev)
Read a single byte from the 1-Wire bus.

Parameters
• dev – [in] Pointer to the device structure for the driver instance.

Return values
• rx_byte – The read byte value on success.
• -errno – Negative error code on error.

int w1_write_byte(const struct device *dev, uint8_t byte)
Write a single byte to the 1-Wire bus.

Parameters
• dev – [in] Pointer to the device structure for the driver instance.
• byte – Transmitting byte.

Return values
• 0 – If successful.
• -errno – Negative error code on error.

int w1_read_block(const struct device *dev, uint8_t *buffer, size_t len)
Read a block of data from the 1-Wire bus.

Parameters
• dev – [in] Pointer to the device structure for the driver instance.
• buffer – [out] Pointer to receive buffer.
• len – Length of receiving buffer (in bytes).

Return values
• 0 – If successful.
• -errno – Negative error code on error.
int w1_write_block(const struct device *dev, const uint8_t *buffer, size_t len)
Write a block of data from the 1-Wire bus.

Parameters
- `dev` – [in] Pointer to the device structure for the driver instance.
- `len` – Length of transmitting buffer (in bytes).

Return values
- 0 – If successful.
- `errno` – Negative error code on error.

size_t w1_get_slave_count(const struct device *dev)
Get the number of slaves on the bus.

Parameters
- `dev` – [in] Pointer to the device structure for the driver instance.

Return values
- `slave_count` – Positive Number of connected 1-Wire slaves on success.
- `errno` – Negative error code on error.

int w1_configure(const struct device *dev, enum w1_settings_type type, uint32_t value)
Configure parameters of the 1-Wire master.

Allowed configuration parameters are defined in enum `w1_settings_type`, but master devices may not support all types.

Parameters
- `dev` – [in] Pointer to the device structure for the driver instance.
- `type` – Enum specifying the setting type.
- `value` – The new value for the passed settings type.

Return values
- 0 – If successful.
- `ENOTSUP` – The master doesn’t support the configuration of the supplied type.
- `EIO` – General input / output error, failed to configure master devices.

1-Wire ROM Commands

W1_CMD_SKIP_ROM

W1_CMD_MATCH_ROM

W1_CMD_RESUME

7.3. Peripherals
W1_CMD_READ_ROM

W1_CMD_SEARCH_ROM

W1_CMD_SEARCH_ALARM

W1_CMD_OVERDRIVE_SKIP_ROM

W1_CMD_OVERDRIVE_MATCH_ROM

**CRC Defines**

W1_CRC8_SEED
   Seed value used to calculate the 1-Wire 8-bit crc.

W1_CRC8_POLYNOMIAL
   Polynomial used to calculate the 1-Wire 8-bit crc.

W1_CRC16_SEED
   Seed value used to calculate the 1-Wire 16-bit crc.

W1_CRC16_POLYNOMIAL
   Polynomial used to calculate the 1-Wire 16-bit crc.

**Defines**

W1_SEARCH_ALL_FAMILIES
   This flag can be passed to searches in order to not filter on family ID.

W1_ROM_INIT_ZERO
   Initialize all `w1_rom` struct members to zero.

**Typedefs**

typedef void (*w1_search_callback_t)(struct w1_rom rom, void *user_data)
   Define the application callback handler function signature for searches.
   
   **Param rom**
   found The ROM of the found slave.

   **Param user_data**
   User data provided to the `w1_search_bus()` call.
Functions

```c
int w1_read_rom(const struct device *dev, struct w1_rom *rom)
```
Read Peripheral 64-bit ROM.

This procedure allows the 1-Wire bus master to read the peripherals' 64-bit ROM without using the Search ROM procedure. This command can be used as long as not more than a single peripheral is connected to the bus. Otherwise data collisions occur and a faulty ROM is read.

Parameters
- `dev` – [in] Pointer to the device structure for the driver instance.
- `rom` – [out] Pointer to the ROM structure.

Return values
- 0 – If successful.
- `ENOMEM` – In case no slave responds to reset.
- `errno` – Other negative error code in case of invalid crc and communication errors.

```c
int w1_match_rom(const struct device *dev, const struct w1_slave_config *config)
```
Select a specific slave by broadcasting a selected ROM.

This routine allows the 1-Wire bus master to select a slave identified by its unique ROM, such that the next command will target only this single selected slave.

This command is only necessary in multidrop environments, otherwise the Skip ROM command can be issued. Once a slave has been selected, to reduce the communication overhead, the resume command can be used instead of this command to communicate with the selected slave.

Parameters
- `dev` – [in] Pointer to the device structure for the driver instance.
- `config` – [in] Pointer to the slave specific 1-Wire config.

Return values
- 0 – If successful.
- `ENOMEM` – In case no slave responds to reset.
- `errno` – Other negative error code on error.

```c
int w1_resume_command(const struct device *dev)
```
Select the slave last addressed with a Match ROM or Search ROM command.

This routine allows the 1-Wire bus master to re-select a slave device that was already addressed using a Match ROM or Search ROM command.

Parameters
- `dev` – Pointer to the device structure for the driver instance.

Return values
- 0 – If successful.
- `ENOMEM` – In case no slave responds to reset.
- `errno` – Other negative error code on error.
int w1_skip_rom(const struct device *dev, const struct w1_slave_config *config)
Select all slaves regardless of ROM.

This routine sets up the bus slaves to receive a command. It is usually used when there is only one peripheral on the bus to avoid the overhead of the Match ROM command. But it can also be used to concurrently write to all slave devices.

Parameters
- dev – [in] Pointer to the device structure for the driver instance.
- config – [in] Pointer to the slave specific 1-Wire config.

Return values
- 0 – If successful.
- -ENODEV – In case no slave responds to reset.
- -errno – Other negative error code on error.

int w1_reset_select(const struct device *dev, const struct w1_slave_config *config)
In single drop configurations use Skip Select command, otherwise use Match ROM command.

Parameters
- dev – [in] Pointer to the device structure for the driver instance.
- config – [in] Pointer to the slave specific 1-Wire config.

Return values
- 0 – If successful.
- -ENODEV – In case no slave responds to reset.
- -errno – Other negative error code on error.

int w1_write_read(const struct device *dev, const struct w1_slave_config *config, const uint8_t *write_buf, size_t write_len, uint8_t *read_buf, size_t read_len)
Write then read data from the 1-Wire slave with matching ROM.

This routine uses w1_reset_select to select the given ROM. Then writes given data and reads the response back from the slave.

Parameters
- dev – [in] Pointer to the device structure for the driver instance.
- config – [in] Pointer to the slave specific 1-Wire config.
- write_buf – [in] Pointer to the data to be written.
- write_len – Number of bytes to write.
- read_buf – [out] Pointer to storage for read data.
- read_len – Number of bytes to read.

Return values
- 0 – If successful.
- -ENODEV – In case no slave responds to reset.
- -errno – Other negative error code on error.

int w1_search_bus(const struct device *dev, uint8_t command, uint8_t *family,
                  w1_search_callback_t callback, void *user_data)
Search 1-wire slaves on the bus.

This function searches slaves on the 1-wire bus, with the possibility to search either all slaves or only slaves that have an active alarm state. If a callback is passed, the callback is called for each found slave.

Note: Filtering on families is not supported.

**Parameters**

- `dev` – [in] Pointer to the device structure for the driver instance.
- `command` – Can either be W1_SEARCH_ALARM or W1_SEARCH_ROM.
- `family` – W1_SEARCH_ALL_FAMILIES searches all families, filtering on a specific family is not yet supported.
- `callback` – Application callback handler function to be called for each found slave.
- `user_data` – [in] User data to pass to the application callback handler function.

**Return values**

- `slave_count` – Number of slaves found.
- `-errno` – Negative error code on error.

```c
static inline int w1_search_rom(const struct device *dev, w1_search_callback_t callback, void *user_data)
```

Search for 1-Wire slave on bus.

This routine can discover unknown slaves on the bus by scanning for the unique 64-bit registration number.

**Parameters**

- `dev` – [in] Pointer to the device structure for the driver instance.
- `callback` – Application callback handler function to be called for each found slave.
- `user_data` – [in] User data to pass to the application callback handler function.

**Return values**

- `slave_count` – Number of slaves found.
- `-errno` – Negative error code on error.

```c
static inline int w1_search_alarm(const struct device *dev, w1_search_callback_t callback, void *user_data)
```

Search for 1-Wire slaves with an active alarm.

This routine searches 1-Wire slaves on the bus, which currently have an active alarm.

**Parameters**

- `dev` – [in] Pointer to the device structure for the driver instance.
- `callback` – Application callback handler function to be called for each found slave.
- `user_data` – [in] User data to pass to the application callback handler function.

**Return values**

- `slave_count` – Number of slaves found.
- ***-errno*** – Negative error code on error.

```c
static inline uint64_t w1_rom_to_uint64(const struct w1_rom *rom)
```

Function to convert a `w1_rom` struct to an `uint64_t`.

**Parameters**

- `rom` – [in] Pointer to the ROM struct.

**Return values**

- `rom64` – The ROM converted to an unsigned integer in endianness.

```c
static inline void w1_uint64_to_rom(const uint64_t rom64, struct w1_rom *rom)
```

Function to write an `uint64_t` to struct `w1_rom` pointer.

**Parameters**

- `rom64` – Unsigned 64 bit integer representing the ROM in host endianness.
- `rom` – [out] The ROM struct pointer.

```c
static inline uint8_t w1_crc8(const uint8_t *src, size_t len)
```

Compute CRC-8 checksum as defined in the 1-Wire specification.

The 1-Wire CRC 8 variant is using 0x31 as its polynomial with the initial value set to 0x00. This CRC is used to check the correctness of the unique 56-bit ROM.

**Parameters**

- `src` – [in] Input bytes for the computation.
- `len` – Length of the input in bytes.

**Return values**

- `crc` – The computed CRC8 value.

```c
static inline uint16_t w1_crc16(const uint16_t seed, const uint8_t *src, const size_t len)
```

Compute 1-Wire variant of CRC 16.

The 16-bit 1-Wire crc variant is using the reflected polynomial function X^16 + X^15 * + X^2 + 1 with the initial value set to 0x0000. See also APPLICATON NOTE 27: “UNDERSTANDING AND USING CYCLIC REDUNDANCY CHECKS WITH MAXIM 1-WIRE AND IBUTTON PRODUCTS” https://www.maximintegrated.com/en/design/technical-documents/app-notes/2/27.html

**Parameters**

- `seed` – Init value for the CRC, it is usually set to 0x0000.
- `src` – [in] Input bytes for the computation.
- `len` – Length of the input in bytes.

**Return values**

- `crc` – The computed CRC16 value.

```c
struct w1_rom
```

```c
#include <w1.h> w1_rom struct.
```

**Public Members**

```c
uint8_t family
```

The 1-Wire family code identifying the slave device type.

An incomplete list of family codes is available at: https://www.maximintegrated.com/en/app-notes/index.mvp/id/155 others are documented in the respective device data sheet.
uint8_t serial[6]
    The serial together with the family code composes the unique 56-bit id

uint8_t crc
    8-bit checksum of the 56-bit unique id.

struct w1_slave_config
    #include <w1.h> Node specific 1-wire configuration struct.
    This struct is passed to network functions, such that they can configure the bus to address the
    specific slave using the selected speed.

Public Members

struct w1_rom rom
    Unique 1-Wire ROM.

uint32_t overdrive
    overdrive speed is used if set to 1.

1-Wire generic functions and helpers  Functions that are not directly related to any of the networking
layers.

group w1_interface
    1-Wire Interface

Enums

defined w1_settings_type
    Defines the 1-Wire master settings types, which are runtime configurable.
    Values:

    enumerator W1_SETTING_SPEED
        Overdrive speed is enabled in case a value of 1 is passed and disabled passing 0.

    enumerator W1_SETTING_STRONG_PULLUP
        The strong pullup resistor is activated immediately after the next written data block by
        passing a value of 1, and deactivated passing 0.

    enumerator W1_SETTINGS_TYPE_COUNT
        Number of different settings types.

Functions
static inline int w1_lock_bus(const struct device *dev)
    Lock the 1-wire bus to prevent simultaneous access.

    This routine locks the bus to prevent simultaneous access from different threads. The calling
    thread waits until the bus becomes available. A thread is permitted to lock a mutex it has
    already locked.

    Parameters
    • dev – [in] Pointer to the device structure for the driver instance.

    Return values
    • 0 – If successful.
    • -errno – Negative error code on error.

static inline int w1_unlock_bus(const struct device *dev)
    Unlock the 1-wire bus.

    This routine unlocks the bus to permit access to bus line.

    Parameters
    • dev – [in] Pointer to the device structure for the driver instance.

    Return values
    • 0 – If successful.
    • -errno – Negative error code on error.

7.4 Pin Control

This is a high-level guide to pin control. See Pin Control API for API reference material.

7.4.1 Introduction

The hardware blocks that control pin multiplexing and pin configuration parameters such as pin direc-
tion, pull-up/down resistors, etc. are named pin controllers. The pin controller's main users are SoC
hardware peripherals, since the controller enables exposing peripheral signals, like for example, map
I2C0 SDA signal to pin PX0. Not only that, but it usually allows configuring certain pin settings that
are necessary for the correct functioning of a peripheral, for example, the slew-rate depending on the
operating frequency. The available configuration options are vendor/SoC dependent and can range from
simple pull-up/down options to more advanced settings such as debouncing, low-power modes, etc.

The way pin control is implemented in hardware is vendor/SoC specific. It is common to find a centralized
approach, that is, all pin configuration parameters are controlled by a single hardware block (typically
named pinmux), including signal mapping. Fig. 7.2 illustrates this approach. PX0 can be mapped to
UART0_TX, I2C0_SCK or SPI0_MOSI depending on the AF control bits. Other configuration parameters
such as pull-up/down are controlled in the same block via CONFIG bits. This model is used by several
SoC families, such as many from NXP and STM32.

Other vendors/SoCs use a distributed approach. In such case, the pin mapping and configuration are
controlled by multiple hardware blocks. Fig. 7.3 illustrates a distributed approach where pin mapping is
controlled by peripherals, such as in Nordic nRF SoCs.

From a user perspective, there is no difference in pin controller usage regardless of the hardware imple-
mentation: a user will always apply a state. The only difference lies in the driver implementation. In
general, implementing a pin controller driver for a hardware that uses a distributed approach requires
more effort, since the driver needs to gather knowledge of peripheral dependent registers.
Fig. 7.2: Example of pin control centralized into a single per-pin block

Fig. 7.3: Example pin control distributed between peripheral registers and per-pin block
Pin control vs. GPIO

Some functionality covered by a pin controller driver overlaps with GPIO drivers. For example, pull-up/down resistors can usually be enabled by both the pin control driver and the GPIO driver. In Zephyr context, the pin control driver purpose is to perform peripheral signal multiplexing and configuration of other pin parameters required for the correct operation of that peripheral. Therefore, the main users of the pin control driver are SoC peripherals. In contrast, GPIO drivers are for general purpose control of a pin, that is, when its logic level is read or controlled manually.

7.4.2 State model

For a device driver to operate correctly, a certain pin configuration needs to be applied. Some device drivers require a static configuration, usually set up at initialization time. Others need to change the configuration at runtime depending on the operating conditions, for example, to enable a low-power mode when suspending the device. Such requirements are modeled using states, a concept that has been adapted from the one in the Linux kernel. Each device driver owns a set of states. Each state has a unique name and contains a full pin configuration set (see Table 7.1). This effectively means that states are independent of each other, so they do not need to be applied in any specific order. Another advantage of the state model is that it isolates device drivers from pin configuration.

Table 7.1: Example pin configuration encoded using the states model

<table>
<thead>
<tr>
<th>UART0 peripheral</th>
<th>default state</th>
<th>sleep state</th>
</tr>
</thead>
<tbody>
<tr>
<td>TX</td>
<td>• Pin: PA0</td>
<td>• Pin: PA0</td>
</tr>
<tr>
<td></td>
<td>• Pull: NONE</td>
<td>• Pull: NONE</td>
</tr>
<tr>
<td></td>
<td>• Low Power: NO</td>
<td>• Low Power: YES</td>
</tr>
<tr>
<td>RX</td>
<td>• Pin: PA1</td>
<td>• Pin: PA1</td>
</tr>
<tr>
<td></td>
<td>• Pull: UP</td>
<td>• Pull: NONE</td>
</tr>
<tr>
<td></td>
<td>• Low Power: NO</td>
<td>• Low Power: YES</td>
</tr>
</tbody>
</table>

Standard states

The name assigned to pin control states or the number of them is up to the device driver requirements. In many cases a single state applied at initialization time will be sufficient, but in some other cases more will be required. In order to make things consistent, a naming convention has been established for the most common use cases. Table 7.2 details the standardized states and its purpose.

Table 7.2: Standardized state names

<table>
<thead>
<tr>
<th>State</th>
<th>Identifier</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>PINCTRL_STATE_DEFAULT</td>
<td>State of the pins when the device is in operational state</td>
</tr>
<tr>
<td>sleep</td>
<td>PINCTRL_STATE_SLEEP</td>
<td>State of the pins when the device is in low power or sleep modes</td>
</tr>
</tbody>
</table>

Note that other standard states could be introduced in the future.

Custom states

Some device drivers may require using custom states beyond the standard ones. To achieve that, the device driver needs to have in its scope definitions for the custom state identifiers named as
PINCTRL_STATE_{STATE_NAME}, where {STATE_NAME} is the capitalized state name. For example, if mystate has to be supported, a definition named PINCTRL_STATE_MYSTATE needs to be in the driver’s scope.

**Note:** It is important that custom state identifiers start from PINCTRL_STATE_PRIV_START

If custom states need to be accessed from outside the driver, for example to perform dynamic pin control, custom identifiers should be placed in a header that is publicly accessible.

**Skipping states**

In most situations, the states defined in Devicetree will be the ones used in the compiled firmware. However, there are some cases where certain states will be conditionally used depending on a compilation flag. A typical case is the sleep state. This state is only used in practice if CONFIG_PM_DEVICE is enabled. If a firmware variant without device power management is needed, one should in theory remove the sleep state from Devicetree to not waste ROM space storing such unused state.

States can be skipped by the pinctrl Devicetree macros if a definition named PINCTRL_SKIP_{STATE_NAME} expanding to 1 is present when pin control configuration is defined. In case of the sleep state, the pinctrl API already provides such definition conditional to the availability of device power management:

```c
#ifndef CONFIG_PM_DEVICE
/** If device power management is not enabled, "sleep" state will be ignored. */
#define PINCTRL_SKIP_SLEEP 1
#endif
```

### 7.4.3 Dynamic pin control

Dynamic pin control refers to the capability of changing pin configuration at runtime. This feature can be useful in situations where the same firmware needs to run onto slightly different boards, each having a peripheral routed at a different set of pins. This feature can be enabled by setting CONFIG_PINCTRL_DYNAMIC.

**Note:** Dynamic pin control should only be used on devices that have not been initialized. Changing pin configurations while a device is operating may lead to unexpected behavior. Since Zephyr does not support device de-initialization yet, this functionality should only be used during early boot stages.

One of the effects of enabling dynamic pin control is that pinctrl_dev_config will be stored in RAM instead of ROM (not states or pin configurations, though). The user can then use pinctrl_update_states() to update the states stored in pinctrl_dev_config with a new set. This effectively means that the device driver will apply the pin configurations stored in the updated states when it applies a state.

### 7.4.4 Devicetree representation

Because Devicetree is meant to describe hardware, it is the natural choice when it comes to storing pin control configuration. In the following sections you will find an overview on how states and pin configurations are represented in Devicetree.
States

Given a device, each of its pin control state is represented in Devicetree by \texttt{pinctrl-N} properties, being \texttt{N} the state index starting from zero. The \texttt{pinctrl-names} property is then used to assign a unique identifier for each state property by index, for example, \texttt{pinctrl-names list entry 0 is the name for pinctrl-0}.

\begin{verbatim}
periph0: periph00 {
    /* state 0 ("default") */
    pinctrl-0 = <...>;
    /* state \texttt{N} ("mystate") */
    pinctrl-N = <...>;
    /* names for state 0 up to state \texttt{N} */
    pinctrl-names = "default", ..., "mystate";
    ...
};
\end{verbatim}

Pin configuration

There are multiple ways to represent the pin configurations in Devicetree. However, all end up encoding the same information: the pin multiplexing and the pin configuration parameters. For example, UART\_RX is mapped to PX0 and pull-up is enabled. The representation choice largely depends on each vendor/SoC, so the Devicetree binding files for the pin control drivers are the best place to look for details.

A popular and versatile option is shown in the example below. One of the advantages of this choice is the grouping capability based on shared pin configuration. This allows to reduce the verbosity of the pin control definitions. Another advantage is that the pin configuration parameters for a particular state are enclosed in a single Devicetree node.

\begin{verbatim}
/* board.dts */
#include "board-pinctrl.dtsi"

&periph0 {
    pinctrl-0 = <&periph0_default>;
    pinctrl-names = "default";
};

/* vnd-soc-pkgxx.h
* File with valid mappings for a specific package (may be autogenerated).
* This file is optional, but recommended.
*/
...
#define PERIPH0_SIGA_PX0 VNDSOC_PIN(X, 0, MUX0)
#define PERIPH0_SIGB_PY7 VNDSOC_PIN(Y, 7, MUX4)
#define PERIPH0_SIGC_PZ1 VNDSOC_PIN(Z, 1, MUX2)
...

/* board-pinctrl.dtsi */
#include <vnd-soc-pkgxx.h>

&pinctrl {
    /* Node with pin configuration for default state */
    periph0_default: periph0_default {
        group1 {
            /* Mappings: PERIPH0_SIGA -> PX0, PERIPH0_SIGC -> PZ1 */
        }
    }
};
\end{verbatim}
Another popular model is based on having a node for each pin configuration and state. While this model may lead to shorter board pin control files, it also requires to have one node for each pin mapping and state, since in general, nodes can not be re-used for multiple states. This method is discouraged if autogeneration is not an option.

**Note:** Because all Devicetree information is parsed into a C header, it is important to make sure its size is kept to a minimum. For this reason it is important to prefix pre-generated nodes with `/omit-if-no-ref/`. This prefix makes sure that the node is discarded when not used.

```c
/* board.dts */
#include "board-pinctrl.dtsi"

&periph0 {
    pinctrl-0 = <&periph0_siga_px0_default &periph0_sigb_py7_default &periph0_sigc_pz1_default>;
    pinctrl-names = "default";
};

/* vnd-soc-pkgxx.dtsi
* File with valid nodes for a specific package (may be autogenerated).
* This file is optional, but recommended.
*/
&pinctrl {
    /* Mapping for PERIPH0_SIGA -> PX0, to be used for default state */
    /omit-if-no-ref/ periph0_siga_px0_default: periph0_siga_px0_default {
        pinmux = <VNDSOC_PIN(X, 0, MUX0)>;
    };

    /* Mapping for PERIPH0_SIGB -> PY7, to be used for default state */
    /omit-if-no-ref/ periph0_sigb_py7_default: periph0_sigb_py7_default {
        pinmux = <VNDSOC_PIN(Y, 7, MUX4)>;
    };

    /* Mapping for PERIPH0_SIGC -> PZ1, to be used for default state */
    /omit-if-no-ref/ periph0_sigc_pz1_default: periph0_sigc_pz1_default {
        pinmux = <VNDSOC_PIN(Z, 1, MUX2)>;
    };
};
/* board-pinctrl.dts */
#include <vnd-soc-pkgxx.dtsi>
```
/* Enable pull-up for PX0 (default state) */
&periph0_siga_px0_default {
    bias-pull-up;
};

/* Enable pull-up for PZ1 (default state) */
&periph0_sigc_pz1_default {
    bias-pull-up;
};

**Note:** It is discouraged to add pin configuration defaults in pre-defined nodes. In general, pin configurations depend on the board design or on the peripheral working conditions, so the decision should be made by the board. For example, enabling a pull-up by default may not always be desired because the board already has one or because its value depends on the operating bus speed. Another downside of defaults is that user may not be aware of them, for example:

/* not evident that "periph0_siga_px0_default" also implies "bias-pull-up" */
/omit-if-no-ref/ periph0_siga_px0_default: periph0_siga_px0_default {
    pinmux = <VNDSOC_PIN(X, 0, MUX0)>;
    bias-pull-up;
};

### 7.4.5 Implementation guidelines

**Pin control drivers**

Pin control drivers need to implement a single function: `pinctrl_configure_pins()`. This function receives an array of pin configurations that need to be applied. Furthermore, if `CONFIG_PINCTRL_STORE_REG` is set, it also receives the associated device register address for the given pins. This information may be required by some drivers to perform device specific actions.

The pin configuration is stored in an opaque type that is vendor/SoC dependent: `pinctrl_soc_pin_t`. This type needs to be defined in a header named `pinctrl_soc.h` file that is in the Zephyr's include path. It can range from a simple integer value to a struct with multiple fields. `pinctrl_soc.h` also needs to define a macro named `Z_PINCTRL_STATE_PINS_INIT` that accepts two arguments: a node identifier and a property name (`pinctrl-N`). With this information the macro needs to define an initializer for all pin configurations contained within the `pinctrl-N` property of the given node.

Regarding Devicetree pin configuration representation, vendors can decide which option is better for their devices. However, the following guidelines should be followed:

- Use `pinctrl-N (N=0, 1, ...)` and `pinctrl-names` properties to define pin control states. These properties are defined in `dts/bindings/pinctrl/pinctrl-device.yaml`.
- Use standard pin configuration properties as defined in `dts/bindings/pinctrl/pincfg-node.yaml`.

Representations not following these guidelines may be accepted if they are already used by the same vendor in other operating systems, e.g. Linux.

**Device drivers**

In this section you will find some tips on how a device driver should use the `pinctrl` API to successfully configure the pins it needs.
The device compatible needs to be modified in the corresponding binding so that the pinctrl-device.yaml is included. For example:

```yaml
include: [base.yaml, pinctrl-device.yaml]
```

This file is needed to add pinctrl-N and pinctrl-names properties to the device.

From a device driver perspective there are two steps that need to be performed to be able to use the pinctrl API. First, the pin control configuration needs to be defined. This includes all states and pins. `PINCTRL_DT_DEFINE` or `PINCTRL_DT_INST_DEFINE` macros should be used for this purpose. Second, a reference to the device instance `pinctrl_dev_config` needs to be stored, since it is required to later use the API. This can be achieved using the `PINCTRL_DT_DEV_CONFIG_GET` and `PINCTRL_DT_INST_DEV_CONFIG_GET` macros.

It is worth to note that the only relationship between a device and its associated pin control configuration is based on variable naming conventions. The way an instance of `pinctrl_dev_config` is named for a corresponding device instance allows to later obtain a reference to it given the device’s Devicetree node identifier. This allows to minimize ROM usage, since only devices requiring pin control will own a reference to a pin control configuration.

Once the driver has defined the pin control configuration and kept a reference to it, it is ready to use the API. The most common way to apply a state is by using `pinctrl_apply_state()`. It is also possible to use the lower level function `pinctrl_apply_state_direct()` to skip state lookup if it is cached in advance (e.g. at init time). Since state lookup time is expected to be fast, it is recommended to use `pinctrl_apply_state()`.

The example below contains a complete example of a device driver that uses the pinctrl API.

```c
/* A driver for the "mydev" compatible device */
#define DT_DRV_COMPAT mydev

... #include <zephyr/drivers/pinctrl.h>
...

struct mydev_config {
    ...
    /* Reference to mydev pinctrl configuration */
    const struct pinctrl_dev_config *pcfg;
    ...
};

...

static int mydev_init(const struct device *dev)
{
    const struct mydev_config *config = dev->config;
    int ret;
    ...
    /* Select "default" state at initialization time */
    ret = pinctrl_apply_state(config->pcfg, PINCTRL_STATE_DEFAULT);
    if (ret < 0) {
        return ret;
    }
    ...
}

#define MYDEV_DEFINE(i) 
/* Define all pinctrl configuration for instance "i" */ 
PINCTRL_DT_INST_DEFINE(i);
(continues on next page)
```

7.4. Pin Control
7.4.6 Pin Control API

**group pinctrl_interface**

Pin Controller Interface.

**Pin control states**

- **PINCTRL_STATE_DEFAULT**
  
  Default state (state used when the device is in operational state).

- **PINCTRL_STATE_SLEEP**
  
  Sleep state (state used when the device is in low power mode).

- **PINCTRL_STATE_PRIV_START**
  
  This and higher values refer to custom private states.

**Defines**

- **PINCTRL_REG_NONE**
  
  Utility macro to indicate no register is used.

- **PINCTRL_DT_DEV_CONFIG_DECLARE(node_id)**
  
  Declare pin control configuration for a given node identifier.

  This macro should be used by tests or applications using runtime pin control to declare the pin control configuration for a device. **PINCTRL_DT_DEV_CONFIG_GET** can later be used to obtain a reference to such configuration.

  Only available if CONFIG_PINCTRL_NON_STATIC is selected.

**Parameters**

- **node_id** – Node identifier.
PINCTRL_DT_DEFINE(node_id)
Define all pin control information for the given node identifier.

This helper macro should be called together with device definition. It defines and initializes
the pin control configuration for the device represented by node_id. Each pin control state
(pinctrl-0, ..., pinctrl-N) is also defined and initialized. Note that states marked to be skipped
will not be defined (refer to Z_PINCTRL_SKIP_STATE for more details).

Parameters
• node_id – Node identifier.

PINCTRL_DT_INST_DEFINE(inst)
Define all pin control information for the given compatible index.

See also:
PINCTRL_DT_DEFINE

Parameters
• inst – Instance number.

PINCTRL_DT_DEV_CONFIG_GET(node_id)
Obtain a reference to the pin control configuration given a node identifier.

Parameters
• node_id – Node identifier.

PINCTRL_DT_INST_DEV_CONFIG_GET(inst)
Obtain a reference to the pin control configuration given current compatible instance number.

See also:
PINCTRL_DT_DEV_CONFIG_GET

Parameters
• inst – Instance number.

Functions

int pinctrl_lookup_state(const struct pinctrl_dev_config *config, uint8_t id, const struct
pinctrl_state **state)
Find the state configuration for the given state id.

Parameters
• config – Pin controller configuration.
• id – Pin controller state id (see PINCTRL_STATES).
• state – Found state.

Return values
• 0 – If state has been found.
• -ENOENT – If the state has not been found.
int pinctrl_configure_pins(const pinctrl_soc_pin_t *pins, uint8_t pin_cnt, uintptr_t reg)
Configure a set of pins.
This function will configure the necessary hardware blocks to make the configuration immediately effective.

**Warning:** This function must never be used to configure pins used by an instantiated device driver.

**Parameters**
- `pins` – List of pins to be configured.
- `pin_cnt` – Number of pins.
- `reg` – Device register (optional, use PINCTRL_REG_NONE if not used).

**Return values**
- `0` – If succeeded
- `-errno` – Negative errno for other failures.

static inline int pinctrl_apply_state_direct(const struct pinctrl_dev_config *config, const struct pinctrl_state *state)
Apply a state directly from the provided state configuration.

**Parameters**
- `config` – Pin control configuration.
- `state` – State.

**Return values**
- `0` – If succeeded
- `-errno` – Negative errno for other failures.

static inline int pinctrl_apply_state(const struct pinctrl_dev_config *config, uint8_t id)
Apply a state from the given device configuration.

**Parameters**
- `config` – Pin control configuration.
- `id` – Id of the state to be applied (see PINCTRL_STATES).

**Return values**
- `0` – If succeeded.
- `-ENOTENT` – If given state id does not exist.
- `-errno` – Negative errno for other failures.

**Public Members**

```c
const pinctrl_soc_pin_t *pins
Pin configurations.
```
typedef uint8_t pin_cnt

Number of pin configurations.

typedef uint8_t id

State identifier (see PINCTRL_STATES).

struct pinctrl_dev_config

#include <pinctrl.h> Pin controller configuration for a given device.

Public Members

typedef uintptr_t reg

Device address (only available if CONFIG_PINCTRL_STORE_REG is enabled).

typedef const struct pinctrl_state *states

List of state configurations.

typedef uint8_t state_cnt

Number of state configurations.

Dynamic pin control

group pinctrl_interface_dynamic

Defines

PINCTRL_DT_STATE_PINS_DEFINE(node_id, prop)

Helper macro to define the pins of a pin control state from Devicetree.

The name of the defined state pins variable is the same used by prop. This macro is expected to be used in conjunction with PINCTRL_DT_STATE_INIT.

See also:

PINCTRL_DT_STATE_INIT

Parameters

• node_id – Node identifier containing prop.
• prop – Property within node_id containing state configuration.

PINCTRL_DT_STATE_INIT(prop, state)

Utility macro to initialize a pin control state.

This macro should be used in conjunction with PINCTRL_DT_STATE_PINS_DEFINE when using dynamic pin control to define an alternative state configuration stored in Devicetree.

Example:
// board.dts
/
{
    zephyr, user {
        // uart0_alt_default node contains alternative pin config
        uart0_alt_default = <&uart0_alt_default>;
    }
};

// application
PINCTRL_DT_STATE_PINS_DEFINE(DT_PATH(zephyr_user), uart0_alt_default);

static const struct pinctrl_state uart0_alt[] = {
    PINCTRL_DT_STATE_INIT(uart0_alt_default, PINCTRL_STATE_DEFAULT)
};

See also:

PINCTRL_DT_STATE_PINS_DEFINE

Parameters

• prop – Property name in Devicetree containing state configuration.
• state – State represented by prop (see PINCTRL_STATES).

Functions

int pinctrl_update_states(struct pinctrl_dev_config *config, const struct pinctrl_state *states, uint8_t state_cnt)

Update states with a new set.

Note: In order to guarantee device drivers correct operation the same states have to be provided. For example, if default and sleep are in the current list of states, it is expected that the new array of states also contains both.

Parameters

• config – Pin control configuration.
• states – New states to be set.
• state_cnt – Number of new states to be set.

Return values

• -EINVAL – If the new configuration does not contain the same states as the current active configuration.
• -ENOSYS – If the functionality is not available.
• 0 – On success.

7.5 Porting

These pages document how to port Zephyr to new hardware.

7.5.1 Architecture Porting Guide

An architecture port is needed to enable Zephyr to run on an ISA (instruction set architecture) or an ABI (Application Binary Interface) that is not currently supported.

The following are examples of ISAs and ABIs that Zephyr supports:

- x86_32 ISA with System V ABI
- ARMv7-M ISA with Thumb2 instruction set and ARM Embedded ABI (aeabi)
- ARCv2 ISA

For information on Kconfig configuration, see Setting Kconfig configuration values. Architectures use a Kconfig configuration scheme similar to boards.

An architecture port can be divided in several parts; most are required and some are optional:

- **The early boot sequence**: each architecture has different steps it must take when the CPU comes out of reset (required).
- **Interrupt and exception handling**: each architecture handles asynchronous and unrequested events in a specific manner (required).
- **Thread context switching**: the Zephyr context switch is dependent on the ABI and each ISA has a different set of registers to save (required).
- **Thread creation and termination**: a thread’s initial stack frame is ABI and architecture-dependent, and thread abortion possibly as well (required).
- **Device drivers**: most often, the system clock timer and the interrupt controller are tied to the architecture (some required, some optional).
- **Utility libraries**: some common kernel APIs rely on a architecture-specific implementation for performance reasons (required).
- **CPU idling/power management**: most architectures implement instructions for putting the CPU to sleep (partly optional, most likely very desired).
- **Fault management**: for implementing architecture-specific debug help and handling of fatal error in threads (partly optional).
- **Linker scripts and toolchains**: architecture-specific details will most likely be needed in the build system and when linking the image (required).

**Early Boot Sequence**

The goal of the early boot sequence is to take the system from the state it is after reset to a state where it can run C code and thus the common kernel initialization sequence. Most of the time, very few steps are needed, while some architectures require a bit more work to be performed.

Common steps for all architectures:

- Setup an initial stack.
• If running an XIP (eXecute-In-Place) kernel, copy initialized data from ROM to RAM.
• If not using an ELF loader, zero the BSS section.
• Jump to _Cstart(), the early kernel initialization
  – _Cstart() is responsible for context switching out of the fake context running at startup into the main thread.

Some examples of architecture-specific steps that have to be taken:
• If given control in real mode on x86_32, switch to 32-bit protected mode.
• Setup the segment registers on x86_32 to handle boot loaders that leave them in an unknown or broken state.
• Initialize a board-specific watchdog on Cortex-M3/4.
• Switch stacks from MSP to PSP on Cortex-M.
• Use a different approach than calling into _Swap() on Cortex-M to prevent race conditions.
• Setup FIRQ and regular IRQ handling on ARCv2.

Interrupt and Exception Handling

Each architecture defines interrupt and exception handling differently.

When a device wants to signal the processor that there is some work to be done on its behalf, it raises an interrupt. When a thread does an operation that is not handled by the serial flow of the software itself, it raises an exception. Both, interrupts and exceptions, pass control to a handler. The handler is known as an ISR (Interrupt Service Routine) in the case of interrupts. The handler performs the work required by the exception or the interrupt. For interrupts, that work is device-specific. For exceptions, it depends on the exception, but most often the core kernel itself is responsible for providing the handler.

The kernel has to perform some work in addition to the work the handler itself performs. For example:
• Prior to handing control to the handler:
  – Save the currently executing context.
  – Possibly getting out of power saving mode, which includes waking up devices.
  – Updating the kernel uptime if getting out of tickless idle mode.
• After getting control back from the handler:
  – Decide whether to perform a context switch.
  – When performing a context switch, restore the context being context switched in.

This work is conceptually the same across architectures, but the details are completely different:
• The registers to save and restore.
• The processor instructions to perform the work.
• The numbering of the exceptions.
• etc.

It thus needs an architecture-specific implementation, called the interrupt/exception stub.

Another issue is that the kernel defines the signature of ISRs as:

```c
void (*isr)(void *parameter)
```

Architectures do not have a consistent or native way of handling parameters to an ISR. As such there are two commonly used methods for handling the parameter.
Using some architecture defined mechanism, the parameter value is forced in the stub. This is commonly found in X86-based architectures.

The parameters to the ISR are inserted and tracked via a separate table requiring the architecture to discover at runtime which interrupt is executing. A common interrupt handler demuxer is installed for all entries of the real interrupt vector table, which then fetches the device's ISR and parameter from the separate table. This approach is commonly used in the ARC and ARM architectures via the CONFIG_GEN_ISR_TABLES implementation. You can find examples of the stubs by looking at _interrupt_enter() in x86, _IntExit() in ARM, _isr_wrapper() in ARM, or the full implementation description for ARC in arch/arc/core/isr_wrapper.S.

Each architecture also has to implement primitives for interrupt control:

- locking interrupts: irq_lock(), irq_unlock().
- registering interrupts: IRQ_CONNECT().
- programming the priority if possible irq_priority_set().
- enabling/disabling interrupts: irq_enable(), irq_disable().

Note: IRQ_CONNECT is a macro that uses assembler and/or linker script tricks to connect interrupts at build time, saving boot time and text size.

The vector table should contain a handler for each interrupt and exception that can possibly occur. The handler can be as simple as a spinning loop. However, we strongly suggest that handlers at least print some debug information. The information helps figuring out what went wrong when hitting an exception that is a fault, like divide-by-zero or invalid memory access, or an interrupt that is not expected (spurious interrupt). See the ARM implementation in arch/arm/core/aarch32/cortex_m/fault.c for an example.

Thread Context Switching

Multi-threading is the basic purpose to have a kernel at all. Zephyr supports two types of threads: preemptible and cooperative.

Two crucial concepts when writing an architecture port are the following:

- Cooperative threads run at a higher priority than preemptible ones, and always preempt them.
- After handling an interrupt, if a cooperative thread was interrupted, the kernel always goes back to running that thread, since it is not preemptible.

A context switch can happen in several circumstances:

- When a thread executes a blocking operation, such as taking a semaphore that is currently unavailable.
- When a preemptible thread unblocks a thread of higher priority by releasing the object on which it was blocked.
- When an interrupt unblocks a thread of higher priority than the one currently executing, if the currently executing thread is preemptible.
- When a thread runs to completion.
- When a thread causes a fatal exception and is removed from the running threads. For example, referencing invalid memory,

Therefore, the context switching must thus be able to handle all these cases.

The kernel keeps the next thread to run in a “cache”, and thus the context switching code only has to fetch from that cache to select which thread to run.

There are two types of context switches: cooperative and preemptive.
A cooperative context switch happens when a thread willfully gives the control to another thread. There are two cases where this happens:
- When a thread explicitly yields.
- When a thread tries to take an object that is currently unavailable and is willing to wait until the object becomes available.

A preemptive context switch happens either because an ISR or a thread causes an operation that schedules a thread of higher priority than the one currently running, if the currently running thread is preemptible. An example of such an operation is releasing an object on which the thread of higher priority was waiting.

**Note:** Control is never taken from cooperative thread when one of them is the running thread.

A cooperative context switch is always done by having a thread call the `_Swap()` kernel internal symbol. When `_Swap` is called, the kernel logic knows that a context switch has to happen: `_Swap` does not check to see if a context switch must happen. Rather, `_Swap` decides what thread to context switch in. `_Swap` is called by the kernel logic when an object being operated on is unavailable, and some thread yielding/sleeping primitives.

**Note:** On x86 and Nios2, `_Swap` is generic enough and the architecture flexible enough that `_Swap` can be called when exiting an interrupt to provoke the context switch. This should not be taken as a rule, since neither the ARM Cortex-M or ARCv2 port do this.

Since `_Swap` is cooperative, the caller-saved registers from the ABI are already on the stack. There is no need to save them in the `k_thread` structure.

A context switch can also be performed preemptively. This happens upon exiting an ISR, in the kernel interrupt exit stub:
- `_interrupt_enter` on x86 after the handler is called.
- `_IntExit` on ARM.
- `_firq_exit` and `_rirq_exit` on ARCv2.

In this case, the context switch must only be invoked when the interrupted thread was preemptible, not when it was a cooperative one, and only when the current interrupt is not nested.

The kernel also has the concept of “locking the scheduler”. This is a concept similar to locking the interrupts, but lighter-weight since interrupts can still occur. If a thread has locked the scheduler, is it temporarily non-preemptible.

So, the decision logic to invoke the context switch when exiting an interrupt is simple:
- If the interrupted thread is not preemptible, do not invoke it.
- Else, fetch the cached thread from the ready queue, and:
  - If the cached thread is not the current thread, invoke the context switch.
  - Else, do not invoke it.

This is simple, but crucial: if this is not implemented correctly, the kernel will not function as intended and will experience bizarre crashes, mostly due to stack corruption.

**Note:** If running a coop-only system, i.e. if `CONFIG_NUM_PREEMPT_PRIORITIES` is 0, no preemptive context switch ever happens. The interrupt code can be optimized to not take any scheduling decision when this is the case.
Thread Creation and Termination

To start a new thread, a stack frame must be constructed so that the context switch can pop it the same way it would pop one from a thread that had been context switched out. This is to be implemented in an architecture-specific _new_thread internal routine.

The thread entry point is also not to be called directly, i.e. it should not be set as the PC (program counter) for the new thread. Rather it must be wrapped in _thread_entry. This means that the PC in the stack frame shall be set to _thread_entry, and the thread entry point shall be passed as the first parameter to _thread_entry. The specifics of this depend on the ABI.

The need for an architecture-specific thread termination implementation depends on the architecture. There is a generic implementation, but it might not work for a given architecture.

One reason that has been encountered for having an architecture-specific implementation of thread termination is that aborting a thread might be different if aborting because of a graceful exit or because of an exception. This is the case for ARM Cortex-M, where the CPU has to be taken out of handler mode if the thread triggered a fatal exception, but not if the thread gracefully exits its entry point function.

This means implementing an architecture-specific version of k_thread_abort(), and setting the Kconfig option CONFIG_ARCH_HAS_THREAD_ABORT as needed for the architecture (e.g. see arch/arm/core/aarch32/cortex_m/Kconfig).

Thread Local Storage

To enable thread local storage on a new architecture:

1. Implement arch_tls_stack_setup() to setup the TLS storage area in stack. Refer to the toolchain documentation on how the storage area needs to be structured. Some helper functions can be used:
   - Function z_tls_data_size() returns the size needed for thread local variables (excluding any extra data required by toolchain and architecture).
   - Function z_tls_copy() prepares the TLS storage area for thread local variables. This only copies the variable themselves and does not do architecture and/or toolchain specific data.
2. In the context switching, grab the tls field inside the new thread's struct k_thread and put it into an appropriate register (or some other variable) for access to the TLS storage area. Refer to toolchain and architecture documentation on which registers to use.
3. In kconfig, add select CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE to kconfig related to the new architecture.
4. Run the tests/kernel/threads/tls to make sure the new code works.

Device Drivers

The kernel requires very few hardware devices to function. In theory, the only required device is the interrupt controller, since the kernel can run without a system clock. In practice, to get access to most, if not all, of the sanity check test suite, a system clock is needed as well. Since these two are usually tied to the architecture, they are part of the architecture port.

Interrupt Controllers There can be significant differences between the interrupt controllers and the interrupt concepts across architectures.

For example, x86 has the concept of an IDT and different interrupt controllers. The position of an interrupt in the IDT determines its priority.

On the other hand, the ARM Cortex-M has the NVIC (Nested Vectored Interrupt Controller) as part of the architecture definition. There is no need for an IDT-like table that is separate from the NVIC vector.
The position in the table has nothing to do with priority of an IRQ: priorities are programmable per-entry.

The ARCv2 has its interrupt unit as part of the architecture definition, which is somewhat similar to the NVIC. However, where ARC defines interrupts as having a one-to-one mapping between exception and interrupt numbers (i.e. exception 1 is IRQ1, and device IRQs start at 16), ARM has IRQ0 being equivalent to exception 16 (and weirdly enough, exception 1 can be seen as IRQ-15).

All these differences mean that very little, if anything, can be shared between architectures with regards to interrupt controllers.

**System Clock**

x86 has APIC timers and the HPET as part of its architecture definition. ARM Cortex-M has the SYSTICK exception. Finally, ARCv2 has the timer0/1 device.

Kernel timeouts are handled in the context of the system clock timer driver's interrupt handler.

**Console Over Serial Line**

There is one other device that is almost a requirement for an architecture port, since it is so useful for debugging. It is a simple polling, output-only, serial port driver on which to send the console (printf) output.

It is not required, and a RAM console (CONFIG_RAM_CONSOLE) can be used to send all output to a circular buffer that can be read by a debugger instead.

**Utility Libraries**

The kernel depends on a few functions that can be implemented with very few instructions or in a lockless manner in modern processors. Those are thus expected to be implemented as part of an architecture port.

- **Atomic operators.**
  - If instructions do exist for a given architecture, the implementation is configured using the CONFIG_ATOMIC_OPERATIONS_ARCH Kconfig option.
  - If instructions do not exist for a given architecture, a generic version that wraps irq_lock() or irq_unlock() around non-atomic operations exists. It is configured using the CONFIG_ATOMIC_OPERATIONS_C Kconfig option.

- **Find-least-significant-bit-set and find-most-significant-bit-set.**
  - If instructions do not exist for a given architecture, it is always possible to implement these functions as generic C functions.

It is possible to use compiler built-ins to implement these, but be careful they use the required compiler barriers.

**CPU Idling/Power Management**

The kernel provides support for CPU power management with two functions: arch_cpu_idle() and arch_cpu_atomic_idle().

arch_cpu_idle() can be as simple as calling the power saving instruction for the architecture with interrupts unlocked, for example hlt on x86, wfi or wfe on ARM, sleep on ARC. This function can be called in a loop within a context that does not care if it get interrupted or not by an interrupt before going to sleep. There are basically two scenarios when it is correct to use this function:

- In a single-threaded system, in the only thread when the thread is not used for doing real work after initialization, i.e. it is sitting in a loop doing nothing for the duration of the application.
- In the idle thread.
`arch_cpu_atomic_idle()` on the other hand, must be able to atomically re-enable interrupts and invoke the power saving instruction. It can thus be used in real application code, again in single-threaded systems.

Normally, idling the CPU should be left to the idle thread, but in some very special scenarios, these APIs can be used by applications.

Both functions must exist for a given architecture. However, the implementation can be simply the following steps, if desired:

1. unlock interrupts
2. NOP

However, a real implementation is strongly recommended.

Fault Management

In the event of an unhandled CPU exception, the architecture code must call into `z_fatal_error()`. This function dumps out architecture-agnostic information and makes a policy decision on what to do next by invoking `k_sys_fatal_error()`. This function can be overridden to implement application-specific policies that could include locking interrupts and spinning forever (the default implementation) or even powering off the system (if supported).

Toolchain and Linking

Toolchain support has to be added to the build system.

Some architecture-specific definitions are needed in include/zephyr/toolchain/gcc.h. See what exists in that file for currently supported architectures.

Each architecture also needs its own linker script, even if most sections can be derived from the linker scripts of other architectures. Some sections might be specific to the new architecture, for example the SCB section on ARM and the IDT section on x86.

Memory Management

If the target platform enables paging and requires drivers to memory-map their I/O regions, `CONFIG_MMU` needs to be enabled and the following API implemented:

- `arch_mem_map()`
- `arch_mem_unmap()`
- `arch_page_phys_get()`

Stack Objects

The presence of memory protection hardware affects how stack objects are created. All architecture ports must specify the required alignment of the stack pointer, which is some combination of CPU and ABI requirements. This is defined in architecture headers with `ARCH_STACK_PTR_ALIGN` and is typically something small like 4, 8, or 16 bytes.

Two types of thread stacks exist:

- “kernel” stacks defined with `K_KERNEL_STACK_DEFINE()` and related APIs, which can host kernel threads running in supervisor mode or used as the stack for interrupt/exception handling. These have significantly relaxed alignment requirements and use less reserved data. No memory is reserved for privilege elevation stacks.
- “thread” stacks which typically use more memory, but are capable of hosting thread running in user mode, as well as any use-cases for kernel stacks.

If CONFIG_USERSPACE is not enabled, “thread” and “kernel” stacks are equivalent.

Additional macros may be defined in the architecture layer to specify the alignment of the base of stack objects, any reserved data inside the stack object not used for the thread’s stack buffer, and how to round up stack sizes to support user mode threads. In the absence of definitions some defaults are assumed:

- ARCH_KERNEL_STACK_RESERVED: default no reserved space
- ARCH_THREAD_STACK_RESERVED: default no reserved space
- ARCH_KERNEL_STACK_OBJ_ALIGN: default align to ARCH_STACK_PTR_ALIGN
- ARCH_THREAD_STACK_OBJ_ALIGN: default align to ARCH_STACK_PTR_ALIGN
- ARCH_THREAD_STACK_SIZE_ALIGN: default round up to ARCH_STACK_PTR_ALIGN

All stack creation macros are defined in terms of these.

Stack objects all have the following layout, with some regions potentially zero-sized depending on configuration. There are always two main parts: reserved memory at the beginning, and then the stack buffer itself. The bounds of some areas can only be determined at runtime in the context of its associated thread object. Other areas are entirely computable at build time.

Some architectures may need to carve-out reserved memory at runtime from the stack buffer, instead of unconditionally reserving it at build time, or to supplement an existing reserved area (as is the case with the ARM FPU). Such carve-outs will always be tracked in thread.stack_info.start. The region specified by thread.stack_info.start and thread.stack_info.size is always fully accessible by a user mode thread. thread.stack_info.delta denotes an offset which can be used to compute the initial stack pointer from the very end of the stack object, taking into account storage for TLS and ASLR random offsets.

```
+---------------------+ <- thread.stack_obj
| Reserved Memory     | } K_(THREAD|KERNEL)_STACK_RESERVED
+---------------------+
| Carved-out memory   |
|.....................| <- thread.stack_info.start
| Unused stack buffer |
|                    |
|.....................| <- thread's current stack pointer
| Used stack buffer   |
|                    |
|.....................| <- Initial stack pointer. Computable with thread.stack_info.delta
| ASLR Random offset  |
| Thread-local data   |
+---------------------+ <- thread.userspace_local_data
```

At present, Zephyr does not support stacks that grow upward.

**No Memory Protection** If no memory protection is in use, then the defaults are sufficient.

**HW-based stack overflow detection** This option uses hardware features to generate a fatal error if a thread in supervisor mode overflows its stack. This is useful for debugging, although for a couple reasons, you can’t reliably make any assertions about the state of the system after this happens:

- The kernel could have been inside a critical section when the overflow occurs, leaving important global data structures in a corrupted state.
• For systems that implement stack protection using a guard memory region, it’s possible to overshoot the guard and corrupt adjacent data structures before the hardware detects this situation.

To enable the `CONFIG_HW_STACK_PROTECTION` feature, the system must provide some kind of hardware-based stack overflow protection, and enable the `CONFIG_ARCH_HAS_STACK_PROTECTION` option.

Two forms of HW-based stack overflow detection are supported: dedicated CPU features for this purpose, or special read-only guard regions immediately preceding stack buffers.

`CONFIG_HW_STACK_PROTECTION` only catches stack overflows for supervisor threads. This is not required to catch stack overflow from user threads; `CONFIG_USERSPACE` is orthogonal.

This feature only detects supervisor mode stack overflows, including stack overflows when handling system calls. It doesn’t guarantee that the kernel has not been corrupted. Any stack overflow in supervisor mode should be treated as a fatal error, with no assertions about the integrity of the overall system possible.

Stack overflows in user mode are recoverable (from the kernel's perspective) and require no special configuration; `CONFIG_HW_STACK_PROTECTION` only applies to catching overflows when the CPU is in supervisor mode.

**CPU-based stack overflow detection**  If we are detecting stack overflows in supervisor mode via special CPU registers (like ARM’s SPLIM), then the defaults are sufficient.

**Guard-based stack overflow detection**  We are detecting supervisor mode stack overflows via special memory protection region located immediately before the stack buffer that generates an exception on write. Reserved memory will be used for the guard region.

`ARCH_KERNEL_STACK_RESERVED` should be defined to the minimum size of a memory protection region. On most ARM CPUs this is 32 bytes. `ARCH_KERNEL_STACK_OBJ_ALIGN` should also be set to the required alignment for this region.

MMU-based systems should not reserve RAM for the guard region and instead simply leave an non-present virtual page below every stack when it is mapped into the address space. The stack object will still need to be properly aligned and sized to page granularity.

```
+-----------------------------+ <- thread.stack_obj
| Guard reserved memory | } K_KERNEL_STACK_RESERVED
+-----------------------------+
| Guard carve-out |
| .........................| <- thread.stack_info.start
| Stack buffer |
```

Guard carve-outs for kernel stacks are uncommon and should be avoided if possible. They tend to be needed for two situations:

• The same stack may be re-purposed to host a user thread, in which case the guard is unnecessary and shouldn’t be unconditionally reserved. This is the case when privilege elevation stacks are not inside the stack object.

• The required guard size is variable and depends on context. For example, some ARM CPUs have lazy floating point stacking during exceptions and may decrement the stack pointer by a large value without writing anything, completely overshooting a minimally-sized guard and corrupting adjacent memory. Rather than unconditionally reserving a larger guard, the extra memory is carved out if the thread uses floating point.

**User mode enabled**  Enabling user mode activates two new requirements:

• A separate fixed-sized privilege mode stack, specified by `CONFIG_PRIVILEGED_STACK_SIZE`, must be allocated that the user thread cannot access. It is used as the stack by the kernel when handling
system calls. If stack guards are implemented, a stack guard region must be able to be placed before it, with support for carve-outs if necessary.

- The memory protection hardware must be able to program a region that exactly covers the thread’s stack buffer, tracked in thread.stack_info. This implies that ARCH_THREAD_STACK_SIZE_ADJUST() will need to round up the requested stack size so that a region may cover it, and that ARCH_THREAD_STACK_OBJ_ALIGN() is also specified per the granularity of the memory protection hardware.

This becomes more complicated if the memory protection hardware requires that all memory regions be sized to a power of two, and aligned to their own size. This is common on older MPUs and is known with CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT.

thread.stack_info always tracks the user-accessible part of the stack object, it must always be correct to program a memory protection region with user access using the range stored within.

Non power-of-two memory region requirements On systems without power-of-two region requirements, the reserved memory area for threads stacks defined by K_THREAD_STACK_RESERVED may be used to contain the privilege mode stack. The layout could be something like:

```
+------------------------------+ <- thread.stack_obj
| Other platform data |
+------------------------------+
| Guard region (if enabled) |
+------------------------------+
| Guard carve-out (if needed) |
|..............................|
| Privilege elevation stack |
+------------------------------| <- thread.stack_obj +
| Stack buffer | K_THREAD_STACK_RESERVED =
.              thread.stack_info.start
```

The guard region, and any carve-out (if needed) would be configured as a read-only region when the thread is created.

- If the thread is a supervisor thread, the privilege elevation region is just extra stack memory. An overflow will eventually crash into the guard region.
- If the thread is running in user mode, a memory protection region will be configured to allow user threads access to the stack buffer, but nothing before or after it. An overflow in user mode will crash into the privilege elevation stack, which the user thread has no access to. An overflow when handling a system call will crash into the guard region.

On an MMU system there should be no physical guards; the privilege mode stack will be mapped into kernel memory, and the stack buffer in the user part of memory, each with non-present virtual guard pages below them to catch runtime stack overflows.

Other platform data may be stored before the guard region, but this is highly discouraged if such data could be stored in thread.arch somewhere.

ARCH_THREAD_STACK_RESERVED will need to be defined to capture the size of the reserved region containing platform data, privilege elevation stacks, and guards. It must be appropriately sized such that an MPU region to grant user mode access to the stack buffer can be placed immediately after it.

Power-of-two memory region requirements Thread stack objects must be sized and aligned to the same power of two, without any reserved memory to allow efficient packing in memory. Thus, any guards in the thread stack must be completely carved out, and the privilege elevation stack must be allocated elsewhere.

ARCH_THREAD_STACK_SIZE_ADJUST() and ARCH_THREAD_STACK_OBJ_ALIGN() should both be defined to Z_POW2_CEIL(). K_THREAD_STACK_RESERVED must be 0.
For the privilege stacks, the `CONFIG_GEN_PRIV_STACKS` must be enabled. For every thread stack found in the system, a corresponding fixed-size kernel stack used for handling system calls is generated. The address of the privilege stacks can be looked up quickly at runtime based on the thread stack address using `z_priv_stack_find()`. These stacks are laid out the same way as other kernel-only stacks.

```
+-----------------------------+ <- z_priv_stack_find(thread.stack_obj)
| Reserved memory            | } K_KERNEL_STACK_RESERVED
+-----------------------------+ <- z_priv_stack_find(thread.stack_obj) +
| Guard carve-out (if needed) |
| Privilege elevation stack   |
+-----------------------------+ <- z_priv_stack_find(thread.stack_obj) +
                  K_KERNEL_STACK_RESERVED +
                  CONFIG_PRIVILEGED_STACK_SIZE
+-----------------------------+ <- thread.stack_obj
| MPU guard carve-out         | (supervisor mode only)
| Stack buffer                |
```

The guard carve-out in the thread stack object is only used if the thread is running in supervisor mode. If the thread drops to user mode, there is no guard and the entire object is used as the stack buffer, with full access to the associated user mode thread and `thread.stack_info` updated appropriately.

**User Mode Threads**

To support user mode threads, several kernel-to-arch APIs need to be implemented, and the system must enable the `CONFIG_ARCH_HAS_USERSPACE` option. Please see the documentation for each of these functions for more details:

- `arch_buffer_validate()` to test whether the current thread has access permissions to a particular memory region
- `arch_user_mode_enter()` which will irreversibly drop a supervisor thread to user mode privileges. The stack must be wiped.
- `arch_syscall_oops()` which generates a kernel oops when system call parameters can’t be validated, in such a way that the oops appears to be generated from where the system call was invoked in the user thread
- `arch_syscall_invoke0()` through `arch_syscall_invoke6()` invoke a system call with the appropriate number of arguments which must all be passed in during the privilege elevation via registers.
- `arch_is_user_context()` return nonzero if the CPU is currently running in user mode
- `arch_mem_domain_max_partitions_get()` which indicates the max number of regions for a memory domain. MMU systems have an unlimited amount, MPU systems have constraints on this.

Some architectures may need to update software memory management structures or modify hardware registers on another CPU when memory domain APIs are invoked. If so, `CONFIG_ARCH_MEM_DOMAIN_SYNCHRONOUS_API` must be selected by the architecture and some additional APIs must be implemented. This is common on MMU systems and uncommon on MPU systems:

- `arch_mem_domain_thread_add()`
- `arch_mem_domain_thread_remove()`
- `arch_mem_domain_partition_add()`

7.5. Porting
• `arch_mem_domain_partition_remove()`

Please see the doxygen documentation of these APIs for details.

In addition to implementing these APIs, there are some other tasks as well:

• `_new_thread()` needs to spawn threads with `K_USER` in user mode

• On context switch, the outgoing thread's stack memory should be marked inaccessible to user mode by making the appropriate configuration changes in the memory management hardware. The incoming thread's stack memory should likewise be marked as accessible. This ensures that threads can't mess with other thread stacks.

• On context switch, the system needs to switch between memory domains for the incoming and outgoing threads.

• Thread stack areas must include a kernel stack region. This should be inaccessible to user threads at all times. This stack will be used when system calls are made. This should be fixed size for all threads, and must be large enough to handle any system call.

• A software interrupt or some kind of privilege elevation mechanism needs to be established. This is closely tied to how the `_arch_syscall_invoke` macros are implemented. On system call, the appropriate handler function needs to be looked up in `_k_syscall_table`. Bad system call IDs should jump to the `K_SYSCALL_BAD` handler. Upon completion of the system call, care must be taken not to leak any register state back to user mode.

GDB Stub

To enable GDB stub for remote debugging on a new architecture:

1. Create a new `gdbstub.h` header file under appropriate architecture include directory (`include/arch/<arch>/gdbstub.h`).
   - Create a new struct `struct gdb_ctx` as the GDB context.
     - Must define a member named `exception` of type `unsigned int` to store the GDB exception reason. This value needs to be set before entering `z_gdb_main_loop()`.
     - Architecture can define as many members as needed for GDB stub to function.
     - Pointer to this struct needs to be passed to `z_gdb_main_loop()`, where this pointer will be passed to other GDB stub functions.

2. Functions for entering and exiting GDB stub main loop.
   - If the architecture relies on interrupts to service breakpoints, interrupt service routines (ISR) need to be implemented, which will serve as the entry point to GDB stub main loop.
   - These functions need to save and restore context so code execution can continue as if no breakpoints have been encountered.
   - These functions need to call `z_gdb_main_loop()` after saving execution context to go into the GDB stub main loop to receive commands from GDB.
   - Before calling `z_gdb_main_loop()`, `gdb_ctx.exception` must be set to specify the exception reason.

3. Implement necessary functions to support GDB stub functionality:
   - `arch_gdb_init()`
     - This needs to initialize necessary bits to support GDB stub functionality, for example, setting up the GDB context and connecting debug interrupts.
     - This must stop code execution via architecture specific method (e.g. raising debug interrupts). This allows GDB to connect during boot.
   - `arch_gdb_continue()`
This function is called when GDB sends a `c` or `continue` command to continue code execution.

- **arch_gdb_step()**
  - This function is called when GDB sends a `si` or `stepi` command to execute one machine instruction, before returning to GDB prompt.

**Hardware register read/write functions:**

- Since the GDB stub is running on the target, manipulation of hardware registers need to cached to avoid affecting the execution of GDB stub. Think of it as context switching, where the execution context is changed to the GDB stub. So that the register values of the running thread before context switch need to be stored. Manipulation of register values must only be done to this cached copy. The updated values will then be written to hardware registers before switching back to the previous running thread.

- **arch_gdb_reg_readall()**
  - This collects all hardware register values that would appear in a `g`/`G` packets which will be sent back to GDB. The format of the G-packet is architecture specific. Consult GDB on what is expected.
  - Note that, for most architectures, a valid G-packet must be returned and sent to GDB. If a packet without incorrect length is sent to GDB, GDB will abort the debugging session.

- **arch_gdb_reg_writeall()**
  - This takes a G-packet sent by GDB and populates the hardware registers with values from the G-packet.

- **arch_gdb_reg_readone()**
  - This reads the value of one hardware register and sends the result to GDB.

- **arch_gdb_reg_writeone()**
  - This writes the value of one hardware register received from GDB.

**Breakpoints:**

- **arch_gdb_add_breakpoint()** and **arch_gdb_remove_breakpoint()**
  - GDB may decide to use software breakpoints which modifies the memory at the breakpoint locations to replace the instruction with software breakpoint or trap instructions. GDB will then restore the memory content once execution reaches the breakpoints. GDB supports this by default and there is usually no need to handle software breakpoints in the architecture code (where breakpoint type is 0).
  - Hardware breakpoints (type 1) are required if the code is in ROM or flash that cannot be modified at runtime. Consult the architecture datasheet on how to enable hardware breakpoints.
  - If hardware breakpoints are not supported by the architecture, there is no need to implement these in architecture code. GDB will then rely on software breakpoints.

4. For architecture where certain memory regions are not accessible, an array named `gdb_mem_region_array` of type `gdb_mem_region` needs to be defined to specify regions that are accessible. For each array item:

- `gdb_mem_region.start` specifies the start of a memory region.
- `gdb_mem_region.end` specifies the end of a memory region.
- `gdb_mem_region.attributes` specifies the permission of a memory region.
  - `GDB_MEM_REGION_RO`: region is read-only.
  - `GDB_MEM_REGION_RW`: region is read-write.
• `gdb_mem_region.alignment` specifies read/write alignment of a memory region. Use 0 if there is no alignment requirement and read/write can be done byte-by-byte.

API Reference

Timing

group arch-timing

Unnamed Group

void arch_timing_init(void)
  Initialize the timing subsystem.
  Perform the necessary steps to initialize the timing subsystem.

  See also:
  `timing_init()`

void arch_timing_start(void)
  Signal the start of the timing information gathering.
  Signal to the timing subsystem that timing information will be gathered from this point forward.

  See also:
  `timing_start()`

  Note: Any call to `arch_timing_counter_get()` must be done between calls to
  `arch_timing_start()` and `arch_timing_stop()`, and on the same CPU core.

void arch_timing_stop(void)
  Signal the end of the timing information gathering.
  Signal to the timing subsystem that timing information is no longer being gathered from this point forward.

  See also:
  `timing_stop()`

  Note: Any call to `arch_timing_counter_get()` must be done between calls to
  `arch_timing_start()` and `arch_timing_stop()`, and on the same CPU core.

timing_t arch_timing_counter_get(void)
  Return timing counter.

  See also:
  `timing_counter_get()`
Note: Any call to `arch_timing_counter_get()` must be done between calls to `arch_timing_start()` and `arch_timing_stop()`, and on the same CPU core.

Note: Not all platforms have a timing counter with 64 bit precision. It is possible to see this value “go backwards” due to internal rollover. Timing code must be prepared to address the rollover (with platform-dependent code, e.g. by casting to a `uint32_t` before subtraction) or by using `arch_timing_cycles_get()` which is required to understand the distinction.

**Returns**
Timing counter.

```c
uint64_t arch_timing_cycles_get(volatile timing_t *const start, volatile timing_t *const end)
```

Get number of cycles between `start` and `end`.

For some architectures or SoCs, the raw numbers from counter need to be scaled to obtain actual number of cycles, or may roll over internally. This function computes a positive-definite interval between two returned cycle values.

See also:
`timing_cycles_get()`

**Parameters**

- `start` – Pointer to counter at start of a measured execution.
- `end` – Pointer to counter at stop of a measured execution.

**Returns**
Number of cycles between start and end.

```c
uint64_t arch_timing_freq_get(void)
```

Get frequency of counter used (in Hz).

See also:
`timing_freq_get()`

**Returns**
Frequency of counter used for timing in Hz.

```c
uint64_t arch_timing_cycles_to_ns(uint64_t cycles)
```

Convert number of cycles into nanoseconds.

See also:
`timing_cycles_to_ns()`

**Parameters**

- `cycles` – Number of cycles

**Returns**
Converted time value
uint64_t arch_timing_cycles_to_ns_avg(uint64_t cycles, uint32_t count)

Convert number of cycles into nanoseconds with averaging.

See also:

timing_cycles_to_ns_avg()

Parameters

• cycles – Number of cycles
• count – Times of accumulated cycles to average over

Returns

Converted time value

uint32_t arch_timing_freq_get_mhz(void)

Get frequency of counter used (in MHz).

See also:

timing_freq_get_mhz()

Returns

Frequency of counter used for timing in MHz.

Functions

void arch_busy_wait(uint32_t usec_to_wait)

Architecture-specific implementation of busy-waiting

Parameters

• usec_to_wait – Wait period, in microseconds

static inline uint32_t arch_k_cycle_get_32(void)

Obtain the current cycle count, in units that are hardware-specific

See also:

k_cycle_get_32()

static inline uint64_t arch_k_cycle_get_64(void)

Obtain the current cycle count, in units that are hardware-specific

See also:

k_cycle_get_64()

Threads

group arch-threads
Functions

void arch_new_thread(struct k_thread *thread, k_thread_stack_t *stack, char *stack_ptr, k_thread_entry_t entry, void *p1, void *p2, void *p3)

Handle arch-specific logic for setting up new threads

The stack and arch-specific thread state variables must be set up such that a later attempt to switch to this thread will succeed and we will enter z_thread_entry with the requested thread and arguments as its parameters.

At some point in this function's implementation, z_setup_new_thread() must be called with the true bounds of the available stack buffer within the thread's stack object.

The provided stack pointer is guaranteed to be properly aligned with respect to the CPU and ABI requirements. There may be space reserved between the stack pointer and the bounds of the stack buffer for initial stack pointer randomization and thread-local storage.

Fields in thread->base will be initialized when this is called.

Parameters

- thread – Pointer to uninitialized struct k_thread
- stack – Pointer to the stack object
- stack_ptr – Aligned initial stack pointer
- entry – Thread entry function
- p1 – 1st entry point parameter
- p2 – 2nd entry point parameter
- p3 – 3rd entry point parameter

static inline void arch_switch(void *switch_to, void **switched_from)

Cooperative context switch primitive

The action of arch_switch() should be to switch to a new context passed in the first argument, and save a pointer to the current context into the address passed in the second argument.

The actual type and interpretation of the switch handle is specified by the architecture. It is the same data structure stored in the “switch_handle” field of a newly-created thread in arch_new_thread(), and passed to the kernel as the “interrupted” argument to z_get_next_switch_handle().

Note that on SMP systems, the kernel uses the store through the second pointer as a synchronization point to detect when a thread context is completely saved (so another CPU can know when it is safe to switch). This store must be done AFTER all relevant state is saved, and must include whatever memory barriers or cache management code is required to be sure another CPU will see the result correctly.

The simplest implementation of arch_switch() is generally to push state onto the thread stack and use the resulting stack pointer as the switch handle. Some architectures may instead decide to use a pointer into the thread struct as the “switch handle” type. These can legally assume that the second argument to arch_switch() is the address of the switch_handle field of struct thread_base and can use an offset on this value to find other parts of the thread struct.

For example a (C pseudocode) implementation of arch_switch() might look like:

void arch_switch(void *switch_to, void **switched_from) {
    struct k_thread *new = switch_to;
    struct k_thread *old = CONTAINER_OF(switched_from, struct k_thread, switch_handle);
    // save old context... *switched_from = old; // restore new context... }

Note that the kernel manages the switch_handle field for synchronization as described above. So it is not legal for architecture code to assume that it has any particular value at any other time. In particular it is not legal to read the field from the address passed in the second argument.
Parameters

- `switch_to` – Incoming thread's switch handle
- `switched_from` – Pointer to outgoing thread's switch handle storage location, which must be updated.

```c
void arch_switch_to_main_thread(struct k_thread *main_thread, char *stack_ptr, k_thread_entry_t _main)
```

Custom logic for entering main thread context at early boot

Used by architectures where the typical trick of setting up a dummy thread in early boot context to “switch out” of isn’t workable.

Parameters

- `main_thread` – main thread object
- `stack_ptr` – Initial stack pointer
- `_main` – Entry point for application main function.

```c
int arch_float_disable(struct k_thread *thread)
```

Disable floating point context preservation.

The function is used to disable the preservation of floating point context information for a particular thread.

**Note:** For ARM architecture, disabling floating point preservation may only be requested for the current thread and cannot be requested in ISRs.

Return values

- 0 – On success.
- -EINVAL – If the floating point disabling could not be performed.
- -ENOTSUP – If the operation is not supported

```c
int arch_float_enable(struct k_thread *thread, unsigned int options)
```

Enable floating point context preservation.

The function is used to enable the preservation of floating point context information for a particular thread. This API depends on each architecture implementation. If the architecture does not support enabling, this API will always be failed.

The `options` parameter indicates which floating point register sets will be used by the specified thread. Currently it is used by x86 only.

Parameters

- `thread` – ID of thread.
- `options` – architecture dependent options

Return values

- 0 – On success.
- -EINVAL – If the floating point enabling could not be performed.
- -ENOTSUP – If the operation is not supported
Functions

size_t arch_tls_stack_setup(struct k_thread *new_thread, char *stack_ptr)

Setup Architecture-specific TLS area in stack.
This sets up the stack area for thread local storage. The structure inside in area is architecture specific.

Parameters

• new_thread – New thread object
• stack_ptr – Stack pointer

Returns
Number of bytes taken by the TLS area

Power Management

group arch-pm

Functions

FUNC_NORETURN void arch_system_halt(unsigned int reason)

Halt the system, optionally propagating a reason code

void arch_cpu_idle(void)

Power save idle routine.
This function will be called by the kernel idle loop or possibly within an implementation of z_pm_save_idle in the kernel when the '_pm_save_flag' variable is non-zero.
Architectures that do not implement power management instructions may immediately return, otherwise a power-saving instruction should be issued to wait for an interrupt.

See also:
k_cpu_idle()

Note: The function is expected to return after the interrupt that has caused the CPU to exit power-saving mode has been serviced, although this is not a firm requirement.

void arch_cpu_atomic_idle(unsigned int key)

Atomically re-enable interrupts and enter low power mode.
The requirements for arch_cpu_atomic_idle() are as follows:

a. Enabling interrupts and entering a low-power mode needs to be atomic, i.e. there should be no period of time where interrupts are enabled before the processor enters a low-power mode. See the comments in k_lifo_get(), for example, of the race condition that occurs if this requirement is not met.
b. After waking up from the low-power mode, the interrupt lockout state must be restored as indicated in the 'key' input parameter.

See also:
k_cpu_atomic_idle()
Parameters

• key – Lockout key returned by previous invocation of `arch_irq_lock()`

Symmetric Multi-Processing

group arch-smp

Typedefs

typedef FUNC_NORETURN void (*arch_cpustart_t)(void *data)

Per-cpu entry function

Param data  
context parameter, implementation specific

Functions

void arch_start_cpu(int cpu_num, k_thread_stack_t *stack, int sz, arch_cpustart_t fn, void *arg)

Start a numbered CPU on a MP-capable system.

This starts and initializes a specific CPU. The main thread on startup is running on CPU zero, other processors are numbered sequentially. On return from this function, the CPU is known to have begun operating and will enter the provided function. Its interrupts will be initialized but disabled such that `irq_unlock()` with the provided key will work to enable them.

Normally, in SMP mode this function will be called by the kernel initialization and should not be used as a user API. But it is defined here for special-purpose apps which want Zephyr running on one core and to use others for design-specific processing.

Parameters

• cpu_num – Integer number of the CPU
• stack – Stack memory for the CPU
• sz – Stack buffer size, in bytes
• fn – Function to begin running on the CPU.
• arg – Untyped argument to be passed to “fn”

bool arch_cpu_active(int cpu_num)

Return CPU power status.

Parameters

• cpu_num – Integer number of the CPU

static inline struct _cpu *arch_curr_cpu(void)

Return the CPU struct for the currently executing CPU

static inline uint32_t arch_proc_id(void)

Processor hardware ID.

Most multiprocessor architectures have a low-level unique ID value associated with the current CPU that can be retrieved rapidly and efficiently in kernel context. Note that while the numbering of the CPUs is guaranteed to be unique, the values are platform-defined. In particular, they are not guaranteed to match Zephyr’s own sequential CPU IDs (even though on some platforms they do).
**Note:** There is an inherent race with this API: the system may preempt the current thread and migrate it to another CPU before the value is used. Safe usage requires knowing the migration is impossible (e.g. because the code is in interrupt context, holds a spinlock, or cannot migrate due to k_cpu_mask state).

**Returns**
Unique ID for currently-executing CPU

```c
void arch_sched_ipi(void)  
Broadcast an interrupt to all CPUs

void arch_num_cpus(void)   
Returns the number of CPUs.

For most systems this will be the same as CONFIG_MP_MAX_NUM_CPUS, however some systems may determine this at runtime instead.

**Returns**
the number of CPUs
```

**Interrupts**

`group arch-irq`

**Functions**

```c
static inline bool arch_is_in_isr(void)  
Test if the current context is in interrupt context

XXX: This is inconsistently handled among arches wrt exception context See: #17656

**Returns**
true if we are in interrupt context

static inline unsigned int arch_irq_lock(void)   
Lock interrupts on the current CPU

**See also:**
* `irq_lock()`
```

```c
static inline void arch_irq_unlock(unsigned int key)   
Unlock interrupts on the current CPU

**See also:**
* `irq_unlock()`
```

```c
static inline bool arch_irq_unlocked(unsigned int key)   
Test if calling `arch_irq_unlock()` with this key would unlock irqs

**Parameters**
* `key` – value returned by `arch_irq_lock()`
Zephyr Project Documentation, Release 3.2.99

**Returns**

true if interrupts were unlocked prior to the `arch_irq_lock()` call that produced the key argument.

```c
void arch_irq_disable(unsigned int irq)
    Disable the specified interrupt line
```

**See also:**

`irq_disable()`

---

**Note:** The behavior of interrupts that arrive after this call returns and before the corresponding call to `arch_irq_enable()` is undefined. The hardware is not required to latch and deliver such an interrupt, though on some architectures that may work. Other architectures will simply lose such an interrupt and never deliver it. Many drivers and subsystems are not tolerant of such dropped interrupts and it is the job of the application layer to ensure that behavior remains correct.

```c
void arch_irq_enable(unsigned int irq)
    Enable the specified interrupt line
```

**See also:**

`irq_enable()`

```c
int arch_irq_is_enabled(unsigned int irq)
    Test if an interrupt line is enabled
```

**See also:**

`irq_is_enabled()`

```c
int arch_irq_connect_dynamic(unsigned int irq, unsigned int priority, void (*routine)(const void *parameter), const void *parameter, uint32_t flags)
    Arch-specific hook to install a dynamic interrupt.
```

**Parameters**

- `irq` – IRQ line number
- `priority` – Interrupt priority
- `routine` – Interrupt service routine
- `parameter` – ISR parameter
- `flags` – Arch-specific IRQ configuration flag

**Returns**

The vector assigned to this interrupt

```c
unsigned int arch_irq_allocate(void)
    Arch-specific hook for allocating IRQs.
```

**Note:** disable/enable IRQ relevantly inside the implementation of such function to avoid concurrency issues. Also, an allocated IRQ is assumed to be used thus a following

```c
void *arch_irq_is_used() should return true.
```
Returns

The newly allocated IRQ or \texttt{UINT\_MAX} on error.

\begin{verbatim}
void arch_irq_set_used(unsigned int irq)
Arch-specific hook for declaring an IRQ being used.
Note: disable/enable IRQ relevantly inside the implementation of such function to avoid concurrency issues.

Parameters

\begin{itemize}
  \item \texttt{irq} – the IRQ to declare being used
\end{itemize}
\end{verbatim}

\begin{verbatim}
bool arch_irq_is_used(unsigned int irq)
Arch-specific hook for checking if an IRQ is being used already.

Parameters

\begin{itemize}
  \item \texttt{irq} – the IRQ to check
\end{itemize}

Returns

true if being, false otherwise
\end{verbatim}

Userspace

group arch-userspace

Functions

\begin{verbatim}
static inline uintptr_t arch_syscall_invoke0(uintptr_t call_id)
Invoke a system call with 0 arguments.

No general-purpose register state other than return value may be preserved when transitioning from supervisor mode back down to user mode for security reasons.

It is required that all arguments be stored in registers when elevating privileges from user to supervisor mode.

Processing of the syscall takes place on a separate kernel stack. Interrupts should be enabled when invoking the system call marshalers from the dispatch table. Thread preemption may occur when handling system calls.

Call ids are untrusted and must be bounds-checked, as the value is used to index the system call dispatch table, containing function pointers to the specific system call code.

Parameters

\begin{itemize}
  \item \texttt{call_id} – System call ID
\end{itemize}

Returns

Return value of the system call. Void system calls return 0 here.
\end{verbatim}

\begin{verbatim}
static inline uintptr_t arch_syscall_invoke1(uintptr_t arg1, uintptr_t call_id)
Invoke a system call with 1 argument.
\end{verbatim}

See also:

\begin{verbatim}
arch_syscall_invoke0()
\end{verbatim}

Parameters

\begin{itemize}
  \item \texttt{arg1} – First argument to the system call.
\end{itemize}
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

**Returns**
Return value of the system call. Void system calls return 0 here.

static inline uintptr_t arch_syscall_invoke2(uintptr_t arg1, uintptr_t arg2, uintptr_t call_id)
Invoke a system call with 2 arguments.

**See also:**
`arch_syscall_invoke0()`

**Parameters**
• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

**Returns**
Return value of the system call. Void system calls return 0 here.

static inline uintptr_t arch_syscall_invoke3(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3, uintptr_t call_id)
Invoke a system call with 3 arguments.

**See also:**
`arch_syscall_invoke0()`

**Parameters**
• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• arg3 – Third argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

**Returns**
Return value of the system call. Void system calls return 0 here.

static inline uintptr_t arch_syscall_invoke4(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3, uintptr_t arg4, uintptr_t call_id)
Invoke a system call with 4 arguments.

**See also:**
`arch_syscall_invoke0()`

**Parameters**
• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• arg3 – Third argument to the system call.
• arg4 – Fourth argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

Returns
Return value of the system call. Void system calls return 0 here.

static inline uintptr_t arch_syscall_invoke5(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3, uintptr_t arg4, uintptr_t arg5, uintptr_t call_id)
Invoke a system call with 5 arguments.

See also:
arch_syscall_invoke0()

Parameters
• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• arg3 – Third argument to the system call.
• arg4 – Fourth argument to the system call.
• arg5 – Fifth argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

Returns
Return value of the system call. Void system calls return 0 here.

static inline uintptr_t arch_syscall_invoke6(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3, uintptr_t arg4, uintptr_t arg5, uintptr_t arg6, uintptr_t call_id)
Invoke a system call with 6 arguments.

See also:
arch_syscall_invoke0()

Parameters
• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• arg3 – Third argument to the system call.
• arg4 – Fourth argument to the system call.
• arg5 – Fifth argument to the system call.
• arg6 – Sixth argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

Returns
Return value of the system call. Void system calls return 0 here.
static inline bool arch_is_user_context(void)
    Indicate whether we are currently running in user mode

Returns
    true if the CPU is currently running with user permissions

int arch_mem_domain_max_partitions_get(void)
    Get the maximum number of partitions for a memory domain.

Returns
    Max number of partitions, or -1 if there is no limit

int arch_buffer_validate(void *addr, size_t size, int write)
    Check memory region permissions.

Given a memory region, return whether the current memory management hardware configu-
ration would allow a user thread to read/write that region. Used by system calls to validate
buffers coming in from userspace.

Notes: The function is guaranteed to never return validation success, if the entire buffer area
is not user accessible.

The function is guaranteed to correctly validate the permissions of the supplied buffer, if
the user access permissions of the entire buffer are enforced by a single, enabled memory
management region.

In some architectures the validation will always return failure if the supplied memory buffer
spans multiple enabled memory management regions (even if all such regions permit user
access).

Warning: 0 size buffer has undefined behavior.

Parameters
    • addr – start address of the buffer
    • size – the size of the buffer
    • write – If nonzero, additionally check if the area is writable. Otherwise, just
        check if the memory can be read.

Returns
    nonzero if the permissions don’t match.

size_t arch_virt_region_align(uintptr_t phys, size_t size)
    Get the optimal virtual region alignment to optimize the MMU table layout

Some MMU HW requires some region to be aligned to some of the intermediate block align-
ment in order to reduce table usage. This call returns the optimal virtual address alignment
in order to permit such optimization in the following MMU mapping call.

Parameters
    • phys – [in] Physical address of region to be mapped, aligned to
        MMU_PAGE_SIZE
    • size – [in] Size of region to be mapped, aligned to MMU_PAGE_SIZE

Return values
    alignment – to apply on the virtual address of this region

FUNC_NORETURN void arch_user_mode_enter(k_thread_entry_t user_entry, void *p1, void
    *p2, void *p3)
Perform a one-way transition from supervisor to kernel mode. Implementations of this function must do the following:

- Reset the thread’s stack pointer to a suitable initial value. We do not need any prior context since this is a one-way operation.
- Set up any kernel stack region for the CPU to use during privilege elevation
- Put the CPU in whatever its equivalent of user mode is
- Transfer execution to `arch_new_thread()` passing along all the supplied arguments, in user mode.

**Parameters**

- `user_entry` – Entry point to start executing as a user thread
- `p1` – 1st parameter to user thread
- `p2` – 2nd parameter to user thread
- `p3` – 3rd parameter to user thread

```c
FUNC_NORETURN void arch_syscall_oops(void *ssf)
```

Induce a kernel oops that appears to come from a specific location.

Normally, `k_oops()` generates an exception that appears to come from the call site of the `k_oops()` itself.

However, when validating arguments to a system call, if there are problems we want the oops to appear to come from where the system call was invoked and not inside the validation function.

**Parameters**

- `ssf` – System call stack frame pointer. This gets passed as an argument to `_k_syscall_handler_t` functions and its contents are completely architecture specific.

```c
size_t arch_user_string_nlen(const char *s, size_t maxsize, int *err)
```

Safely take the length of a potentially bad string.

This must not fault, instead the err parameter must have -1 written to it. This function otherwise should work exactly like libc `strnlen()`. On success *err should be set to 0.

**Parameters**

- `s` – String to measure
- `maxsize` – Max length of the string
- `err` – Error value to write

**Returns**

Length of the string, not counting NULL byte, up to maxsize

```c
static inline bool arch_mem_coherent(void *ptr)
```

Detect memory coherence type.

Required when ARCH_HAS_COHERENCE is true. This function returns true if the byte pointed to lies within an architecture-defined “coherence region” (typically implemented with uncached memory) and can safely be used in multiprocessor code without explicit flush or invalidate operations.
**Note:** The result is for only the single byte at the specified address, this API is not required to check region boundaries or to expect aligned pointers. The expectation is that the code above will have queried the appropriate address(es).

```c
static inline void arch_cohere_stacks(struct k_thread *old_thread, void *old_switch_handle, struct k_thread *new_thread)
Ensure cache coherence prior to context switch.
Required when ARCH_HAS_COHERENCE is true. On cache-incoherent multiprocessor architectures, thread stacks are cached by default for performance reasons. They must therefore be flushed appropriately on context switch. The rules are:

a. The region containing live data in the old stack (generally the bytes between the current stack pointer and the top of the stack memory) must be flushed to underlying storage so a new CPU that runs the same thread sees the correct data. This must happen before the assignment of the switch_handle field in the thread struct which signals the completion of context switch.
b. Any data areas to be read from the new stack (generally the same as the live region when it was saved) should be invalidated (and NOT flushed!) in the data cache. This is because another CPU may have run or re-initialized the thread since this CPU suspended it, and any data present in cache will be stale.

- old_thread The old thread to be flushed before being allowed to run on other CPUs.
- old_switch_handle The switch handle to be stored into old_thread (it will not be valid until the cache is flushed so is not present yet). This will be NULL if inside z_swap() (because the arch_switch() has not saved it yet).
- new_thread The new thread to be invalidated before it runs locally.

**Note:** The kernel will call this function during interrupt exit when a new thread has been chosen to run, and also immediately before entering arch_switch() to effect a code-driven context switch. In the latter case, it is very likely that more data will be written to the old_thread stack region after this function returns but before the completion of the switch. Simply flushing naively here is not sufficient on many architectures and coordination with the arch_switch() implementation is likely required.

**Memory Management**

*group arch-mmu*

**Defines**

ARCH_DATA_PAGE_ACCESSED
Bit indicating the data page was accessed since the value was last cleared.
Used by marking eviction algorithms. Safe to set this if uncertain.
This bit is undefined if ARCH_DATA_PAGE_LOADED is not set.
ARCH_DATA_PAGE_DIRTY
Bit indicating the data page, if evicted, will need to be paged out.
Set if the data page was modified since it was last paged out, or if it has never been paged out before. Safe to set this if uncertain.
This bit is undefined if ARCH_DATA_PAGE_LOADED is not set.

ARCH_DATA_PAGE_LOADED
Bit indicating that the data page is loaded into a physical page frame.
If un-set, the data page is paged out or not mapped.

ARCH_DATA_PAGE_NOT_MAPPED
If ARCH_DATA_PAGE_LOADED is un-set, this will indicate that the page is not mapped at all.
This bit is undefined if ARCH_DATA_PAGE_LOADED is set.

Enums

enum arch_page_location

Values:

enumerator ARCH_PAGE_LOCATION_PAGED_OUT
enumerator ARCH_PAGE_LOCATION_PAGED_IN
enumerator ARCH_PAGE_LOCATION_BAD

Functions

void arch_mem_map(void *virt, uintptr_t phys, size_t size, uint32_t flags)
Map physical memory into the virtual address space
This is a low-level interface to mapping pages into the address space. Behavior when providing unaligned addresses/sizes is undefined, these are assumed to be aligned to CONFIG_MMU_PAGE_SIZE.
The core kernel handles all management of the virtual address space; by the time we invoke this function, we know exactly where this mapping will be established. If the page tables already had mappings installed for the virtual memory region, these will be overwritten.
If the target architecture supports multiple page sizes, currently only the smallest page size will be used.
The memory range itself is never accessed by this operation.
This API must be safe to call in ISRs or exception handlers. Calls to this API are assumed to be serialized, and indeed all usage will originate from kernel/mm.c which handles virtual memory management.
Architectures are expected to pre-allocate page tables for the entire address space, as defined by CONFIG_KERNEL_VM_BASE and CONFIG_KERNEL_VM_SIZE. This operation should never require any kind of allocation for paging structures.
Validation of arguments should be done via assertions.
This API is part of infrastructure still under development and may change.
Parameters

- **virt** – Page-aligned Destination virtual address to map
- **phys** – Page-aligned Source physical address to map
- **size** – Page-aligned size of the mapped memory region in bytes
- **flags** – Caching, access and control flags, see K_MAP_* macros

```c
void arch_mem_unmap(void *addr, size_t size)
```

Remove mappings for a provided virtual address range

This is a low-level interface for un-mapping pages from the address space. When this completes, the relevant page table entries will be updated as if no mapping was ever made for that memory range. No previous context needs to be preserved. This function must update mappings in all active page tables.

Behavior when providing unaligned addresses/sizes is undefined, these are assumed to be aligned to CONFIG_MMU_PAGE_SIZE.

Behavior when providing an address range that is not already mapped is undefined.

This function should never require memory allocations for paging structures, and it is not necessary to free any paging structures. Empty page tables due to all contained entries being un-mapped may remain in place.

Implementations must invalidate TLBs as necessary.

This API is part of infrastructure still under development and may change.

```c
int arch_page_phys_get(void *virt, uintptr_t *phys)
```

Get the mapped physical memory address from virtual address.

The function only needs to query the current set of page tables as the information it reports must be common to all of them if multiple page tables are in use. If multiple page tables are active it is unnecessary to iterate over all of them.

Unless otherwise specified, virtual pages have the same mappings across all page tables. Calling this function on data pages that are exceptions to this rule (such as the scratch page) is undefined behavior. Just check the currently installed page tables and return the information in that.

Parameters

- **addr** – Page-aligned base virtual address to un-map
- **size** – Page-aligned region size

```c
void arch_reserved_pages_update(void)
```

Update page frame database with reserved pages

Some page frames within system RAM may not be available for use. A good example of this is reserved regions in the first megabyte on PC-like systems.

Implementations of this function should mark all relevant entries in z_page_frames with K_PAGE_FRAME_RESERVED. This function is called at early system initialization with mm_lock held.
void arch_mem_page_out(void *addr, uintptr_t location)
Update all page tables for a paged-out data page

This function:

• Sets the data page virtual address to trigger a fault if accessed that can be distinguished from access violations or un-mapped pages.
• Saves the provided location value so that it can retrieved for that data page in the page fault handler.
• The location value semantics are undefined here but the value will be always be page-aligned. It could be 0.

If multiple page tables are in use, this must update all page tables. This function is called with interrupts locked.

Calling this function on data pages which are already paged out is undefined behavior.

This API is part of infrastructure still under development and may change.

void arch_mem_page_in(void *addr, uintptr_t phys)
Update all page tables for a paged-in data page

This function:

• Maps the specified virtual data page address to the provided physical page frame address, such that future memory accesses will function as expected. Access and caching attributes are undisturbed.
• Clears any accounting for “accessed” and “dirty” states.

If multiple page tables are in use, this must update all page tables. This function is called with interrupts locked.

Calling this function on data pages which are already paged in is undefined behavior.

This API is part of infrastructure still under development and may change.

void arch_mem_scratch(uintptr_t phys)
Update current page tables for a temporary mapping

Map a physical page frame address to a special virtual address Z_SCRATCH_PAGE, with read/write access to supervisor mode, such that when this function returns, the calling context can read/write the page frame's contents from the Z_SCRATCH_PAGE address.

This mapping only needs to be done on the current set of page tables, as it is only used for a short period of time exclusively by the caller. This function is called with interrupts locked.

This API is part of infrastructure still under development and may change.

defined arch_page_location
enum arch_page_location
arch_page_location_get(void *addr, uintptr_t *location)
Fetch location information about a page at a particular address

The function only needs to query the current set of page tables as the information it reports must be common to all of them if multiple page tables are in use. If multiple page tables are active it is unnecessary to iterate over all of them. This may allow certain types of optimizations (such as reverse page table mapping on x86).

This function is called with interrupts locked, so that the reported information can’t become stale while decisions are being made based on it.

Unless otherwise specified, virtual data pages have the same mappings across all page tables. Calling this function on data pages that are exceptions to this rule (such as the scratch page) is undefined behavior. Just check the currently installed page tables and return the information in that.

Parameters
• addr – Virtual data page address that took the page fault

• location – [out] In the case of ARCH_PAGE_FAULT_PAGED_OUT, the backing store location value used to retrieve the data page. In the case of ARCH_PAGE_FAULT_PAGED_IN, the physical address the page is mapped to.

Return values

• ARCH_PAGE_FAULT_PAGED_OUT – The page was evicted to the backing store.

• ARCH_PAGE_FAULT_PAGED_IN – The data page is resident in memory.

• ARCH_PAGE_FAULT_BAD – The page is un-mapped or otherwise has had invalid access

uintptr_t arch_page_info_get(void *addr, uintptr_t *location, bool clear_accessed)

Retrieve page characteristics from the page table(s)

The architecture is responsible for maintaining “accessed” and “dirty” states of data pages to support marking eviction algorithms. This can either be directly supported by hardware or emulated by modifying protection policy to generate faults on reads or writes. In all cases the architecture must maintain this information in some way.

For the provided virtual address, report the logical OR of the accessed and dirty states for the relevant entries in all active page tables in the system if the page is mapped and not paged out.

If clear_accessed is true, the ARCH_DATA_PAGE_ACCESS flag will be reset. This function will report its prior state. If multiple page tables are in use, this function clears accessed state in all of them.

This function is called with interrupts locked, so that the reported information can’t become stale while decisions are being made based on it.

The return value may have other bits set which the caller must ignore.

Clearing accessed state for data pages that are not ARCH_DATA_PAGE_LOADED is undefined behavior.

ARCH_DATA_PAGE_DIRTY and ARCH_DATA_PAGE_ACCESS bits in the return value are only significant if ARCH_DATA_PAGE_LOADED is set, otherwise ignore them.

ARCH_DATA_PAGE_NOT_MAPPED bit in the return value is only significant if ARCH_DATA_PAGE_LOADED is un-set, otherwise ignore it.

Unless otherwise specified, virtual data pages have the same mappings across all page tables. Calling this function on data pages that are exceptions to this rule (such as the scratch page) is undefined behavior.

This API is part of infrastructure still under development and may change.

Parameters

• addr – Virtual address to look up in page tables

• location – [out] If non-NULL, updated with either physical page frame address or backing store location depending on ARCH_DATA_PAGE_LOADED state. This is not touched if ARCH_DATA_PAGE_NOT_MAPPED.

• clear_accessed – Whether to clear ARCH_DATA_PAGE_ACCESS state

Return values

Value – with ARCH_DATA_PAGE_* bits set reflecting the data page configuration
Functions

```
int arch_printk_char_out(int c)

Early boot console output hook

Definition of this function is optional. If implemented, any invocation of printk() (or logging
calls with CONFIG_LOG_MODE_MINIMAL which are backed by printk) will default to sending
characters to this function. It is useful for early boot debugging before main serial or console
drivers come up.

This can be overridden at runtime with __printk_hook_install().
The default __weak implementation of this does nothing.
```

Parameters

- c – Character to print

Returns

The character printed

```
static inline void arch_kernel_init(void)

Architecture-specific kernel initialization hook

This function is invoked near the top of _Cstart, for additional architecture-specific setup
before the rest of the kernel is brought up.

TODO: Deprecate, most arches are using a prep_c() function to do the same thing in a simpler
way
```

```
static inline void arch_nop(void)

Do nothing and return. Yawn.
```

GDB Stub APIs

group arch-gdbstub

Functions

```
void arch_gdb_init(void)

Architecture layer debug start.

This function is called by gdb_init()

void arch_gdb_continue(void)

Continue running program.

Continue software execution.

void arch_gdb_step(void)

Continue with one step.

Continue software execution until reaches the next statement.
```

```
size_t arch_gdb_reg_readall(struct gdb_ctx *ctx, uint8_t *buf, size_t buflen)

Read all registers, and outputs as hexadecimal string.

This reads all CPU registers and outputs as hexadecimal string. The output string must be parsable by GDB.
```

Parameters

- ctx – GDB context
- buf – Buffer to output hexadecimal string.

• buflen – Length of buffer.

**Returns**
Length of hexadecimal string written. Return 0 if error or not supported.

```c
size_t arch_gdb_reg_writeall(struct gdb_ctx *ctx, uint8_t *hex, size_t hexlen)
```
Take a hexadecimal string and update all registers.

This takes in a hexadecimal string as presented from GDB, and updates all CPU registers with new values.

**Parameters**
- `ctx` – GDB context
- `hex` – Input hexadecimal string.
- `hexlen` – Length of hexadecimal string.

**Returns**
Length of hexadecimal string parsed. Return 0 if error or not supported.

```c
size_t arch_gdb_reg_readone(struct gdb_ctx *ctx, uint8_t *buf, size_t buflen, uint32_t regno)
```
Read one register, and outputs as hexadecimal string.

This reads one CPU register and outputs as hexadecimal string. The output string must be parsable by GDB.

**Parameters**
- `ctx` – GDB context
- `buf` – Buffer to output hexadecimal string.
- `buflen` – Length of buffer.
- `regno` – Register number

**Returns**
Length of hexadecimal string written. Return 0 if error or not supported.

```c
size_t arch_gdb_reg_writeone(struct gdb_ctx *ctx, uint8_t *hex, size_t hexlen, uint32_t regno)
```
Take a hexadecimal string and update one register.

This takes in a hexadecimal string as presented from GDB, and updates one CPU registers with new value.

**Parameters**
- `ctx` – GDB context
- `hex` – Input hexadecimal string.
- `hexlen` – Length of hexadecimal string.
- `regno` – Register number

**Returns**
Length of hexadecimal string parsed. Return 0 if error or not supported.

```c
int arch_gdb_add_breakpoint(struct gdb_ctx *ctx, uint8_t *type, uintptr_t addr, uint32_t kind)
```
Add breakpoint or watchpoint.

**Parameters**
- `ctx` – GDB context
- `type` – Breakpoint or watchpoint type
- `addr` – Address of breakpoint or watchpoint
- `kind` – Size of breakpoint/watchpoint in bytes
Return values

• 0 – Operation successful
• -1 – Error encountered
• -2 – Not supported

```c
int arch_gdb_remove_breakpoint(struct gdb_ctx *ctx, uint8_t type, uintptr_t addr, uint32_t kind)
```

Remove breakpoint or watchpoint.

Parameters

• ctx – GDB context
• type – Breakpoint or watchpoint type
• addr – Address of breakpoint or watchpoint
• kind – Size of breakpoint/watchpoint in bytes

Return values

• 0 – Operation successful
• -1 – Error encountered
• -2 – Not supported

7.5.2 Board Porting Guide

To add Zephyr support for a new board, you at least need a board directory with various files in it. Files in the board directory inherit support for at least one SoC and all of its features. Therefore, Zephyr must support your SoC as well.

Boards, SoCs, etc.

Zephyr’s hardware support hierarchy has these layers, from most to least specific:

• Board: a particular CPU instance and its peripherals in a concrete hardware specification
• SoC: the exact system on a chip the board’s CPU is part of
• SoC series: a smaller group of tightly related SoCs
• SoC family: a wider group of SoCs with similar characteristics
• CPU core: a particular CPU in an architecture
• Architecture: an instruction set architecture

You can visualize the hierarchy like this:

Here are some examples. Notice how the SoC series and family levels are not always used.

<table>
<thead>
<tr>
<th>Board</th>
<th>SoC</th>
<th>SoC series</th>
<th>SoC family</th>
<th>CPU core</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>nrf52dk_nrf52832</td>
<td>nRF52832</td>
<td>nRF52</td>
<td>Nordic nRF5</td>

<td>RV32M1</td>
<td>(Not used)</td>
<td>(Not used)</td>
<td>RISCY</td>
<td>RISC-V</td>
</tr>
</tbody>
</table>
Make sure your SoC is supported

Start by making sure your SoC is supported by Zephyr. If it is, it's time to Create your board directory. If you don't know, try:

- checking boards for names that look relevant, and reading individual board documentation to find out for sure.
- asking your SoC vendor

If you need to add SoC, CPU core, or even architecture support, this is the wrong page, but here is some general advice.

Architecture  See Architecture Porting Guide.

CPU Core  CPU core support files go in core subdirectories under arch, e.g. arch/x86/core.

See Install a Toolchain for information about toolchains (compiler, linker, etc.) supported by Zephyr. If you need to support a new toolchain, Build and Configuration Systems is a good place to start learning about the build system. Please reach out to the community if you are looking for advice or want to collaborate on toolchain support.

SoC  Zephyr SoC support files are in architecture-specific subdirectories of soc. They are generally grouped by SoC family.

When adding a new SoC family or series for a vendor that already has SoC support within Zephyr, please try to extract common functionality into shared files to avoid duplication. If there is no support for your vendor yet, you can add it in a new directory zephyr/soc/<YOUR-ARCH>/YOUR-SOC; please use self-explanatory directory names.
Create your board directory

Once you've found an existing board that uses your SoC, you can usually start by copy/pasting its board directory and changing its contents for your hardware.

You need to give your board a unique name. Run `west boards` for a list of names that are already taken, and pick something new. Let's say your board is called `plank` (please don't actually use that name).

Start by creating the board directory `zephyr/boards/<ARCH>/plank`, where `<ARCH>` is your SoC's architecture subdirectory. (You don't have to put your board directory in the zephyr repository, but it's the easiest way to get started. See Custom Board, Devicetree and SOC Definitions for documentation on moving your board directory to a separate repository once it's working.)

**Note:** The board directory name does not need to match the name of the board. Multiple boards can even be defined in one directory. For example, for boards with multi-core SoC, a logical board might be created for each core following the naming scheme `<board>_<(soc-core)`, with definitions for all of these different boards defined inside the same directory. This and similar schemes are common for upstream vendor boards.

Your board directory should look like this:

```bash
boards/<ARCH>/plank
  └── board.cmake
  │   └── CMakeLists.txt
  │       └── doc
  │           └── plank.png
  │                   └── index.rst
  │                       └── Kconfig.board
  │                               └── Kconfig.defconfig
  │                                               └── plank_defconfig
  │                                                   └── plank.dts
  │                                                           └── plank.yaml
```

Replace `plank` with your board’s name, of course.

The mandatory files are:

1. `plank.dts`: a hardware description in Devicetree format. This declares your SoC, connectors, and any other hardware components such as LEDs, buttons, sensors, or communication peripherals (USB, BLE controller, etc).

2. `Kconfig.board`, `Kconfig.defconfig`, `plank_defconfig`: software configuration in Configuration System (Kconfig) formats. This provides default settings for software features and peripheral drivers.

The optional files are:

- `board.cmake`: used for Flash and debug support
- `CMakeLists.txt`: if you need to add additional source files to your build.
- `doc/index.rst`, `doc/plank.png`: documentation for and a picture of your board. You only need this if you're Contributing your board to Zephyr.
- `plank.yaml`: a YAML file with miscellaneous metadata used by the Test Runner (Twister).

Write your devicetree

The devicetree file `boards/<ARCH>/plank/plank.dts` describes your board hardware in the Devicetree Source (DTS) format (as usual, change `plank` to your board's name). If you're new to devicetree, see Introduction to devicetree.
In general, `plank.dts` should look like this:

```dts
/dts-v1/
#include <your_soc_vendor/your_soc.dtsi>
{
    model = "A human readable name";
    compatible = "yourcompany,plank";

    chosen {
        zephyr,console = &your_uart_console;
        zephyr,sram = &your_memory_node;
        /* other chosen settings for your hardware */
    };

    /* Your board-specific hardware: buttons, LEDs, sensors, etc. */
    leds {
        compatible = "gpio-leds";
        led0: led_0 {
            gpios = < /* GPIO your LED is hooked up to */ >;
            label = "LED 0";
        };
        /* ... other LEDs ... */
    }

    buttons {
        compatible = "gpio-keys";
        /* ... your button definitions ... */
    }

    /* These aliases are provided for compatibility with samples */
    aliases {
        led0 = &led0; /* now you support the blinky sample! */
        /* other aliases go here */
    };

    &some_peripheral_you_want_to_enable {
        /* like a GPIO or SPI controller */
        status = "okay";
    };

    &another_peripheral_you_want {
        status = "okay";
    };
}

&some_peripheral_you_want_to_enable {
    /* like a GPIO or SPI controller */
    status = "okay";
};
```

If you're in a hurry, simple hardware can usually be supported by copy/paste followed by trial and error. If you want to understand details, you will need to read the rest of the devicetree documentation and the devicetree specification.

**Example: FRDM-K64F and Hexiwear K64**  This section contains concrete examples related to writing your board's devicetree.

The FRDM-K64F and Hexiwear K64 board devicetrees are defined in `frdm_k64fs.dts` and `hexiwear_k64.dts` respectively. Both boards have NXP SoCs from the same Kinetis SoC family, the K6X.

Common devicetree definitions for K6X are stored in `npx_k6x.dtsi`, which is included by both board .dts files.
files. `nxp_k6x.dtsi` in turn includes `armv7-m.dtsi`, which has common definitions for Arm v7-M cores.

Since `nxp_k6x.dtsi` is meant to be generic across K6X-based boards, it leaves many devices disabled by default using `status` properties. For example, there is a CAN controller defined as follows (with unimportant parts skipped):

```dts
can0: can@40024000 {
    ...
    status = "disabled";
    ...
};
```

It is up to the board `.dts` or application overlay files to enable these devices as desired, by setting `status` = "okay". The board `.dts` files are also responsible for any board-specific configuration of the device, such as adding nodes for on-board sensors, LEDs, buttons, etc.

For example, FRDM-K64 (but not Hexiwear K64) `.dts` enables the CAN controller and sets the bus speed:

```dts
&can0 {
    status = "okay";
    bus-speed = <125000>;
};
```

The `&can0 { ... };` syntax adds/overrides properties on the node with label `can0`, i.e. the `can@40024000` node defined in the `.dtsi` file.

Other examples of board-specific customization is pointing properties in aliases and chosen to the right nodes (see *Aliases and chosen nodes*), and making GPIO/pinmux assignments.

### Write Kconfig files

Zephyr uses the Kconfig language to configure software features. Your board needs to provide some Kconfig settings before you can compile a Zephyr application for it.

Setting Kconfig configuration values is documented in detail in *Setting Kconfig configuration values*.

There are three mandatory Kconfig files in the board directory for a board named `plank`:

- `boards/<ARCH>/plank/` Kconfig.board
- `boards/<ARCH>/plank/` Kconfig.defconfig
- `boards/<ARCH>/plank/` plank_defconfig

#### Kconfig.board

Included by `boards/Kconfig` to include your board in the list of options.

This should at least contain a definition for a `BOARD_PLANK` option, which looks something like this:

```kconfig
config BOARD_PLANK
    bool "Plank board"
    depends on SOC_SERIES_YOUR_SOC_SERIES_HERE
    select SOC_PART_NUMBER_ABCDEFGH
```

#### Kconfig.defconfig

Board-specific default values for Kconfig options.

The entire file should be inside an `if BOARD_PLANK / endif` pair of lines, like this:

```kconfig
if BOARD_PLANK
    # Always set CONFIG_BOARD here. This isn't meant to be customized,
    ...
endif
```

(continues on next page)
A Kconfig fragment that is merged as-is into the final build directory .config whenever an application is compiled for your board.

You should at least select your board's SOC and do any mandatory settings for your system clock, console, etc. The results are architecture-specific, but typically look something like this:

```plaintext
CONFIG_SOC_${VENDOR_XYZ3000}=y /* select your SoC */
CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC=120000000 /* set up your clock, etc */
CONFIG_SERIAL=y
```

A Kconfig fragment that is merged as-is into the final build directory .config whenever an application is compiled for your board revision x.y.z.

Build, test, and fix

Now it's time to build and test the application(s) you want to run on your board until you're satisfied.

For example:

```plaintext
west build -b plank samples/hello_world
west flash
```

For `west flash` to work, see Flash and debug support below. You can also just flash `build/zephyr/zephyr.elf`, `zephyr.hex`, or `zephyr.bin` with any other tools you prefer.

General recommendations

For consistency and to make it easier for users to build generic applications that are not board specific for your board, please follow these guidelines while porting.

- Unless explicitly recommended otherwise by this section, leave peripherals and their drivers disabled by default.
- Configure and enable a system clock, along with a tick source.
- Provide pin and driver configuration that matches the board's valuable components such as sensors, buttons or LEDs, and communication interfaces such as USB, Ethernet connector, or Bluetooth/Wi-Fi chip.
- If your board uses a well-known connector standard (like Arduino, Mikrobus, Grove, or 96Boards connectors), add connector nodes to your DTS and configure pin muxes accordingly.
• Configure components that enable the use of these pins, such as configuring an SPI instance to use the usual Arduino SPI pins.

• If available, configure and enable a serial output for the console using the \texttt{zephyr,console} chosen node in the devicetree.

• If your board supports networking, configure a default interface.

• Enable all GPIO ports connected to peripherals or expansion connectors.

• If available, enable pinmux and interrupt controller drivers.

• It is recommended to enable the MPU by default, if there is support for it in hardware. For boards with limited memory resources it is acceptable to disable it. When the MPU is enabled, it is recommended to also enable hardware stack protection (\texttt{CONFIG_HW_STACK_PROTECTION=y}) and, thus, allow the kernel to detect stack overflows when the system is running in privileged mode.

\textbf{Flash and debug support}

\textit{Zephyr} supports \textit{Building, Flashing and Debugging} via west extension commands.

To add \texttt{west flash} and \texttt{west debug} support for your board, you need to create a \texttt{board.cmake} file in your board directory. This file's job is to configure a “runner” for your board. (There's nothing special you need to do to get \texttt{west build} support for your board.)

“Runners” are \textit{Zephyr}-specific Python classes that wrap \textit{flash and debug host tools} and integrate with \texttt{west} to support \texttt{west flash} and related commands. Each runner supports flashing, debugging, or both. You need to configure the arguments to these Python scripts in your \texttt{board.cmake} to support those commands like this example \texttt{board.cmake}:

\begin{verbatim}
board_runner_args(jlink "--device=nrf52" "--speed=4000")
board_runner_args(pyocd "--target=nrf52" "--frequency=4000000")

include(${ZEPHYR_BASE}/boards/common/nrfjprog.board.cmake)
include(${ZEPHYR_BASE}/boards/common/jlink.board.cmake)
include(${ZEPHYR_BASE}/boards/common/pyocd.board.cmake)
\end{verbatim}

This example configures the \texttt{nrfjprog}, \texttt{jlink}, and \texttt{pyocd} runners.

\textbf{Warning:} Runners usually have names which match the tools they wrap, so the \texttt{jlink} runner wraps Segger's J-Link tools, and so on. But the runner command line options like \texttt{--speed} etc. are specific to the Python scripts.

For more details:

• Run \texttt{west flash --context} to see a list of available runners which support flashing, and \texttt{west flash --context -r <RUNNER>} to view the specific options available for an individual runner.

• Run \texttt{west debug --context} and \texttt{west debug --context <RUNNER>} to get the same output for runners which support debugging.

• Run \texttt{west flash --help} and \texttt{west debug --help} for top-level options for flashing and debugging.

• See \textit{Flash and debug runners} for Python APIs.

• Look for \texttt{board.cmake} files for other boards similar to your own for more examples.

To see what a \texttt{west flash} or \texttt{west debug} command is doing exactly, run it in verbose mode:

\begin{verbatim}
west --verbose flash
west --verbose debug
\end{verbatim}
Verbose mode prints any host tool commands the runner uses.

The order of the include() calls in your board.cmake matters. The first include sets the default runner if it’s not already set. For example, including nrfjprog.board.cmake first means that nrfjprog is the default flash runner for this board. Since nrfjprog does not support debugging, jlink is the default debug runner.

**Multiple board revisions**

See *Building for a board revision* for basics on this feature from the user perspective.

To create a new board revision for the plank board, create these additional files in the board folder:

```plaintext
boards/<ARCH>/plank
    ├── plank_<revision>.conf  # optional
    │   └── plank_<revision>.overlay  # optional
    └── revision.cmake
```

When the user builds for board plank@<revision>:

- The optional Kconfig settings specified in the file plank_<revision>.conf will be merged into the board's default Kconfig configuration.
- The optional devicetree overlay plank_<revision>.overlay will be added to the common plank.dts devicetree file.
- The revision.cmake file controls how the Zephyr build system matches the <board>@<revision> string specified by the user when building an application for the board.

Currently, <revision> can be either a numeric MAJOR.MINOR.PATCH style revision like 1.5.0, an integer number like 1, or single letter like A, B, etc. Zephyr provides a CMake board extension function, board_check_revision(), to make it easy to match either style from revision.cmake.

Valid board revisions may be specified as arguments to the board_check_revision() function, like:

```plaintext
board_check_revision(FORMAT MAJOR.MINOR.PATCH
                      VALID_REVISIONS 0.1.0 0.3.0 ...)
```

**Note:** VALID_REVISIONS can be omitted if all valid revisions have specific Kconfig fragments, such as <board>_0_1_0.conf, <board>_0_3_0.conf. This allows you to just place Kconfig revision fragments in the board folder and not have to keep the corresponding VALID_REVISIONS in sync.

The following sections describe how to support these styles of revision numbers.

**MAJOR.MINOR.PATCH revisions** Let’s say you want to add support for revisions 0.5.0, 1.0.0, and 1.5.0 of the plank board with both Kconfig fragments and devicetree overlays. Create revision.cmake with board_check_revision(FORMAT MAJOR.MINOR.PATCH), and create the following additional files in the board directory:

```plaintext
boards/<ARCH>/plank
    ├── plank_0_5_0.conf
    ├── plank_0_5_0.overlay
    ├── plank_1_0_0.conf
    ├── plank_1_0_0.overlay
    ├── plank_1_5_0.conf
    └── plank_1_5_0.overlay
    └── revision.cmake
```
Notice how the board files have changed periods (\text{``.''}\text{''}) in the revision number to underscores (\text{``\_''}).

**Fuzzy revision matching** To support “fuzzy” \texttt{MAJOR.MINOR.PATCH} revision matching for the plank board, use the following code in \texttt{revision.cmake}:

\begin{verbatim}
board_check_revision(FORMAT MAJOR.MINOR.PATCH)
\end{verbatim}

If the user selects a revision between those available, the closest revision number that is not larger than the user's choice is used. For example, if the user builds for \texttt{plank@0.7.0}, the build system will target revision \texttt{0.5.0}.

The build system will print this at CMake configuration time:

\begin{verbatim}
-- Board: plank, Revision: 0.7.0 (Active: 0.5.0)
\end{verbatim}

This allows you to only create revision configuration files for board revision numbers that introduce incompatible changes.

Any revision less than the minimum defined will be treated as an error.

You may use \texttt{0.0.0} as a minimum revision to build for by creating the file \texttt{plank_0_0_0.conf} in the board directory. This will be used for any revision lower than \texttt{0.5.0}, for example if the user builds for \texttt{plank@0.1.0}.

**Exact revision matching** Alternatively, the \texttt{EXACT} keyword can be given to \texttt{board_check_revision()} in \texttt{revision.cmake} to allow exact matches only, like this:

\begin{verbatim}
board_check_revision(FORMAT MAJOR.MINOR.PATCH EXACT)
\end{verbatim}

With this \texttt{revision.cmake}, building for \texttt{plank@0.7.0} in the above example will result in the following error message:

\begin{verbatim}
Board revision `0.7.0` not found. Please specify a valid board revision.
\end{verbatim}

**Letter revision matching** Let's say instead that you need to support revisions A, B, and C of the plank board. Create the following additional files in the board directory:

\begin{verbatim}
boards/<ARCH>/plank
    └── plank_A.conf
    └── plank_A.overlay
    └── plank_B.conf
    └── plank_B.overlay
    └── plank_C.conf
    └── plank_C.overlay
    └── revision.cmake
\end{verbatim}

And add the following to \texttt{revision.cmake}:

\begin{verbatim}
board_check_revision(FORMAT LETTER)
\end{verbatim}

**Number revision matching** Let's say instead that you need to support revisions 1, 2, and 3 of the plank board. Create the following additional files in the board directory:

\begin{verbatim}
boards/<ARCH>/plank
    └── plank_1.conf
    └── plank_1.overlay
\end{verbatim}

(continues on next page)
And add the following to revision.cmake:

```bash
board_check_revision(FORMAT NUMBER)
```

This function supports the following arguments:

- **FORMAT LETTER**: matches single letter revisions from A to Z only
- **FORMAT NUMBER**: matches integer revisions
- **FORMAT MAJOR.MINOR.PATCH**: matches exactly three digits. The command line allows for loose typing, that is `-DBOARD=<board>@1` and `-DBOARD=<board>@1.0` will be handled as `-DBOARD=<board>@1.0.0`. Kconfig fragment and devicetree overlay files must use full numbering to avoid ambiguity, so only `<board>_1_0_0.conf` and `<board>_1_0_0.overlay` are allowed.
- **EXACT**: if given, the revision is required to be an exact match. Otherwise, the closest matching revision not greater than the user's choice will be selected.
- **DEFAULT_REVISION <revision>**: if given, `<revision>` is the default revision to use when user has not selected a revision number. If not given, the build system prints an error when the user does not specify a board revision.
- **HIGHEST_REVISION <revision>**: if given, specifies the highest valid revision for a board. This can be used to ensure that a newer board cannot be used with an older Zephyr. For example, if the current board directory supports revisions 0.x.0-0.99.99 and 1.0.0-1.99.99, and it is expected that the implementation will not work with board revision 2.0.0, then giving `HIGHEST_REVISION 1.99.99` causes an error if the user builds using `<board>@2.0.0`.
- **VALID_REVISIONS**: if given, specifies a list of revisions that are valid for this board. If this argument is not given, then each Kconfig fragment of the form `<board>_<revision>.conf` in the board folder will be used as a valid revision for the board.

### Custom revision.cmake files

Some boards may not use board revisions supported by `board_check_revision()`. To support revisions of any type, the file `revision.cmake` can implement custom revision matching without calling `board_check_revision()`.

To signal to the build system that it should use a different revision than the one specified by the user, `revision.cmake` can set the variable `ACTIVE_BOARD_REVISION` to the revision to use instead. The corresponding Kconfig files and devicetree overlays must be named `<board>_<ACTIVE_BOARD_REVISION>.conf` and `<board>_<ACTIVE_BOARD_REVISION>.overlay`.

For example, if the user builds for `plank@zero`, `revision.cmake` can set `ACTIVE_BOARD_REVISION` to one to use the files `plank_one.conf` and `plank_one.overlay`. 
Contributing your board

If you want to contribute your board to Zephyr, first – thanks!

There are some extra things you'll need to do:

1. Make sure you've followed all the General recommendations. They are requirements for boards included with Zephyr.

2. Add documentation for your board using the template file doc/templates/board.tmpl. See Documentation Generation for information on how to build your documentation before submitting your pull request.

3. Prepare a pull request adding your board which follows the Contribution Guidelines.

7.5.3 Shields

Shields, also known as “add-on” or “daughter boards”, attach to a board to extend its features and services for easier and modularized prototyping. In Zephyr, the shield feature provides Zephyr-formatted shield descriptions for easier compatibility with applications.

Shield porting and configuration

Shield configuration files are available in the board directory under /boards/shields:

```
boards/shields/<shield>
   ├── <shield>.overlay
   │    └── Kconfig.shield
   │         └── Kconfig.defconfig
```

These files provide shield configuration as follows:

- `<shield>.overlay`: This file provides a shield description in devicetree format that is merged with the board’s devicetree before compilation.

- `Kconfig.shield`: This file defines shield Kconfig symbols that will be used for default shield configuration. To ease use with applications, the default shield configuration here should be consistent with those in the Write your devicetree.

- `Kconfig.defconfig`: This file defines the default shield configuration. It is made to be consistent with the Write your devicetree. Hence, shield configuration should be done by keeping in mind that features activation is application responsibility.

Besides, in order to avoid name conflicts with devices that may be defined at board level, it is advised, specifically for shields devicetree descriptions, to provide a device nodelabel is the form `<device>_<shield>`, for instance:

```
sdhc_myshield: sdhc01 {
    reg = <1>;
    ...
};
```

Board compatibility

Hardware shield-to-board compatibility depends on the use of well-known connectors used on popular boards (such as Arduino and 96boards). For software compatibility, boards must also provide a configuration matching their supported connectors.

This should be done at two different level:
• Pinmux: Connector pins should be correctly configured to match shield pins

• Devicetree: A board devicetree file, BOARD.dts should define an alternate nodelabel for each connector interface. For example, for Arduino I2C:

```c
arduino_i2c: &i2c1 {
```

**Board specific shield configuration**  If modifications are needed to fit a shield to a particular board or board revision, you can override a shield description for a specific board by adding board or board revision overriding files to a shield, as follows:

```plaintext
boards/shields/<shield>
  |__ boards
  |   |__ <board>_<revision>.overlay
  |   |__ <board>.overlay
  |   |__ <board>.defconfig
  |   |__ <board>_<revision>.conf
  |__ <board>.conf
```

**Shield activation**

Activate support for one or more shields by adding the matching -DSHIELD arg to CMake command

```bash
# From the root of the zephyr repository
west build -b None your_app -- -DSHIELD="x_nucleo_idb05a1 x_nucleo_iks01a1"
```

Alternatively, it could be set by default in a project’s CMakeLists.txt:

```bash
set(SHIELD x_nucleo_iks01a1)
```

**Shield variants**

Some shields may support several variants or revisions. In that case, it is possible to provide multiple version of the shields description:

```plaintext
boards/shields/<shield>
  |__ <shield_v1>.overlay
  |__ <shield_v1>.defconfig
  |__ <shield_v2>.overlay
  |__ <shield_v2>.defconfig
```

In this case, a shield-particular revision name can be used:

```bash
# From the root of the zephyr repository
west build -b None your_app -- -DSHIELD=shield_v2
```

You can also provide a board-specific configuration to a specific shield revision:

```plaintext
boards/shields/<shield>
  |__ <shield_v1>.overlay
  |__ <shield_v1>.defconfig
  |__ <shield_v2>.overlay
  |__ <shield_v2>.defconfig
  |__ boards
    |__ <shield_v2>
```

(continues on next page)
GPIO nexus nodes

GPIOs accessed by the shield peripherals must be identified using the shield GPIO abstraction, for example from the arduino-header-r3 compatible. Boards that provide the header must map the header pins to SOC-specific pins. This is accomplished by including a nexus node that looks like the following into the board devicetree file:

```c
arduino_header: connector {
    compatible = "arduino-header-r3";
    #gpio-cells = <2>;
    gpio-map-mask = <0xffffffff 0xffffffffc0>;
    gpio-map-pass-thru = <0 0x3f>;
    gpio-map = <0 0 &gpioa 0 0>, /* A0 */
              <1 0 &gpioa 1 0>, /* A1 */
              <2 0 &gpioa 4 0>, /* A2 */
              <3 0 &gpiob 0 0>, /* A3 */
              <4 0 &gpioc 1 0>, /* A4 */
              <5 0 &gpioc 0 0>, /* A5 */
              <6 0 &gpiob 3 0>, /* A6 */
              <7 0 &gpiob 2 0>, /* A7 */
              <8 0 &gpiob 10 0>, /* A8 */
              <9 0 &gpiob 3 0>, /* A9 */
              <10 0 &gpiob 5 0>, /* A10 */
              <11 0 &gpiob 4 0>, /* A11 */
              <12 0 &gpiob 10 0>, /* A12 */
              <13 0 &gpioa 8 0>, /* A13 */
              <14 0 &gpioa 9 0>, /* A14 */
              <15 0 &gpioc 7 0>, /* A15 */
              <16 0 &gpiob 6 0>, /* A16 */
              <17 0 &gpioa 7 0>, /* A17 */
              <18 0 &gpioa 6 0>, /* A18 */
              <19 0 &gpiob 5 0>, /* A19 */
              <20 0 &gpiob 9 0>, /* A20 */
              <21 0 &gpiob 8 0>; /* A21 */
}
```

This specifies how Arduino pin references like `<&arduino_header 11 0>` are converted to SOC gpio pin references like `<&gpiob 4 0>`.

In Zephyr GPIO specifiers generally have two parameters (indicated by `#gpio-cells = <2>`): the pin number and a set of flags. The low 6 bits of the flags correspond to features that can be configured in devicetree. In some cases it’s necessary to use a non-zero flag value to tell the driver how a particular pin behaves, as with:

```c
drdy-gpios = <&arduino_header 11 GPIO_ACTIVE_LOW>;
```

After preprocessing this becomes `<&arduino_header 11 1>`. Normally the presence of such a flag would cause the map lookup to fail, because there is no map entry with a non-zero flags value. The `gpio-map-mask` property specifies that, for lookup, all bits of the pin and all but the low 6 bits of the flags are used to identify the specifier. Then the `gpio-map-pass-thru` specifies that the low 6 bits of the flags are copied over, so the SOC GPIO reference becomes `<&gpiob 4 1>` as intended.

See [nexus node](#) for more information about this capability.

7.5. Porting

Chapter 8

Contributing to Zephyr

8.1 Contribution Guidelines

As an open-source project, we welcome and encourage the community to submit patches directly to the project. In our collaborative open source environment, standards and methods for submitting changes help reduce the chaos that can result from an active development community.

This document explains how to participate in project conversations, log bugs and enhancement requests, and submit patches to the project so your patch will be accepted quickly in the codebase.

8.1.1 Licensing

Licensing is very important to open source projects. It helps ensure the software continues to be available under the terms that the author desired.

Zephyr uses the Apache 2.0 license (as found in the LICENSE file in the project’s GitHub repo) to strike a balance between open contribution and allowing you to use the software however you would like to. The Apache 2.0 license is a permissive open source license that allows you to freely use, modify, distribute and sell your own products that include Apache 2.0 licensed software. (For more information about this, check out articles such as Why choose Apache 2.0 licensing and Top 10 Apache License Questions Answered).

A license tells you what rights you have as a developer, as provided by the copyright holder. It is important that the contributor fully understands the licensing rights and agrees to them. Sometimes the copyright holder isn’t the contributor, such as when the contributor is doing work on behalf of a company.

Components using other Licenses

There are some imported or reused components of the Zephyr project that use other licensing, as described in Licensing of Zephyr Project components.

Importing code into the Zephyr OS from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board.

By carefully reviewing potential contributions and also enforcing a Developer Certification of Origin (DCO) for contributed code, we can ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

See Contributing External Components for more information about this contributing and review process for imported components.
Licensing of Zephyr Project components  The Zephyr kernel tree imports or reuses packages, scripts and other files that are not covered by the Apache 2.0 License. In some places there is no LICENSE file or way to put a LICENSE file there, so we describe the licensing in this document.

scripts/{checkpatch.pl,checkstack.pl,get_maintainers.pl,spelling.txt}

Origin: Linux Kernel
Licensing: GPLv2 License

8.1.2 Copyrights Notices

Please follow this Community Best Practice for Copyright Notices from the Linux Foundation.

8.1.3 Developer Certification of Origin (DCO)

To make a good faith effort to ensure licensing criteria are met, the Zephyr project requires the Developer Certificate of Origin (DCO) process to be followed.

The DCO is an attestation attached to every contribution made by every developer. In the commit message of the contribution, (described more fully later in this document), the developer simply adds a Signed-off-by statement and thereby agrees to the DCO.

When a developer submits a patch, it is a commitment that the contributor has the right to submit the patch per the license. The DCO agreement is shown below and at http://developercertificate.org/.

Developer's Certificate of Origin 1.1

By making a contribution to this project, I certify that:

(a) The contribution was created in whole or in part by me and I have the right to submit it under the open source license indicated in the file; or

(b) The contribution is based upon previous work that, to the best of my knowledge, is covered under an appropriate open source license and I have the right under that license to submit that work with modifications, whether created in whole or in part by me, under the same open source license (unless I am permitted to submit under a different license), as indicated in the file; or

(c) The contribution was provided directly to me by some other person who certified (a), (b) or (c) and I have not modified it.

(d) I understand and agree that this project and the contribution are public and that a record of the contribution (including all personal information I submit with it, including my sign-off) is maintained indefinitely and may be redistributed consistent with this project or the open source license(s) involved.

DCO Sign-Off

The “sign-off” in the DCO is a “Signed-off-by:” line in each commit's log message. The Signed-off-by: line must be in the following format:
Signed-off-by: Your Name <your.email@yourdomain.com>

For your commits, replace:

- Your Name with your legal name (pseudonyms, hacker handles, and the names of groups are not allowed)
- your.email@example.com with the same email address you are using to author the commit (CI will fail if there is no match)

You can automatically add the Signed-off-by: line to your commit body using git commit -s. Use other commits in the zephyr git history as examples.

Additional requirements:

- If you are altering an existing commit created by someone else, you must add your Signed-off-by: line without removing the existing one.
- If you forget to add the Signed-off-by: line, you can add it to your previous commit by running git commit --amend -s.
- If you've pushed your changes to GitHub already you'll need to force push your branch after this with git push -f.

Notes

Any contributions made as part of submitted pull requests are considered free for the Project to use. Developers are permitted to cherry-pick patches that are included in pull requests submitted by other contributors. It is expected that

- the content of the patches will not be substantially modified,
- the cherry-picked commits or portions of a commit shall preserve the original sign-off messages and the author identity.

Modifying Contributions made by other developers describes additional recommended policies around working with contributions submitted by other developers.

8.1.4 Prerequisites

As a contributor, you'll want to be familiar with the Zephyr project, how to configure, install, and use it as explained in the Zephyr Project website and how to set up your development environment as introduced in the Zephyr Getting Started Guide.

You should be familiar with common developer tools such as Git and CMake, and platforms such as GitHub.

If you haven't already done so, you'll need to create a (free) GitHub account on https://github.com and have Git tools available on your development system.

Note: The Zephyr development workflow supports all 3 major operating systems (Linux, macOS, and Windows) but some of the tools used in the sections below are only available on Linux and macOS. On Windows, instead of running these tools yourself, you will need to rely on the Continuous Integration (CI) service using Github Actions, which runs automatically on GitHub when you submit your Pull Request (PR). You can see any failure results in the workflow details link near the end of the PR conversation list. See Continuous Integration for more information.
8.1.5 Source Tree Structure

To clone the main Zephyr Project repository use the instructions in Get Zephyr and install Python dependencies.

This section describes the main repository’s source tree. In addition to the Zephyr kernel itself, you’ll also find the sources for technical documentation, sample code, supported board configurations, and a collection of subsystem tests. All of these are available for developers to contribute to and enhance.

Understanding the Zephyr source tree can help locate the code associated with a particular Zephyr feature.

At the top of the tree, several files are of importance:

CMakeLists.txt
The top-level file for the CMake build system, containing a lot of the logic required to build Zephyr.

Kconfig
The top-level Kconfig file, which refers to the file Kconfig.zephyr also found in the top-level directory.
See the Kconfig section of the manual for detailed Kconfig documentation.

west.yml
The West (Zephyr’s meta-tool) manifest, listing the external repositories managed by the west command-line tool.

The Zephyr source tree also contains the following top-level directories, each of which may have one or more additional levels of subdirectories not described here.

arch
Architecture-specific kernel and system-on-chip (SoC) code. Each supported architecture (for example, x86 and ARM) has its own subdirectory, which contains additional subdirectories for the following areas:

• architecture-specific kernel source files
• architecture-specific kernel include files for private APIs

soc
SoC related code and configuration files.

boards
Board related code and configuration files.

doc
Zephyr technical documentation source files and tools used to generate the https://docs.zephyrproject.org web content.

drivers
Device driver code.

dts
devicetree source files used to describe non-discoverable board-specific hardware details.

include
Include files for all public APIs, except those defined under lib.

kernel
Architecture-independent kernel code.

lib
Library code, including the minimal standard C library.

misc
Miscellaneous code that doesn’t belong to any of the other top-level directories.
samples
   Sample applications that demonstrate the use of Zephyr features.

scripts
   Various programs and other files used to build and test Zephyr applications.

cmake
   Additional build scripts needed to build Zephyr.

subsys
   Subsystems of Zephyr, including:
   • USB device stack code
   • Networking code, including the Bluetooth stack and networking stacks
   • File system code
   • Bluetooth host and controller

tests
   Test code and benchmarks for Zephyr features.

share
   Additional architecture independent data. It currently contains Zephyr’s CMake package.

8.1.6 Pull Requests and Issues

Before starting on a patch, first check in our issues Zephyr Project Issues system to see what’s been reported on the issue you’d like to address. Have a conversation on the Zephyr devel mailing list (or the Zephyr Discord Server) to see what others think of your issue (and proposed solution). You may find others that have encountered the issue you’re finding, or that have similar ideas for changes or additions. Send a message to the Zephyr devel mailing list to introduce and discuss your idea with the development community.

It's always a good practice to search for existing or related issues before submitting your own. When you submit an issue (bug or feature request), the triage team will review and comment on the submission, typically within a few business days.

You can find all open pull requests on GitHub and open Zephyr Project Issues in Github issues.

8.1.7 Tools and Git Setup

Signed-off-by

The name in the commit message Signed-off-by: line and your email must match the change author-ship information. Make sure your .gitconfig is set up correctly:

```bash
git config --global user.name "David Developer"
git config --global user.email "david.developer@company.com"
```

gitlint

When you submit a pull request to the project, a series of checks are performed to verify your commit messages meet the requirements. The same step done during the CI process can be performed locally using the gitlint command.

Run gitlint locally in your tree and branch where your patches have been committed:
gitlint

Note, gitlint only checks HEAD (the most recent commit), so you should run it after each commit, or use the --commits option to specify a commit range covering all the development patches to be submitted.

twister

**Note:** twister does not currently run on Windows.

To verify that your changes did not break any tests or samples, please run the twister script locally before submitting your pull request to GitHub. To run the same tests the CI system runs, follow these steps from within your local Zephyr source working directory:

```
source zephyr-env.sh
./scripts/twister
```

The above will execute the basic twister script, which will run various kernel tests using the QEMU emulator. It will also do some build tests on various samples with advanced features that can’t run in QEMU.

We highly recommend you run these tests locally to avoid any CI failures.

clang-format

The clang-format tool can be helpful to quickly reformat large amounts of new source code to our Coding Style standards together with the .clang-format configuration file provided in the repository. clang-format is well integrated into most editors, but you can also run it manually like this:

```
clang-format -i my_source_file.c
```

clang-format is part of LLVM, which can be downloaded from the project releases page [https://github.com/llvm/llvm-project/releases](https://github.com/llvm/llvm-project/releases). Note that if you are a Linux user, clang-format will likely be available as a package in your distribution repositories.

### 8.1.8 Coding Style

Use these coding guidelines to ensure that your development complies with the project's style and naming conventions.

In general, follow the Linux kernel coding style, with the following exceptions:

- Add braces to every if, else, do, while, for and switch body, even for single-line code blocks. Use the --ignore BRACES flag to make checkpatch stop complaining.
- Use spaces instead of tabs to align comments after declarations, as needed.
- Use C89-style single line comments, /* */. The C99-style single line comment, //, is not allowed.
- Use /** */ for doxygen comments that need to appear in the documentation.

The Linux kernel GPL-licensed tool checkpatch is used to check coding style conformity.

**Note:** checkpatch does not currently run on Windows.

Checkpatch is available in the scripts directory. To invoke it when committing code, make the file `$ZEPHYR_BASE/.git/hooks/pre-commit` executable and edit it to contain:
Instead of running checkpatch at each commit, you may prefer to run it only before pushing on zephyr repo. To do this, make the file `$ZEPHYR_BASE/.git/hooks/pre-push` executable and edit it to contain:

```bash
#!/bin/sh
remote="$1"
url="$2"

z40=0000000000000000000000000000000000000000

echo "Run push hook"

while read local_ref local_sha remote_ref remote_sha
do
    args="$remote $url $local_ref $local_sha $remote_ref $remote_sha"
    exec $(ZEPHYR_BASE)/scripts/series-push-hook.sh $args
done

exit 0
```

If you want to override checkpatch verdict and push you branch despite reported issues, you can add option –no-verify to the git push command.

A more complete alternative to this is using check_compliance.py script from ci-tools repo.

### 8.1.9 Contribution Workflow

One general practice we encourage, is to make small, controlled changes. This practice simplifies review, makes merging and rebasing easier, and keeps the change history clear and clean.

When contributing to the Zephyr Project, it is also important you provide as much information as you can about your change, update appropriate documentation, and test your changes thoroughly before submitting.

The general GitHub workflow used by Zephyr developers uses a combination of command line Git commands and browser interaction with GitHub. As it is with Git, there are multiple ways of getting a task done. We’ll describe a typical workflow here:

1. Create a Fork of Zephyr to your personal account on GitHub. (Click on the fork button in the top right corner of the Zephyr project repo page in GitHub.)

2. On your development computer, change into the `zephyr` folder that was created when you obtained the code:

   ```bash
cd zephyrproject/zephyr
   ```

   Rename the default remote pointing to the upstream repository from origin to upstream:

   ```bash
git remote rename origin upstream
   ```

   Let Git know about the fork you just created, naming it origin:

   ```bash
git remote add origin https://github.com/<your github id>/zephyr
   ```

   and verify the remote repos:
git remote -v

The output should look similar to:

<table>
<thead>
<tr>
<th>Origin</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>origin</td>
<td><a href="https://github.com/">https://github.com/</a>&lt;your github id&gt;/zephyr (fetch)</td>
</tr>
<tr>
<td>origin</td>
<td><a href="https://github.com/">https://github.com/</a>&lt;your github id&gt;/zephyr (push)</td>
</tr>
<tr>
<td>upstream</td>
<td><a href="https://github.com/zephyrproject-rtos/zephyr">https://github.com/zephyrproject-rtos/zephyr</a> (fetch)</td>
</tr>
<tr>
<td>upstream</td>
<td><a href="https://github.com/zephyrproject-rtos/zephyr">https://github.com/zephyrproject-rtos/zephyr</a> (push)</td>
</tr>
</tbody>
</table>

3. Create a topic branch (off of main) for your work (if you're addressing an issue, we suggest including the issue number in the branch name):

   ```
git checkout main
```  

   ```
git checkout -b fix_comment_typo
```  

Some Zephyr subsystems do development work on a separate branch from main so you may need to indicate this in your checkout:

   ```
git checkout -b fix_out_of_date_patch origin/net
```  

4. Make changes, test locally, change, test, test again, ... (Check out the prior chapter on twister as well).

5. When things look good, start the pull request process by adding your changed files:

   ```
git add [file(s) that changed, add -p if you want to be more specific]
```  

You can see files that are not yet staged using:

   ```
git status
```  

6. Verify changes to be committed look as you expected:

   ```
git diff --cached
```  

7. Commit your changes to your local repo:

   ```
git commit -s
```  

   The -s option automatically adds your Signed-off-by: to your commit message. Your commit will be rejected without this line that indicates your agreement with the DCO. See the Commit Guidelines section for specific guidelines for writing your commit messages.

8. Push your topic branch with your changes to your fork in your personal GitHub account:

   ```
git push origin fix_comment_typo
```  

9. In your web browser, go to your forked repo and click on the Compare & pull request button for the branch you just worked on and you want to open a pull request with.

10. Review the pull request changes, and verify that you are opening a pull request for the appropriate branch. The title and message from your commit message should appear as well.

11. If you're working on a subsystem branch that's not main, you may need to change the intended branch for the pull request here, for example, by changing the base branch from main to net.

12. GitHub will assign one or more suggested reviewers (based on the CODEOWNERS file in the repo). If you are a project member, you can select additional reviewers now too.

13. Click on the submit button and your pull request is sent and awaits review. Email will be sent as review comments are made, or you can check on your pull request at https://github.com/zephyrproject-rtos/zephyr/pulls.
14. While you're waiting for your pull request to be accepted and merged, you can create another branch to work on another issue. (Be sure to make your new branch off of main and not the previous branch.):

```
git checkout main
```

```
git checkout -b fix_another_issue
```

and use the same process described above to work on this new topic branch.

15. If reviewers do request changes to your patch, you can interactively rebase commit(s) to fix review issues. In your development repo:

```
git fetch --all
```

```
git rebase --ignore-whitespace upstream/main
```

The `--ignore-whitespace` option stops `git apply` (called by rebase) from changing any whitespace. Continuing:

```
git rebase -i <offending-commit-id>^`

In the interactive rebase editor, replace `pick` with `edit` to select a specific commit (if there's more than one in your pull request), or remove the line to delete a commit entirely. Then edit files to fix the issues in the review.

As before, inspect and test your changes. When ready, continue the patch submission:

```
git add [file(s)]
git rebase --continue
```

```
git push --force origin fix_comment_typo
```

By force pushing your update, your original pull request will be updated with your changes so you won't need to resubmit the pull request.

**Note:** While amending commits and force pushing is a common review model outside GitHub, and the one recommended by Zephyr, it’s not the main model supported by GitHub. Forced pushes can cause unexpected behavior, such as not being able to use “View Changes” buttons except for the last one - GitHub complains it can’t find older commits. You’re also not always able to compare the latest reviewed version with the latest submitted version. When rewriting history GitHub only guarantees access to the latest version.

16. If the CI run fails, you will need to make changes to your code in order to fix the issues and amend your commits by rebasing as described above. Additional information about the CI system can be found in *Continuous Integration*.

### 8.1.10 Commit Guidelines

Changes are submitted as Git commits. Each commit message must contain:

- A short and descriptive subject line that is less than 72 characters, followed by a blank line. The subject line must include a prefix that identifies the subsystem being changed, followed by a colon, and a short title, for example: `doc: update wiki references to new site`. (If you’re updating an existing file, you can use `git log <filename>` to see what developers used as the prefix for previous patches of this file.)

- A change description with your logic or reasoning for the changes, followed by a blank line. (Every single line has to be less than 75 characters.)
• A Signed-off-by line, Signed-off-by: <name> <email> typically added automatically by using
  `git commit -s`
• If the change addresses an issue, include a line of the form:
  `Fixes #<issue number>`.

All changes and topics sent to GitHub must be well-formed, as described above.

Commit Message Body

When editing the commit message, please briefly explain what your change does and why it’s needed. A change summary of “Fixes stuff” will be rejected.

**Warning:** An empty change summary body is not permitted. Even for trivial changes, please include a summary body in the commit message.

The description body of the commit message must include:

- **what** the change does,
- **why** you chose that approach,
- **what** assumptions were made, and
- **how** you know it works – for example, which tests you ran.

For examples of accepted commit messages, you can refer to the Zephyr GitHub changelog.

Other Commit Expectations

- Commits must build cleanly when applied on top of each other, thus avoiding breaking bisectability.
- Commits must pass all CI checks (see *Continuous Integration* for more information)
- Each commit must address a single identifiable issue and must be logically self-contained. Unrelated changes should be submitted as separate commits.
- You may submit pull request RFCs (requests for comments) to send work proposals, progress snapshots of your work, or to get early feedback on features or changes that will affect multiple areas in the code base.
- When major new functionality is added, tests for the new functionality MUST be added to the automated test suite. All new APIs MUST be documented and tested and tests MUST cover at least 80% of the added functionality using the code coverage tool and reporting provided by the project.

Submitting Proposals

You can request a new feature or submit a proposal by submitting an issue to our GitHub Repository. If you would like to implement a new feature, please submit an issue with a proposal (RFC) for your work first, to be sure that we can use it. Please consider what kind of change it is:

- For a Major Feature, first open an issue and outline your proposal so that it can be discussed. This will also allow us to better coordinate our efforts, prevent duplication of work, and help you to craft the change so that it is successfully accepted into the project. Providing the following information will increase the chances of your issue being dealt with quickly:
  - Overview of the Proposal
  - Motivation for or Use Case
• Small Features can be crafted and directly submitted as a Pull Request.

### Identifying Contribution Origin

When adding a new file to the tree, it is important to detail the source of origin on the file, provide attributions, and detail the intended usage. In cases where the file is an original to Zephyr, the commit message should include the following (“Original” is the assumption if no Origin tag is present):

**Origin: Original**

In cases where the file is *imported from an external project*, the commit message shall contain details regarding the original project, the location of the project, the SHA-id of the origin commit for the file and the intended purpose.

For example, a copy of a locally maintained import:

**Origin: Contiki OS**
License: BSD 3-Clause
URL: [http://www.contiki-os.org/](http://www.contiki-os.org/)
commit: 853207acf6d549b10eb3e44504b1a75ae1ad63a
Purpose: Introduction of networking stack.

For example, a copy of an externally maintained import in a module repository:

**Origin: Tiny Crypt**
License: BSD 3-Clause
URL: [https://github.com/01org/tinycrypt](https://github.com/01org/tinycrypt)
commit: 08ded7f215269c39e7513668f1b939da9d0c94e6c6e
Purpose: Introduction of TinyCrypt

### 8.1.11 Continuous Integration (CI)

The Zephyr Project operates a Continuous Integration (CI) system that runs on every Pull Request (PR) in order to verify several aspects of the PR:

- Git commit formatting
- Coding Style
- Twister builds for multiple architectures and boards
- Documentation build to verify any doc changes

CI is run on Github Actions and it uses the same tools described in the *Contribution Tools* section. The CI results must be green indicating “All checks have passed” before the Pull Request can be merged. CI is run when the PR is created, and again every time the PR is modified with a commit.

The current status of the CI run can always be found at the bottom of the GitHub PR page, below the review status. Depending on the success or failure of the run you will see:

- “All checks have passed”
- “All checks have failed”

In case of failure you can click on the “Details” link presented below the failure message in order to navigate to Github Actions and inspect the results. Once you click on the link you will be taken to the
Github actions summary results page where a table with all the different builds will be shown. To see what build or test failed click on the row that contains the failed (i.e. non-green) build. The builds@lists.zephyrproject.org mailing list archives any nightly build results produced by CI.

8.1.12 Contributions to External Modules

Follow the guidelines in the Modules (External projects) section for contributing new modules and submitting changes to existing modules.

8.1.13 Treewide Changes

This section describes contributions that are treewide changes and some additional associated requirements that apply to them. These requirements exist to try to give such changes increased review and user visibility due to their large impact.

Definition and Decision Making

A treewide change is defined as any change to Zephyr APIs, coding practices, or other development requirements that either implies required changes throughout the zephyr source code repository or can reasonably be expected to do so for a wide class of external Zephyr-based source code.

This definition is informal by necessity. This is because the decision on whether any particular change is treewide can be subjective and may depend on additional context.

Project maintainers should use good judgement and prioritize the Zephyr developer experience when deciding when a proposed change is treewide. Protracted disagreements can be resolved by the Zephyr Project’s Technical Steering Committee (TSC), but please avoid premature escalation to the TSC.

Requirements for Treewide Changes

- The zephyr repository must apply the ‘treewide’ GitHub label to any issues or pull requests that are treewide changes
- The person proposing a treewide change must create an RFC issue describing the change, its rationale and impact, etc. before any pull requests related to the change can be merged
- The project's Architecture Working Group (WG) must include the issue on the agenda and discuss whether the project will accept or reject the change before any pull requests related to the change can be merged (with escalation to the TSC if consensus is not reached at the WG)
- The Architecture WG must specify the procedure for merging any PRs associated with each individual treewide change, including any required approvals for pull requests affecting specific subsystems or extra review time requirements
- The person proposing a treewide change must email devel@lists.zephyrproject.org about the RFC if it is accepted by the Architecture WG before any pull requests related to the change can be merged

Examples

Some example past treewide changes are:

- the deprecation of version 1 of the Logging API in favor of version 2 (see commit 262cc55609)
- the removal of support for a legacy Devicetree bindings syntax (6bf761fc0a)

Note that adding a new version of a widely used API while maintaining support for the old one is not a treewide change. Deprecation and removal of such APIs, however, are treewide changes.
8.2 Coding Guidelines

The project TSC and the Safety Committee of the project agreed to implement a staged and incremental approach for complying with a set of coding rules (AKA Coding Guidelines) to improve quality and consistency of the code base. Below are the agreed upon stages and the approximate timelines:

**Stage I**
Coding guideline rules are available to be followed and referenced, but not enforced. Rules are not yet enforced in CI and pull-requests cannot be blocked by reviewers/approvers due to violations.

**Stage II**
Begin enforcement on a limited scope of the code base. Initially, this would be the safety certification scope. For rules easily applied across codebase, we should not limit compliance to initial scope. This step requires tooling and CI setup and will start sometime after LTS2.

**Stage III**
Revisit the coding guideline rules and based on experience from previous stages, refine/iterate on selected rules.

**Stage IV**
Expand enforcement to the wider codebase. Exceptions may be granted on some areas of the codebase with a proper justification. Exception would require TSC approval.

**Note:** Coding guideline rules may be removed/changed at any time by filing a GH issue/RFC.

8.2.1 Main rules

The coding guideline rules are based on MISRA-C 2012 and are a subset of MISRA-C. The subset is listed in the table below with a summary of the rules, its severity and the equivalent rules from other standards for reference.

**Note:** For existing Zephyr maintainers and collaborators, if you are unable to obtain a copy through your employer, a limited number of copies will be made available through the project. If you need a copy of MISRA-C 2012, please send email to safety@lists.zephyrproject.org and provide details on reason why you can’t obtain one through other options and expected contributions once you have one. The safety committee will review all requests.

</tbody>
</table>

### 8.2.2 Additional rules
Rule A.1: Conditional Compilation

Severity  Required

Description  Do not conditionally compile function declarations in header files. Do not conditionally compile structure declarations in header files. You may conditionally exclude fields within structure definitions to avoid wasting memory when the feature they support is not enabled.

Rationale  Excluding declarations from the header based on compile-time options may prevent their documentation from being generated. Their absence also prevents use of if (IS_ENABLED(CONFIG_FOO)) {} as an alternative to preprocessor conditionals when the code path should change based on the selected options.

Rule A.2: Inclusive Language

Severity  Required

Description  Do not introduce new usage of offensive terms listed below. This rule applies but is not limited to source code, comments, documentation, and branch names. Replacement terms may vary by area or subsystem, but should aim to follow updated industry standards when possible.

Exceptions are allowed for maintaining existing implementations or adding new implementations of industry standard specifications governed externally to the Zephyr Project.

Existing usage is recommended to change as soon as updated industry standard specifications become available or new terms are publicly announced by the governing body, or immediately if no specifications apply.

<table>
<thead>
<tr>
<th>Offensive Terms</th>
<th>Recommended Replacements</th>
</tr>
</thead>
<tbody>
<tr>
<td>{master,leader} / slave</td>
<td>• {primary,main} / {secondary, replica}</td>
</tr>
<tr>
<td></td>
<td>• {initiator,requester} / {target, responder}</td>
</tr>
<tr>
<td></td>
<td>• {controller,host} / {device,worker, proxy,target}</td>
</tr>
<tr>
<td></td>
<td>• director / performer</td>
</tr>
<tr>
<td></td>
<td>• central / peripheral</td>
</tr>
<tr>
<td>blacklist / whitelist</td>
<td>• denylist / allowlist</td>
</tr>
<tr>
<td></td>
<td>• blocklist / allowlist</td>
</tr>
<tr>
<td></td>
<td>• rejectlist / acceptlist</td>
</tr>
<tr>
<td>grandfather policy</td>
<td>• legacy</td>
</tr>
<tr>
<td>sanity</td>
<td>• coherence</td>
</tr>
<tr>
<td></td>
<td>• confidence</td>
</tr>
</tbody>
</table>

Rationale  Offensive terms do not create an inclusive community environment and therefore violate the Zephyr Project Code of Conduct. This coding rule was inspired by a similar rule in Linux.
**Status**  Related GitHub Issues and Pull Requests are tagged with the Inclusive Language Label.

### 8.2.3 Parasoft Codescan Tool

Parasoft Codescan is an official static code analysis tool used by the Zephyr project. It is used to automate compliance with a range of coding and security standards. The tool is currently set to the MISRA-C:2012 Coding Standard because the Zephyr Coding Guidelines are based on that standard. It is used together with the Coverity Scan tool to achieve the best code health and precision in bug findings.
Violations fixing process

Step 1
Any Zephyr Project member, company or a developer can request access to the Parasoft reporting centre if they wish to get involved in fixing violations by submitting issues.

Step 2
A developer starts to review violations.

Step 3
A developer submits a Github PR with the fix. Commit messages should follow the same guidelines as other PRs in the Zephyr project. Please add a comment that your fix was found by a static coding scanning tool. Developers should follow and refer to the Zephyr Coding Guidelines as basic rules for coding. These rules are based on the MISRA-C standard.

Below you can find an example of a recommended commit message:

```
lib: os: add braces to 'if' statements

An 'if' (expression) construct shall be followed by a compound statement. Add braces to improve readability and maintainability.

Found as a coding guideline violation (Rule 15.6) by static coding scanning tool.

Signed-off-by: Johnny Developer <johnny.developer@company.com>
```

Step 4
If a violation is a false positive, the developer should mark it for the Codescan tool just like they would do for the Coverity tool. The developer should also add a comment to the code explaining that the violation raised by the static code analysis tool should be considered a false positive.

Step 5
If the developer has found a real violation that the community decided to ignore, the developer must submit a PR with a suppression tag and a comment explaining why the violation has been deviated. The template structure of the comment and tag in the code should be:

```
/* Explain why that part of the code doesn't follow the standard,
   * explain why it is a deliberate deviation from the standard.
   * Don't refer to the Parasoft tool here, just mention that static code
   * analysis tool raised a violation in the line below.
   */

code_line_with_a_violation /* parasoft-suppress Rule ID */
```

Below you can find an example of a recommended commit message:

```
testsuite: suppress usage of setjmp in a testcode (rule 21.4)

According to the Rule 21.4 the standard header file <setjmp.h> shall not be used. We will suppress this violation because it is in test code. Tag suppresses reporting of the violation for the line where the violation is located. This is a deliberate deviation.

Found as a coding guideline violation (Rule 21.4) by static coding scanning tool.

Signed-off-by: Johnny Developer <johnny.developer@company.com>
```

The example below demonstrates how deviations can be suppressed in the code:
/* Static code analysis tool can raise a violation that the standard header <setjmp.h> shall not be used.
   Since this violation is in test code, we will suppress it.
   Deliberate deviation.
*/
#include <setjmp.h> /* parasoft-suppress MISRAC2012-RULE_21_4-a MISRAC2012-RULE_21_4-b */

This variant above suppresses items MISRAC2012-RULE_21_4-a and MISRAC2012-RULE_21_4-b on the line with “setjmp” header include. You can add as many rules to suppress you want - just make sure to keep the Parasoft tag on one line and separate rules with a space. To read more about suppressing findings in the Parasoft tool, refer to the official Parasoft documentation.

Step 6
After a PR is submitted, the developer should add the Coding guidelines and MISRA-C Github labels so their PR can be easily tracked by maintainers. If you have any concerns about what your PR should look like, you can search on Github using those tags and refer to similar PRs that have already been merged.

8.3 Documentation

8.3.1 Documentation Guidelines

Note: For instructions on building the documentation, see Documentation Generation.

Zephyr Project content is written using the reStructuredText markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted standalone website. Developers can view this content either in its raw form as .rst markup files, or (with Sphinx installed) they can build the documentation using the Makefile on Linux systems, or make.bat on Windows, to generate the HTML content. The HTML content can then be viewed using a web browser. This same .rst content is also fed into the Zephyr documentation website (with a different theme applied).

You can read details about reStructuredText and about Sphinx extensions from their respective websites. This document provides a quick reference for commonly used reST and Sphinx-defined directives and roles used to create the documentation you're reading.

Headings

While reST allows use of both and overline and matching underline to indicate a heading, we only use an underline indicator for headings.

- Document title (h1) use “#” for the underline character
- First section heading level (h2) use “*”
- Second section heading level (h3) use “=”
- Third section heading level (h4) use “-”

The heading underline must be at least as long as the title it’s under.

For example:

This is a title heading
********************************

(continues on next page)
some content goes here

First section heading
********************

Content Highlighting

Some common reST inline markup samples:

- one asterisk: *text* for emphasis (*italics*),
- two asterisks: **text** for strong emphasis (**boldface**), and
- two backquotes: `text` for inline code samples.

If asterisks or backquotes appear in running text and could be confused with inline markup delimiters, you can eliminate the confusion by adding a backslash (\) before it.

Lists

For bullet lists, place an asterisk (*) or hyphen (-) at the start of a paragraph and indent continuation lines with two spaces.

The first item in a list (or sublist) must have a blank line before it and should be indented at the same level as the preceding paragraph (and not indented itself).

For numbered lists start with a 1. or a. for example, and continue with autonumbering by using a # sign. Indent continuation lines with three spaces:

* This is a bulleted list.
* It has two items, the second item and has more than one line of reST text. Additional lines are indented to the first character of the text of the bullet list.

1. This is a new numbered list. If the wasn't a blank line before it, it would be a continuation of the previous list (or paragraph).
#. It has two items too.

a. This is a numbered list using alphabetic list headings
#. It has three items (and uses autonumbering for the rest of the list)
#. Here's the third item

#. This is an autonumbered list (default is to use numbers starting with 1).

   #. This is a second-level list under the first item (also autonumbered). Notice the indenting.
   #. And a second item in the nested list.
   #. And a second item back in the containing list. No blank line needed, but it wouldn't hurt for readability.

Definition lists (with a term and its definition) are a convenient way to document a word or phrase with an explanation. For example this reST content:

The Makefile has targets that include:
html
  Build the HTML output for the project

clean
  Remove all generated output, restoring the folders to a clean state.

Would be rendered as:

The Makefile has targets that include:

```
html
  Build the HTML output for the project

clean
  Remove all generated output, restoring the folders to a clean state.
```

Multi-column lists

If you have a long bullet list of items, where each item is short, you can indicate the list items should be rendered in multiple columns with a special .. rst-class:: rst-columns directive. The directive will apply to the next non-comment element (e.g., paragraph), or to content indented under the directive. For example, this unordered list:

```
.. rst-class:: rst-columns

* A list of
* short items
* that should be
* displayed
* horizontally
* so it doesn't
* use up so much
* space on
* the page
```

would be rendered as:

```
• A list of
• short items
• that should be
• displayed
• horizontally
• so it doesn't
• use up so much
• space on
• the page
```

A maximum of three columns will be displayed, and change based on the available width of the display window; reducing to one column on narrow (phone) screens if necessary. We’ve deprecated use of the hlist directive because it misbehaves on smaller screens.
Tables

There are a few ways to create tables, each with their limitations or quirks. Grid tables offer the most capability for defining merged rows and columns, but are hard to maintain:

<table>
<thead>
<tr>
<th>Header row, column 1</th>
<th>Header 2</th>
<th>Header 3</th>
<th>Header 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>(header rows optional)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

+------------------------+------------+----------+----------+
| body row 1, column 1  | column 2   | column 3 | column 4 |
| body row 2            | ...        | ...      | you can  |
| body row 3 with a two column span | ... | span     | rows     |
| body row 4            | ...        | ...      | too       |

This example would render as:

<table>
<thead>
<tr>
<th>Header row, column 1 (header rows optional)</th>
<th>Header 2</th>
<th>Header 3</th>
<th>Header 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>body row 1, column 1</td>
<td>column 2</td>
<td>column 3</td>
<td>column 4</td>
</tr>
<tr>
<td>body row 2</td>
<td>...</td>
<td>...</td>
<td>you can</td>
</tr>
<tr>
<td>body row 3 with a two column span</td>
<td>...</td>
<td>span</td>
<td>rows</td>
</tr>
<tr>
<td>body row 4</td>
<td>...</td>
<td>...</td>
<td>too</td>
</tr>
</tbody>
</table>

List tables are much easier to maintain, but don’t support row or column spans:

```
.. list-table:: Table title
    :widths: 15 20 40
    :header-rows: 1

    * - Heading 1
    - Heading 2
    - Heading 3
    * - body row 1, column 1
    - body row 1, column 2
    - body row 1, column 3
    * - body row 2, column 1
    - body row 2, column 2
    - body row 2, column 3
```

This example would render as:

<table>
<thead>
<tr>
<th>Table 8.2: Table title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Heading 1</td>
</tr>
<tr>
<td>body row 1, column 1</td>
</tr>
<tr>
<td>body row 2, column 1</td>
</tr>
</tbody>
</table>

The :widths: parameter lets you define relative column widths. The default is equal column widths. If you have a three-column table and you want the first column to be half as wide as the other two equal-width columns, you can specify :widths: 1 2 2. If you'd like the browser to set the column widths automatically based on the column contents, you can use :widths: auto.
File names and Commands

Sphinx extends reST by supporting additional inline markup elements (called “roles”) used to tag text with special meanings and allow style output formatting. (You can refer to the Sphinx Inline Markup documentation for the full list).

For example, there are roles for marking filenames (:file:`name`) and command names such as make (:command:`make`). You can also use the ``inline code`` markup (double backticks) to indicate a filename.

For references to files that are in the Zephyr GitHub tree, a special role can be used that creates a hyperlink to that file. For example a reference to the reST file used to create this document can be generated using :zephyr_file:`doc/contribute/documentation/index.rst` that will show up as doc/contribute/documentation/index.rst, a link to the “blob” file in the github repo. There’s also a :zephyr_raw:`doc/guides/documentation/index.rst` role that will link to the “raw” content, doc/contribute/documentation/index.rst. (You can click on these links to see the difference.)

Internal Cross-Reference Linking

Traditional ReST links are only supported within the current file using the notation:

Refer to the `internal-linking` page

which renders as,

Refer to the internal-linking page

Note the use of a trailing underscore to indicate an outbound link. In this example, the label was added immediately before a heading, so the text that’s displayed is the heading text itself. You can change the text that’s displayed as the link writing this as:

Refer to the `show this text instead <internal-linking>` page

which renders as,

Refer to the show this text instead page

External Cross-Reference Linking

With Sphinx’s help, we can create link-references to any tagged text within the Zephyr Project documentation.

Target locations in a document are defined with a label directive:

.. _my label name:

Heading ======

Note the leading underscore indicating an inbound link. The content immediately following this label must be a heading, and is the target for a :ref:`my label name` reference from anywhere within the Zephyr documentation. The heading text is shown when referencing this label. You can also change the text that’s displayed for this link, such as:

:ref:`some other text <my label name>`

To enable easy cross-page linking within the site, each file should have a reference label before its title so it can be referenced from another file. These reference labels must be unique across the whole site, so generic names such as “samples” should be avoided. For example the top of this document’s .rst file is:
Documentation Guidelines for the Zephyr Project

Other .rst documents can link to this document using the :ref:`doc_guidelines` tag and it will show up as Documentation Guidelines. This type of internal cross reference works across multiple files, and the link text is obtained from the document source so if the title changes, the link text will update as well.

You can also define links to any URL and then reference it in your document. For example, with this label definition in the document:

.. _Zephyr Wikipedia Page:
   https://en.wikipedia.org/wiki/Zephyr_(operating_system)

you can reference it with:

Read the `Zephyr Wikipedia Page`_ for more information about the project.

`any` links

Within the Zephyr project, we’ve defined the default role to be “any”, meaning if you just write a phrase in back-ticks, e.g., `doc_guidelines`, Sphinx will search through all domains looking for something called doc_guidelines to link to. In this case it will find the label at the top of this document, and link to doc_guidelines. This can be useful for linking to doxygen-generated links for function names and such, but will cause a warning such as:

```
WARNING: 'any' reference target not found: doc_guidelines
```

if you misspelled `doc_guidelines` as `doc_giudelines`.

Non-ASCII Characters

You can insert non-ASCII characters such as a Trademark symbol (™), by using the notation \|trade|. Available replacement names are defined in an include file used during the Sphinx processing of the reST files. The names of these replacement characters are the same as used in HTML entities used to insert characters in HTML, e.g., &trade; and are defined in the file sphinx_build/substitutions.txt as listed here:

```
.. |br| raw:: html .. force a line break in HTML output (blank lines needed here)
   <br />
.. |p| raw:: html .. force a blank line in HTML output (blank lines needed here)
   <p></p>
.. These are replacement strings for non-ASCII characters used within the project using the same name as the html entity names (e.g., &copy;) for that character
```

(continues on next page)
We've kept the substitutions list small but others can be added as needed by submitting a change to the substitutions.txt file.

Code and Command Examples

Use the reST code-block directive to create a highlighted block of fixed-width text, typically used for showing formatted code or console commands and output. Smart syntax highlighting is also supported (using the Pygments package). You can also directly specify the highlighting language. For example:

```c
struct z_object {
    char *name;
    uint8_t perms[CONFIG_MAX_THREAD_BYTES];
    uint8_t type;
    uint8_t flags;
    uint32_t data;
} __packed;
```

Note the blank line between the code-block directive and the first line of the code-block body, and the body content is indented three spaces (to the first non-white space of the directive name).

This would be rendered as:

```c
struct z_object {
    char *name;
    uint8_t perms[CONFIG_MAX_THREAD_BYTES];
    uint8_t type;
    uint8_t flags;
    uint32_t data;
} __packed;
```

You can specify other languages for the code-block directive, including c, python, and rst, and also console, bash, or shell. If you want no syntax highlighting, use the language none, for example:

```none
This would be a block of text styled with a background and box, but with no syntax highlighting.
```

Would display as:

This would be a block of text styled with a background and box, but with no syntax highlighting.
There's a shorthand for writing code blocks too: end the introductory paragraph with a double colon (::) and indent the code block content by three spaces. On output, only one colon will be shown. The highlighting package makes a best guess at the type of content in the block and highlighting purposes.

Images

Images are included in documentation by using an image directive:

```restructuredtext
.. image:: ../../../images/doc-gen-flow.png
   :align: center
   :alt: alt text for the image
```

or if you'd like to add an image caption, use:

```restructuredtext
.. figure:: ../../../images/doc-gen-flow.png
   :alt: image description

   Caption for the figure
```

The file name specified is relative to the document source file, and we recommend putting images into an `images` folder where the document source is found. The usual image formats handled by a web browser are supported: JPEG, PNG, GIF, and SVG. Keep the image size only as large as needed, generally at least 500 px wide but no more than 1000 px, and no more than 250 KB unless a particularly large image is needed for clarity.

Tabs, spaces, and indenting

Indenting is significant in reST file content, and using spaces is preferred. Extra indenting can (unintentionally) change the way content is rendered too. For lists and directives, indent the content text to the first non-white space in the preceding line. For example:

```restructuredtext
* List item that spans multiple lines of text
  showing where to indent the continuation line.

1. And for numbered list items, the continuation
   line should align with the text of the line above.

   .. code-block::

      The text within a directive block should align with the
      first character of the directive name.
```

Keep the line length for documentation less than 80 characters to make it easier for reviewing in GitHub. Long lines because of URL references are an allowed exception.

**zephyr-app-commands Directive**

This is a Zephyr directive for generating consistent documentation of the shell commands needed to manage (build, flash, etc.) an application.

For example, to generate commands to build samples/hello_world for qemu_x86 use:

```restructuredtext
.. zephyr-app-commands::
   :zephyr-app: samples/hello_world
   :board: qemu_x86
   :goals: build
```
Directive options:

:tool:
   which tool to use. Valid options are currently ‘cmake’, ‘west’ and ‘all’. The default is ‘west’.

:app:
   path to the application to build.

:zephyr-app:
   path to the application to build, this is an app present in the upstream zephyr repository. Mutually exclusive with :app:

:cd-into:
   if set, build instructions are given from within the :app: folder, instead of outside of it.

:generator:
   which build system to generate. Valid options are currently ‘ninja’ and ‘make’. The default is ‘ninja’. This option is not case sensitive.

:host-os:
   which host OS the instructions are for. Valid options are ‘unix’, ‘win’ and ‘all’. The default is ‘all’.

:board:
   if set, the application build will target the given board.

:shield:
   if set, the application build will target the given shield.

:conf:
   if set, the application build will use the given configuration file. If multiple conf files are provided, enclose the space-separated list of files with quotes, e.g., “a.conf b.conf”.

:gen-args:
   if set, additional arguments to the CMake invocation

:build-args:
   if set, additional arguments to the build invocation

:build-dir:
   if set, the application build directory will APPEND this (relative, Unix-separated) path to the standard build directory. This is mostly useful for distinguishing builds for one application within a single page.

:goals:
   a whitespace-separated list of what to do with the app (in ‘build’, ‘flash’, ‘debug’, ‘debugserver’, ‘run’). Commands to accomplish these tasks will be generated in the right order.

:maybe-skip-config:
   if set, this indicates the reader may have already created a build directory and changed there, and will tweak the text to note that doing so again is not necessary.

:compact:
   if set, the generated output is a single code block with no additional comment lines

:west-args:
   if set, additional arguments to the west invocation (ignored for CMake)

For example, the .. zephyr-app-commands listed above would render like this in the generated HTML output:

# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
### Alternative Tabbed Content

As introduced in the *Getting Started Guide*, you can provide alternative content to the reader via a tabbed interface. When the reader clicks on a tab, the content for that tab is displayed, for example:

```latex
.. tabs::

  .. tab:: Apples
    
    Apples are green, or sometimes red.

  .. tab:: Pears
    
    Pears are green.

  .. tab:: Oranges
    
    Oranges are orange.
```

will display as:

**Apples**

Apples are green, or sometimes red.

**Pears**

Pears are green.

**Oranges**

Oranges are orange.

Tabs can also be grouped, so that changing the current tab in one area changes all tabs with the same name throughout the page. For example:

**Linux**

Linux Line 1

macOS

macOS Line 1

Windows

Windows Line 1

**Linux**

Linux Line 2

macOS

macOS Line 2

Windows

Windows Line 2

In this latter case, we're using `.. group-tab::` instead of simply `.. tab::`. Under the hood, we're using the `sphinx-tabs` extension that's included in the Zephyr setup. Within a tab, you can have almost any content *other than a heading* (code-blocks, ordered and unordered lists, pictures, paragraphs, and such). You can read more about `sphinx-tabs` from the link above.
**Instruction Steps**

Also introduced in the *Getting Started Guide* is a style that makes it easy to create tutorial guides with clearly identified steps. Add the `.. rst-class:: numbered-step` directive immediately before a second-level heading (by project convention, a heading underlined with asterisks `******`, and it will be displayed as a numbered step, sequentially numbered within the document. For example:

```
.. rst-class:: numbered-step

Put your right hand in

**************
```

**Put your right hand in**

See the `doc/develop/getting_started/index.rst` source file and compare with the *Getting Started Guide* to see a full example. As implemented, only one set of numbered steps is intended per document.

For instructions on building the documentation, see *Documentation Generation*.

### 8.3.2 Documentation Generation

These instructions will walk you through generating the Zephyr Project’s documentation on your local system using the same documentation sources as we use to create the online documentation found at [https://docs.zephyrproject.org](https://docs.zephyrproject.org)

**Documentation overview**

Zephyr Project content is written using the reStructuredText markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted stand-alone website. Developers can view this content either in its raw form as .rst markup files, or you can generate the HTML content and view it with a web browser directly on your workstation. This same .rst content is also fed into the Zephyr Project’s public website documentation area (with a different theme applied).

You can read details about reStructuredText, and Sphinx from their respective websites.

The project’s documentation contains the following items:

- ReStructuredText source files used to generate documentation found at the [https://docs.zephyrproject.org](https://docs.zephyrproject.org) website. Most of the reStructuredText sources are found in the `/doc` directory, but others are stored within the code source tree near their specific component (such as `/samples` and `/boards`)
- Doxygen-generated material used to create all API-specific documents also found at [https://docs.zephyrproject.org](https://docs.zephyrproject.org)
- Script-generated material for kernel configuration options based on Kconfig files found in the source code tree

The reStructuredText files are processed by the Sphinx documentation system, and make use of the breathe extension for including the doxygen-generated API material. Additional tools are required to generate the documentation locally, as described in the following sections.

**Installing the documentation processors**

Our documentation processing has been tested to run with:

- Doxygen version 1.8.13
- Graphviz 2.43
In order to install the documentation tools, first install Zephyr as described in `Getting Started Guide`. Then install additional tools that are only required to generate the documentation, as described below:

**Linux**

On Ubuntu Linux:

```bash
sudo apt-get install --no-install-recommends doxygen graphviz librsvg2-bin \
texlive-latex-base texlive-latex-extra latexmk texlive-fonts-recommended
```

On Fedora Linux:

```bash
sudo dnf install doxygen graphviz texlive-latex latexmk \
texlive-collection-fontsrecommended librsvg2-tools
```

On Clear Linux:

```bash
sudo swupd bundle-add texlive graphviz
```

On Arch Linux:

```bash
sudo pacman -S graphviz doxygen librsvg texlive-core texlive-bin \
texlive-latexextra texlive-fontsextra
```

**macOS**

Use `brew` and `tlmgr` to install the tools:

```bash
brew install doxygen graphviz mactex librsvg
tlmgr install latexmk
tlmgr install collection-fontsrecommended
```

**Windows**

Open a `cmd.exe` window as **Administrator** and run the following command:

```bash
choco install doxygen.install graphviz strawberryperl miktex rsvg-convert
```
Note: On Windows, the Sphinx executable `sphinx-build.exe` is placed in the `Scripts` folder of your Python installation path. Depending on how you have installed Python, you might need to add this folder to your `PATH` environment variable. Follow the instructions in Windows Python Path to add those if needed.

Documentation presentation theme

Sphinx supports easy customization of the generated documentation appearance through the use of themes. Replace the theme files and do another `make html` and the output layout and style is changed. The `read-the-docs` theme is installed as part of the Get Zephyr and install Python dependencies step you took in the getting started guide.

Running the documentation processors

The `/doc` directory in your cloned copy of the Zephyr project git repo has all the .rst source files, extra tools, and Makefile for generating a local copy of the Zephyr project's technical documentation. Assuming the local Zephyr project copy is in a folder `zephyr` in your home folder, here are the commands to generate the html content locally:

```
# On Linux/macOS
cd ~/zephyr/doc
# On Windows
cd %userprofile%\zephyr\doc

# Use cmake to configure a Ninja-based build system:
cmake -GNinja -B_build .

# Enter the build directory
cd _build

# To generate HTML output, run ninja on the generated build system:
ninja html
# If you modify or add .rst files, run ninja again:
ninja html

# To generate PDF output, run ninja on the generated build system:
ninja pdf
```

Warning: The documentation build system creates copies in the build directory of every .rst file used to generate the documentation, along with dependencies referenced by those .rst files. This means that Sphinx warnings and errors refer to the copies, and not the version-controlled original files in Zephyr. Be careful to make sure you don’t accidentally edit the copy of the file in an error message, as these changes will not be saved.

Depending on your development system, it will take up to 15 minutes to collect and generate the HTML content. When done, you can view the HTML output with your browser started at `doc/_build/html/index.html` and if generated, the PDF file is available at `doc/_build/pdf/zephyr.pdf`.

If you want to build the documentation from scratch just delete the contents of the build folder and run `cmake` and then `ninja` again.

8.3. Documentation
Note: If you add or remove a file from the documentation, you need to re-run CMake.

On Unix platforms a convenience doc/Makefile can be used to build the documentation directly from there:

```bash
cd ~/zephyr/doc

# To generate HTML output
make html

# To generate PDF output
make pdf
```

Filtering expected warnings

There are some known issues with Sphinx/Breathe that generate Sphinx warnings even though the input is valid C code. While these issues are being considered for fixing we have created a Sphinx extension that allows to filter them out based on a set of regular expressions. The extension is named zephyr_warnings_filter and it is located at doc/_extensions/zephyr/warnings_filter.py. The warnings to be filtered out can be added to the doc/known-warnings.txt file.

The most common warning reported by Sphinx/Breathe is related to duplicate C declarations. This warning may be caused by different Sphinx/Breathe issues:

- Multiple declarations of the same object are not supported
- Different objects (e.g. a struct and a function) can not share the same name
- Nested elements (e.g. in a struct or union) can not share the same name

Developer-mode Document Building

When making and testing major changes to the documentation, we provide an option to temporarily stub-out the auto-generated Devicetree bindings documentation so the doc build process runs faster.

To enable this mode, set the following option when invoking cmake:

```
-DDT_TURBO_MODE=1
```

or invoke make with the following target:

```bash
cd ~/zephyr

# To generate HTML output without detailed Kconfig
make html-fast
```

Linking external Doxygen projects against Zephyr

External projects that build upon Zephyr functionality and wish to refer to Zephyr documentation in Doxygen (through the use of @ref), can utilize the tag file exported at zephyr.tag

Once downloaded, the tag file can be used in a custom doxyfile.in as follows:

```
TAGFILES = "/path/to/zephyr.tag=https://docs.zephyrproject.org/latest/doxygen/html/"
```

For additional information refer to Doxygen External Documentation.
8.4 Contributing External Components

In some cases it is desirable to leverage existing, external source code in order to avoid re-implementing basic functionality or features that are readily available in other open source projects.

This section describes the circumstances under which external source code can be imported into Zephyr, and the process that governs the inclusion.

There are three main factors that will be considered during the inclusion process in order to determine whether it will be accepted. These will be described in the following sections.

8.4.1 Software License

Note: External source code licensed under the Apache-2.0 license is not subject to this section.

Integrating code into the Zephyr Project from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board, as described in the Zephyr project charter. The board will automatically reject licenses that have not been approved by the Open Source Initiative (OSI). See the Submission and review process section for more details.

By carefully reviewing potential contributions and also enforcing a Developer Certification of Origin (DCO) for contributed code, we ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

8.4.2 Merit

Just like with any other regular contribution, one that contains external code needs to be evaluated for merit. However, in the particular case of code that comes from an existing project, there are additional questions that must be answered in order to accept the contribution. More specifically, the following will be considered by the Technical Steering Committee and evaluated carefully before the external source code is accepted into the project:

- Is this the most optimal way to introduce the functionality to the project? Both the cost of implementing this internally and the one incurred in maintaining an externally developed codebase need to be evaluated.
- Is the external project being actively maintained? This is particularly important for source code that deals with security or cryptography.
- Have alternatives to the particular implementation proposed been considered? Are there other open source project that implement the same functionality?

8.4.3 Mode of integration

There are two ways of integrating external source code into the Zephyr Project, and careful consideration must be taken to choose the appropriate one for each particular case.

Integration in the main tree

The first way to integrate external source code into the project is to simply import the source code files into the main zephyr repository. This automatically implies that the imported source code becomes part of the “mainline” codebase, which in turn requires that:

- The code is formatted according to the Zephyr Coding Style
• The code adheres to the project's Coding Guidelines
• The code is subject to the same checks and verification requirements as the rest of the code in the main tree, including static analysis
• All files contain an SPDX tag if not already present
• An entry is added to the licensing page <zephyr_licensing>

This mode of integration can be applicable to both small and large external codebases, but it is typically used more commonly with the former.

**Integration as a module**

The second way of integrating external source code into the project is to import the whole or parts of the third-party open source project into a separate repository, and then include it under the form of a module. With this approach the code is considered as being developed externally, and thus it is not automatically subject to the requirements of the previous section.

**8.4.4 Ongoing maintenance**

Regardless of the mode of integration, external source code that is integrated in Zephyr requires regular ongoing maintenance. The submitter of the proposal to integrate external source code must therefore commit to maintain the integration of such code for the foreseeable future. This may require adding an entry in the `MAINTAINERS.yml` as part of the process.

**8.4.5 Submission and review process**

Before external source code can be included in the project, it must be reviewed and accepted by the Technical Steering Committee (TSC) and, in some cases, by the Zephyr governing board.

A request for external source code integration must be made by creating a new issue in the Zephyr project issue tracking system on GitHub with details about the source code and how it integrates into the project.

Follow the steps below to begin the submission process:

1. Make sure to read through the Contributing External Components section in detail, so that you are informed of the criteria used by the TSC and board in order to approve or reject a request
2. Use the New External Source Code Issue to open an issue
3. Fill out all required sections, making sure you provide enough detail for the TSC to assess the merit of the request. Optionally you can also create a Pull Request that demonstrates the integration of the external source code and link to it from the issue
4. Wait for feedback from the TSC, respond to any additional questions added as GitHub issue comments

If, after consideration by the TSC, the conclusion is that integrating external source code is the best solution, and the external source code is licensed under the Apache-2.0 license, the submission process is complete and the external source code can be integrated.

If, however, the external source code uses a license other than Apache-2.0, then these additional steps must be followed:

1. The TSC chair will forward the link to the GitHub issue created during the early submission process to the Zephyr governing board for further review
2. The Zephyr governing board has two weeks to review and ask questions:
   • If there are no objections, the matter is closed. Approval can be accelerated by unanimous approval of the board before the two weeks are up
- If a governing board member raises an objection that cannot be resolved via email, the board will meet to discuss whether to override the TSC approval or identify other approaches that can resolve the objections.

3. On approval of the Zephyr TSC and governing board the submission process is complete.

The flowchart below shows an overview of the process:

---

### 8.5 Binary Blobs

In the context of an operating system that supports multiple architectures and many different IC families, some functionality may be unavailable without the help of executable code distributed in binary form. Binary blobs (or blobs for short) are files containing proprietary machine code or data in a binary format, e.g., without corresponding source code released under an OSI approved license.

Zephyr supports downloading and using third-party binary blobs via its built-in mechanisms, with some important caveats, described in the following sections. It is important to note that all the information in this section applies only to upstream (vanilla) Zephyr.

There are no limitations whatsoever (except perhaps license compatibility) in the support for binary blobs in forks or third-party distributions of Zephyr. In fact, Zephyr's build system supports arbitrary use cases related to blobs. This includes linking against libraries, flashing images to targets, etc. Users are therefore free to create Zephyr-based downstream software which uses binary blobs if they cannot meet the requirements described in this page.

#### 8.5.1 Software license

Most binary blobs are distributed under proprietary licenses which vary significantly in nature and conditions. It is up to the vendor to specify the license as part of the blob submission process. Blob vendors may impose a click-through or other EULA-like workflow when users fetch and install blobs.
8.5.2 Hosting

Blobs must be hosted on the Internet and managed by third-party infrastructure. Two potential examples are Git repositories and web servers managed by individual hardware vendors.

The Zephyr Project does not host binary blobs in its Git repositories or anywhere else.

8.5.3 Fetching blobs

Blobs are fetched from official third-party sources by the west blobs command command.

The blobs themselves must be specified in the module.yml files included in separate Zephyr module repositories maintained by their respective vendors. This means that in order to include a reference to a binary blob to the upstream Zephyr distribution, a module repository must exist first or be created as part of the submission process.

Each blob which may be fetched must be individually identified in the corresponding module.yml file. A specification for a blob must contain:

- An abstract description of the blob itself
- Version information
- A reference to vendor-provided documentation
- The blob’s type, which must be one of the allowed types
- A checksum for the blob, which west blobs checks after downloading. This is required for reproducibility and to allow bisecting issues as blobs change using Git and west
- License text applicable to the blob or a reference to such text, in SPDX format

See the corresponding section for a more formal definition of the fields.

The west blobs command can be used to list metadata of available blobs and to fetch blobs from user-selected modules.

The west blobs command only fetches and stores the binary blobs themselves. Any accompanying code, including interface header files for the blobs, must be present in the corresponding module repository.

8.5.4 Tainting

Inclusion of binary blobs will taint the Zephyr build. The definition of tainting originates in the Linux kernel and, in the context of Zephyr, a tainted image will be one that includes binary blobs in it.

Tainting will be communicated to the user in the following manners:

- One or more Kconfig options TAINT_BLOBS_ will be set to y
- The Zephyr build system, during its configuration phase, will issue a warning. It will be possible to disable the warning using Kconfig
- The west spdx command will include the tainted status in its output
- The kernel’s default fatal error handler will also explicitly print out the kernel’s tainted status

8.5.5 Allowed types

The following binary blob types are acceptable in Zephyr:

- Precompiled libraries: Hardware enablement libraries, distributed in precompiled binary form, typically for SoC peripherals. An example could be an enablement library for a wireless peripheral
• Firmware images: An image containing the executable code for a secondary processor or CPU. This can be full or partial (typically delta or patch data) and is generally copied into RAM or flash memory by the main CPU. An example could be the firmware for the core running a Bluetooth LE Controller

• Miscellaneous binary data files. An example could be pre-trained neural network model data

Hardware agnostic features provided via a proprietary library are not acceptable. For example, a proprietary and hardware agnostic TCP/IP stack distributed as a static archive would be rejected.

Note that just because a blob has an acceptable type does not imply that it will be unconditionally accepted by the project; any blob may be rejected for other reasons on a case by case basis (see library-specific requirements below). In case of disagreement, the TSC is the arbiter of whether a particular blob fits in one of the above types.

8.5.6 Precompiled library-specific requirements

This section contains additional requirements specific to precompiled library blobs.

Any person who wishes to submit a precompiled library must represent that it meets these requirements. The project may remove a blob from the upstream distribution if it is discovered that the blob fails to meet these requirements later on.

Interface header files

The precompiled library must be accompanied by one or more header files, distributed under a non-copyleft OSI approved license, that define the interface to the library.

Allowed dependencies

This section defines requirements related to external symbols that a library blob requires the build system to provide.

• The blob must not depend on Zephyr APIs directly. In other words, it must have been possible to build the binary without any Zephyr source code present at all. This is required for loose coupling and maintainability, since Zephyr APIs may change and such blobs cannot be modified by all project maintainers

• Instead, if the code in the precompiled library requires functionality provided by Zephyr (or an RTOS in general), an implementation of an OS abstraction layer (aka porting layer) can be provided alongside the library. The implementation of this OS abstraction layer must be in source code form, released under an OSI approved license and documented using Doxygen

Toolchain requirements

Precompiled library blobs must be in a data format which is compatible with and can be linked by a toolchain supported by the Zephyr Project. This is required for maintainability and usability. Use of such libraries may require special compiler and/or linker flags, however. For example, a porting layer may require special flags, or a static archive may require use of specific linker flags.

Limited scope

Allowing arbitrary library blobs carries a risk of degrading the degree to which the upstream Zephyr software distribution is open source. As an extreme example, a target with a zephyr kernel clock driver that is just a porting layer around a library blob would not be bootable with open source software.
To mitigate this risk, the scope of upstream library blobs is limited. The project maintainers define an open source test suite that an upstream target must be able to pass using only open source software included in the mainline distribution and its modules. The open source test suite currently consists of:

- samples/philosophers
- tests/kernel

The scope of this test suite may grow over time. The goal is to specify tests for a minimal feature set which must be supported via open source software for any target with upstream Zephyr support.

At the discretion of the release team, the project may remove support for a hardware target if it cannot pass this test suite.

### 8.5.7 Support and maintenance

The Zephyr Project is not expected to be responsible for the maintenance and support of contributed binary blobs. As a consequence, at the discretion of the Zephyr Project release team, and on a case-by-case basis:

- GitHub issues reported on the zephyr repository tracker that require use of blobs to reproduce may not be treated as bugs
- Such issues may be closed as out of scope of the Zephyr project

This does not imply that issues which require blobs to reproduce will be closed without investigation. For example, the issue may be exposing a bug in a Zephyr code path that is difficult or impossible to trigger without a blob. Project maintainers may accept and attempt to resolve such issues.

However, some flexibility is required because project maintainers may not be able to determine if a given issue is due to a bug in Zephyr or the blob itself, may be unable to reproduce the bug due to lack of hardware, etc.

Blobs must have designated maintainers that must be responsive to issue reports from users and provide updates to the blobs to address issues. At the discretion of the Zephyr Project release team, module revisions referencing blobs may be removed from zephyr/west.yml at any time due to lack of responsiveness or support from their maintainers. This is required to maintain project control over bit-rot, security issues, etc.

The submitter of the proposal to integrate a binary blob must commit to maintain the integration of such blob for the foreseeable future.

### 8.5.8 Submission and review process

For references to binary blobs to be included in the project, they must be reviewed and accepted by the Technical Steering Committee (TSC). This process is only required for new binary blobs, updates to binary blobs follow the module update procedure.

A request for integration with binary blobs must be made by creating a new issue in the Zephyr project issue tracking system on GitHub with details about the blobs and the functionality they provide to the project.

Follow the steps below to begin the submission process:

1. Make sure to read through the Binary Blobs section in detail, so that you are informed of the criteria used by the TSC in order to approve or reject a request
2. Use the New Binary Blobs Issue to open an issue
3. Fill out all required sections, making sure you provide enough detail for the TSC to assess the merit of the request. Additionally you must also create a Pull Request that demonstrates the integration of the binary blobs and then link to it from the issue
4. Wait for feedback from the TSC, respond to any additional questions added as GitHub issue comments.

If, after consideration by the TSC, the submission of the binary blob(s) is approved, the submission process is complete and the binary blob(s) can be integrated.
Chapter 9

Project and Governance

9.1 TSC Project Roles

9.1.1 Main Roles

TSC projects generally will involve Maintainers, Collaborators, and Contributors:

*Maintainer:* lead Collaborators on an area identified by the TSC (e.g. Architecture, code subsystems, etc.). Maintainers shall also serve as the area’s representative on the TSC as needed. Maintainers may become voting members of the TSC under the guidelines stated in the project Charter.

*Collaborator:* A highly involved Contributor in one or more areas. May become a Maintainer with approval of existing TSC voting members.

*Contributor:* anyone in the community that contributes code or documentation to the project. Contributors may become Collaborators by approval of the existing Collaborators and Maintainers of the particular code base areas or subsystems.

Contributor

A Contributor is a developer who wishes to contribute to the project, at any level.

Contributors are granted the following rights and responsibilities:

- Right to contribute code, documentation, translations, artwork, etc.
- Right to report defects (bugs) and suggestions for enhancement.
- Right to participate in the process of reviewing contributions by others.
- Right to initiate and participate in discussions in any communication methods.
- Right to approach any member of the community with matters they believe to be important.
- Right to participate in the feature development process.
- Responsibility to abide by decisions, once made. They are welcome to provide new, relevant information to reopen decisions.
- Responsibility for issues and bugs introduced by one’s own contributions.
- Responsibility to respect the rules of the community.
- Responsibility to provide constructive advice whenever participating in discussions and in the review of contributions.
- Responsibility to follow the project’s code of conduct (https://github.com/zephyrproject-rtos/zephyr/blob/main/CODE_OF_CONDUCT.md)
Contributors are initially only given Read access to the Zephyr GitHub repository. Specifically, at the Read access level, Contributors are not allowed to assign reviewers to their own pull requests. An automated process will assign reviewers. You may also share the pull request on the Zephyr devel mailing list or on the Zephyr Discord Server.

Contributors who show dedication and skill are granted the Triage permission level to the Zephyr GitHub repository.

You may nominate yourself, or another GitHub user, for promotion to the Triage permission level by creating a GitHub issue, using the nomination template.

Contributors granted the Triage permission level are permitted to add reviewers to a pull request and can be added as a reviewer by other GitHub users. Contributor votes on pull requests are not counted with respect to accepting and merging a pull request. However, Contributors comments and requested changes should still be considered by the pull request author.

Collaborator

A Collaborator is a Contributor who is also responsible for the maintenance of Zephyr source code. Their opinions weigh more when decisions are made, in a fully meritocratic fashion.

Collaborators have the following rights and responsibilities, in addition to those listed for Contributors:

- Right to set goals for the short and medium terms for the project being maintained, alongside the Maintainer.
- Responsibility to participate in the feature development process.
- Responsibility to review relevant code changes within reasonable time.
- Responsibility to ensure the quality of the code to expected levels.
- Responsibility to participate in community discussions.
- Responsibility to mentor new contributors when appropriate
- Responsibility to participate in the quality verification and release process, when those happen.

Contributors are promoted to the Collaborator role by adding the GitHub user name to one or more collaborators sections of the MAINTAINERS File in the Zephyr repository.

Collaborator votes on pull requests can block or approve the pull request.

Maintainer

A Maintainer is a Collaborator who is also responsible for knowing, directing and anticipating the needs of a given zephyr source code area.

Maintainers have the following rights and responsibilities, in addition to those listed for Contributors and Collaborators:

- Right to set the overall architecture of the relevant subsystems or areas of involvement.
- Right to make decisions in the relevant subsystems or areas of involvement, in conjunction with the collaborators.
- Responsibility to convey the direction of the relevant subsystem or areas to the TSC
- Responsibility to ensure all contributions of the project have been reviewed within reasonable time.
- Responsibility to enforce the code of conduct.

Contributors or Collaborators are promoted to the Maintainer role by adding the GitHub user name to one or more maintainers sections of the MAINTAINERS File in the Zephyr repository.

Maintainer votes on pull requests can block or approve the pull request.
9.1.2 Role Retirement

- Individuals elected to the following Project roles, including, Maintainer, Release Engineering Team member, Release Manager, but are no longer engaged in the project as described by the rights and responsibilities of that role, may be requested by the TSC to retire from the role they are elected.
- Such a request needs to be raised as a motion in the TSC and be approved by the TSC voting members. By approval of the TSC the individual is considered to be retired from the role they have been elected.
- The above applies to elected TSC Project roles that may be defined in addition.

9.1.3 Teams and Supporting Activities

Assignee

An Assignee is one of the maintainers of a subsystem or code being changed. Assignees are set either automatically based on the code being changed or set by the other Maintainers, the Release Engineering team can set an assignee when the latter is not possible.

- Right to dismiss stale reviews and seek reviews from additional maintainers, developers and contributors
- Right to block pull requests from being merged
- Responsibility to re-assign a pull request if they are the original submitter of the code
- Responsibility to drive the pull request to a mergeable state
- Solicit approvals from maintainers of the subsystems affected
- Responsibility to drive the escalation process

Release Engineering Team

A team of active Maintainers involved in multiple areas.

- The members of the Release Engineering team are expected to fill the Release Manager role based on a defined cadence and selection process.
- The cadence and selection process are defined by the Release Engineering team and are approved by the TSC.
- The team reports directly into the TSC.

Release Engineering team has the following rights and responsibilities:

- Right to merge code changes to the zephyr tree following the project rules.
- Right to revert any changes that have broken the code base
- Right to close any stale changes after \(<N>\) months of no activity
- Responsibility to take directions from the TSC and follow them.
- Responsibility to coordinate code merges with maintainers.
- Responsibility to merge all contributions regardless of their origin and area if they have been approved by the respective maintainers and follow the merge criteria of a change.
- Responsibility to keep the Zephyr code base in a working and passing state (as per CI)

Joining the Release Engineering team
• Maintainers highly involved in the project may be nominated by a TSC voting member to join the Release Engineering team. Nominees may become members of the team by approval of the existing TSC voting members.

• To ensure a functional Release Engineering team the TSC shall periodically review the team’s followed processes, the appropriate size, and the membership composition (ensure, for example, that team members are geographically distributed across multiple locations and time-zones).

**Release Manager**

A *Maintainer* responsible for driving a specific release to completion following the milestones and the roadmap of the project for this specific release.

- TSC has to approve a release manager.

A Release Manager is a member of the Release Engineering team and has the rights and responsibilities of that team in addition to the following:

- Right to manage and coordinate all code merges after the code freeze milestone (M3, see program management overview.)
- Responsibility to drive and coordinate the triaging process for the release
- Responsibility to create the release notes of the release
- Responsibility to notify all stakeholders of the project, including the community at large about the status of the release in a timely manner.
- Responsibility to coordinate with QA and validation and verify changes either directly or through QA before major changes and major milestones.

**Roles / Permissions**

### 9.1.4 MAINTAINERS File

Generic guidelines for deciding and filling in the Maintainers’ list

- The MAINTAINERS.yml file shall replace the CODEOWNERS file and will be used for both setting assignees and reviewers.
- We should keep the granularity of code maintainership at a manageable level
- We should be looking for maintainers for areas of code that are orphaned (i.e. without an explicit maintainer)
  - Un-maintained areas should be indicated clearly in the MAINTAINERS file
- All submitted pull requests should have an assignee
- We Introduce an area/subsystem hierarchy to address the above point
– Parent-area maintainer should be acting as default substitute/fallback assignee for unmaintained sub-areas
– Area maintainer gets precedence over parent-area maintainer

• Pull requests may be re-assigned if this is needed or more appropriate
  – Re-assigned by original assignee (see “Assignee” slide)

• In general, updates to the MAINTAINERS file should be in a standalone commit alongside other changes introducing new files and directories to the tree.

• Major changes to the file, including the addition of new areas with new maintainers should come in as standalone pull requests and require TSC review.

• If additional review by the TSC is required, the maintainers of the file should send the requested changes to the TSC and give members of the TSC two (2) days to object to any of the changes to maintainership of areas or the addition of new maintainers or areas.

• Path, collaborator and name changes do not require a review by the TSC.

• Addition of new areas without a maintainer do not require review by the TSC.

• The MAINTAINERS file itself shall have a maintainer

• Architectures, core components, sub-systems, samples, tests
  – Each area shall have an explicit maintainer

• Boards (incl relevant samples, tests), SoCs (incl DTS) * May have a maintainer, shall have a higher-level platform maintainer

• Drivers
  – Shall have a driver-area (and API) maintainer
  – Could have individual driver implementation maintainers but preferably collaborator/contributors
  – In the above case, platform-specific PRs may be re-assigned to respective collaborator/contributor of driver implementation

### 9.1.5 Release Activity

#### Merge Criteria

• All continuous integration checks have passed
  – Codeowners
  – Device Tree
  – Documentation
  – Gitlint
  – Identity/Emails
  – Kconfig
  – License
  – Checkpatch (Coding Style)
  – Pylint
  – Integration Tests (Via twister) on emulation/simulation platforms
- Simulated Bluetooth Tests

• Planned
  - Footprint
  - Code coverage
  - Coding Guidelines
  - Static Analysis (Coverity)
  - Documentation coverage (APIs)

• PR template with checklist

• Minimal of 2 approvals
  - A collaborator from the same subsystem.
  - Alternately another maintainer of another subsystem
  - Approval by the assignee

• A minimum review period of 2 days, 4 hours for trivial changes (see *Give reviewers time to review before code merge*). Hotfixes can be merged at any time after CI passes.

• All required checks are passing

Escalation Process

• Contributors may object to change requests or decisions made by Maintainers.

• Process
  - Resolve in the PR among assignee, maintainers and reviewer
    * Assignee to act as moderator if applicable
Optionally resolve in the dev review meeting with more Maintainers and project stakeholders

* The involved parties and the Assignee to be present when the (escalated) issue is discussed

- TSC: Assignees can escalate to the TSC voting members and get a binding resolution in the TSC.
- Assignee to ensure the resolution of the escalation is reflected in the PR review.

9.2 Release Process

The Zephyr project releases on a time-based cycle, rather than a feature-driven one. Zephyr releases represent an aggregation of the work of many contributors, companies, and individuals from the community.

A time-based release process enables the Zephyr project to provide users with a balance of the latest technologies and features and excellent overall quality. A roughly 4-month release cycle allows the project to coordinate development of the features that have actually been implemented, allowing the project to maintain the quality of the overall release without delays because of one or two features that are not ready yet.

The Zephyr release model was loosely based on the Linux kernel model:

- Release tagging procedure:
  - linear mode on main branch,
  - release branches for maintenance after release tagging.
- Each release period will consist of a development phase followed by a stabilization phase. Release candidates will be tagged during the stabilization phase. During the stabilization phase, only stabilization changes such as bug fixes and documentation will be merged unless granted a special exemption by the Technical Steering Committee.
  - Development phase: all changes are accepted (subject to approval from the respective maintainers).
  - Stabilisation phase: the release manager creates a vN-rc1 tag and the tree enters the stabilization phase
  - CI sees the tag, builds and runs tests; Test teams analyse the report from the build and test run and give an ACK/NAK to the build
  - The release owner, with test teams and any other needed input, determines if the release candidate is a go for release
  - If it is a go for a release, the release owner lays a tag release vN at the same point

Fig. 9.1: Release Cycle
9.2.1 Development Phase

A relatively straightforward discipline is followed with regard to the merging of patches for each release. At the beginning of each development cycle, the main branch is said to be open for development. At that time, code which is deemed to be sufficiently stable (and which is accepted by the maintainers and the wide community) is merged into the mainline tree. The bulk of changes for a new development cycle (and all of the major changes) will be merged during this time.

The development phase lasts for approximately two months. At the end of this time, the release owner will declare that the development phase is over and releases the first of the release candidates. For the codebase release which is destined to be 3.1.0, for example, the release which happens at the end of the development phase will be called 3.1.0-rc1. The -rc1 release is the signal that the time to merge new features has passed, and that the time to stabilize the next release of the code base has begun.

9.2.2 Stabilization Phase

Over the next weeks, only patches which fix problems should be submitted to the mainline. On occasion, a more significant change will be allowed, but such occasions are rare and require a TSC approval (Change Control Board). As a general rule, if you miss submitting your code during the development phase for a given feature, the best thing to do is to wait for the next development cycle. (An occasional exception is made for drivers for previously unsupported hardware; if they do not touch any other in-tree code, they cannot cause regressions and should be safe to add at any time).

As fixes make their way into the mainline, the patch rate will slow over time. The mainline release owner releases new -rc drops once or twice a week; a normal series will get up to somewhere between -rc4 and -rc6 before the code base is considered to be sufficiently stable and the release criteria have been achieved at which point the final 3.1.0 release is made.

At that point, the whole process starts over again.

9.2.3 Release Quality Criteria

The current backlog of prioritized bugs shall be used as a quality metric to gate the final release. The following counts shall be used:

Table 9.2: Bug Count Release Thresholds

<table>
<thead>
<tr>
<th>High</th>
<th>Medium</th>
<th>Low</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&lt;20</td>
<td>&lt;50</td>
</tr>
</tbody>
</table>

Note: The “low” bug count target of <50 will be a phased approach starting with 150 for release 2.4.0, 100 for release 2.5.0, and 50 for release 2.6.0
9.2.4 Release Milestones

Table 9.3: Release Milestones

<table>

</tr>
</tbody>
</table>

9.2.5 Releases

The following syntax should be used for releases and tags in Git:

- Release [Major].[Minor].[Patch Level]
- Release Candidate [Major].[Minor].[Patch Level]-rc[RC Number]
- Tagging:
  - v[Major].[Minor].[Patch Level]-rc[RC Number]
  - v[Major].[Minor].[Patch Level]
  - v[Major].[Minor].99 - A tag applied to main branch to signify that work on v[Major].[Minor+1] has started. For example, v1.7.99 will be tagged at the start of v1.8 process. The tag corresponds to VERSION_MAJOR/VERSION_MINOR/PATCHLEVEL macros as defined for a work-in-progress main branch version. Presence of this tag allows generation of sensible output for “git describe” on main branch, as typically used for automated builds and CI tools.

Long Term Support (LTS)

Long-term support releases are designed to be supported and maintained for an extended period and is the recommended release for products and the auditable branch used for certification.

An LTS release is defined as:

- **Product focused**
- **Extended Stabilisation period**: Allow for more testing and bug fixing
- **Stable APIs**
- **Quality Driven Process**
- **Long Term**: Maintained for an extended period of time (at least 2.5 years) overlapping previous LTS release for at least half a year.
Product Focused  Zephyr LTS is the recommended release for product makers with an extended support and maintenance which includes general stability and bug fixes, security fixes. An LTS includes both mature and new features. API and feature maturity is documented and tracked. The footprint and scope of mature and stable APIs expands as we move from one LTS to the next giving users access to bleeding edge features and new hardware while keeping a stable foundation that evolves over time.

Extended Stabilisation Period  Zephyr LTS development cycle differs from regular releases and has an extended stabilization period. Feature freeze of regular releases happens 3-4 weeks before the scheduled release date. The stabilization period for LTS is extended by 3 weeks with the feature freeze occurring 6-7 weeks before the anticipated release date. The time between code freeze and release date is extended in this case.

Stable APIs  Zephyr LTS provides a stable and long-lived foundation for developing products. To guarantee stability of the APIs and the implementation of such APIs it is required that any release software that makes the core of the OS went through the Zephyr API lifecycle and stabilized over at least 2 releases. This guarantees that we release many of the highlighted and core features with mature and well-established implementations with stable APIs that are supported during the lifetime of the release LTS.

- API Freeze (LTS - 2)
  - All stable APIs need to be frozen 2 releases before an LTS. APIs can be extended with additional features, but the core implementation is not modified. This is valid for the following subsystems for example:
    * Device Drivers (i2c.h, spi.h)...
    * Kernel (k_*):
    * OS services (logging, debugging, ..)
    * DTS: API and bindings stability
    * Kconfig
  - New APIs for experimental features can be added at any time as long as they are standalone and documented as experimental or unstable features/APIs.

- Feature Freeze (LTS - 1) - No new features or overhaul/restructuring of code covering major LTS features.
- Kernel + Base OS
- Additional advertised LTS features
- Auxiliary features on top of and/or extending the base OS and advertised LTS features can be added at any time and should be marked as experimental if applicable

**Quality Driven Process** The Zephyr project follows industry standards and processes with the goal of providing a quality oriented releases. This is achieved by providing the following products to track progress, integrity and quality of the software components provided by the project:

- Compliance with published coding guidelines, style guides and naming conventions and documentation of deviations.
- Regular static analysis on the complete tree using available commercial and open-source tools and documentation of deviations and false positives.
- Documented components and APIs
- Requirements Catalog
- Verification Plans
- Verification Reports
- Coverage Reports
- Requirements Traceability Matrix (RTM)
- SPDX License Reports

Each release is created with the above products to document the quality and the state of the software when it was released.

**Long Term Support and Maintenance** A Zephyr LTS release is published every 2 years and is branched and maintained independently from the main tree for at least 2.5 years after it was released. Support and maintenance for an LTS release stops at least half a year after the following LTS release is published.

Changes and fixes flow in both directions. However, changes from main branch to an LTS branch will be limited to fixes that apply to both branches and for existing features only.

All fixes for an LTS branch that apply to the mainline tree shall be submitted to mainline tree as well.

**Auditable Code Base**

An auditable code base is to be established from a defined subset of Zephyr OS features and will be limited in scope. The LTS, development tree, and the auditable code bases shall be kept in sync after the audit branch is created, but with a more rigorous process in place for adding new features into the audit branch used for certification.

This process will be applied before new features move into the auditable code base.
The initial and subsequent certification targets will be decided by the Zephyr project governing board. Processes to achieve selected certification will be determined by the Security and Safety Working Groups and coordinated with the TSC.

9.2.6 Release Procedure

This section documents the Release manager responsibilities so that it serves as a knowledge repository for Release managers.

Release Checklist

Each release has a GitHub issue associated with it that contains the full checklist. After a release is complete, a checklist for the next release is created.

Tagging

The final release and each release candidate shall be tagged using the following steps:

Note: Tagging needs to be done via explicit git commands and not via GitHub's release interface. The GitHub release interface does not generate annotated tags (it generates 'lightweight' tags regardless of release or pre-release). You should also upload your gpg public key to your GitHub account, since the instructions below involve creating signed tags. However, if you do not have a gpg public key you can opt to remove the -s option from the commands below.

Release Candidate

Note: This section uses tagging 1.11.0-rc1 as an example, replace with the appropriate release candidate version.

1. Update the version variables in the VERSION file located in the root of the Git repository to match the version for this release candidate. The EXTRAVERSION variable is used to identify the rc[RC Number] value for this candidate:

   EXTRAVERSION = rc1

2. Post a PR with the updated VERSION file using release: Zephyr 1.11.0-rc1 as the commit subject. Merge the PR after successful CI.

3. Tag and push the version, using an annotated tag:

   $ git pull
   $ git tag -s -m "Zephyr 1.11.0-rc1" v1.11.0-rc1
   $ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0-rc1

4. Send an email to the mailing lists (announce and devel) with a link to the release

Final Release

Note: This section uses tagging 1.11.0 as an example, replace with the appropriate final release version.

When all final release criteria has been met and the final release notes have been approved and merged into the repository, the final release version will be set and repository tagged using the following procedure:
1. Update the version variables in the `VERSION` file located in the root of the Git repository. Set `EXTRAVERSION` variable to an empty string to indicate final release:

   ```
   EXTRAVERSION =
   ```

2. Post a PR with the updated `VERSION` file using `release: Zephyr 1.11.0` as the commit subject. Merge the PR after successful CI.

3. Tag and push the version, using two annotated tags:

   ```
   $ git pull
   $ git tag -s -m "Zephyr 1.11.0" v1.11.0
   $ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0
   ```

4. Find the new `v1.11.0` tag at the top of the releases page and edit the release with the `Edit tag` button with the following:
   - Copy the overview of `docs/releases/release-notes-1.11.rst` into the release notes textbox and link to the full release notes file on docs.zephyrproject.org.

5. Send an email to the mailing lists (announce and devel) with a link to the release

**Listing all closed GitHub issues**

The release notes for a final release contain the list of GitHub issues that have been closed during the development process of that release.

In order to obtain the list of issues closed during the release development cycle you can do the following:

1. Look for the last release before the current one and find the day it was tagged:

   ```
   $ git show -s --format=%ci v1.10.0
   tag v1.10.0
   Tagger: Kumar Gala <kumar.gala@linaro.org>
   Zephyr 1.10.0
   2017-12-08 13:32:22 -0600
   ```

2. Use available release tools to list all the issues that have been closed between that date and the day of the release.

### 9.3 Feature Tracking

For feature tracking we use Github labels to classify new features and enhancements. The following is the description of each category:

**Enhancement**

Changes to existing features that are not considered a bug and would not block a release. This is an incremental enhancement to a feature that already exists in Zephyr.

**Feature request**

A request for the implementation or inclusion of a new unit of functionality that is not part of any release plans yet, that has not been vetted, and needs further discussion and details.

**Feature**

A committed and planned unit of functionality with a detailed design and implementation proposal and an owner. Features must go through an RFC process and must be vetted and discussed in the TSC before a target milestone is set.
Hardware Support
A request or plan to port an existing feature or enhancement to a particular hardware platform. This ranges from porting Zephyr itself to a new architecture, SoC or board to adding an implementation of a peripheral driver API for an existing hardware platform.

Meta
A label to group other GitHub issues that are part of a single feature or unit of work.

The following workflow should be used to process features:

This is the formal way for asking for a new feature in Zephyr and indicating its importance to the project. Often, the requester may have a readiness and willingness to drive implementation of the feature in an upcoming release, and should assign the request to themselves. If not though, an owner will be assigned after evaluation by the TSC. A feature request can also have a companion RFC with more details on the feature and a proposed design or implementation.

- Label new features requests as feature-request
- The TSC discusses new feature-request items regularly and triages them. Items are examined for similarity with existing features, how they fit with the project goals and other timeline considerations. The priority is determined as follows:
  - High = Next milestone
  - Medium = As soon as possible
  - Low = Best effort
- After the initial discussion and triaging, the label is moved from feature-request to feature with the target milestone and an assignee.

All items marked as feature-request are non-binding and those without an assignee are open for grabs, meaning that they can be picked up and implemented by any project member or the community. You should contact an assigned owner if you’d like to discuss or contribute to that feature’s implementation.

9.3.1 Proposals and RFCs

Many changes, including bug fixes and documentation improvements can be implemented and reviewed via the normal GitHub pull request workflow.

Many changes however are “substantial” and need to go through a design process and produce a consensus among the project stakeholders.

The “RFC” (request for comments) process is intended to provide a consistent and controlled path for new features to enter the project.

Contributors and project stakeholders should consider using this process if they intend to make “substantial” changes to Zephyr or its documentation. Some examples that would benefit from an RFC are:

- A new feature that creates new API surface area, and would require a feature flag if introduced.
- The modification of an existing stable API
- The removal of features that already shipped as part of Zephyr.
- The introduction of new idiomatic usage or conventions, even if they do not include code changes to Zephyr itself.

The RFC process is a great opportunity to get more eyeballs on proposals coming from contributors before it becomes a part of Zephyr. Quite often, even proposals that seem “obvious” can be significantly improved once a wider group of interested people have a chance to weigh in.

The RFC process can also be helpful to encourage discussions about a proposed feature as it is being designed, and incorporate important constraints into the design while it's easier to change, before the design has been fully implemented.

Some changes do not require an RFC:
• Rephrasing, reorganizing or refactoring
• Addition or removal of warnings
• Addition of new boards, SoCs or drivers to existing subsystems
• ...

The process in itself consists in creating a GitHub issue with the RFC label that documents the proposal thoroughly. There is an RFC template included in the main Zephyr GitHub repository that serves as a guideline to write a new RFC.

As with Pull Requests, RFCs might require discussion in the context of one of the Zephyr meetings in order to move it forward in cases where there is either disagreement or not enough voiced opinions in order to proceed. Make sure to either label it appropriately or include it in the corresponding GitHub project in order for it to be examined during the next meeting.

### 9.3.2 Roadmap and Release Plans

Project roadmaps and release plans are both important tools for the project, but they have very different purposes and should not be confused. A project roadmap communicates the high-level overview of a project's strategy, while a release plan is a tactical document designed to capture and track the features planned for upcoming releases.

- The project roadmap communicates the why; a release plan details the what
- A release plan spans only a few months; a product roadmap might cover a year or more

#### Project Roadmap

The project roadmap should serve as a high-level, visual summary of the project's strategic objectives and expectations.

If built properly, the roadmap can be a valuable tool for several reasons. It can help the project present its plan in a compelling way to existing and new stakeholders, to help recruit new members and it can be a helpful resource the team and community can refer to throughout the project's development, to ensure they are still executing according to plan.

As such, the roadmap should contain only strategic-level details, major project themes, epics, and goals.

#### Release Plans

The release plan comes into play when the project roadmap's high-level strategy is translated into an actionable plan built on specific features, enhancements, and fixes that need to go into a specific release or milestone.

The release plan communicates those features and enhancements slated for your project' next release (or the next few releases). So it acts as more of a project plan, breaking the big ideas down into smaller projects the community and main stakeholders of the project can make progress on.

Items labeled as features are short or long term release items that shall have an assignee and a milestone set.

### 9.4 Code Flow and Branches

#### 9.4.1 Introduction

The zephyr Git repository has three types of branches:
main
Which contains the latest state of development

topic-
Topic branches that are used for shared development of a new feature

vx.y-branch
Branches which track maintenance releases based on a major release

Development in topic branches before features go to mainline allows teams to work independently on a subsystem or a feature, improves efficiency and turnaround time, and encourages collaboration and streamlines communication between developers.

Changes submitted to a development topic branch can evolve and improve incrementally in a branch, before they are submitted to the mainline tree for final integration.

By dedicating an isolated branch to complex features, it’s possible to initiate in-depth discussions around new additions before integrating them into the official project.

9.4.2 Roles and Responsibilities

Development topic branch owners have the following responsibilities:

- Use the infrastructure and tools provided by the project (GitHub, Git)
- Review changes coming from team members and request review from branch owners when submitting changes.
- Keep the branch in sync with upstream and update on a regular basis.
- Push changes frequently to upstream using the following methods:
  - GitHub pull requests: for example, when reviews have not been done in the local branch (one-man branch).
  - Merge requests: When a set of changes has been done in a local branch and has been reviewed and tested in a topic branch.

9.5 Modifying Contributions made by other developers

9.5.1 Scenarios

Zephyr contributors and collaborators are encouraged to assist as reviewers in pull requests, so that patches may be approved and merged to Zephyr's main branch as part of the original pull requests. The authors of the pull requests are responsible for amending their original commits following the review process.

There are occasions, however, when a contributor might need to modify patches included in pull requests that are submitted by other Zephyr contributors. For instance, this is the case when:

- a developer cherry-picks commits submitted by other contributors into their own pull requests in order to:
  - integrate useful content which is part of a stale pull request, or
  - get content merged to the project's main branch as part of a larger patch
- a developer pushes to a branch or pull request opened by another contributor in order to:
  - assist in updating pull requests in order to get the patches merged to the project's main branch
  - drive stale pull requests to completion so they can be merged
9.5.2 Accepted policies

A developer who intends to cherry-pick and potentially modify patches sent by another contributor shall:

- clarify in their pull request the reason for cherry-picking the patches, instead of assisting in getting the patches merged in their original pull request, and
- invite the original author of the patches to their pull request review.

A developer who intends to force-push to a branch or pull request of another Zephyr contributor shall clarify in the pull request the reason for pushing and for modifying the existing patches (e.g. stating that it is done to drive the pull request review to completion, when the pull request author is not able to do so).

**Note:** Developers should try to limit the above practice to pull requests identified as stale. Read about how to identify pull requests as stale in development processes and tools.

If the original patches are substantially modified, the developer can either:

- (preferably) reach out to the original author and request them to acknowledge that the modified patches may be merged while having the original sign-off line and author identity, or
- submit the modified patches as their own work (i.e. with their own sign-off line and author identity). In this case, the developer shall identify in the commit message(s) the original source the submitted work is based on (mentioning, for example, the original PR number).

**Note:** Contributors should uncheck the box “Allow Edits By Maintainers” to indicate that they do not wish their patches to be amended, inside their original branch or pull request, by other Zephyr developers.

9.6 Development Environment and Tools

9.6.1 Code Review

GitHub is intended to provide a framework for reviewing every commit before it is accepted into the code base. Changes, in the form of Pull Requests (PR) are uploaded to GitHub but don't actually become a part of the project until they've been reviewed, passed a series of checks (CI), and are approved by maintainers. GitHub is used to support the standard open source practice of submitting patches, which are then reviewed by the project members before being applied to the code base.

Pull requests should be appropriately labeled, and linked to any relevant bug or feature tracking issues.

The Zephyr project uses GitHub for code reviews and Git tree management. When submitting a change or an enhancement to any Zephyr component, a developer should use GitHub. GitHub automatically assigns a responsible reviewer on a component basis, as defined in the CODEOWNERS file stored with the code tree in the Zephyr project repository. A limited set of release managers are allowed to merge a pull request into the main branch once reviews are complete.

Give reviewers time to review before code merge

The Zephyr project is a global project that is not tied to a certain geography or timezone. We have developers and contributors from across the globe. When changes are proposed using pull request, we need to allow for a minimal review time to give developers and contributors the opportunity to review and comment on changes. There are different categories of changes and we know that some changes do require reviews by subject matter experts and owners of the subsystem being changed. Many changes fall under the “trivial” category that can be addressed with general reviews and do not need to be queued for a maintainer or code-owner review. Additionally, some changes might require further discussions.
and a decision by the TSC or the Security working group. To summarize the above, the diagram below proposes minimal review times for each category:

**Workflow**

- An author of a change can suggest in his pull-request which category a change should belong to. A project maintainers or TSC member monitoring the inflow of changes can change the label of a pull request by adding a comment justifying why a change should belong to another category.
- The project will use the label system to categorize the pull requests.
- Changes should not be merged before the minimal time has expired.

**Categories/Labels**

**Hotfix**  Any change that is a fix to an issue that blocks developers from doing their daily work, for example CI breakage, Test breakage, Minor documentation fixes that impact the user experience. Such fixes can be merged at any time after they have passed CI checks. Depending on the fix, severity, and availability of someone to review them (other than the author) they can be merged with justification without review by one of the project owners.

**Trivial**  Trivial changes are those that appear obvious enough and do not require maintainer or code-owner involvement. Such changes should not change the logic or the design of a subsystem or component. For example a trivial change can be:

- Documentation changes
• Configuration changes
• Minor Build System tweaks
• Minor optimization to code logic without changing the logic
• Test changes and fixes
• Sample modifications to support additional configuration or boards etc.

**Maintainer** Any changes that touch the logic or the original design of a subsystem or component will need to be reviewed by the code owner or the designated subsystem maintainer. If the code changes is initiated by a contributor or developer other than the owner the pull request needs to be assigned to the code owner who will have to drive the pull request to a mergeable state by giving feedback to the author and asking for more reviews from other developers.

**Security** Changes that appear to have an impact to the overall security of the system need to be reviewed by a security expert from the security working group.

**TSC and Working Groups** Changes that introduce new features or functionality or change the way the overall system works need to be reviewed by the TSC or the responsible Working Group. For example for **stable API changes**, the proposal needs to be presented in the Architecture meeting so that the relevant stakeholders are made aware of the change.

**A Pull-Request should have an Assignee**

• An assignee to a pull request should not be the same as the author of the pull-request
• An assignee to a pull request is responsible for driving the pull request to a mergeable state
• An assignee is responsible for dismissing stale reviews and seeking reviews from additional developers and contributors
• Pull requests should not be merged without an approval by the assignee.

**Pull Request should not be merged by author without review**

All pull requests need to be reviewed and should not be merged by the author without a review. The following exceptions apply:

• Hot fixes: Fixing CI issues, reverts, and system breakage
• Release related changes: Changing version file, applying tags and release related activities without any code changes.

Developers and contributors should always seek review, however there are cases when reviewers are not available and there is a need to get a code change into the tree as soon as possible.

**Reviewers shall not ‘Request Changes’ without comments or justification**

Any change requests (-1) on a pull request have to be justified. A reviewer should avoid blocking a pull-request with no justification. If a reviewer feels that a change should not be merged without their review, then: Request change of the category: for example:

• Trivial -> Maintainer
• Assign Pull Request to yourself, this will mean that a pull request should not be merged without your approval.
Pull Requests should have at least 2 approvals before they are merged

A pull-request shall be merged only with two positive reviews (approval). Beside the person merging the pull-request (merging != approval), two additional approvals are required to be able to merge a pull request. The person merging the request can merge without approving or approve and merge to get to the 2 approvals required.

Reviewers should keep track of pull requests they have provided feedback to

If a reviewer has requested changes in a pull request, he or she should monitor the state of the pull request and/or respond to mention requests to see if his feedback has been addressed. Failing to do so, negative reviews shall be dismissed by the assignee or an owner of the repository. Reviews will be dismissed following the criteria below:

- The feedback or concerns were visibly addressed by the author
- The reviewer did not revisit the pull request after 2 week and multiple pings by the author
- The review is unrelated to the code change or asking for unjustified structural changes such as:
  - Split the PR
  - Can you fix this unrelated code that happens to appear in the diff
  - Can you fix unrelated issues
  - Etc.

Closing Stale Issues and Pull Requests

- The Pull requests and issues sections on Github are NOT discussion forums. They are items that we need to execute and drive to closure. Use the mailing lists for discussions.
- In case of both issues and pull-requests the original poster needs to respond to questions and provide clarifications regarding the issue or the change. After one week without a response to a request, a second attempt to elicit a response from the contributor will be made. After one more week without a response the item may be closed (draft and DNM tagged pull requests are excluded).

9.6.2 Continuous Integration

All changes submitted to GitHub are subject to tests that are run on emulated platforms and architectures to identify breakage and regressions that can be immediately identified. Testing using Twister additionally performs build tests of all boards and platforms. Documentation changes are also verified through review and build testing to verify doc generation will be successful.

Any failures found during the CI test run will result in a negative review assigned automatically by the CI system. Developers are expected to fix issues and rework their patches and submit again.

The CI infrastructure currently runs the following tests:

- Run “checkpatch” for code style issues (can vote -1 on errors; see note)
- Gitlint: Git commit style based on project requirements
- License Check: Check for conflicting licenses
- Run “twister” script
  - Run kernel tests in QEMU (can vote -1 on errors)
  - Build various samples for different boards (can vote -1 on errors)
- Verify documentation builds correctly.
**Note:** "checkpatch" is a Perl script that uses regular expressions to extract information that requires a C language parser to process accurately. As such it sometimes issues false positives. Known cases include constructs like:

```
static uint8_t __aligned(PAGE_SIZE) page_pool[PAGE_SIZE * POOL_PAGES];
IOPCTL_Type *base = config->base;
```

Both lines produce a diagnostic regarding spaces around the * operator: the first is misidentified as a pointer type declaration that would be correct as PAGE_SIZE * POOL_PAGES while the second is misidentified as a multiplication expression that would be correct as IOPCTL_Type * base.

Maintainers can override the -1 in cases where the CI infrastructure gets the wrong answer.

### 9.6.3 Labeling issues and pull requests in GitHub

The project uses GitHub issues and pull requests (PRs) to track and manage daily and long-term work and contributions to the Zephyr project. We use GitHub *labels* to classify and organize these issues and PRs by area, type, priority, and more, making it easier to find and report on relevant items.

All GitHub issues or pull requests must be appropriately labeled. Issues and PRs often have multiple labels assigned, to help classify them in the different available categories. When reviewing a PR, if it has missing or incorrect labels, maintainers shall fix it.

This saves us all time when searching, reduces the chances of the PR or issue being forgotten, speeds up reviewing, avoids duplicate issue reports, etc.

These are the labels we currently have, grouped by applicability:

**Labels applicable to issues only**

- **priority: {high|medium|low}**

  To classify the impact and importance of a bug or feature.

  Note: Issue priorities are generally set or changed during the bug-triage or TSC meetings.

- **Regression**

  Something, which was working, but does not anymore (bug subtype).

- **Enhancement**

  Changes/Updates/Additions to existing features.

- **Feature request**

  A request for a new feature.

- **Feature**

  A planned feature with a milestone.

- **Hardware Support**

  Covers porting an existing feature (including Zephyr itself) to new hardware.

- **Duplicate**

  This issue is a duplicate of another issue (please specify).

- **Good first issue**

  Good for a first time contributor to take.

- **Release Notes**

9.6. Development Environment and Tools 2597
Issues that need to be mentioned in release notes as known issues with additional information. Any issue must be classified and labeled as either Bug, Enhancement, RFC, Feature, Feature Request or Hardware Support. More information on how feature requests are handled and become features can be found in Feature Tracking.

Labels applicable to pull requests only

The issue or PR describes a change to a stable API.

- Hotfix
Fix for an issue blocking development.

- Trivial
- Maintainer
Maintainer review required.

- Security Review
To be reviewed by a security expert.

- DNM
This PR should not be merged (Do Not Merge). For work in progress, GitHub “draft” PRs are preferred.

- Needs review
The PR needs attention from the maintainers.

- Backport
The PR is a backport or should be backported.

- Licensing
The PR has licensing issues which require a licensing expert to review it.

Note: For all labels applicable to PRs: Please note that the label, together with PR complexity, affects how long a merge should be held to ensure proper review. See review process for details.

Labels applicable to both pull requests and issues

- area: *
Indicates Zephyr subsystems (e.g., area: Kernel, area: I2C, area: Memory Management), project functions (e.g., area: Debugging, area: Documentation, area: Process), or other categories (e.g., area: Coding Style, area: MISRA-C) affected by the bug or the pull request.
An area maintainer should be able to filter by an area label and find all issues and PRs which relate to that area.

- platform: *
An issue or PR which affects only a particular platform.

- dev-review
The issue is to be discussed in the following dev-review if time permits.

- TSC
TSC stands for Technical Steering Committee. The issue is to be discussed in the following TSC meeting if time permits.
• Stable API Change
The issue or PR describes a change to a stable API. See additional information in *Introducing incompatible changes*.
• Bug
The issue is a bug, or the PR is fixing a bug.
• Coverity
A Coverity detected issue or its fix.
• Waiting for response
The Zephyr developers are waiting for the submitter to respond to a question, or address an issue.
• Blocked
Blocked by another PR or issue.
• Stale
An issue or a PR which seems abandoned, and requires attention by the author.
• In progress
For PRs: is work in progress and should not be merged yet. For issues: Is being worked on.
• RFC
The author would like input from the community. For a PR it should be considered a draft.
• LTS
Long term release branch related.
• EXT
Related to an external component.

### 9.7 Bug Reporting

To maintain traceability and relation between proposals, changes, features, and issues, it is recommended to cross-reference source code commits with the relevant GitHub issues and vice versa. Any changes that originate from a tracked feature or issue should contain a reference to the feature by mentioning the corresponding issue or pull-request identifiers. At any time it should be possible to establish the origin of a change and the reason behind it by following the references in the code.

#### 9.7.1 Reporting a regression issue

It could happen that the issue being reported is identified as a regression, as the use case is known to be working on earlier commit or release. In this case, providing directly the guilty commit when submitting the bug gains a lot of time in the eventual bug fixing.

To identify the commit causing the regression, several methods could be used, but tree bisecting method is an efficient one that doesn’t require deep code expertise and can be used by every one.

For this, `git bisect` is the recommended tool.

Recommendations on the process:
• Run `west update` on each bisection step.
• Once the bisection is over and a culprit identified, verify manually the result.
9.8 Communication and Collaboration

The Zephyr project mailing lists are used as the primary communication tool by project members, contributors, and the community. The mailing list is open for topics related to the project and should be used for collaboration among team members working on the same feature or subsystem or for discussing project direction and daily development of the code base. In general, bug reports and issues should be entered and tracked in the bug tracking system (GitHub Issues) and not broadcasted to the mailing list, the same applies to code reviews. Code should be submitted to GitHub using the appropriate tools.

9.9 Code Documentation

9.9.1 API Documentation

Well documented APIs enhance the experience for developers and are an essential requirement for defining an API's success. Doxygen is a general purpose documentation tool that the zephyr project uses for documenting APIs. It generates either an on-line documentation browser (in HTML) and/or provides input for other tools that is used to generate a reference manual from documented source files. In particular, doxygen's XML output is used as an input when producing the Zephyr project's online documentation.

9.9.2 Reference to Requirements

APIs for the most part document the implementation of requirements or advertised features and can be traced back to features. We use the API documentation as the main interface to trace implementation back to documented features. This is done using custom _doxygen_ tags that reference requirements maintained somewhere else in a requirement catalogue.

9.9.3 Test Documentation

To help understand what each test does and which functionality it tests we also document all test code using the same tools and in the same context and generate documentation for all unit and integration tests maintained in the same environment. Tests are documented using references to the APIs or functionality they validate by creating a link back to the APIs and by adding a reference to the original requirements.

9.9.4 Documentation Guidelines

Test Code

The Zephyr project uses several test methodologies, the most common being the Ztest framework. Test documentation should only be done on the entry test functions (usually prefixed with test_) and those that are called directly by the Ztest framework. Those tests are going to appear in test reports and using their name and identifier is the best way to identify them and trace back to them from requirements.

Test documentation should not interfere with the actual API documentation and needs to follow a new structure to avoid confusion. Using a consistent naming scheme and following a well-defined structure we will be able to group this documentation in its own module and identify it uniquely when parsing test data for traceability reports. Here are a few guidelines to be followed:

- All test code documentation should be grouped under the all_tests doxygen group
- All test documentation should be under doxygen groups that are prefixed with tests_

The custom doxygen @verify directive signifies that a test verifies a requirement:
/**
 * @brief Tests for the Semaphore kernel object
 * @defgroup kernel_semaphore_tests Semaphore
 * @ingroup all_tests
 * @{
 * @
 * ...
 */
/**
 * @brief A brief description of the tests
 * Some details about the test
 * more details
 *
 * @verify{@req{1111}}
 */
void test_sema_thread2thread(void)
{
    ...
}
/**
 * @}
 */

To get coverage of how an implementation or a piece of code satisfies a requirements, we use the satisfy alias in doxygen:

/**
 * @brief Give a semaphore.
 *
 * This routine gives @a sem, unless the semaphore is already at its maximum
 * permitted count.
 *
 * @note Can be called by ISRs.
 *
 * @param sem Address of the semaphore.
 *
 * @satisfy{@req{015}}
 */
__syscall void k_sem_give(struct k_sem *sem);

To generate the matrix, you will first need to build the documentation, specifically you will need to build the doxygen XML output:

$ make doxygen

Parse the generated XML data from doxygen to generate the traceability matrix.

The Zephyr project defines a development process workflow using GitHub Issues to track feature, enhancement, and bug reports together with GitHub Pull Requests (PRs) for submitting and reviewing changes. Zephyr community members work together to review these Issues and PRs, managing feature enhancements and quality improvements of Zephyr through its regular releases, as outlined in the program management overview.

We can only manage the volume of Issues and PRs, by requiring timely reviews, feedback, and responses from the community and contributors, both for initial submissions and for followup questions and clarifications. Read about the project's development processes and tools and specifics about review timelines to learn about the project's goals and guidelines for our active developer community.
TSC Project Roles describes in detail the Zephyr project roles and associated permissions with respect to the development process workflow.

9.10 Terminology

- **mainline**: The main tree where the core functionality and core features are being developed.
- **subsystem/feature branch**: is a branch within the same repository. In our case, we will use the term branch also when referencing branches not in the same repository, which are a copy of a repository sharing the same history.
- **upstream**: A parent branch the source code is based on. This is the branch you pull from and push to, basically your upstream.
- **LTS**: Long Term Support
Chapter 10

Security

These documents describe the requirements, processes, and developer guidelines for ensuring security is addressed within the Zephyr project.

10.1 Zephyr Security Overview

10.1.1 Introduction

This document outlines the steps of the Zephyr Security Subcommittee towards a defined security process that helps developers build more secure software while addressing security compliance requirements. It presents the key ideas of the security process and outlines which documents need to be created. After the process is implemented and all supporting documents are created, this document is a top-level overview and entry point.

Overview and Scope

We begin with an overview of the Zephyr development process, which mainly focuses on security functionality.

In subsequent sections, the individual parts of the process are treated in detail. As depicted in Figure 1, these main steps are:

1. **Secure Development**: Defines the system architecture and development process that ensures adherence to relevant coding principles and quality assurance procedures.

2. **Secure Design**: Defines security procedures and implement measures to enforce them. A security architecture of the system and relevant sub-modules is created, threats are identified, and countermeasures designed. Their correct implementation and the validity of the threat models are checked by code reviews. Finally, a process shall be defined for reporting, classifying, and mitigating security issues.

3. **Security Certification**: Defines the certifiable part of the Zephyr RTOS. This includes an evaluation target, its assets, and how these assets are protected. Certification claims shall be determined and backed with appropriate evidence.

Intended Audience

This document is a guideline for the development of a security process by the Zephyr Security Subcommittee and the Zephyr Technical Steering Committee. It provides an overview of the Zephyr security process for (security) engineers and architects.
Nomenclature

In this document, the keywords “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” are to be interpreted as described in [?].

These words are used to define absolute requirements (or prohibitions), highly recommended requirements, and truly optional requirements. As noted in RFC-2119, “These terms are frequently used to specify behavior with security implications. The effects on security of not implementing a MUST or SHOULD, or doing something the specification says MUST NOT or SHOULD NOT be done may be very subtle. Document authors should take the time to elaborate the security implications of not following recommendations or requirements as most implementors will not have had the benefit of the experience and discussion that produced the specification.”

Security Document Update

This document is a living document. As new requirements, features, and changes are identified, they will be added to this document through the following process:

1. Changes will be submitted from the interested party(ies) via pull requests to the Zephyr documentation repository.
2. The Zephyr Security Subcommittee will review these changes and provide feedback or acceptance of the changes.
3. Once accepted, these changes will become part of the document.

10.1.2 Current Security Definition

This section recapitulates the current status of secure development within the Zephyr RTOS. Currently, focus is put on functional security and code quality assurance, although additional security features are scoped.

The three major security measures currently implemented are:

- **Security Functionality** with a focus on cryptographic algorithms and protocols. Support for cryptographic hardware is scoped for future releases. The Zephyr runtime architecture is a monolithic binary and removes the need for dynamic loaders, thereby reducing the exposed attack surface.
**Quality Assurance** is driven by using a development process that requires all code to be reviewed before being committed to the common repository. Furthermore, the reuse of proven building blocks such as network stacks increases the overall quality level and guarantees stable APIs. Static code analyses are provided by Coverity Scan.

**Execution Protection** including thread separation, stack and memory protection is currently available in the upstream Zephyr RTOS starting with version 1.9.0 (stack protection). Memory protection and thread separation was added in version 1.10.0 for X86 and in version 1.11.0 for ARM and ARC.

These topics are discussed in more detail in the following subsections.

### Security Functionality

The security functionality in Zephyr hinges mainly on the inclusion of cryptographic algorithms, and on its monolithic system design.

The cryptographic features are provided through a set of cryptographic libraries. Applications can choose TinyCrypt2 or mbedTLS based on their needs. TinyCrypt2 supports key cryptographic algorithms required by the connectivity stacks. Tinycrypt2, however, only provides a limited set of algorithms. mbedTLS supports a wider range of algorithms, but at the cost of additional requirements such as malloc support. Applications can choose the solution that matches their individual requirements. Future work may include APIs to abstract the underlying crypto library choice.

APIs for vendor specific cryptographic IPs in both hardware and software are planned, including secure key storage in the form of secure access modules (SAMs), Trusted Platform Modules (TPMs), and Trusted Execution Environments (TEEs).

The security architecture is based on a monolithic design where the Zephyr kernel and all applications are compiled into a single static binary. System calls are implemented as function calls without requiring context switches. Static linking eliminates the potential for dynamically loading malicious code.

Additional protection features are available in later releases. Stack protection mechanisms are provided to protect against stack overruns. In addition, applications can take advantage of thread separation features to split the system into privileged and unprivileged execution environments. Memory protection features provide the capability to partition system resources (memory, peripheral address space, etc) and assign resources to individual threads or groups of threads. Stack, thread execution level, and memory protection constraints are enforced at the time of context switch.

### Quality Assurance

The Zephyr project uses an automated quality assurance process. The goal is to have a process including mandatory code reviews, feature and issue management/tracking, and static code analyses.

Code reviews are documented and enforced using a voting system before getting checked into the repository by the responsible subsystem’s maintainer. The main goals of the code review are:

- Verifying correct functionality of the implementation
- Increasing the readability and maintainability of the contributed source code
- Ensuring appropriate usage of string and memory functions
- Validation of the user input
- Reviewing the security relevant code for potential issues

The current coding principles focus mostly on coding styles and conventions. Functional correctness is ensured by the build system and the experience of the reviewer. Especially for security relevant code, concrete and detailed guidelines need to be developed and aligned with the developers (see: *Secure Coding*).
Static code analyses are run on the Zephyr code tree on a regular basis using the open source Coverity Scan tool. Coverity Scan now includes complexity analysis.

Bug and issue tracking and management is performed using Jira. The term “survivability” was coined to cover pro-active security tasks such as security issue categorization and management. Initial effort has been started on the definition of vulnerability categorization and mitigation processes within Jira.

Issues determined by Coverity should have more stringent reviews before they are closed as non issues (at least another person educated in security processes need to agree on non-issue before closing).

A security subcommittee has been formed to develop a security process in more detail; this document is part of that process.

**Execution Protection**

Execution protection is supported and can be categorized into the following tasks:

- **Memory separation**: Memory will be partitioned into regions and assigned attributes based on the owner of that region of memory. Threads will only have access to regions they control.
- **Stack protection**: Stack guards would provide mechanisms for detecting and trapping stack over-runs. Individual threads should only have access to their own stacks.
- **Thread separation**: Individual threads should only have access to their own memory resources. As threads are scheduled, only memory resources owned by that thread will be accessible. Topics such as program flow protection and other measures for tamper resistance are currently not in scope.

**System Level Security (Ecosystem, …)**

System level security encompasses a wide variety of categories. Some examples of these would be:

- Secure/trusted boot
- Over the air (OTA) updates
- External Communication
- Device authentication
- Access control of onboard resources
  - Flash updating
  - Secure storage
  - Peripherals
- Root of trust
- Reduction of attack surface

Some of these categories are interconnected and rely on multiple pieces to be in place to produce a full solution for the application.

**10.1.3 Secure Development Process**

The development of secure code shall adhere to certain criteria. These include coding guidelines and development processes that can be roughly separated into two categories related to software quality and related to software security. Furthermore, a system architecture document shall be created and kept up-to-date with future development.
Fig. 10.2: Figure 2: Zephyr System Architecture
System Architecture

A high-level schematic of the Zephyr system architecture is given in Figure 2. It separates the architecture into an OS part (kernel + OS Services) and a user-specific part (Application Services). The OS part itself contains low-level, platform specific drivers and the generic implementation of I/O APIs, file systems, kernel-specific functions, and the cryptographic library.

A document describing the system architecture and design choices shall be created and kept up to date with future development. This document shall include the base architecture of the Zephyr OS and an overview of important submodules. For each of the modules, a dedicated architecture document shall be created and evaluated against the implementation. These documents shall serve as an entry point to new developers and as a basis for the security architecture. Please refer to the Zephyr subsystem documentation for detailed information.

Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. These standards are included in the Zephyr Project documentation, specifically in its Secure Coding section. In [?], the following, widely accepted principles for protection mechanisms are defined to prevent security violations and limit their impact:

- **Open design** as a design principle incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well established cryptographic libraries shall be used.

- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [?] and abstracted APIs.

- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.

- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [?].

- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [?].

- **Least privilege** describes an access model in which each user, program and thread shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.

- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [?] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.

- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure its usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth**: do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth [?] paradigm shall be used.

- **Less commonly used services off by default**: to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely used (a threshold
of 80% is given in [?]). For the Zephyr project, this can be realized using the configuration man-
agement. Each functionality and module shall be represented as a configuration option and needs
to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use
case can be disabled. The user shall be notified if low-level options and APIs are enabled but not
used by the application.

- **Change management:** to guarantee a traceability of changes to the system, each change shall
follow a specified process including a change request, impact analysis, ratification, implementation,
and validation phase. In each stage, appropriate documentation shall be provided. All commits
shall be related to a bug report or change request in the issue tracker. Commits without a valid
reference shall be denied.

Based on these design principles and commonly accepted best practices, a secure development guide
shall be developed, published, and implemented into the Zephyr development process. Further details
on this are given in the *Secure Design* section.

**Quality Assurance**

The quality assurance part encompasses the following criteria:

- **Adherence to the Coding Conventions** with respect to coding style, naming schemes of modules,
functions, variables, and so forth. This increases the readability of the Zephyr code base and eases
the code review. These coding conventions are enforced by automated scripts prior to check-in.

- **Adherence to Deployment Guidelines** is required to ensure consistent releases with a well-
documented feature set and a trackable list of security issues.

- **Code Reviews** ensure the functional correctness of the code base and shall be performed on each
proposed code change prior to check-in. Code reviews shall be performed by at least one inde-
pendent reviewer other than the author(s) of the code change. These reviews shall be performed
by the subsystem maintainers and developers on a functional level and are to be distinguished
from security reviews as laid out in the *Secure Design* section. Refer to the *Project and Governance*
documentation for more information.

- **Static Code Analysis** tools efficiently detect common coding mistakes in large code bases. All code
shall be analyzed using an appropriate tool prior to merges into the main repository. This is not per
individual commit, but is to be run on some interval on specific branches. It is mandatory to remove
all findings or waive potential false-positives before each release. Waivers shall be documented
centrally and in the form of a comment inside the source code itself. The documentation shall
include the employed tool and its version, the date of the analysis, the branch and parent revision
number, the reason for the waiver, the author of the respective code, and the approver(s) of the
waiver. This shall as a minimum run on the main release branch and on the security branch. It
shall be ensured that each release has zero issues with regard to static code analysis (including
waivers). Refer to the *Project and Governance* documentation for more information.

- **Complexity Analyses** shall be performed as part of the development process and metrics such as
cyclomatic complexity shall be evaluated. The main goal is to keep the code as simple as possible.

- **Automation:** the review process and checks for coding rule adherence are a mandatory part of
the precommit checks. To ensure consistent application, they shall be automated as part of the
precommit procedure. Prior to merging large pieces of code in from subsystems, in addition to
review process and coding rule adherence, all static code analysis must have been run and issues
resolved.

**Release and Lifecycle Management**

Lifecycle management contains several aspects:

- **Device management** encompasses the possibility to update the operating system and/or security
related sub-systems of Zephyr enabled devices in the field.
• **Lifecycle management**: system stages shall be defined and documented along with the transactions between the stages in a system state diagram. For security reasons, this shall include locking of the device in case an attack has been detected, and a termination if the end of life is reached.

• **Release management** describes the process of defining the release cycle, documenting releases, and maintaining a record of known vulnerabilities and mitigations. Especially for certification purposes the integrity of the release needs to be ensured in a way that later manipulation (e.g. inserting of backdoors, etc.) can be easily detected.

• **Rights management and NDAs**: if required by the chosen certification, the confidentiality and integrity of the system needs to be ensured by an appropriate rights management (e.g. separate source code repository) and non-disclosure agreements between the relevant parties. In case of a repository shared between several parties, measures shall be taken that no malicious code is checked in.

These points shall be evaluated with respect to their impact on the development process employed for the Zephyr project.

### 10.1.4 Secure Design

In order to obtain a certifiable system or product, the security process needs to be clearly defined and its application needs to be monitored and driven. This process includes the development of security related modules in all of its stages and the management of reported security issues. Furthermore, threat models need to be created for currently known and future attack vectors, and their impact on the system needs to be investigated and mitigated. Please refer to the Secure Coding outlined in the Zephyr project documentation for detailed information.

The software security process includes:

• **Adherence to the Secure Development Coding** is mandatory to avoid that individual components breach the system security and to minimize the vulnerability of individual modules. While this can be partially achieved by automated tests, it is inevitable to investigate the correct implementation of security features such as countermeasures manually in security-critical modules.

• **Security Reviews** shall be performed by a security architect in preparation of each security-targeted release and each time a security-related module of the Zephyr project is changed. This process includes the validation of the effectiveness of implemented security measures, the adherence to the global security strategy and architecture, and the preparation of audits towards a security certification if required.

• **Security Issue Management** encompasses the evaluation of potential system vulnerabilities and their mitigation as described in Security Issue Management.

These criteria and tasks need to be integrated into the development process for secure software and shall be automated wherever possible. On system level, and for each security related module of the secure branch of Zephyr, a directly responsible security architect shall be defined to guide the secure development process.

### Security Architecture

The general guidelines above shall be accompanied by an architectural security design on system- and module-level. The high level considerations include

• The identification of security and compliance requirements

• **Functional security** such as the use of cryptographic functions whenever applicable

• Design of countermeasures against known attack vectors

• Recording of security relevant auditable events

• Support for Trusted Platform Modules (TPM) and Trusted Execution Environments (TEE)
• Mechanisms to allow for in-the-field updates of devices using Zephyr
• Task scheduler and separation

The security architecture development is based on assets derived from the structural overview of the overall system architecture. Based on this, the individual steps include:

1. **Identification of assets** such as user data, authentication and encryption keys, key generation data (obtained from RNG), security relevant status information.

2. **Identification of threats** against the assets such as breaches of confidentiality, manipulation of user data, etc.

3. **Definition of requirements** regarding security and protection of the assets, e.g. countermeasures or memory protection schemes.

The security architecture shall be harmonized with the existing system architecture and implementation to determine potential deviations and mitigate existing weaknesses. Newly developed sub-modules that are integrated into the secure branch of the Zephyr project shall provide individual documents describing their security architecture. Additionally, their impact on the system level security shall be considered and documented.

**Security Vulnerability Reporting**

Please see *Security Vulnerability Reporting* for information on reporting security vulnerabilities.

**Threat Modeling and Mitigation**

The modeling of security threats against the Zephyr RTOS is required for the development of an accurate security architecture and for most certification schemes. The first step of this process is the definition of assets to be protected by the system. The next step then models how these assets are protected by the system and which threats against them are present. After a threat has been identified, a corresponding threat model is created. This model contains the asset and system vulnerabilities, as well as the description of the potential exploits of these vulnerabilities. Additionally, the impact on the asset, the module it resides in, and the overall system is to be estimated. This threat model is then considered in the module and system security architecture and appropriate counter-measures are defined to mitigate the threat or limit the impact of exploits.

In short, the threat modeling process can be separated into these steps (adapted from [?]):

1. Definition of assets
2. Application decomposition and creation of appropriate data flow diagrams (DFDs)
3. Threat identification and categorization using the [?] and [?] approaches
4. Determination of countermeasures and other mitigation approaches

This procedure shall be carried out during the design phase of modules and before major changes of the module or system architecture. Additionally, new models shall be created or existing ones shall be updated whenever new vulnerabilities or exploits are discovered. During security reviews, the threat models and the mitigation techniques shall be evaluated by the responsible security architect.

From these threat models and mitigation techniques tests shall be derived that prove the effectiveness of the countermeasures. These tests shall be integrated into the continuous integration workflow to ensure that the security is not impaired by regressions.

**Vulnerability Analyses**

In order to find weak spots in the software implementation, vulnerability analyses (VA) shall be performed. Of special interest are investigations on cryptographic algorithms, critical OS tasks, and connectivity protocols.
On a pure software level, this encompasses

- **Penetration testing** of the RTOS on a particular hardware platform, which involves testing the respective Zephyr OS configuration and hardware as one system.

- **Side channel attacks** (timing invariance, power invariance, etc.) should be considered. For instance, ensuring timing invariance of the cryptographic algorithms and modules is required to reduce the attack surface. This applies to both the software implementations and when using cryptographic hardware.

- **Fuzzing tests** shall be performed on both exposed APIs and protocols.

The list given above serves primarily illustration purposes. For each module and for the complete Zephyr system (in general on a particular hardware platform), a suitable VA plan shall be created and executed. The findings of these analyses shall be considered in the security issue management process, and learnings shall be formulated as guidelines and incorporated into the secure coding guide.

If possible (as in case of fuzzing analyses), these tests shall be integrated into the continuous integration process.

### 10.1.5 Security Certification

One goal of creating a secure branch of the Zephyr RTOS is to create a certifiable system or certifiable submodules thereof. The certification scope and scheme is yet to be decided. However, many certification such as Common Criteria [?] require evidence that the evaluation claims are indeed fulfilled, so a general certification process is outlined in the following. Based on the final choices for the certification scheme and evaluation level, this process needs to be refined.

#### Generic Certification Process

In general, the steps towards a certification or precertification (compare [?]) are:

1. **The definition of assets** to be protected within the Zephyr RTOS. Potential candidates are confidential information such as cryptographic keys, user data such as communication logs, and potentially IP of the vendor or manufacturer.

2. Developing a **threat model** and **security architecture** to protect the assets against exploits of vulnerabilities of the system. As a complete threat model includes the overall product including the hardware platform, this might be realized by a split model containing a precertified secure branch of Zephyr which the vendor could use to certify their Zephyr-enabled product.

3. Formulating an **evaluation target** that includes the **certification claims** on the security of the assets to be evaluated and certified, as well as assumptions on the operating conditions.

4. Providing **proof** that the claims are fulfilled. This includes consistent documentation of the security development process, etc.

These steps are partially covered in previous sections as well. In contrast to these sections, the certification process only requires to consider those components that shall be covered by the certification. The security architecture, for example, considers assets on system level and might include items not relevant for the certification.

#### Certification Options

For the security certification as such, the following options can be pursued:

1. **Abstract precertification of Zephyr as a pure software system**: this option requires assumptions on the underlying hardware platform and the final application running on top of Zephyr. If these assumptions are met by the hardware and the application, a full certification can be more easily achieved. This option is the most flexible approach but puts the largest burden on the product vendor.
2. **Certification of Zephyr on specific hardware platform without a specific application in mind:** this scenario describes the enablement of a secure platform running the Zephyr RTOS. The hardware manufacturer certifies the platform under defined assumptions on the application. If these are met, the final product can be certified with little effort.

3. **Certification of an actual product:** in this case, a full product including a specific hardware, the Zephyr RTOS, and an application is certified.

In all three cases, the certification scheme (e.g. FIPS 140-2 or Common Criteria), the scope of the certification (main-stream Zephyr, security branch, or certain modules), and the certification/assurance level need to be determined.

In case of partial certifications (options 1 and 2), assumptions on hardware and/or software are required for certifications. These can include:

- **Appropriate physical security** of the hardware platform and its environment.
- **Sufficient protection of storage and timing channels** on the hardware platform itself and all connected devices. (No mentioning of remote connections.)
- Only **trusted/assured applications** running on the device
- The device and its software stack is configured and operated by **properly trained and trusted individuals** with no malicious intent.

These assumptions shall be part of the security claim and evaluation target documents.

### 10.2 Security Vulnerability Reporting

#### 10.2.1 Introduction

Vulnerabilities to the Zephyr project may be reported via email to the vulnerabilities@zephyrproject.org mailing list. These reports will be acknowledged and analyzed by the security response team within 1 week. Each vulnerability will be entered into the Zephyr Project security advisory GitHub. The original submitter will be granted permission to view the issues that they have reported.

#### 10.2.2 Security Issue Management

Issues within this bug tracking system will transition through a number of states according to this diagram:
New: This state represents new reports that have been entered directly by a reporter. When entered by the response team in response to an email, the issue shall be transitioned directly to Triage.

Triage: This issue is awaiting Triage by the response team. The response team will analyze the issue, determine a responsible entity, assign it to that individual, and move the issue to the Assigned state. Part of triage will be to set the issue's priority.

Assigned: The issue has been assigned, and is awaiting a fix by the assignee.

Review: Once there is a Zephyr pull request for the issue, the PR link will be added to a comment in the issue, and the issue moved to the Review state.

Accepted: Indicates that this issue has been merged into the appropriate branch within Zephyr.

Public: The embargo period has ended. The issue will be made publicly visible, the associated CVE updated, and the vulnerabilities page in the docs updated to include the detailed information.
The security advisories created are kept private, due to the sensitive nature of security reports. The issues are only visible to certain parties:

- Members of the PSIRT mailing list
- the reporter
- others, as proposed and ratified by the Zephyr Security Subcommittee. In the general case, this will include:
  - The code owner responsible for the fix.
  - The Zephyr release owners for the relevant releases affected by this vulnerability.

The Zephyr Security Subcommittee shall review the reported vulnerabilities during any meeting with more than three people in attendance. During this review, they shall determine if new issues need to be embargoed.

The guideline for embargo will be based on: 1. Severity of the issue, and 2. Exploitability of the issue. Issues that the subcommittee decides do not need an embargo will be reproduced in the regular Zephyr project bug tracking system.

Security sensitive vulnerabilities shall be made public after an embargo period of at most 90 days. The intent is to allow 30 days within the Zephyr project to fix the issues, and 60 days for external parties building products using Zephyr to be able to apply and distribute these fixes.

Fixes to the code shall be made through pull requests PR in the Zephyr project github. Developers shall make an attempt to not reveal the sensitive nature of what is being fixed, and shall not refer to CVE numbers that have been assigned to the issue. The developer instead should merely describe what has been fixed.

The security subcommittee will maintain information mapping embargoed CVEs to these PRs (this information is within the Github security advisories), and produce regular reports of the state of security issues.

Each issue that is considered a security vulnerability shall be assigned a CVE number. As fixes are created, it may be necessary to allocate additional CVE numbers, or to retire numbers that were assigned.

### 10.2.3 Vulnerability Notification

Each Zephyr release shall contain a report of CVEs that were fixed in that release. Because of the sensitive nature of these vulnerabilities, the release shall merely include a list of CVEs that have been fixed. After the embargo period, the vulnerabilities page shall be updated to include additional details of these vulnerabilities. The vulnerability page shall give credit to the reporter(s) unless a reporter specifically requests anonymity.

The Zephyr project shall maintain a vulnerability-alerts mailing list. This list will be seeded initially with a contact from each project member. Additional parties can request to join this list by filling out the form at the Vulnerability Registry. These parties will be vetted by the project director to determine that they have a legitimate interest in knowing about security vulnerabilities during the embargo period.

Periodically, the security subcommittee will send information to this mailing list describing known embargoed issues, and their backport status within the project. This information is intended to allow them to determine if they need to backport these changes to any internal trees.

When issues have been triaged, this list will be informed of:

- The Zephyr Project security advisory link (GitHub).
- The CVE number assigned.
- The subsystem involved.
- The severity of the issue.

After acceptance of a PR fixing the issue (merged), in addition to the above, the list will be informed of:
• The association between the CVE number and the PR fixing it.
• Backport plans within the Zephyr project.

10.2.4 Backporting of Security Vulnerabilities

Each security issue fixed within zephyr shall be backported to the following releases:
• The current Long Term Stable (LTS) release.
• The most recent two releases.

The developer of the fix shall be responsible for any necessary backports, and apply them to any of the above listed release branches, unless the fix does not apply (the vulnerability was introduced after this release was made).

Backports will be tracked on the security advisory.

10.2.5 Need to Know

Due to the sensitive nature of security vulnerabilities, it is important to share details and fixes only with those parties that have a need to know. The following parties will need to know details about security vulnerabilities before the embargo period ends:
• Maintainers will have access to all information within their domain area only.
• The current release manager, and the release manager for historical releases affected by the vulnerability (see backporting above).
• The Project Security Incident Response (PSIRT) team will have full access to information. The PSIRT is made up of representatives from platinum members, and volunteers who do work on triage from other members.
• As needed, release managers and maintainers may be invited to attend additional security meetings to discuss vulnerabilities.

10.3 Secure Coding

Traditionally, microcontroller-based systems have not placed much emphasis on security. They have usually been thought of as isolated, disconnected from the world, and not very vulnerable, just because of the difficulty in accessing them. The Internet of Things has changed this. Now, code running on small microcontrollers often has access to the internet, or at least to other devices (that may themselves have vulnerabilities). Given the volume they are often deployed at, uncontrolled access can be devastating.

This document describes the requirements and process for ensuring security is addressed within the Zephyr project. All code submitted should comply with these principles.

Much of this document comes from [...].

10.3.1 Introduction and Scope

This document covers guidelines for the Zephyr Project, from a security perspective. Many of the ideas contained herein are captured from other open source efforts.

We begin with an overview of secure design as it relates to Zephyr. This is followed by a section on Secure development knowledge, which gives basic requirements that a developer working on the project will need to have. This section gives references to other security documents, and full details of how to write secure software are beyond the scope of this document. This section also describes vulnerability

1 An attack resulted in a significant portion of DNS infrastructure being taken down.
knowledge that at least one of the primary developers should have. This knowledge will be necessary for the review process described below this.

Following this is a description of the review process used to incorporate changes into the Zephyr code-base. This is followed by documentation about how security-sensitive issues are handled by the project. Finally, the document covers how changes are to be made to this document.

10.3.2 Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. In [?], the following, widely accepted principles for protection mechanisms are defined to help prevent security violations and limit their impact:

- **Open design** as a design guideline incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well established cryptographic libraries shall be used.

- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [?] and abstracted APIs.

- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.

- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [?].

- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [?].

- **Least privilege** describes an access model in which each user, program, and thread, shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.

- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [?] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.

- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure their usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth**: do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth [?] paradigm shall be used.

- **Less commonly used services off by default**: to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely used (a threshold of 80% is given in [?]). For the Zephyr project, this can be realized using the configuration management. Each functionality and module shall be represented as a configuration option and needs to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use case can be disabled. The user shall be notified if low-level options and APIs are enabled but not used by the application.

- **Change management**: to guarantee a traceability of changes to the system, each change shall follow a specified process including a change request, impact analysis, ratification, implementation,
and validation phase. In each stage, appropriate documentation shall be provided. All commits shall be related to a bug report or change request in the issue tracker. Commits without a valid reference shall be denied.

10.3.3 Secure development knowledge

Secure designer

The Zephyr project must have at least one primary developer who knows how to design secure software. This requires understanding the following design principles, including the 8 principles from [?]:

- economy of mechanism (keep the design as simple and small as practical, e.g., by adopting sweeping simplifications)
- fail-safe defaults (access decisions shall deny by default, and projects' installation shall be secure by default)
- complete mediation (every access that might be limited must be checked for authority and be non-bypassable)
- open design (security mechanisms should not depend on attacker ignorance of its design, but instead on more easily protected and changed information like keys and passwords)
- separation of privilege (ideally, access to important objects should depend on more than one condition, so that defeating one protection system won't enable complete access. For example, multi-factor authentication, such as requiring both a password and a hardware token, is stronger than single-factor authentication)
- least privilege (processes should operate with the least privilege necessary)
- least common mechanism (the design should minimize the mechanisms common to more than one user and depended on by all users, e.g., directories for temporary files)
- psychological acceptability (the human interface must be designed for ease of use - designing for "least astonishment" can help)
- limited attack surface (the set of the different points where an attacker can try to enter or extract data)
- input validation with whitelists (inputs should typically be checked to determine if they are valid before they are accepted; this validation should use whitelists (which only accept known-good values), not blacklists (which attempt to list known-bad values)).

Vulnerability Knowledge

A "primary developer" in a project is anyone who is familiar with the project's code base, is comfortable making changes to it, and is acknowledged as such by most other participants in the project. A primary developer would typically make a number of contributions over the past year (via code, documentation, or answering questions). Developers would typically be considered primary developers if they initiated the project (and have not left the project more than three years ago), have the option of receiving information on a private vulnerability reporting channel (if there is one), can accept commits on behalf of the project, or perform final releases of the project software. If there is only one developer, that individual is the primary developer.

At least one of the primary developers must know of common kinds of errors that lead to vulnerabilities in this kind of software, as well as at least one method to counter or mitigate each of them.

Examples (depending on the type of software) include SQL injection, OS injection, classic buffer overflow, cross-site scripting, missing authentication, and missing authorization. See the CWE/SANS top 25 or OWASP Top 10 for commonly used lists.
Zephyr Security Subcommittee

There shall be a “Zephyr Security Subcommittee”, responsible for enforcing this guideline, monitoring reviews, and improving these guidelines.

This team will be established according to the Zephyr Project charter.

10.3.4 Code Review

The Zephyr project shall use a code review system that all changes are required to go through. Each change shall be reviewed by at least one primary developer that is not the author of the change. This developer shall determine if this change affects the security of the system (based on their general understanding of security), and if so, shall request the developer with vulnerability knowledge, or the secure designer to also review the code. Any of these individuals shall have the ability to block the change from being merged into the mainline code until the security issues have been addressed.

10.3.5 Issues and Bug Tracking

The Zephyr project shall have an issue tracking system (such as GitHub) that can be used to record and track defects that are found in the system.

Because security issues are often sensitive, this issue tracking system shall have a field to indicate a security issue. Setting this field shall result in the issue only being visible to the Zephyr Security Subcommittee. In addition, there shall be a field to allow the Zephyr Security Subcommittee to add additional users that will have visibility to a given issue.

This embargo, or limited visibility, shall only be for a fixed duration, with a default being a project-decided value. However, because security considerations are often external to the Zephyr project itself, it may be necessary to increase this embargo time. The time necessary shall be clearly annotated in the issue itself.

The list of issues shall be reviewed at least once a month by the Zephyr Security Subcommittee. This review should focus on tracking the fixes, determining if any external parties need to be notified or involved, and determining when to lift the embargo on the issue. The embargo should not be lifted via an automated means, but the review team should avoid unnecessary delay in lifting issues that have been resolved.

10.3.6 Modifications to This Document

Changes to this document shall be reviewed by the Zephyr Security Subcommittee, and approved by consensus.

10.4 Sensor Device Threat Model

This document describes a threat model for an IoT sensor device. Spelling out a threat model helps direct development effort, and can be used to help prioritize these efforts as well.

This device contains a sensor of some type (for example temperature, or a pressure in a pipe), which sends this data to an SoC running a microcontroller. This microcontroller connects to a cloud service, and relays this sensor data to this service. The cloud service is also able to send configuration data to the device, as well as software update images. A general diagram can be seen in Figure 1:

In this sensor device, the sensor connects with the SoC via an SPI bus, and the SoC has a network interface that it uses to communicate with the cloud service. The particulars of these interfaces can impact the threat model in unexpected ways, and variants on this will need to be considered (for example, using a separate network interface SoC connected via some type of bus).
This model also focuses on communicating via the MQTT-over-TLS protocol, as this seems to be in wide use\(^1\).

### 10.4.1 Assets

One aspect of the threat model to consider are assets involved in the operation of the device. The following list enumerates the assets included in this model:

1. **The bootloader.** This is a small code/data image contained in on-device flash that is the first code to run. In order to establish a root of trust, this image must be immutable. This model assumes that the SoC provides a mechanism to protect a region of the flash from future writes, and that this will be done after this image is programmed into the device, early in production \([th-imboot]\).

2. **The application firmware image.** This asset consists of the remainder of the firmware run by the microcontroller. The distinction is made because this part of the image will need to be updated periodically as security vulnerabilities are discovered. Requirements for updates to this image are:
   a. The image shall only be replaced with an authorized image \([th-authrepl]\).
   b. When an authorized replacement image is available, the update shall be done in a timely manner \([th-timely-update]\).
   c. The image update shall be seen as atomic, meaning that when the image is run, the flash shall contain either the update image in its entirety, or the old image in its entirety \([th-atomic-update]\).

3. **Root certificate list.** In order to authenticate the cloud service (server), the IoT device must have a list of root certificates that are allowed to sign the certificate on the server. For cloud-provider based services, this list will generally be provided by the service provider. Because the root certificates can expire, and possibly be revoked, this list will need to be periodically updated \([th-root-certs]\), \([th-root-check]\).

4. **Client secrets.** To authenticate the client to the service, the client must possess some kind of secret. This is generally a private key, usually either an RSA key or an EC private key. When

---

\(^1\) See https://www.slideshare.net/kartben/iot-developer-survey-2018. As of this writing, the three major cloud IoT service providers, AWS IoT, Google Cloud IoT, and Microsoft Azure IoT all provide MQTT over TLS. Some feedback has suggested that some find difficulty with UDP protocols and routing issues on various networks.
establishing communication with the server, the device will use this secret either as part of the TLS establishment, or to sign a message used in the communication.

This secret is generally generated by the service provider, or by software running elsewhere, and must be securely installed on the device. Policy may dictate that this secret be replaced periodically, which will require a way to update the client secret. Typically, the service will allow two or three active keys to allow this update to proceed while the old key is used.

These secrets must be protected from read, and the smallest amount of code necessary shall have access to them. [th-secret-storage]

5. **Current date/time.** TLS certificate verification requires knowledge of the current date and time in order to determine if the current time falls within the certificate's current validity time. Also, token based client authentication will generally require the client to sign a message containing a time window that the token is valid. Certificate validation requires the device's notion of date and time to be accurate within a day or so. Token generation generally requires the time to be accurate within 5-10 minutes.

   It may be possible to approximate secure time by querying an external time server. Secure NTP is possibly beyond the capabilities of an IoT device. The main risks of having incorrect time are denial of service (the device rejects valid certificates), and the generation of tokens with invalid times. It could be possible to trick the device into generating tokens that are valid in the future, but the attacker would also have to spoof the server's certificate to be able to intercept this. [th-time]

6. **Sensor data.** The data received from the sensor itself, and delivered to the service shall be delivered without modification or tampering.

7. **Device configuration.** Various configuration data, such as the hostname of the service to connect to, the address of a time server, frequency and parameters of when sensor data is sent to the service, and other need to be kept by the device. This configuration data will need to be updated periodically as the configuration changes. Updates should be allowed only from authorized parties. [th-conf]

8. **Logs.** In order to assist with analysis of security issues, the device shall log information about security-pertinent events. IoT devices generally have limited storage, and as such, these logs need to be carefully selected. It may also be possible to send these log events to the cloud service where they can be stored in a more resource-available environment. Types of events that should be logged include:

   a. **Firmware image updates.** The system should log the download of new images, and when an image is successfully updated.

   b. **Client secret changes.** Changes and new client secrets should be logged.

   c. **Changes to the device configuration.** [th-logs]

### 10.4.2 Communication

In addition to assets, the threat model also considers the locations where data or assets are communicated between entities of the system.

1. **Flash contents.** The flash device contains several regions. The contents of flash can be modified programmatically by the SoC's CPU.

   a. **The bootloader.** As described in the Assets section, the bootloader is a small section of the flash device containing the code initially run. This section shall be written early in the lifecycle of the device, and the flash device then configured to permanently disallow modification of this section. This configuration should also prevent modification via external interfaces, such as JTAG or SWD debuggers.

   The bootloader is responsible for verifying the signature of the application image as well as updating the application image from the update image when an update is needed.
The bootloader shall verify the signature of the update image before installing it.

The bootloader shall only accept an update image with a newer version number than the current image.

b. **The application image.** The application image contains the code executed during normal operation of the device. Before running this image, the bootloader shall verify a digital signature of the image, to avoid running an image that has been tampered with. The flash/system shall be configured such that after the bootloader has completed, the CPU will be unable to write to the application image.

c. **The update image.** This is an area of flash that holds a new version of the application image. This image will be downloaded and stored by the application during normal operation. When this has completed, the application can trigger a reboot, and the bootloader can install the new image.

d. **Secret storage.** An area of the flash will be used to store client secrets. This area is written and read by a subset of the application image. The application shall be configured to protect this area from both reads and writes by code that does not need to have access to it, giving consideration to possible exploits found within a majority of the application code. Revealing the contents of the secrets would allow the attacker to spoof this device.

    Initial secrets shall be placed in the device during a provisioning activity, distinct from normal operation of the device. Later updates can be made under the direction of communication received over a secured channel to the service.

e. **Configuration storage.** There shall be an area to store other configuration information. On resource-constrained devices, it is allowed for this to be stored in the same region as the secret storage, however, this adds additional code that has access to the secret storage area, and as such, more code that must be scrutinized.

f. **Log storage.** The device may have an area of flash where log events can be written.

2. **Sensor/Actuator interface.** In this design, the sensor or actuator communicates with the SoC via a bus, such as SPI. The hardware design shall be made to make intercepting this bus difficult for an attack. Required techniques depend on the sensitivity and use of the sensor data, and can range from having the sensor mounted on the same PCB as the MCU to epoxy potting the entire device.

3. **Communication with cloud service.** Communication between the device, and the cloud service will be done over the general internet. As such, it shall be assumed that an attacker can arbitrarily intercept this channel and, for example, return spoofed DNS results or attempt man-in-the-middle attacks against communication with cloud services.

    The device shall use TLS for all communication with the cloud service [th-all-tls]. The TLS stack shall be configured to use only cipher suites that are generally considered secure\(^2\), including forward secrecy. The communication shall be secured by the following:

    a. **Cipher suite selection.** The device shall only allow communication with generally agreed secure cipher suites [th-tls-ciphers].

    b. **Server certificate verification.** The server presented by the server shall be verified [th-root-check].

        i. **Naming.** The certificate shall name the host and service the cloud service server is providing. RFC6125 describes best practices for this. It is permissible for the device to require the certificate to be more restrictive than as described in this RFC, provided the service can use a certificate that can comply.

        ii. **Path validation.** The device shall verify that the certificate chain has a valid signature path from a root certificate contained within the device, to the certificate presented by the service. RFC4158 describes this is general. The device is permitted to require a more restricted path, provided the server certificate used complies with this restriction.

\(^2\) As new exploits are discovered, what is considered secure can change. Organizations such as https://www.ssllabs.com/ provide information on current ideas of how TLS must be configured to be secure.
iii. **Validity period.** The validity period of all presented certificates shall be checked against the device’s best notion of the current time.

c. **Client authentication.** The client shall authenticate itself to the service using a secret known only to that particular device. There are several options, and the technique used is generally mandated by the particular service provider being used [th-tls-client-auth].

i. **TLS client certificates.** The TLS protocol allows the client to present a certificate, and assert its knowledge of the secret described by that certificate. Generally, these certificates will be stored within the service provider. These certificates can be self-signed, or signed by a CA. Since the service provider maintains a list of valid certificates (mapping them to a device identity), having these certificates signed by a CA does not add any additional security, but may be useful in the management of these certificates.

ii. **Token-based authentication.** It is also possible for the client to authenticate itself using the `password` field of the MQTT CONNECT packet. However, the secret itself must not be transmitted in this packet. Instead, a token-based protocol, such as RFC7519’s JSON Web Token (JWT) can be used. These tokens will generally have a small validity period (e.g. 1 hour), to prevent them from being reused if they are intercepted. The token shall not be sent until the device has verified the identity of the server.

d. **Random/Entropy source.** Cryptographic communication requires the generation of secure pseudorandom numbers. The device shall use a modern, accepted cryptographic random-bit generator to generate these random numbers. It shall use either a Non-Deterministic Random Bit Generator (True RBG) implemented in hardware within the SoC, or a Deterministic Random Bit Generator (Pseudo RBG) seeded by an entropy source within the SoC. Please see NIST SP 800-90A for information on approved RBGs and NIST SP 800-90B for information on testing a device’s entropy source [th-entropy].

4. **Communication with the time service.** Ideally, the device shall contain hardware that maintains a secure time. However, most SoCs in use do not have support for this, and it will be necessary to consult an external time service. RFC4330 and referenced RFCs describe the Simple Network Time Protocol that can be used to query the current time from a network time server.

5. **Device lifecycle.** An IoT device will have a lifecycle from production to destruction and disposal of the device. Aspects of this lifecycle that impact security include initial provisioning, normal operation, re-provisioning, and destruction.

a. **Initial provisioning.** During the initial provisioning stage, it is necessary to program the bootloader, an initial application image, a device secret, and initial configuration data [th-initial-provision]. In addition, the bootloader flash protection shall be installed. Of this information, only the device secret needs to differ per device. This secret shall be securely maintained, and destroyed in all locations outside of the device once it has been programmed [th-initial-secret].

b. **Normal operation.** Normal operation includes the behavior described by the rest of this document.

c. **Re-provisioning.** Sometimes it is necessary to re-provision a device, such as for a different application. One way to do this is to keep the same device secret, and replace the configuration data, as well as the cloud service data associated with the device. It is also possible to program a new device secret, but if this is done it shall be done securely, and the new secret destroyed externally once programmed into the device [th-reprovision].

d. **Destruction.** To prevent the device secret from being used to spoof the device, upon decommissioning, the secret for a particular device shall be rendered ineffective [th-destruction]. Possibilities include:

   i. Hardware destruction of the device.

   ii. Securely wiping the flash area containing the secret.

   iii. Removing the device identity and certificate from the service.

---

3 Note that merely erasing this flash area is unlikely to be sufficient.
10.4.3 Other Considerations

In addition to the above, network connected devices generally will need a way to configure them to connect to the network environment they are placed in. There are numerous ways of doing this, and it is important for these configuration methods to not circumvent the security requirements described above.

10.4.4 Threats

10.4.5 Notes

10.5 Hardening Tool

Zephyr contains several optional features that make the overall system more secure. As we take advantage of hardware features, many of these options are platform specific and besides it, some of them are unknown by developers.

To address this problem, Zephyr provides a tool that helps to check an application configuration option list against a list of hardening preferences defined by the Security Group. The tool can identify the build target and based on that provides suggestions and recommendations on how to optimize the configuration for security.

10.5.1 Usage

After configure of your application, change directory to the build folder and:

```
# ninja build system:
$ ninja hardenconfig
# make build system:
$ make hardenconfig
```

The output should be similar to the one bellow:

<table>
<thead>
<tr>
<th>name</th>
<th>current</th>
<th>recommended</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONFIG_HW_STACK_PROTECTION</td>
<td>n</td>
<td>y</td>
</tr>
<tr>
<td>CONFIG_BOOT_BANNER</td>
<td>y</td>
<td>n</td>
</tr>
<tr>
<td>CONFIG_PRINTK</td>
<td>y</td>
<td>n</td>
</tr>
<tr>
<td>CONFIG_EARLY_CONSOLE</td>
<td>y</td>
<td>n</td>
</tr>
<tr>
<td>CONFIG_OVERRIDE_FRAME_POINTER_DEFAULT</td>
<td>n</td>
<td>y</td>
</tr>
<tr>
<td>CONFIG_DEBUG_INFO</td>
<td>y</td>
<td>n</td>
</tr>
<tr>
<td>CONFIG_TEST_RANDOM_GENERATOR</td>
<td>y</td>
<td>n</td>
</tr>
<tr>
<td>CONFIG_BUILD_OUTPUT_STRIPPED</td>
<td>n</td>
<td>y</td>
</tr>
<tr>
<td>CONFIG_STACK_SENTINEL</td>
<td>n</td>
<td>y</td>
</tr>
</tbody>
</table>
10.6 Vulnerabilities

This page collects all of the vulnerabilities that are discovered and fixed in each release. It will also often have more details than is available in the releases. Some vulnerabilities are deemed to be sensitive, and will not be publicly discussed until there is sufficient time to fix them. Because the release notes are locked to a version, the information here can be updated after the embargo is lifted.

10.6.1 CVE-2017

CVE-2017-14199

Buffer overflow in getaddrinfo().

- CVE-2017-14199
- Zephyr project bug tracker ZEPSEC-12
- PR6158 fix for 1.11.0

CVE-2017-14201

The shell DNS command can cause unpredictable results due to misuse of stack variables. Use After Free vulnerability in the Zephyr shell allows a serial or telnet connected user to cause denial of service, and possibly remote code execution.

This has been fixed in release v1.14.0.

- CVE-2017-14201
- Zephyr project bug tracker ZEPSEC-17
- PR13260 fix for v1.14.0

CVE-2017-14202

The shell implementation does not protect against buffer overruns resulting in unpredictable behavior. Improper Restriction of Operations within the Bounds of a Memory Buffer vulnerability in the shell component of Zephyr allows a serial or telnet connected user to cause a crash, possibly with arbitrary code execution.

This has been fixed in release v1.14.0.

- CVE-2017-14202
- Zephyr project bug tracker ZEPSEC-18
- PR13048 fix for v1.14.0

10.6.2 CVE-2019

CVE-2019-9506

The Bluetooth BR/EDR specification up to and including version 5.1 permits sufficiently low encryption key length and does not prevent an attacker from influencing the key length negotiation. This allows practical brute-force attacks (aka “KNOB”) that can decrypt traffic and inject arbitrary ciphertext without the victim noticing.

- CVE-2019-9506
10.6.3  CVE-2020

**CVE-2020-10019**

Buffer Overflow vulnerability in USB DFU of zephyr allows a USB connected host to cause possible remote code execution.

This has been fixed in releases v1.14.2, v2.2.0, and v2.1.1.

- CVE-2020-10019
- Zephyr project bug tracker ZEPSEC-25
- PR23460 fix for 1.14.x
- PR23457 fix for 2.1.x
- PR23190 fix in 2.2.0

**CVE-2020-10021**

Out-of-bounds write in USB Mass Storage with unaligned sizes

Out-of-bounds Write in the USB Mass Storage memoryWrite handler with unaligned Sizes.

See NCC-ZEP-024, NCC-ZEP-025, NCC-ZEP-026

This has been fixed in releases v1.14.2, and v2.2.0.

- CVE-2020-10021
- Zephyr project bug tracker ZEPSEC-26
- PR23455 fix for v1.14.2
- PR23456 fix for the v2.1 branch
- PR23240 fix for v2.2.0

**CVE-2020-10022**

UpdateHub Module Copies a Variable-Size Hash String Into a Fixed-Size Array

A malformed JSON payload that is received from an UpdateHub server may trigger memory corruption in the Zephyr OS. This could result in a denial of service in the best case, or code execution in the worst case.

See NCC-ZEP-016

This has been fixed in the below pull requests for main, branch from v2.1.0, and branch from v2.2.0.

- CVE-2020-10022
- Zephyr project bug tracker ZEPSEC-28
- PR24154 fix for main
- PR24065 fix for branch from v2.1.0
- PR24066 fix for branch from v2.2.0
CVE-2020-10023

Shell Subsystem Contains a Buffer Overflow Vulnerability In shell_spaces_trim

The shell subsystem contains a buffer overflow, whereby an adversary with physical access to the device is able to cause a memory corruption, resulting in denial of service or possibly code execution within the Zephyr kernel.

See NCC-ZEP-019

This has been fixed in releases v1.14.2, v2.2.0, and in a branch from v2.1.0,

- CVE-2020-10023
- Zephyr project bug tracker ZEPSEC-29
- PR23646 fix for v1.14.2
- PR23649 fix for branch from v2.1.0
- PR23304 fix for v2.2.0

CVE-2020-10024

ARM Platform Uses Signed Integer Comparison When Validating Syscall Numbers

The arm platform-specific code uses a signed integer comparison when validating system call numbers. An attacker who has obtained code execution within a user thread is able to elevate privileges to that of the kernel.

See NCC-ZEP-001

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0,

- CVE-2020-10024
- Zephyr project bug tracker ZEPSEC-30
- PR23535 fix for v1.14.2
- PR23498 fix for branch from v2.1.0
- PR23323 fix for v2.2.0

CVE-2020-10027

ARC Platform Uses Signed Integer Comparison When Validating Syscall Numbers

An attacker who has obtained code execution within a user thread is able to elevate privileges to that of the kernel.

See NCC-ZEP-001

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0,

- CVE-2020-10027
- Zephyr project bug tracker ZEPSEC-35
- PR23500 fix for v1.14.2
- PR23499 fix for branch from v2.1.0
- PR23328 fix for v2.2.0
CVE-2020-10028

Multiple Syscalls In GPIO Subsystem Performs No Argument Validation

Multiple syscalls with insufficient argument validation

See NCC-ZEP-006

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0.

- CVE-2020-10028
- Zephyr project bug tracker ZEPSEC-32
- PR23733 fix for v1.14.2
- PR23737 fix for branch from v2.1.0
- PR23308 fix for v2.2.0 (gpio patch)

CVE-2020-10058

Multiple Syscalls In kscan Subsystem Performs No Argument Validation

Multiple syscalls in the Kscan subsystem perform insufficient argument validation, allowing code executing in userspace to potentially gain elevated privileges.

See NCC-ZEP-006

This has been fixed in a branch from v2.1.0, and release v2.2.0.

- CVE-2020-10058
- Zephyr project bug tracker ZEPSEC-34
- PR23748 fix for branch from v2.1.0
- PR23308 fix for v2.2.0 (kscan patch)

CVE-2020-10059

UpdateHub Module Explicitly Disables TLS Verification

The UpdateHub module disables DTLS peer checking, which allows for a man in the middle attack. This is mitigated by firmware images requiring valid signatures. However, there is no benefit to using DTLS without the peer checking.

See NCC-ZEP-018

This has been fixed in a PR against Zephyr main.

- CVE-2020-10059
- Zephyr project bug tracker ZEPSEC-36
- PR24954 fix on main (to be fixed in v2.3.0)
- PR24954 fix v2.1.0
- PR24954 fix v2.2.0
CVE-2020-10060

UpdateHub Might Dereference An Uninitialized Pointer

In updatehub_probe, right after JSON parsing is complete, objects[1] is accessed from the output structure in two different places. If the JSON contained less than two elements, this access would reference uninitialized stack memory. This could result in a crash, denial of service, or possibly an information leak.

Recommend disabling updatehub until such a time as a fix can be made available.

See NCC-ZEP-030

This has been fixed in a PR against Zephyr main.

- CVE-2020-10060
- Zephyr project bug tracker ZEPSEC-37
- PR27865 fix on main (to be fixed in v2.4.0)
- PR27865 fix for v2.3.0
- PR27865 fix for v2.2.0
- PR27865 fix for v2.1.0

CVE-2020-10061

Error handling invalid packet sequence

Improper handling of the full-buffer case in the Zephyr Bluetooth implementation can result in memory corruption.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- CVE-2020-10061
- Zephyr project bug tracker ZEPSEC-75
- PR23516 fix for v2.3 (split driver)
- PR23517 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23547 fix for branch from v2.2.0

CVE-2020-10062

Packet length decoding error in MQTT

CVE: An off-by-one error in the Zephyr project MQTT packet length decoder can result in memory corruption and possible remote code execution. NCC-ZEP-031

The MQTT packet header length can be 1 to 4 bytes. An off-by-one error in the code can result in this being interpreted as 5 bytes, which can cause an integer overflow, resulting in memory corruption.

This has been fixed in main for v2.3.

- CVE-2020-10062
- Zephyr project bug tracker ZEPSEC-84
- commit 11b7a37d for v2.3
- NCC-ZEP report (NCC-ZEP-031)
CVE-2020-10063

Remote Denial of Service in CoAP Option Parsing Due To Integer Overflow

A remote adversary with the ability to send arbitrary CoAP packets to be parsed by Zephyr is able to cause a denial of service.

This has been fixed in main for v2.3.

- CVE-2020-10063
- Zephyr project bug tracker ZEPSEC-55
- PR24435 fix in main for v2.3
- PR24531 fix for branch from v2.2
- PR24535 fix for branch from v2.1
- PR24530 fix for branch from v1.14
- NCC-ZEP report (NCC-ZEP-032)

CVE-2020-10064

Improper Input Frame Validation in ieee802154 Processing

- CVE-2020-10064
- Zephyr project bug tracker ZEPSEC-65
- PR24971 fix for v2.4
- PR33451 fix for v1.4

CVE-2020-10065

OOB Write after not validating user-supplied length (\(\leq 0xffff\)) and copying to fixed-size buffer (default: 77 bytes) for HCI_ACL packets in bluetooth HCI over SPI driver.

- CVE-2020-10065
- Zephyr project bug tracker ZEPSEC-66
- This issue has not been fixed.

CVE-2020-10066

Incorrect Error Handling in Bluetooth HCI core

In hci_cmd_done, the buf argument being passed as null causes nullpointer dereference.

- CVE-2020-10066
- Zephyr project bug tracker ZEPSEC-67
- PR24902 fix for v2.4
- PR25089 fix for v1.4
CVE-2020-10067

Integer Overflow In is_in_region Allows User Thread To Access Kernel Memory

A malicious userspace application can cause a integer overflow and bypass security checks performed by system call handlers. The impact would depend on the underlying system call and can range from denial of service to information leak to memory corruption resulting in code execution within the kernel.

See NCC-ZEP-005

This has been fixed in releases v1.14.2, and v2.2.0.

- CVE-2020-10067
- Zephyr project bug tracker ZEPSEC-27
- PR23653 fix for v1.14.2
- PR23654 fix for the v2.1 branch
- PR23239 fix for v2.2.0

CVE-2020-10068

Zephyr Bluetooth DLE duplicate requests vulnerability

In the Zephyr project Bluetooth subsystem, certain duplicate and back-to-back packets can cause incorrect behavior, resulting in a denial of service.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- CVE-2020-10068
- Zephyr project bug tracker ZEPSEC-78
- PR23707 fix for v2.3 (split driver)
- PR23708 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23964 fix for v2.2.0

CVE-2020-10069

Zephyr Bluetooth unchecked packet data results in denial of service

An unchecked parameter in bluetooth data can result in an assertion failure, or division by zero, resulting in a denial of service attack.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- CVE-2020-10069
- Zephyr project bug tracker ZEPSEC-81
- PR23705 fix for v2.3 (split driver)
- PR23706 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23963 fix for branch from v2.2.0
**CVE-2020-10070**

MQTT buffer overflow on receive buffer

In the Zephyr Project MQTT code, improper bounds checking can result in memory corruption and possibly remote code execution. NCC-ZEP-031

When calculating the packet length, arithmetic overflow can result in accepting a receive buffer larger than the available buffer space, resulting in user data being written beyond this buffer.

This has been fixed in main for v2.3.

- CVE-2020-10070
- Zephyr project bug tracker ZEPSEC-85
- commit 0b39cbf3 for v2.3
- NCC-ZEP report (NCC-ZEP-031)

**CVE-2020-10071**

Insufficient publish message length validation in MQTT

The Zephyr MQTT parsing code performs insufficient checking of the length field on publish messages, allowing a buffer overflow and potentially remote code execution. NCC-ZEP-031

This has been fixed in main for v2.3.

- CVE-2020-10071
- Zephyr project bug tracker ZEPSEC-86
- commit 989c4713 fix for v2.3
- NCC-ZEP report (NCC-ZEP-031)

**CVE-2020-10072**

All threads can access all socket file descriptors

There is no management of permissions to network socket API file descriptors. Any thread running on the system may read/write a socket file descriptor knowing only the numerical value of the file descriptor.

- CVE-2020-10072
- Zephyr project bug tracker ZEPSEC-87
- PR25804 fix for v2.4
- PR27176 fix for v1.4

**CVE-2020-10136**

IP-in-IP protocol routes arbitrary traffic by default zephyrproject

- CVE-2020-10136
- Zephyr project bug tracker ZEPSEC-64
CVE-2020-13598

FS: Buffer Overflow when enabling Long File Names in FAT_FS and calling fs_stat

Performing fs_stat on a file with a filename longer than 12 characters long will cause a buffer overflow.

- CVE-2020-13598
- Zephyr project bug tracker ZEPSEC-88
- PR25852 fix for v2.4
- PR28782 fix for v2.3
- PR33577 fix for v1.4

CVE-2020-13599

Security problem with settings and littlefs

When settings is used in combination with littlefs all security related information can be extracted from the device using MCUmgr and this could be used e.g in bt-mesh to get the device key, network key, app keys from the device.

- CVE-2020-13599
- Zephyr project bug tracker ZEPSEC-57
- PR26083 fix for v2.4

CVE-2020-13600

Malformed SPI in response for eswifi can corrupt kernel memory

- CVE-2020-13600
- Zephyr project bug tracker ZEPSEC-91
- PR26712 fix for v2.4

CVE-2020-13601

Possible read out of bounds in dns read

- CVE-2020-13601
- Zephyr project bug tracker ZEPSEC-92
- PR27774 fix for v2.4
- PR30503 fix for v1.4

CVE-2020-13602

Remote Denial of Service in LwM2M do_write_op_tlv

In the Zephyr LwM2M implementation, malformed input can result in an infinite loop, resulting in a denial of service attack.

- CVE-2020-13602
- Zephyr project bug tracker ZEPSEC-56
- PR26571 fix for v2.4
- PR33578 fix for v1.4
CVE-2020-13603

Possible overflow in mempool

- Zephyr offers pre-built 'malloc' wrapper function instead.
- The 'malloc' function is wrapper for the 'sys_mem_pool_alloc' function
- sys_mem_pool_alloc allocates 'size + WB_UP(sizeof(struct sys_mem_pool_block))' in an unsafe manner.
- Asking for very large size values leads to internal integer wrap-around.
- Integer wrap-around leads to successful allocation of very small memory.
- For example: calling malloc(0xffffffff) leads to successful allocation of 7 bytes.
- That leads to heap overflow.
- CVE-2020-13603
- Zephyr project bug tracker ZEPSEC-111
  - PR31796 fix for v2.4
  - PR32808 fix for v1.4

10.6.4 CVE-2021

CVE-2021-3319

DOS: Incorrect 802154 Frame Validation for Omitted Source / Dest Addresses

Improper processing of omitted source and destination addresses in ieee802154 frame validation (ieee802154_validate_frame)

This has been fixed in main for v2.5.0

- CVE-2020-3319
- Zephyr project bug tracker GHSA-94jg-2p6q-5364
- PR31908 fix for main

CVE-2021-3320

Mismatch between validation and handling of 802154 ACK frames, where ACK frames are considered during validation, but not during actual processing, leading to a type confusion.

- CVE-2020-3320
- PR31908 fix for main

CVE-2021-3321

Incomplete check of minimum IEEE 802154 fragment size leading to an integer underflow.

- CVE-2020-3321
- Zephyr project bug tracker ZEPSEC-114
- PR33453 fix for v2.4
CVE-2021-3323

Integer Underflow in 6LoWPAN IPHC Header Uncompression
This has been fixed in main for v2.5.0

- CVE-2020-3323
- Zephyr project bug tracker GHSA-89j6-qpxf-pfpc
- PR 31971 fix for main

CVE-2021-3430

Assertion reachable with repeated LL_CONNECTION_PARAM_REQ.
This has been fixed in main for v2.6.0

- CVE-2021-3430
- Zephyr project bug tracker GHSA-46h3-hjcq-2jjr
- PR 33272 fix for main
- PR 33369 fix for 2.5
- PR 33759 fix for 1.14.2

CVE-2021-3431

BT: Assertion failure on repeated LL_FEATURE_REQ
This has been fixed in main for v2.6.0

- CVE-2021-3431
- Zephyr project bug tracker GHSA-7548-5m6f-mqv9
- PR 33340 fix for main
- PR 33369 fix for 2.5

CVE-2021-3432

Invalid interval in CONNECT_IND leads to Division by Zero
This has been fixed in main for v2.6.0

- CVE-2021-3432
- Zephyr project bug tracker GHSA-7364-p4wc-8mj4
- PR 33278 fix for main
- PR 33369 fix for 2.5

CVE-2021-3433

BT: Invalid channel map in CONNECT_IND results to Deadlock
This has been fixed in main for v2.6.0

- CVE-2021-3433
- Zephyr project bug tracker GHSA-3c2f-w4v6-qxrp
• PR 33278 fix for main
• PR 33369 fix for 2.5

CVE-2021-3434
L2CAP: Stack based buffer overflow in le_ecred_conn_req()
This has been fixed in main for v2.6.0
  • CVE-2021-3434
  • Zephyr project bug tracker GHSA-8w87-6rfp-cfrm
  • PR 33305 fix for main
  • PR 33419 fix for 2.5
  • PR 33418 fix for 1.14.2

CVE-2021-3435
L2CAP: Information leakage in le_ecred_conn_req()
This has been fixed in main for v2.6.0
  • CVE-2021-3435
  • Zephyr project bug tracker GHSA-xhg3-gvj6-4rqh
  • PR 33305 fix for main
  • PR 33419 fix for 2.5
  • PR 33418 fix for 1.14.2

CVE-2021-3436
Bluetooth: Possible to overwrite an existing bond during keys distribution phase when the identity address of the bond is known
During the distribution of the identity address information we don't check for an existing bond with the same identity address. This means that a duplicate entry will be created in RAM while the newest entry will overwrite the existing one in persistent storage.
This has been fixed in main for v2.6.0
  • CVE-2021-3436
  • Zephyr project bug tracker GHSA-j76f-35mc-4h63
  • PR 33266 fix for main
  • PR 33432 fix for 2.5
  • PR 33433 fix for 2.4
  • PR 33718 fix for 1.14.2
CVE-2021-3454

Truncated L2CAP K-frame causes assertion failure

For example, sending L2CAP K-frame where SDU length field is truncated to only one byte, causes assertion failure in previous releases of Zephyr. This has been fixed in master by commit 0ba9437 but has not yet been backported to older release branches.

This has been fixed in main for v2.6.0

- CVE-2021-3454
- Zephyr project bug tracker GHSA-fx88-6c29-vrp3
- PR 32588 fix for main
- PR 33513 fix for 2.5
- PR 33514 fix for 2.4

CVE-2021-3455

Disconnecting L2CAP channel right after invalid ATT request leads freeze

When Central device connects to peripheral and creates L2CAP connection for Enhanced ATT, sending some invalid ATT request and disconnecting immediately causes freeze.

This has been fixed in main for v2.6.0

- CVE-2021-3455
- Zephyr project bug tracker GHSA-7g38-3x9v-v7vp
- PR 35597 fix for main
- PR 36104 fix for 2.5
- PR 36105 fix for 2.4

CVE-2021-3510

Zephyr JSON decoder incorrectly decodes array of array

When using JSON_OBJ_DESCR_ARRAY_ARRAY, the subarray is has the token type JSON_TOK_LIST_START, but then assigns to the object part of the union. arr_parse then takes the offset of the array-object (which has nothing todo with the list) treats it as relative to the parent object, and stores the length of the subarray in there.

This has been fixed in main for v2.7.0

- CVE-2021-3510
- Zephyr project bug tracker GHSA-289f-7mw3-2qf4
- PR 36340 fix for main
- PR 37816 fix for 2.6

CVE-2021-3581

HCI data not properly checked leads to memory overflow in the Bluetooth stack

In the process of setting SCAN_RSP through the HCI command, the Zephyr Bluetooth protocol stack did not effectively check the length of the incoming HCI data. Causes memory overflow, and then the data in the memory is overwritten, and may even cause arbitrary code execution.
This has been fixed in main for v2.6.0

- CVE-2021-3581
- Zephyr project bug tracker GHSA-8q65-5gqf-fmw5
- PR 35935 fix for main
- PR 35984 fix for 2.5
- PR 35985 fix for 2.4
- PR 35985 fix for 1.14

**CVE-2021-3625**

Buffer overflow in Zephyr USB DFU DNLOAD

This has been fixed in main for v2.6.0

Bibliography

[th-imboot] Must boot with an immutable bootloader.
[th-authrepl] Application image shall only be replaced with an authorized image.
[th-timely-update] Application updates shall be done in a timely manner.
[th-atomic-update] Application updates shall be atomic.
[th-root-certs] TLS must have a list of trusted root certificates.
[th-root-check] TLS must verify root certificate from server is valid.
[th-secret-storage] There must be a mechanism to securely store client secrets. The least amount of code necessary shall have access to these secrets.
[th-time] System must have moderately accurate notion of the current date/time.
[th-conf] The system must receive, and keep configuration data.
[th-logs] The system must log security-related events, and either store them locally, or send to a service.
[th-all-tls] All communications with the cloud service shall use TLS.
[th-tls-ciphers] TLS shall be configured to allow only generally agreed cipher suites (including forward secrecy).
[th-tls-client-auth] The device shall authenticate itself with the cloud provider using one of the methods described.
[th-entropy] The TLS layer shall use a modern, accepted cryptographic random-bit generator seeded by an entropy source within the SoC.
[th-initial-provision] The device shall have a per-device secret loaded before deployment.
[th-initial-secret] The initial secret shall be securely maintained, and destroyed in any external location as soon as the device is provisioned.
[th-reprovision] Reprovisioning a device shall be done securely.
[th-destruction] Upon decommissioning, the device secret shall be rendered ineffective.
