Chapter 1

Introduction

The Zephyr OS is based on a small-footprint kernel designed for use on resource-constrained and embedded systems: from simple embedded environmental sensors and LED wearables to sophisticated embedded controllers, smart watches, and IoT wireless applications.

The Zephyr kernel supports multiple architectures, including:

- ARCv2 (EM and HS) and ARCv3 (HS6X)
- ARMv6-M, ARMv7-M, and ARMv8-M (Cortex-M)
- ARMv7-A and ARMv8-A (Cortex-A, 32- and 64-bit)
- ARMv7-R, ARMv8-R (Cortex-R, 32- and 64-bit)
- Intel x86 (32- and 64-bit)
- MIPS (MIPS32 Release 1 specification)
- NIOS II Gen 2
- RISC-V (32- and 64-bit)
- SPARC V8
- Tensilica Xtensa

The full list of supported boards based on these architectures can be found here.

1.1 Licensing

Zephyr is permissively licensed using the Apache 2.0 license (as found in the LICENSE file in the project’s GitHub repo). There are some imported or reused components of the Zephyr project that use other licensing, as described in Licensing of Zephyr Project components.

1.2 Distinguishing Features

Zephyr offers a large and ever growing number of features including:

**Extensive suite of Kernel services**  Zephyr offers a number of familiar services for development:

- *Multi-threading Services* for cooperative, priority-based, non-preemptive, and preemptive threads with optional round robin time-slicing. Includes POSIX pthreads compatible API support.
- *Interrupt Services* for compile-time registration of interrupt handlers.
• Memory Allocation Services for dynamic allocation and freeing of fixed-size or variable-size memory blocks.

• Inter-thread Synchronization Services for binary semaphores, counting semaphores, and mutex semaphores.

• Inter-thread Data Passing Services for basic message queues, enhanced message queues, and byte streams.

• Power Management Services such as tickless idle and an advanced idling infrastructure.

Multiple Scheduling Algorithms Zephyr provides a comprehensive set of thread scheduling choices:

• Cooperative and Preemptive Scheduling

• Earliest Deadline First (EDF)

• Meta IRQ scheduling implementing “interrupt bottom half” or “tasklet” behavior

• Timeslicing: Enables time slicing between preemptible threads of equal priority

• Multiple queuing strategies:
  – Simple linked-list ready queue
  – Red/black tree ready queue
  – Traditional multi-queue ready queue

Highly configurable / Modular for flexibility Allows an application to incorporate only the capabilities it needs as it needs them, and to specify their quantity and size.

Cross Architecture Supports a wide variety of supported boards with different CPU architectures and developer tools. Contributions have added support for an increasing number of SoCs, platforms, and drivers.

Memory Protection Implements configurable architecture-specific stack-overflow protection, kernel object and device driver permission tracking, and thread isolation with thread-level memory protection on x86, ARC, and ARM architectures, userspace, and memory domains.

For platforms without MMU/MPU and memory constrained devices, supports combining application-specific code with a custom kernel to create a monolithic image that gets loaded and executed on a system’s hardware. Both the application code and kernel code execute in a single shared address space.

Compile-time resource definition Allows system resources to be defined at compile-time, which reduces code size and increases performance for resource-limited systems.

Optimized Device Driver Model Provides a consistent device model for configuring the drivers that are part of the platform/system and a consistent model for initializing all the drivers configured into the system and Allows the reuse of drivers across platforms that have common devices/IP blocks

Devicetree Support Use of devicetree to describe hardware. Information from devicetree is used to create the application image.

Native Networking Stack supporting multiple protocols Networking support is fully featured and optimized, including LwM2M and BSD sockets compatible support. OpenThread support (on Nordic chipsets) is also provided - a mesh network designed to securely and reliably connect hundreds of products around the home.

Bluetooth Low Energy 5.0 support Bluetooth 5.0 compliant (ESR10) and Bluetooth Low Energy Controller support (LE Link Layer). Includes Bluetooth mesh and a Bluetooth qualification-ready Bluetooth controller:

• Generic Access Profile (GAP) with all possible LE roles.

• GATT (Generic Attribute Profile)

• Pairing support, including the Secure Connections feature from Bluetooth 4.2

• Clean HCI driver abstraction
• Raw HCI interface to run Zephyr as a Controller instead of a full Host stack
• Verified with multiple popular controllers
• Highly configurable

Mesh Support:
• Relay, Friend Node, Low-Power Node (LPN) and GATT Proxy features
• Both Provisioning bearers supported (PB-ADV & PB-GATT)
• Highly configurable, fitting in devices with at least 16k RAM

Native Linux, macOS, and Windows Development A command-line CMake build environment runs on popular developer OS systems. A native POSIX port, lets you build and run Zephyr as a native application on Linux and other OSes, aiding development and testing.

Virtual File System Interface with LittleFS and FATFS Support LittleFS and FATFS Support, FCB (Flash Circular Buffer) for memory constrained applications, and file system enhancements for logging and configuration.

Powerful multi-backend logging Framework Support for log filtering, object dumping, panic mode, multiple backends (memory, networking, filesystem, console, ..) and integration with the shell subsystem.

User friendly and full-featured Shell interface A multi-instance shell subsystem with user-friendly features such as autocompletion, wildcards, coloring, metakeys (arrows, backspace, ctrl+u, etc.) and history. Support for static commands and dynamic sub-commands.

Settings on non-volatile storage The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. Settings items are stored as key-value pair strings.

Non-volatile storage (NVS) NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Native POSIX port Supports running Zephyr as a Linux application with support for various subsystems and networking.

1.3 Community Support

Community support is provided via mailing lists and Discord; see the Resources below for details.

1.4 Resources

Here's a quick summary of resources to help you find your way around:

• Help: Asking for Help Tips
• Documentation: http://docs.zephyrproject.org (Getting Started Guide)
• Source Code: https://github.com/zephyrproject-rtos/zephyr is the main repository; https://elixir.bootlin.com/zephyr/latest/source contains a searchable index
• Releases: https://github.com/zephyrproject-rtos/zephyr/releases
• Samples and example code: see Sample and Demo Code Examples
• Mailing Lists: users@lists.zephyrproject.org and devel@lists.zephyrproject.org are the main user and developer mailing lists, respectively. You can join the developer's list and search its archives at Zephyr Development mailing list. The other Zephyr mailing list subgroups have their own archives and sign-up pages.
• Nightly CI Build Status: https://lists.zephyrproject.org/g/builds The builds@lists.zephyrproject.org mailing list archives the CI nightly build results.

• Chat: Real-time chat happens in Zephyr's Discord Server. Use this Discord Invite to register.

• Contributing: see the Contribution Guide

• Wiki: Zephyr GitHub wiki

• Issues: https://github.com/zephyrproject-rtos/zephyr/issues

• Security Issues: Email vulnerabilities@zephyrproject.org to report security issues; also see our Security documentation. Security issues are tracked separately at https://zephyrprojectsec.atlassian.net.

• Zephyr Project Website: https://zephyrproject.org

1.5 Fundamental Terms and Concepts

See glossary
Chapter 2

Getting Started Guide

Follow this guide to:

- Set up a command-line Zephyr development environment on Ubuntu, macOS, or Windows (instructions for other Linux distributions are discussed in Install Linux Host Dependencies)
- Get the source code
- Build, flash, and run a sample application

2.1 Select and Update OS

Click the operating system you are using.

Ubuntu
This guide covers Ubuntu version 18.04 LTS and later.

```
sudo apt update
sudo apt upgrade
```

macOS
On macOS Mojave or later, select System Preferences > Software Update. Click Update Now if necessary.
On other versions, see this Apple support topic.

Windows
Select Start > Settings > Update & Security > Windows Update. Click Check for updates and install any that are available.

2.2 Install dependencies

Next, you'll install some host dependencies using your package manager.

The current minimum required version for the main dependencies are:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Min. Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMake</td>
<td>3.20.0</td>
</tr>
<tr>
<td>Python</td>
<td>3.6</td>
</tr>
<tr>
<td>Devicetree compiler</td>
<td>1.4.6</td>
</tr>
</tbody>
</table>

Ubuntu
1. Download, inspect and execute the Kitware archive script to add the Kitware APT repository to your sources list. A detailed explanation of kitware-archive.sh can be found here [kitware third-party apt repository](#):

   ```
   wget https://apt.kitware.com/kitware-archive.sh
   sudo bash kitware-archive.sh
   ```

2. Use `apt` to install the required dependencies:

   ```
   sudo apt install --no-install-recommends git cmake ninja-build gperf \
   ccache dfu-util device-tree-compiler wget \
   python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils \
   make gcc gcc-multilib g++-multilib libsd12-dev
   ```

3. Verify the versions of the main dependencies installed on your system by entering:

   ```
   cmake --version
   python3 --version
   dtc --version
   ```

   Check those against the versions in the table in the beginning of this section. Refer to the [Install Linux Host Dependencies](#) page for additional information on updating the dependencies manually.

**macOS**

1. Install Homebrew:

   ```
   /bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/\n   HEAD/install.sh)"
   ```

2. Use `brew` to install the required dependencies:

   ```
   brew install cmake ninja gperf python3 ccache qemu dtc
   ```

**Windows**

*Note: Due to issues finding executables, the Zephyr Project doesn’t currently support application flashing using the Windows Subsystem for Linux (WSL) (WSL). Therefore, we don’t recommend using WSL when getting started.*

These instructions must be run in a `cmd.exe` command prompt. The required commands differ on PowerShell.

These instructions rely on Chocolatey. If Chocolatey isn’t an option, you can install dependencies from their respective websites and ensure the command line tools are on your PATH environment variable.

1. Install chocolatey.

2. Open a `cmd.exe` window as Administrator. To do so, press the Windows key, type “cmd.exe”, right-click the result, and choose Run as Administrator.

3. Disable global confirmation to avoid having to confirm the installation of individual programs:

   ```
   choco feature enable -n allowGlobalConfirmation
   ```

4. Use choco to install the required dependencies:

   ```
   choco install cmake --installargs 'ADD_CMAKE_TO_PATH=System'
   choco install ninja gperf python git dtc-msys2
   ```
5. Close the window and open a new `cmd.exe` window as a **regular user** to continue.

### 2.3 Get Zephyr and install Python dependencies

Next, clone Zephyr and its **modules** into a new **west** workspace named `zephyrproject`. You’ll also install Zephyr’s additional Python dependencies.

Python is used by the **west** meta-tool as well as by many scripts invoked by the build system. It is easy to run into package incompatibilities when installing dependencies at a system or user level. This situation can happen, for example, if working on multiple Zephyr versions at the same time. For this reason it is suggested to use **Python virtual environments**.

**Ubuntu**

**Install globally**

1. Install west, and make sure `~/.local/bin` is on your PATH **environment variable**:

   ```
   pip3 install --user -U west
   echo 'export PATH=~/local/bin:$$PATH' >> ~/.bashrc
   source ~/.bashrc
   ```

2. Get the Zephyr source code:

   ```
   west init ~/zephyrproject
   cd ~/zephyrproject
   west update
   ```

3. Export a **Zephyr CMake package**. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   ```
   west zephyr-export
   ```

4. Zephyr’s `scripts/requirements.txt` file declares additional Python dependencies. Install them with pip3.

   ```
   pip3 install --user -r ~/zephyrproject/zephyr/scripts/requirements.txt
   ```

**Install within virtual environment**

1. Create a new virtual environment:

   ```
   python3 -m venv ~/zephyrproject/.venv
   ```

2. Activate the virtual environment:

   ```
   source ~/zephyrproject/.venv/bin/activate
   ```

Once activated your shell will be prefixed with `.venv`. The virtual environment can be deactivated at any time by running `deactivate`.

**Note:** Remember to activate the virtual environment every time you start working.

3. Install west:

   ```
   pip install west
   ```

4. Get the Zephyr source code:
5. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   ```shell
   west zephyr-export
   ```

6. Zephyr's `scripts/requirements.txt` file declares additional Python dependencies. Install them with `pip`.

   ```shell
   pip install -r ~/zephyrproject/zephyr/scripts/requirements.txt
   ```

**macOS**

Install globally

1. Install west:

   ```shell
   pip3 install -U west
   ```

2. Get the Zephyr source code:

   ```shell
   west init ~/zephyrproject
   cd ~/zephyrproject
   west update
   ```

3. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   ```shell
   west zephyr-export
   ```

4. Zephyr's `scripts/requirements.txt` file declares additional Python dependencies. Install them with `pip3`.

   ```shell
   pip3 install -r ~/zephyrproject/zephyr/scripts/requirements.txt
   ```

**Install within virtual environment**

1. Create a new virtual environment:

   ```shell
   python3 -m venv ~/zephyrproject/.venv
   ```

2. Activate the virtual environment:

   ```shell
   source ~/zephyrproject/.venv/bin/activate
   ```

   Once activated your shell will be prefixed with `(.venv)`. The virtual environment can be deactivated at any time by running `deactivate`.

   **Note:** Remember to activate the virtual environment every time you start working.

3. Install west:

   ```shell
   pip install west
   ```

4. Get the Zephyr source code:
5. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

west zephyr-export

6. Zephyr's scripts/requirements.txt file declares additional Python dependencies. Install them with pip.

pip install -r ~/zephyrproject/zephyr/scripts/requirements.txt

Windows
Install globally
1. Install west:

    pip3 install -U west

2. Get the Zephyr source code:

    cd %HOMEPATH%
    west init zephyrproject
    cd zephyrproject
    west update

3. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

west zephyr-export

4. Zephyr's scripts\requirements.txt file declares additional Python dependencies. Install them with pip3.

    pip3 install -r %HOMEPATH%\zephyrproject\zephyr\scripts\requirements.txt

Install within virtual environment
1. Create a new virtual environment:

    cd %HOMEPATH%
    python3 -m venv zephyrproject\.venv

2. Activate the virtual environment:

    :: cmd.exe
    zephyrproject\.venv\Scripts\activate.bat
    :: PowerShell
    zephyrproject\.venv\Scripts\Activate.ps1

Once activated your shell will be prefixed with (.venv). The virtual environment can be deactivated at any time by running deactivate.

**Note:** Remember to activate the virtual environment every time you start working.

3. Install west:
pip install west

4. Get the Zephyr source code:

```bash
west init zephyrproject

cd zephyrproject

west update
```

5. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```bash
west zephyr-export
```

6. Zephyr's `scripts\requirements.txt` file declares additional Python dependencies. Install them with pip.

```bash
pip install -r %HOMEPATH%\zephyrproject\zephyr\scripts\requirements.txt
```

### 2.4 Install a Toolchain

A toolchain provides a compiler, assembler, linker, and other programs required to build Zephyr applications.

**Ubuntu**

The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr's supported architectures. It also includes additional host tools, such as custom QEMU binaries and a host compiler.

1. Download the latest SDK installer:

```bash
cd ~

wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.13.2/zephyr-sdk-0.13.2-linux-x86_64-setup.run
```

2. Run the installer, installing the SDK in `~/zephyr-sdk-0.13.2`:

```bash
chmod +x zephyr-sdk-0.13.2-linux-x86_64-setup.run

./zephyr-sdk-0.13.2-linux-x86_64-setup.run -- -d ~/zephyr-sdk-0.13.2
```

**Note:** It is recommended to install the Zephyr SDK at one of the following locations:

- `~/zephyr-sdk[-x.y.z]`
- `~/.local/zephyr-sdk[-x.y.z]`
- `~/.local/opt/zephyr-sdk[-x.y.z]`
- `~/.local/bin/zephyr-sdk[-x.y.z]`
- `/opt/zephyr-sdk[-x.y.z]`
- `/usr/zephyr-sdk[-x.y.z]`
- `/usr/local/zephyr-sdk[-x.y.z]`

where `[-x.y.z]` is optional text, and can be any text, for example `-0.13.2`.

If installing the Zephyr SDK outside any of those locations, please read: [Install the Zephyr Software Development Kit (SDK)](install.md)
You cannot move the SDK directory after you have installed it.

3. Install udev rules, which allow you to flash most Zephyr boards as a regular user:

```bash
sudo cp ~/zephyr-sdk-0.13.2/sysroots/x86_64-pokysdk-linux/usr/share/openocd/
˓→contrib/60-openocd.rules /etc/udev/rules.d
sudo udevadm control --reload
```

macOS

Follow the instructions in *Set Up a Toolchain*. Note that the Zephyr SDK is not available on macOS.

Do not forget to set the required *environment variables* (*ZEPHYR_TOOLCHAIN_VARIANT* and toolchain specific ones).

Windows

Follow the instructions in *Set Up a Toolchain*. Note that the Zephyr SDK is not available on Windows.

Do not forget to set the required *environment variables* (*ZEPHYR_TOOLCHAIN_VARIANT* and toolchain specific ones).

### 2.5 Build the Blinky Sample

**Note:** Blinky is compatible with most, but not all, boards. If your board does not meet Blinky’s blinky-sample-requirements, then hello_world is a good alternative.

Build the blinky-sample with `west build`, changing `<your-board-name>` appropriately for your board:

**Ubuntu**

```bash
cd ~/zephyrproject/zephyr
west build -p auto -b <your-board-name> samples/basic/blinky
```

**macOS**

```bash
cd ~/zephyrproject/zephyr
west build -p auto -b <your-board-name> samples/basic/blinky
```

**Windows**

```bash
cd %HOMEPATH%\zephyrproject\zephyr
west build -p auto -b <your-board-name> samples\basic\blinky
```

The `-p auto` option automatically cleans byproducts from a previous build if necessary, which is useful if you try building another sample.

### 2.6 Flash the Sample

Connect your board, usually via USB, and turn it on if there's a power switch. If in doubt about what to do, check your board’s page in boards.

Then flash the sample using `west flash`:

```bash
west flash
```
You may need to install additional *host tools* required by your board. The `west flash` command will print an error if any required dependencies are missing.

If you're using blinky, the LED will start to blink as shown in this figure:

![Reel Board Running Blinky](image)

Fig. 2.1: Phytec reel_board running blinky

### 2.7 Next Steps

Here are some next steps for exploring Zephyr:

- Try other samples-and-demos
- Learn about *Application Development* and the `west` tool
- Find out about west’s *flashing and debugging* features, or more about *Flashing and Hardware Debugging* in general
- Check out *Beyond the Getting Started Guide* for additional setup alternatives and ideas
- Discover *Resources* for getting help from the Zephyr community

### 2.8 Asking for Help

You can ask for help on a mailing list or on Discord. Please send bug reports and feature requests to GitHub.

- **Mailing Lists**: users@lists.zephyrproject.org is usually the right list to ask for help. Search archives and sign up here.
- **Discord**: You can join with this Discord invite.
- **GitHub**: Use GitHub issues for bugs and feature requests.

#### 2.8.1 How to Ask

*Important*: Please search this documentation and the mailing list archives first. Your question may have an answer there.
Don’t just say “this isn’t working” or ask “is this working?”. Include as much detail as you can about:

1. What you want to do
2. What you tried (commands you typed, etc.)
3. What happened (output of each command, etc.)

### 2.8.2 Use Copy/Paste

Please copy/paste text instead of taking a picture or a screenshot of it. Text includes source code, terminal commands, and their output.

Doing this makes it easier for people to help you, and also helps other users search the archives.

When copy/pasting more than 5 lines of text into Discord, create a snippet using three backticks to delimit the snippet.
Chapter 3

Contribution Guidelines

As an open-source project, we welcome and encourage the community to submit patches directly to the project. In our collaborative open source environment, standards and methods for submitting changes help reduce the chaos that can result from an active development community.

This document explains how to participate in project conversations, log bugs and enhancement requests, and submit patches to the project so your patch will be accepted quickly in the codebase.

3.1 Licensing

Licensing is very important to open source projects. It helps ensure the software continues to be available under the terms that the author desired.

Zephyr uses the Apache 2.0 license (as found in the LICENSE file in the project’s GitHub repo) to strike a balance between open contribution and allowing you to use the software however you would like to. The Apache 2.0 license is a permissive open source license that allows you to freely use, modify, distribute and sell your own products that include Apache 2.0 licensed software. (For more information about this, check out articles such as Why choose Apache 2.0 licensing and Top 10 Apache License Questions Answered).

A license tells you what rights you have as a developer, as provided by the copyright holder. It is important that the contributor fully understands the licensing rights and agrees to them. Sometimes the copyright holder isn’t the contributor, such as when the contributor is doing work on behalf of a company.

3.1.1 Components using other Licenses

There are some imported or reused components of the Zephyr project that use other licensing, as described in Licensing of Zephyr Project components.

Importing code into the Zephyr OS from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board.

By carefully reviewing potential contributions and also enforcing a Developer Certification of Origin (DCO) for contributed code, we can ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

See Contributing source code from external projects for more information about this contributing and review process for imported components.
Licensing of Zephyr Project components

The Zephyr kernel tree imports or reuses packages, scripts and other files that are not covered by the Apache 2.0 License. In some places there is no LICENSE file or way to put a LICENSE file there, so we describe the licensing in this document.

scripts/\{checkpatch.pl,checkstack.pl,get_maintainers.pl,spelling.txt\}  Origin: Linux Kernel  
 Licensing: GPLv2 License

3.2 Copyrights Notices

Please follow this Community Best Practice for Copyright Notices from the Linux Foundation.

3.3 Developer Certification of Origin (DCO)

To make a good faith effort to ensure licensing criteria are met, the Zephyr project requires the Developer Certificate of Origin (DCO) process to be followed.

The DCO is an attestation attached to every contribution made by every developer. In the commit message of the contribution, (described more fully later in this document), the developer simply adds a Signed-off-by statement and thereby agrees to the DCO.

When a developer submits a patch, it is a commitment that the contributor has the right to submit the patch per the license. The DCO agreement is shown below and at http://developercertificate.org/.

Developer's Certificate of Origin 1.1

By making a contribution to this project, I certify that:

(a) The contribution was created in whole or in part by me and I have the right to submit it under the open source license indicated in the file; or

(b) The contribution is based upon previous work that, to the best of my knowledge, is covered under an appropriate open source license and I have the right under that license to submit that work with modifications, whether created in whole or in part by me, under the same open source license (unless I am permitted to submit under a different license), as indicated in the file; or

(c) The contribution was provided directly to me by some other person who certified (a), (b) or (c) and I have not modified it.

(d) I understand and agree that this project and the contribution are public and that a record of the contribution (including all personal information I submit with it, including my sign-off) is maintained indefinitely and may be redistributed consistent with this project or the open source license(s) involved.
3.3.1 DCO Sign-Off

The “sign-off” in the DCO is a “Signed-off-by:” line in each commit's log message. The Signed-off-by: line must be in the following format:

```
Signed-off-by: Your Name <your.email@example.com>
```

For your commits, replace:

- **Your Name** with your legal name (pseudonyms, hacker handles, and the names of groups are not allowed)
- **your.email@example.com** with the same email address you are using to author the commit (CI will fail if there is no match)

You can automatically add the Signed-off-by: line to your commit body using `git commit -s`. Use other commits in the zephyr git history as examples.

Additional requirements:

- If you are altering an existing commit created by someone else, you must add your Signed-off-by: line without removing the existing one.
- If you forget to add the Signed-off-by: line, you can add it to your previous commit by running `git commit --amend -s`.
- If you've pushed your changes to GitHub already you'll need to force push your branch after this with `git push -f`.

3.3.2 Notes

Any contributions made as part of submitted pull requests are considered free for the Project to use. Developers are permitted to cherry-pick patches that are included in pull requests submitted by other contributors. It is expected that

- the content of the patches will not be substantially modified,
- the cherry-picked commits or portions of a commit shall preserve the original sign-off messages and the author identity.

`Modifying Contributions made by other developers` describes additional recommended policies around working with contributions submitted by other developers.

3.4 Prerequisites

As a contributor, you'll want to be familiar with the Zephyr project, how to configure, install, and use it as explained in the Zephyr Project website and how to set up your development environment as introduced in the Zephyr Getting Started Guide.

You should be familiar with common developer tools such as Git and CMake, and platforms such as GitHub.

If you haven't already done so, you'll need to create a (free) GitHub account on https://github.com and have Git tools available on your development system.

**Note:** The Zephyr development workflow supports all 3 major operating systems (Linux, macOS, and Windows) but some of the tools used in the sections below are only available on Linux and macOS. On Windows, instead of running these tools yourself, you will need to rely on the Continuous Integration (CI) service using Github Actions, which runs automatically on GitHub when you submit your Pull Request.
(PR). You can see any failure results in the workflow details link near the end of the PR conversation list. See *Continuous Integration* for more information

## 3.5 Repository layout

To clone the main Zephyr Project repositories use the instructions in *Get Zephyr and install Python dependencies*.

The Zephyr project directory structure is described in *Source Tree Structure* documentation. In addition to the Zephyr kernel itself, you’ll also find the sources for technical documentation, sample code, supported board configurations, and a collection of subsystem tests. All of these are available for developers to contribute to and enhance.

## 3.6 Pull Requests and Issues

Before starting on a patch, first check in our issues Zephyr Project Issues system to see what’s been reported on the issue you’d like to address. Have a conversation on the Zephyr devel mailing list (or the Zephyr Discord Server) to see what others think of your issue (and proposed solution). You may find others that have encountered the issue you’re finding, or that have similar ideas for changes or additions. Send a message to the Zephyr devel mailing list to introduce and discuss your idea with the development community.

It’s always a good practice to search for existing or related issues before submitting your own. When you submit an issue (bug or feature request), the triage team will review and comment on the submission, typically within a few business days.

You can find all open pull requests on GitHub and open Zephyr Project Issues in Github issues.

## 3.7 Tools and Git Setup

### 3.7.1 Signed-off-by

The name in the commit message `Signed-off-by:` line and your email must match the change authorship information. Make sure your `.gitconfig` is set up correctly:

```sh
git config --global user.name "David Developer"
git config --global user.email "david.developer@company.com"
```

### 3.7.2 gitlint

When you submit a pull request to the project, a series of checks are performed to verify your commit messages meet the requirements. The same step done during the CI process can be performed locally using the `gitlint` command.

Run `gitlint` locally in your tree and branch where your patches have been committed:

```sh
gitlint
```

Note, `gitlint` only checks HEAD (the most recent commit), so you should run it after each commit, or use the `--commits` option to specify a commit range covering all the development patches to be submitted.
3.7.3 twister

Note: twister does not currently run on Windows.

To verify that your changes did not break any tests or samples, please run the twister script locally before submitting your pull request to GitHub. To run the same tests the CI system runs, follow these steps from within your local Zephyr source working directory:

```
source zephyr-env.sh
./scripts/twister
```

The above will execute the basic twister script, which will run various kernel tests using the QEMU emulator. It will also do some build tests on various samples with advanced features that can’t run in QEMU.

We highly recommend you run these tests locally to avoid any CI failures.

3.7.4 uncrustify

The uncrustify tool can be helpful to quickly reformat large amounts of new source code to our Coding Style standards together with a configuration file we’ve provided:

```
# On Linux/macOS
uncrustify --replace --no-backup -l C -c $ZEPHYR_BASE/.uncrustify.cfg my_source_file.c

# On Windows
uncrustify --replace --no-backup -l C -c %ZEPHYR_BASE%\.uncrustify.cfg my_source_file.c
```

But note that you should not use uncrustify to reformat existing Zephyr code, or to modify files in which you only introduce a small fix. This would create a lot of unwelcome extra changed lines.

On Linux systems, you can install uncrustify with

```
sudo apt install uncrustify
```

For Windows installation instructions see the sourceforge listing for uncrustify.

3.8 Coding Style

Use these coding guidelines to ensure that your development complies with the project’s style and naming conventions.

In general, follow the Linux kernel coding style, with the following exceptions:

- Add braces to every if, else, do, while, for and switch body, even for single-line code blocks. Use the --ignore BRACES flag to make checkpatch stop complaining.
- Use spaces instead of tabs to align comments after declarations, as needed.
- Use C89-style single line comments, /* */. The C99-style single line comment, //, is not allowed.
- Use /** */ for doxygen comments that need to appear in the documentation.

The Linux kernel GPL-licensed tool checkpatch is used to check coding style conformity.

Note: checkpatch does not currently run on Windows.
Checkpatch is available in the scripts directory. To invoke it when committing code, make the file 
$ZEPHYR_BASE/.git/hooks/pre-commit executable and edit it to contain:

```bash
#!/bin/sh
set -e
exec
exec git diff --cached | $(ZEPHYR_BASE)/scripts/checkpatch.pl -
```

Instead of running checkpatch at each commit, you may prefer to run it only before pushing on zephyr repo. To do this, make the file $ZEPHYR_BASE/.git/hooks/pre-push executable and edit it to contain:

```bash
#!/bin/sh
remote="$1"
url="$2"

z40=0000000000000000000000000000000000000000

echo "Run push hook"

while read local_ref local_sha remote_ref remote_sha
do
  args="$remote $url $local_ref $local_sha $remote_ref $remote_sha"
  exec $(ZEPHYR_BASE)/scripts/series-push-hook.sh $args
done

exit 0
```

If you want to override checkpatch verdict and push your branch despite reported issues, you can add option --no-verify to the git push command.

A more complete alternative to this is using check_compliance.py script from ci-tools repo.

### 3.9 Other Guidelines

Beyond the Coding Style that Zephyr enforces for all code that is submitted for inclusion, the project targets compliance with a series of coding guidelines. Refer to the Coding Guidelines section of the documentation for additional details.

#### 3.9.1 Coding Guidelines

The project TSC and the Safety Committee of the project agreed to implement a staged and incremental approach for complying with a set of coding rules (AKA Coding Guidelines) to improve quality and consistency of the code base. Below are the agreed upon stages and the approximate timelines:

**Stage I** Coding guideline rules are available to be followed and referenced, but not enforced. Rules are not yet enforced in CI and pull-requests cannot be blocked by reviewers/approvers due to violations.

**Stage II** Begin enforcement on a limited scope of the code base. Initially, this would be the safety certification scope. For rules easily applied across codebase, we should not limit compliance to initial scope. This step requires tooling and CI setup and will start sometime after LTS2.

**Stage III** Revisit the coding guideline rules and based on experience from previous stages, refine/iterate on selected rules.

**Stage IV** Expand enforcement to the wider codebase. Exceptions may be granted on some areas of the codebase with a proper justification. Exception would require TSC approval.
Main rules

The coding guideline rules are based on MISRA-C 2012 and are a subset of MISRA-C. The subset is listed in the table below with a summary of the rules, its severity and the equivalent rules from other standards for reference.

Note: For existing Zephyr maintainers and collaborators, if you are unable to obtain a copy through your employer, a limited number of copies will be made available through the project. If you need a copy of MISRA-C 2012, please send email to safety@lists.zephyrproject.org and provide details on reason why you can't obtain one through other options and expected contributions once you have one. The safety committee will review all requests.

<td>The value of errno shall be set to zero prior to a call to an errno-setting-function</td>
<td>N/A</td>
<td>Rule 22.8</td>
</tr>
<tr>
<td>Rule 22.9</td>
<td>Required</td>
<td>The value of errno shall be tested against zero after calling an errno-setting-function</td>
<td>N/A</td>
<td>Rule 22.9</td>
</tr>
<tr>
<td>Rule 22.10</td>
<td>Required</td>
<td>The value of errno shall only be tested when the last function to be called was an errno-setting-function</td>
<td>N/A</td>
<td>Rule 22.10</td>
</tr>
</tbody>
</table>

### Additional rules

#### Rule A.1: Conditional Compilation

**Severity** Required

**Description** Do not conditionally compile function declarations in header files. Do not conditionally compile structure declarations in header files. You may conditionally exclude fields within structure definitions to avoid wasting memory when the feature they support is not enabled.

**Rationale** Excluding declarations from the header based on compile-time options may prevent their documentation from being generated. Their absence also prevents use of `if (IS_ENABLED(CONFIG_FOO)) {}` as an alternative to preprocessor conditionals when the code path should change based on the selected options.

#### Rule A.2: Inclusive Language

**Severity** Required
Description  Do not introduce new usage of offensive terms listed below. This rule applies but is not limited to source code, comments, documentation, and branch names. Replacement terms may vary by area or subsystem, but should aim to follow updated industry standards when possible.

Exceptions are allowed for maintaining existing implementations or adding new implementations of industry standard specifications governed externally to the Zephyr Project.

Existing usage is recommended to change as soon as updated industry standard specifications become available or new terms are publicly announced by the governing body, or immediately if no specifications apply.

<table>
<thead>
<tr>
<th>Offensive Terms</th>
<th>Recommended Replacements</th>
</tr>
</thead>
<tbody>
<tr>
<td>{master,leader} / slave</td>
<td>• {primary,main} / {secondary, replica}</td>
</tr>
<tr>
<td></td>
<td>• {initiator,requester} / {target, responder}</td>
</tr>
<tr>
<td></td>
<td>• {controller,host} / {device,worker, proxy,target}</td>
</tr>
<tr>
<td></td>
<td>• director / performer</td>
</tr>
<tr>
<td></td>
<td>• central / peripheral</td>
</tr>
<tr>
<td>blacklist / whitelist</td>
<td>• denylist / allowlist</td>
</tr>
<tr>
<td></td>
<td>• blocklist / allowlist</td>
</tr>
<tr>
<td></td>
<td>• rejectlist / acceptlist</td>
</tr>
<tr>
<td>grandfather policy</td>
<td>• legacy</td>
</tr>
<tr>
<td>sanity</td>
<td>• coherence</td>
</tr>
<tr>
<td></td>
<td>• confidence</td>
</tr>
</tbody>
</table>

Rationale  Offensive terms do not create an inclusive community environment and therefore violate the Zephyr Project Code of Conduct. This coding rule was inspired by a similar rule in Linux.

Status  Related GitHub Issues and Pull Requests are tagged with the Inclusive Language Label.

</table>

Parasoft Codescan Tool

Parasoft Codescan is an official static code analysis tool used by the Zephyr project. It is used to automate compliance with a range of coding and security standards. The tool is currently set to the MISRA-C:2012 Coding Standard because the Zephyr Coding Guidelines are based on that standard. It is used together with the Coverity Scan tool to achieve the best code health and precision in bug findings.

Violations fixing process

**Step 1** Any Zephyr Project member, company or a developer can request access to the Parasoft reporting centre if they wish to get involved in fixing violations by submitting issues.

**Step 2** A developer starts to review violations.

**Step 3** A developer submits a Github PR with the fix. Commit messages should follow the same guidelines as other PRs in the Zephyr project. Please add a comment that your fix was found by a static coding scanning tool. Developers should follow and refer to the Zephyr Coding Guidelines as basic rules for coding. These rules are based on the MISRA-C standard.
Below you can find an example of a recommended commit message:

```
lib: os: add braces to 'if' statements

An 'if' (expression) construct shall be followed by a compound statement. Add braces to improve readability and maintainability.

Found as a coding guideline violation (Rule 15.6) by static coding scanning tool.

Signed-off-by: Johnny Developer <johnny.developer@company.com>
```

**Step 4** If a violation is a false positive, the developer should mark it for the Codescan tool just like they would do for the Coverity tool. The developer should also add a comment to the code explaining that the violation raised by the static code analysis tool should be considered a false positive.

**Step 5** If the developer has found a real violation that the community decided to ignore, the developer must submit a PR with a suppression tag and a comment explaining why the violation has been deviated. The template structure of the comment and tag in the code should be:

```
/* Explain why that part of the code doesn't follow the standard, explain why it is a deliberate deviation from the standard. Don't refer to the Parasoft tool here, just mention that static code analysis tool raised a violation in the line below. */

code_line_with_a_violation /* parasoft-suppress Rule ID */
```

Below you can find an example of a recommended commit message:

```
testsuite: suppress usage of setjmp in a test code (rule 21.4)

According to the Rule 21.4 the standard header file <setjmp.h> shall not be used. We will suppress this violation because it is in test code. Tag suppresses reporting of the violation for the line where the violation is located. This is a deliberate deviation.

Found as a coding guideline violation (Rule 21.4) by static coding scanning tool.

Signed-off-by: Johnny Developer <johnny.developer@company.com>
```

The example below demonstrates how deviations can be suppressed in the code:

```
/* Static code analysis tool can raise a violation that the standard header <setjmp.h> shall not be used. Since this violation is in test code, we will suppress it. * Deliberate deviation. */

#include <setjmp.h> /* parasoft-suppress MISRAC2012-RULE_21_4-a MISRAC2012-RULE_21_4-b */
```

This variant above suppresses item MISRAC2012-RULE_21_4-a and MISRAC2012-RULE_21_4-b on the line with "setjmp" header include. You can add as many rules to suppress you want - just make sure to keep the Parasoft tag on one line and separate rules with a space. To read more about suppressing findings in the Parasoft tool, refer to the official Parasoft documentation.

**Step 6** After a PR is submitted, the developer should add the Coding guidelines and MISRA-C Github labels so their PR can be easily tracked by maintainers. If you have any concerns about what your
PR should look like, you can search on Github using those tags and refer to similar PRs that have already been merged.

### 3.9.2 Documentation Guidelines

**Note:** For instructions on building the documentation, see [Documentation Generation](https://github.com/zephyr-pj/docs).

Zephyr Project content is written using the reStructuredText markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted standalone website. Developers can view this content either in its raw form as .rst markup files, or (with Sphinx installed) they can build the documentation using the Makefile on Linux systems, or make.bat on Windows, to generate the HTML content. The HTML content can then be viewed using a web browser. This same .rst content is also fed into the Zephyr documentation website (with a different theme applied).

You can read details about reStructuredText and about Sphinx extensions from their respective websites. This document provides a quick reference for commonly used reST and Sphinx-defined directives and roles used to create the documentation you're reading.

**Headings**

While reST allows use of both and overline and matching underline to indicate a heading, we only use an underline indicator for headings.

- Document title (h1) use “#” for the underline character
- First section heading level (h2) use “*”
- Second section heading level (h3) use “=”
- Third section heading level (h4) use “-“

The heading underline must be at least as long as the title it’s under.

For example:

```
This is a title heading
########################

some content goes here

First section heading
........................
```

**Content Highlighting**

Some common reST inline markup samples:

- one asterisk: *text* for emphasis (*italics*),
- two asterisks: **text** for strong emphasis (**boldface**), and
- two backquotes: `text` for inline code samples.

If asterisks or backquotes appear in running text and could be confused with inline markup delimiters, you can eliminate the confusion by adding a backslash (\) before it.
Lists

For bullet lists, place an asterisk (*) or hyphen (-) at the start of a paragraph and indent continuation lines with two spaces.

The first item in a list (or sublist) must have a blank line before it and should be indented at the same level as the preceding paragraph (and not indented itself).

For numbered lists start with a 1. or a. for example, and continue with autonumbering by using a # sign. Indent continuation lines with three spaces:

* This is a bulleted list.
  * It has two items, the second item and has more than one line of reST text. Additional lines are indented to the first character of the text of the bullet list.

1. This is a new numbered list. If the wasn't a blank line before it, it would be a continuation of the previous list (or paragraph).
   #. It has two items too.

a. This is a numbered list using alphabetic list headings
   #. It has three items (and uses autonumbering for the rest of the list)
   #. Here's the third item

#. This is an autonumbered list (default is to use numbers starting with 1).

   #. This is a second-level list under the first item (also autonumbered). Notice the indenting.
   #. And a second item in the nested list.
   #. And a second item back in the containing list. No blank line needed, but it wouldn't hurt for readability.

Definition lists (with a term and its definition) are a convenient way to document a word or phrase with an explanation. For example this reST content:

The Makefile has targets that include:

html   Build the HTML output for the project

clean  Remove all generated output, restoring the folders to a clean state.

Would be rendered as:

The Makefile has targets that include:

  html   Build the HTML output for the project
  clean  Remove all generated output, restoring the folders to a clean state.

Multi-column lists

If you have a long bullet list of items, where each item is short, you can indicate the list items should be rendered in multiple columns with a special .. rst-class:: rst-columns directive. The directive will apply to the next non-comment element (e.g., paragraph), or to content indented under the directive. For example, this unordered list:
A list of short items that should be displayed horizontally so it doesn't use up so much space on the page

A maximum of three columns will be displayed, and change based on the available width of the display window, reducing to one column on narrow (phone) screens if necessary. We've deprecated use of the hlist directive because it misbehaves on smaller screens.

Tables

There are a few ways to create tables, each with their limitations or quirks. Grid tables offer the most capability for defining merged rows and columns, but are hard to maintain:

<table>
<thead>
<tr>
<th>Header row, column 1</th>
<th>Header 2</th>
<th>Header 3</th>
<th>Header 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>(header rows optional)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>body row 1, column 1</th>
<th>column 2</th>
<th>column 3</th>
<th>column 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>body row 2</td>
<td>...</td>
<td>...</td>
<td>you can</td>
</tr>
<tr>
<td>body row 3 with a two column span</td>
<td>...</td>
<td>span</td>
<td></td>
</tr>
<tr>
<td>body row 4</td>
<td>...</td>
<td>...</td>
<td>too</td>
</tr>
</tbody>
</table>

A maximum of three columns will be displayed, and change based on the available width of the display window, reducing to one column on narrow (phone) screens if necessary. We've deprecated use of the hlist directive because it misbehaves on smaller screens.

This example would render as:
List tables are much easier to maintain, but don’t support row or column spans:

```rst
.. list-table:: Table title
   :widths: 15 20 40
   :header-rows: 1

   * - Heading 1
     - Heading 2
     - Heading 3
   * - body row 1, column 1
     - body row 1, column 2
     - body row 1, column 3
   * - body row 2, column 1
     - body row 2, column 2
     - body row 2, column 3

This example would render as:

<table>
<thead>
<tr>
<th>Heading 1</th>
<th>Heading 2</th>
<th>Heading 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>body row 1, column 1</td>
<td>body row 1, column 2</td>
<td>body row 1, column 3</td>
</tr>
<tr>
<td>body row 2, column 1</td>
<td>body row 2, column 2</td>
<td>body row 2, column 3</td>
</tr>
</tbody>
</table>

The :widths: parameter lets you define relative column widths. The default is equal column widths. If you have a three-column table and you want the first column to be half as wide as the other two equal-width columns, you can specify :widths: 1 2 2. If you’d like the browser to set the column widths automatically based on the column contents, you can use :widths: auto.

File names and Commands

Sphinx extends reST by supporting additional inline markup elements (called “roles”) used to tag text with special meanings and allow style output formatting. (You can refer to the Sphinx Inline Markup documentation for the full list).

For example, there are roles for marking filenames (:file:`name`) and command names such as make (:command:`make`). You can also use the `inline code` markup (double backticks) to indicate a filename.

For references to files that are in the Zephyr GitHub tree, a special role can be used that creates a hyperlink to that file. For example a reference to the reST file used to create this document can be generated using :zephyr_file:`doc/guides/documentation/index.rst` that will show up as `doc/guides/documentation/index.rst`, a link to the "blob" file in the github repo. There’s also a :zephyr_raw:`doc/guides/documentation/index.rst` role that will link to the “raw” content, `doc/guides/documentation/index.rst`. (You can click on these links to see the difference.)
Internal Cross-Reference Linking

Traditional ReST links are only supported within the current file using the notation:

Refer to the `internal-linking` page

which renders as,

Refer to the internal-linking page

Note the use of a trailing underscore to indicate an outbound link. In this example, the label was added immediately before a heading, so the text that's displayed is the heading text itself. You can change the text that's displayed as the link writing this as:

Refer to the `show this text instead <internal-linking>` page

which renders as,

Refer to the show this text instead page

External Cross-Reference Linking

With Sphinx's help, we can create link-references to any tagged text within the Zephyr Project documentation.

Target locations in a document are defined with a label directive:

.. _my label name:

Heading
=======

Note the leading underscore indicating an inbound link. The content immediately following this label must be a heading, and is the target for a :ref:`my label name` reference from anywhere within the Zephyr documentation. The heading text is shown when referencing this label. You can also change the text that's displayed for this link, such as:

:ref:`some other text <my label name>`

To enable easy cross-page linking within the site, each file should have a reference label before its title so it can be referenced from another file. These reference labels must be unique across the whole site, so generic names such as "samples" should be avoided. For example the top of this document's .rst file is:

.. _doc_guidelines:

Documentation Guidelines for the Zephyr Project
#################################################

Other .rst documents can link to this document using the :ref:`doc_guidelines` tag and it will show up as Documentation Guidelines. This type of internal cross reference works across multiple files, and the link text is obtained from the document source so if the title changes, the link text will update as well.

You can also define links to any URL and then reference it in your document. For example, with this label definition in the document:

.. _Zephyr Wikipedia Page:
   https://en.wikipedia.org/wiki/Zephyr_(operating_system)

you can reference it with:
Read the `Zephyr Wikipedia Page` for more information about the project.

`any` links

Within the Zephyr project, we've defined the default role to be “any”, meaning if you just write a phrase in back-ticks, e.g., `doc_guidelines`, Sphinx will search through all domains looking for something called doc_guidelines to link to. In this case it will find the label at the top of this document, and link to doc_guidelines. This can be useful for linking to doxygen-generated links for function names and such, but will cause a warning such as:

```
WARNING: 'any' reference target not found: doc_guidelines
```

if you misspelled `doc_guidelines` as `doc_giudelines`.

Non-ASCII Characters

You can insert non-ASCII characters such as a Trademark symbol ("™"), by using the notation `|trade|`. Available replacement names are defined in an include file used during the Sphinx processing of the reST files. The names of these replacement characters are the same as used in HTML entities used to insert characters in HTML, e.g., &trade; and are defined in the file sphinx_build/substitutions.txt as listed here:

```
.. |br| raw:: html .. force a line break in HTML output (blank lines
   
   .. |p| raw:: html .. force a blank line in HTML output (blank lines needed
   
   .. These are replacement strings for non-ASCII characters used within the project
   using the same name as the html entity names (e.g., &copy;) for that character

   .. |copy| unicode:: U+000A9 .. COPYRIGHT SIGN
   :ltrim:
   .. |trade| unicode:: U+02122 .. TRADEMARK SIGN
   :ltrim:
   .. |reg| unicode:: U+000AE .. REGISTERED TRADEMARK SIGN
   :ltrim:
   .. |deg| unicode:: U+000B0 .. DEGREE SIGN
   :ltrim:
   .. |plusminus| unicode:: U+00B1 .. PLUS-MINUS SIGN
   :rtrim:
   .. |micro| unicode:: U+00B5 .. MICRO SIGN
   :rtrim:
   .. |sup2| unicode:: U+00B2 .. SUPERSCRIPT TWO
   :ltrim:
```

We've kept the substitutions list small but others can be added as needed by submitting a change to the substitutions.txt file.
Code and Command Examples

Use the reST code-block directive to create a highlighted block of fixed-width text, typically used for showing formatted code or console commands and output. Smart syntax highlighting is also supported (using the Pygments package). You can also directly specify the highlighting language. For example:

```c
struct z_object {
    char *name;
    uint8_t perms[CONFIG_MAX_THREAD_BYTES];
    uint8_t type;
    uint8_t flags;
    uint32_t data;
} __packed;
```

Note the blank line between the code-block directive and the first line of the code-block body, and the body content is indented three spaces (to the first non-white space of the directive name).

This would be rendered as:

```c
struct z_object {
    char *name;
    uint8_t perms[CONFIG_MAX_THREAD_BYTES];
    uint8_t type;
    uint8_t flags;
    uint32_t data;
} __packed;
```

You can specify other languages for the code-block directive, including c, python, and rst, and also console, bash, or shell. If you want no syntax highlighting, use the language none, for example:

```none
This would be a block of text styled with a background and box, but with no syntax highlighting.
```

Would display as:

```
This would be a block of text styled with a background and box, but with no syntax highlighting.
```

There's a shorthand for writing code blocks too: end the introductory paragraph with a double colon (::) and indent the code block content by three spaces. On output, only one colon will be shown. The highlighting package makes a best guess at the type of content in the block and highlighting purposes.

Images

Images are included in documentation by using an image directive:

```image:: ./././././images/doc-gen-flow.png
:align: center
:alt: alt text for the image```

or if you'd like to add an image caption, use:

```figure:: ./././././images/doc-gen-flow.png
:alt: image description```

(continues on next page)
The file name specified is relative to the document source file, and we recommend putting images into an images folder where the document source is found. The usual image formats handled by a web browser are supported: JPEG, PNG, GIF, and SVG. Keep the image size only as large as needed, generally at least 500 px wide but no more than 1000 px, and no more than 250 KB unless a particularly large image is needed for clarity.

**Tabs, spaces, and indenting**

Indenting is significant in reST file content, and using spaces is preferred. Extra indenting can (unintentionally) change the way content is rendered too. For lists and directives, indent the content text to the first non-white space in the preceding line. For example:

* List item that spans multiple lines of text
  showing where to indent the continuation line.

1. And for numbered list items, the continuation
   line should align with the text of the line above.

   .. code-block::

   The text within a directive block should align with the first character of the directive name.

Keep the line length for documentation less than 80 characters to make it easier for reviewing in GitHub. Long lines because of URL references are an allowed exception.

**zephyr-app-commands Directive**

This is a Zephyr directive for generating consistent documentation of the shell commands needed to manage (build, flash, etc.) an application.

For example, to generate commands to build samples/hello_world for qemu_x86 use:

   .. zephyr-app-commands::
   :zephyr-app: samples/hello_world
   :board: qemu_x86
   :goals: build

Directive options:

:tool: which tool to use. Valid options are currently 'cmake', 'west' and 'all'. The default is 'west'.

:app: path to the application to build.

:zephyr-app: path to the application to build, this is an app present in the upstream zephyr repository. Mutually exclusive with :app:.

:cd-into: if set, build instructions are given from within the :app: folder, instead of outside of it.

:generator: which build system to generate. Valid options are currently 'ninja' and 'make'. The default is 'ninja'. This option is not case sensitive.

:host-os: which host OS the instructions are for. Valid options are 'unix', 'win' and 'all'. The default is 'all'.
:board: if set, the application build will target the given board.

:shield: if set, the application build will target the given shield.

:conf: if set, the application build will use the given configuration file. If multiple conf files are provided, enclose the space-separated list of files with quotes, e.g., “a.conf b.conf”.

:gen-args: if set, additional arguments to the CMake invocation

:build-args: if set, additional arguments to the build invocation

:build-dir: if set, the application build directory will APPEND this (relative, Unix-separated) path to the standard build directory. This is mostly useful for distinguishing builds for one application within a single page.

:goals: a whitespace-separated list of what to do with the app (in ‘build’, ‘flash’, ‘debug’, ‘debugserver’, ‘run’). Commands to accomplish these tasks will be generated in the right order.

:maybe-skip-config: if set, this indicates the reader may have already created a build directory and changed there, and will tweak the text to note that doing so again is not necessary.

:compact: if set, the generated output is a single code block with no additional comment lines

For example, the .. zephyr-app-commands listed above would render like this in the generated HTML output:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
```

### Alternative Tabbed Content

As introduced in the Getting Started Guide, you can provide alternative content to the reader via a tabbed interface. When the reader clicks on a tab, the content for that tab is displayed, for example:

```
.. tabs::
   .. tab:: Apples
       Apples are green, or sometimes red.
   .. tab:: Pears
       Pears are green.
   .. tab:: Oranges
       Oranges are orange.
```

will display as:

Apples

Apples are green, or sometimes red.

Pears

Pears are green.

Oranges

Oranges are orange.
Tabs can also be grouped, so that changing the current tab in one area changes all tabs with the same name throughout the page. For example:

Linux
Linux Line 1
macOS
macOS Line 1
Windows
Windows Line 1
Linux
Linux Line 2
macOS
macOS Line 2
Windows
Windows Line 2

In this latter case, we're using `.. group-tab::` instead of simply `.. tab::`. Under the hood, we're using the sphinx-tabs extension that's included in the Zephyr setup. Within a tab, you can have most any content *other than a heading* (code-blocks, ordered and unordered lists, pictures, paragraphs, and such). You can read more about sphinx-tabs from the link above.

**Instruction Steps**

Also introduced in the *Getting Started Guide* is a style that makes it easy to create tutorial guides with clearly identified steps. Add the `.. rst-class:: numbered-step` directive immediately before a second-level heading (by project convention, a heading underlined with asterisks `******`, and it will be displayed as a numbered step, sequentially numbered within the document. For example:

```
.. rst-class:: numbered-step

Put your right hand in

**************
```

**Put your right hand in**

See the `doc/getting_started/index.rst` source file and compare with the *Getting Started Guide* to see a full example. As implemented, only one set of numbered steps is intended per document.

For instructions on building the documentation, see *Documentation Generation*.

### 3.10 Contribution Workflow

One general practice we encourage, is to make small, controlled changes. This practice simplifies review, makes merging and rebasing easier, and keeps the change history clear and clean.

When contributing to the Zephyr Project, it is also important you provide as much information as you can about your change, update appropriate documentation, and test your changes thoroughly before submitting.
The general GitHub workflow used by Zephyr developers uses a combination of command line Git commands and browser interaction with GitHub. As it is with Git, there are multiple ways of getting a task done. We’ll describe a typical workflow here:

1. **Create a Fork of Zephyr** to your personal account on GitHub. (Click on the fork button in the top right corner of the Zephyr project repo page in GitHub.)

2. On your development computer, change into the `zephyr` folder that was created when you obtained the code:

   ```
   cd zephyrproject/zephyr
   ```

   Rename the default remote pointing to the **upstream repository** from `origin` to `upstream`:

   ```
   git remote rename origin upstream
   ```

   Let Git know about the fork you just created, naming it `origin`:

   ```
   git remote add origin https://github.com/<your github id>/zephyr
   ```

   and verify the remote repos:

   ```
   git remote -v
   ```

   The output should look similar to:

   ```
   origin https://github.com/<your github id>/zephyr (fetch)
   origin https://github.com/<your github id>/zephyr (push)
   upstream https://github.com/zephyrproject-rtos/zephyr (fetch)
   upstream https://github.com/zephyrproject-rtos/zephyr (push)
   ```

3. Create a topic branch (off of main) for your work (if you’re addressing an issue, we suggest including the issue number in the branch name):

   ```
   git checkout main
   git checkout -b fix_comment_typo
   ```

   Some Zephyr subsystems do development work on a separate branch from main so you may need to indicate this in your checkout:

   ```
   git checkout -b fix_out_of_date_patch origin/net
   ```

4. Make changes, test locally, change, test, test again, ... (Check out the prior chapter on `twister` as well).

5. When things look good, start the pull request process by adding your changed files:

   ```
   git add [file(s) that changed, add -p if you want to be more specific]
   ```

   You can see files that are not yet staged using:

   ```
   git status
   ```

6. Verify changes to be committed look as you expected:

   ```
   git diff --cached
   ```

7. Commit your changes to your local repo:

   ```
   git commit -s
   ```

---

3.10. Contribution Workflow
The `-s` option automatically adds your `Signed-off-by:` to your commit message. Your commit will be rejected without this line that indicates your agreement with the `DCO`. See the `Commit Guidelines` section for specific guidelines for writing your commit messages.

8. Push your topic branch with your changes to your fork in your personal GitHub account:

```
git push origin fix_comment_typo
```

9. In your web browser, go to your forked repo and click on the `Compare & pull request` button for the branch you just worked on and you want to open a pull request with.

10. Review the pull request changes, and verify that you are opening a pull request for the appropriate branch. The title and message from your commit message should appear as well.

11. If you’re working on a subsystem branch that’s not `main`, you may need to change the intended branch for the pull request here, for example, by changing the base branch from `main` to `net`.

12. GitHub will assign one or more suggested reviewers (based on the `CODEOWNERS` file in the repo). If you are a project member, you can select additional reviewers now too.

13. Click on the submit button and your pull request is sent and awaits review. Email will be sent as review comments are made, or you can check on your pull request at https://github.com/zephyrproject-rtos/zephyr/pulls.

14. While you’re waiting for your pull request to be accepted and merged, you can create another branch to work on another issue. (Be sure to make your new branch off of `main` and not the previous branch.):

```
git checkout main
```

```
git checkout -b fix_another_issue
```

and use the same process described above to work on this new topic branch.

15. If reviewers do request changes to your patch, you can interactively rebase commit(s) to fix review issues. In your development repo:

```
git fetch --all
```

```
git rebase --ignore-whitespace upstream/main
```

The `--ignore-whitespace` option stops `git apply` (called by rebase) from changing any whitespace. Continuing:

```
git rebase -i `<offending-commit-id>`
```

In the interactive rebase editor, replace `pick` with `edit` to select a specific commit (if there’s more than one in your pull request), or remove the line to delete a commit entirely. Then edit files to fix the issues in the review.

As before, inspect and test your changes. When ready, continue the patch submission:

```
git add [file(s)]
```

```
git rebase --continue
```

Update commit comment if needed, and continue:

```
git push --force origin fix_comment_typo
```

By force pushing your update, your original pull request will be updated with your changes so you won’t need to resubmit the pull request.

**Note:** While amending commits and force pushing is a common review model outside GitHub, and the one recommended by Zephyr, it’s not the main model supported by GitHub. Forced pushes can cause unexpected behavior, such as not being able to use “View Changes” buttons except for
the last one - GitHub complains it can’t find older commits. You’re also not always able to compare the latest reviewed version with the latest submitted version. When rewriting history GitHub only guarantees access to the latest version.

16. If the CI run fails, you will need to make changes to your code in order to fix the issues and amend your commits by rebasing as described above. Additional information about the CI system can be found in Continuous Integration.

3.11 Commit Guidelines

Changes are submitted as Git commits. Each commit message must contain:

- A short and descriptive subject line that is less than 72 characters, followed by a blank line. The subject line must include a prefix that identifies the subsystem being changed, followed by a colon, and a short title, for example: doc: update wiki references to new site. (If you're updating an existing file, you can use git log <filename> to see what developers used as the prefix for previous patches of this file.)
- A change description with your logic or reasoning for the changes, followed by a blank line.
- A Signed-off-by line, Signed-off-by: <name> <email> typically added automatically by using git commit -s
- If the change addresses an issue, include a line of the form:

  Fixes #<issue number>.

All changes and topics sent to GitHub must be well-formed, as described above.

3.11.1 Commit Message Body

When editing the commit message, please briefly explain what your change does and why it's needed. A change summary of "Fixes stuff" will be rejected.

**Warning:** An empty change summary body is not permitted. Even for trivial changes, please include a summary body in the commit message.

The description body of the commit message must include:

- **what** the change does,
- **why** you chose that approach,
- **what** assumptions were made, and
- **how** you know it works – for example, which tests you ran.

For examples of accepted commit messages, you can refer to the Zephyr GitHub changelog.

3.11.2 Other Commit Expectations

- Commits must build cleanly when applied on top of each other, thus avoiding breaking bisectability.
- Commits must pass all CI checks (see Continuous Integration for more information)
- Each commit must address a single identifiable issue and must be logically self-contained. Unrelated changes should be submitted as separate commits.
• You may submit pull request RFCs (requests for comments) to send work proposals, progress snapshots of your work, or to get early feedback on features or changes that will affect multiple areas in the code base.

• When major new functionality is added, tests for the new functionality MUST be added to the automated test suite. All new APIs MUST be documented and tested and tests MUST cover at least 80% of the added functionality using the code coverage tool and reporting provided by the project.

3.11.3 Submitting Proposals

You can request a new feature or submit a proposal by submitting an issue to our GitHub Repository. If you would like to implement a new feature, please submit an issue with a proposal (RFC) for your work first, to be sure that we can use it. Please consider what kind of change it is:

• For a Major Feature, first open an issue and outline your proposal so that it can be discussed. This will also allow us to better coordinate our efforts, prevent duplication of work, and help you to craft the change so that it is successfully accepted into the project. Providing the following information will increase the chances of your issue being dealt with quickly:

  – Overview of the Proposal
  – Motivation for or Use Case
  – Design Details
  – Alternatives
  – Test Strategy

• Small Features can be crafted and directly submitted as a Pull Request.

3.11.4 Identifying Contribution Origin

When adding a new file to the tree, it is important to detail the source of origin on the file, provide attributions, and detail the intended usage. In cases where the file is an original to Zephyr, the commit message should include the following ("Original" is the assumption if no Origin tag is present):

Origin: Original

In cases where the file is imported from an external project, the commit message shall contain details regarding the original project, the location of the project, the SHA-id of the origin commit for the file and the intended purpose.

For example, a copy of a locally maintained import:

Origin: Contiki OS
License: BSD 3-Clause
URL: http://www.contiki-os.org/
commit: 853207acfd6549b10eb3e44504b1a75ae1ad63a
Purpose: Introduction of networking stack.

For example, a copy of an externally maintained import in a module repository:

Origin: Tiny Crypt
License: BSD 3-Clause
URL: https://github.com/01org/tinycrypt
commit: 08ed7f215269c39e5133688ff56b93a9d0c94e6c6e
Purpose: Introduction of TinyCrypt
3.12 Continuous Integration (CI)

The Zephyr Project operates a Continuous Integration (CI) system that runs on every Pull Request (PR) in order to verify several aspects of the PR:

- Git commit formatting
- Coding Style
- Twister builds for multiple architectures and boards
- Documentation build to verify any doc changes

CI is run on Github Actions and it uses the same tools described in the Contribution Tools section. The CI results must be green indicating “All checks have passed” before the Pull Request can be merged. CI is run when the PR is created, and again every time the PR is modified with a commit.

The current status of the CI run can always be found at the bottom of the GitHub PR page, below the review status. Depending on the success or failure of the run you will see:

- “All checks have passed”
- “All checks have failed”

In case of failure you can click on the “Details” link presented below the failure message in order to navigate to Github Actions and inspect the results. Once you click on the link you will be taken to the Github actions summary results page where a table with all the different builds will be shown. To see what build or test failed click on the row that contains the failed (i.e. non-green) build.

The builds@lists.zephyrproject.org mailing list archives any nightly build results produced by CI.

3.13 Contributions to External Modules

Follow the guidelines in the Modules (External projects) section for contributing new modules and submitting changes to existing modules.

3.14 Contributing External Components

3.14.1 Contributing source code from external projects

In some cases it is desirable to leverage existing, external source code in order to avoid re-implementing basic functionality or features that are readily available in other open source projects.

This section describes the circumstances under which external source code can be imported into Zephyr, and the process that governs the inclusion.

There are three main factors that will be considered during the inclusion process in order to determine whether it will be accepted. These will be described in the following sections.

Software License

Note: External source code licensed under the Apache-2.0 license is not subject to this section.

Integrating code into the Zephyr Project from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board, as described in the Zephyr project charter. The board will automatically reject licenses that have not been
approved by the Open Source Initiative (OSI). See the Submission and review process section for more details.

By carefully reviewing potential contributions and also enforcing a Developer Certification of Origin (DCO) for contributed code, we ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

Merit

Just like with any other regular contribution, one that contains external code needs to be evaluated for merit. However, in the particular case of code that comes from an existing project, there are additional questions that must be answered in order to accept the contribution. More specifically, the following will be considered by the Technical Steering Committee and evaluated carefully before the external source code is accepted into the project:

- Is this the most optimal way to introduce the functionality to the project? Both the cost of implementing this internally and the one incurred in maintaining an externally developed codebase need to be evaluated.
- Is the external project being actively maintained? This is particularly important for source code that deals with security or cryptography.
- Have alternatives to the particular implementation proposed been considered? Are there other open source projects that implement the same functionality?

Mode of integration

There are two ways of integrating external source code into the Zephyr Project, and careful consideration must be taken to choose the appropriate one for each particular case.

Integration in the main tree

The first way to integrate external source code into the project is to simply import the source code files into the main zephyr repository. This automatically implies that the imported source code becomes part of the “mainline” codebase, which in turn requires that:

- The code is formatted according to the Zephyr Coding Style
- The code adheres to the project’s Coding Guidelines
- The code is subject to the same checks and verification requirements as the rest of the code in the main tree, including static analysis
- All files contain an SPDX tag if not already present
- An entry is added to the licensing page <zephyr_licensing>

This mode of integration can be applicable to both small and large external codebases, but it is typically used more commonly with the former.

Integration as a module

The second way of integrating external source code into the project is to import the whole or parts of the third-party open source project into a separate repository, and then include it under the form of a module. With this approach the code is considered as being developed externally, and thus it is not automatically subject to the requirements of the previous section.

Ongoing maintenance

Regardless of the mode of integration, external source code that is integrated in Zephyr requires regular ongoing maintenance. The submitter of the proposal to integrate external source code must therefore commit to maintain the integration of such code for the foreseeable future. This may require adding an entry in the MAINTAINERS . ym1 as part of the process.
Submission and review process

Before external source code can be included in the project, it must be reviewed and accepted by the Technical Steering Committee (TSC) and, in some cases, by the Zephyr governing board.

A request for external source code integration must be made by creating a new issue in the Zephyr project issue tracking system on GitHub with details about the source code and how it integrates into the project.

Follow the steps below to begin the submission process:

1. Make sure to read through the Contributing source code from external projects section in detail, so that you are informed of the criteria used by the TSC and board in order to approve or reject a request
2. Use the New External Source Code Issue to open an issue
3. Fill out all required sections, making sure you provide enough detail for the TSC to assess the merit of the request. Optionally you can also create a Pull Request that demonstrates the integration of the external source code and link to it from the issue
4. Wait for feedback from the TSC, respond to any additional questions added as GitHub issue comments

If, after consideration by the TSC, the conclusion is that integrating external source code is the best solution, and the external source code is licensed under the Apache-2.0 license, the submission process is complete and the external source code can be integrated.

If, however, the external source code uses a license other than Apache-2.0, then these additional steps must be followed:

1. The TSC chair will forward the link to the GitHub issue created during the early submission process to the Zephyr governing board for further review
2. The Zephyr governing board has two weeks to review and ask questions:
   • If there are no objections, the matter is closed. Approval can be accelerated by unanimous approval of the board before the two weeks are up
   • If a governing board member raises an objection that cannot be resolved via email, the board will meet to discuss whether to override the TSC approval or identify other approaches that can resolve the objections
3. On approval of the Zephyr TSC and governing board the submission process is complete

The flowchart below shows an overview of the process:
Fig. 3.1: Submission process
Chapter 4

Development and Contribution Process

4.1 TSC Project Roles

4.1.1 Main Roles

TSC projects generally will involve Maintainers, Collaborators, and Contributors:

Maintainer: lead Collaborators on an area identified by the TSC (e.g. Architecture, code subsystems, etc.). Maintainers shall also serve as the area's representative on the TSC as needed. Maintainers may become voting members of the TSC under the guidelines stated in the project Charter.

Collaborator: A highly involved Contributor in one or more areas. May become a Maintainer with approval of existing TSC voting members.

Contributor: anyone in the community that contributes code or documentation to the project. Contributors may become Collaborators by approval of the existing Collaborators and Maintainers of the particular code base areas or subsystems.

Contributor

A Contributor is a developer who wishes to contribute to the project, at any level.

Contributors are granted the following rights and responsibilities:

• Right to contribute code, documentation, translations, artwork, etc.
• Right to report defects (bugs) and suggestions for enhancement.
• Right to participate in the process of reviewing contributions by others.
• Right to initiate and participate in discussions in any communication methods.
• Right to approach any member of the community with matters they believe to be important.
• Right to participate in the feature development process.
• Responsibility to abide by decisions, once made. They are welcome to provide new, relevant information to reopen decisions.
• Responsibility for issues and bugs introduced by one's own contributions.
• Responsibility to respect the rules of the community.
• Responsibility to provide constructive advice whenever participating in discussions and in the review of contributions.
• Responsibility to follow the project's code of conduct (https://github.com/zephyrproject-rtos/zephyr/blob/main/CODE_OF_CONDUCT.md)
Contributors are initially only given Read access to the Zephyr GitHub repository. Specifically, at the Read access level, Contributors are not allowed to assign reviewers to their own pull requests. An automated process will assign reviewers. You may also share the pull request on the Zephyr devel mailing list or on the Zephyr Discord Server.

Contributors who show dedication and skill are granted the Triage permission level to the Zephyr GitHub repository.

You may nominate yourself, or another GitHub user, for promotion to the Triage permission level by creating a GitHub issue, using the nomination template.

Contributors granted the Triage permission level are permitted to add reviewers to a pull request and can be added as a reviewer by other GitHub users. Contributor votes on pull requests are not counted with respect to accepting and merging a pull request. However, Contributors comments and requested changes should still be considered by the pull request author.

**Collaborator**

A Collaborator is a Contributor who is also responsible for the maintenance of Zephyr source code. Their opinions weigh more when decisions are made, in a fully meritocratic fashion.

Collaborators have the following rights and responsibilities, in addition to those listed for Contributors:

- Right to set goals for the short and medium terms for the project being maintained, alongside the Maintainer.
- Responsibility to participate in the feature development process.
- Responsibility to review relevant code changes within reasonable time.
- Responsibility to ensure the quality of the code to expected levels.
- Responsibility to participate in community discussions.
- Responsibility to mentor new contributors when appropriate.
- Responsibility to participate in the quality verification and release process, when those happen.

Contributors are promoted to the Collaborator role by adding the GitHub user name to one or more collaborators sections of the MAINTAINERS File in the Zephyr repository.

Collaborator votes on pull requests can block or approve the pull request.

**Maintainer**

A Maintainer is a Collaborator who is also responsible for knowing, directing and anticipating the needs of a given zephyr source code area.

Maintainers have the following rights and responsibilities, in addition to those listed for Contributors and Collaborators:

- Right to set the overall architecture of the relevant subsystems or areas of involvement.
- Right to make decisions in the relevant subsystems or areas of involvement, in conjunction with the collaborators.
- Responsibility to convey the direction of the relevant subsystem or areas to the TSC.
- Responsibility to ensure all contributions of the project have been reviewed within reasonable time.
- Responsibility to enforce the code of conduct.

Contributors or Collaborators are promoted to the Maintainer role by adding the GitHub user name to one or more maintainers sections of the MAINTAINERS File in the Zephyr repository.

Maintainer votes on pull requests can block or approve the pull request.
4.1.2 Role Retirement

- Individuals elected to the following Project roles, including, Maintainer, Release Engineering Team member, Release Manager, but are no longer engaged in the project as described by the rights and responsibilities of that role, may be requested by the TSC to retire from the role they are elected.
- Such a request needs to be raised as a motion in the TSC and be approved by the TSC voting members. By approval of the TSC the individual is considered to be retired from the role they have been elected.
- The above applies to elected TSC Project roles that may be defined in addition.

4.1.3 Teams and Supporting Activities

Assignee

An Assignee is one of the maintainers of a subsystem or code being changed. Assignees are set either automatically based on the code being changed or set by the other Maintainers, the Release Engineering team can set an assignee when the latter is not possible.

- Right to dismiss stale reviews and seek reviews from additional maintainers, developers and contributors
- Right to block pull requests from being merged
- Responsibility to re-assign a pull request if they are the original submitter of the code
- Responsibility to drive the pull request to a mergeable state
- Solicit approvals from maintainers of the subsystems affected
- Responsibility to drive the escalation process

Release Engineering Team

A team of active Maintainers involved in multiple areas.

- The members of the Release Engineering team are expected to fill the Release Manager role based on a defined cadence and selection process.
- The cadence and selection process are defined by the Release Engineering team and are approved by the TSC.
- The team reports directly into the TSC.

Release Engineering team has the following rights and responsibilities:

- Right to merge code changes to the zephyr tree following the project rules.
- Right to revert any changes that have broken the code base
- Right to close any stale changes after <N> months of no activity
- Responsibility to take directions from the TSC and follow them.
- Responsibility to coordinate code merges with maintainers.
- Responsibility to merge all contributions regardless of their origin and area if they have been approved by the respective maintainers and follow the merge criteria of a change.
- Responsibility to keep the Zephyr code base in a working and passing state (as per CI)

Joining the Release Engineering team
Maintainers highly involved in the project may be nominated by a TSC voting member to join the Release Engineering team. Nominees may become members of the team by approval of the existing TSC voting members.

To ensure a functional Release Engineering team the TSC shall periodically review the team’s followed processes, the appropriate size, and the membership composition (ensure, for example, that team members are geographically distributed across multiple locations and time-zones).

Release Manager

A Maintainer responsible for driving a specific release to completion following the milestones and the roadmap of the project for this specific release.

TSC has to approve a release manager.

A Release Manager is a member of the Release Engineering team and has the rights and responsibilities of that team in addition to the following:

- Right to manage and coordinate all code merges after the code freeze milestone (M3, see program management overview.)
- Responsibility to drive and coordinate the triaging process for the release
- Responsibility to create the release notes of the release
- Responsibility to notify all stakeholders of the project, including the community at large about the status of the release in a timely manner.
- Responsibility to coordinate with QA and validation and verify changes either directly or through QA before major changes and major milestones.

Roles / Permissions

Table 4.1: Project Roles vs GitHub Permissions

4.1.4 MAINTAINERS File

Generic guidelines for deciding and filling in the Maintainers’ list

- The MAINTAINERS.yml file shall replace the CODEOWNERS file and will be used for both setting assignees and reviewers.
- We should keep the granularity of code maintainership at a manageable level
- We should be looking for maintainers for areas of code that are orphaned (i.e. without an explicit maintainer)
  - Un-maintained areas should be indicated clearly in the MAINTAINERS file
- All submitted pull requests should have an assignee
- We Introduce an area/subsystem hierarchy to address the above point
– Parent-area maintainer should be acting as default substitute/fallback assignee for un-maintained sub-areas
– Area maintainer gets precedence over parent-area maintainer

• Pull requests may be re-assigned if this is needed or more appropriate
  – Re-assigned by original assignee (see “Assignee” slide)

• In general, updates to the MAINTAINERS file should be in a standalone commit alongside other changes introducing new files and directories to the tree.

• Major changes to the file, including the addition of new areas with new maintainers should come in as standalone pull requests and require TSC review.

• If additional review by the TSC is required, the maintainers of the file should send the requested changes to the TSC and give members of the TSC two (2) days to object to any of the changes to maintainership of areas or the addition of new maintainers or areas.

• Path, collaborator and name changes do not require a review by the TSC.

• Addition of new areas without a maintainer do not require review by the TSC.

• The MAINTAINERS file itself shall have a maintainer

• Architectures, core components, sub-systems, samples, tests
  – Each area shall have an explicit maintainer

• Boards (incl relevant samples, tests), SoCs (incl DTS) * May have a maintainer, shall have a higher-level platform maintainer

• Drivers
  – Shall have a driver-area (and API) maintainer
  – Could have individual driver implementation maintainers but preferably collaborator/contributors
  – In the above case, platform-specific PRs may be re-assigned to respective collaborator/contributor of driver implementation

4.1.5 Release Activity

Merge Criteria

• All continuous integration checks have passed
  – Codeowners
  – Device Tree
  – Documentation
  – Gitlint
  – Identity/Emails
  – Kconfig
  – License
  – Checkpatch (Coding Style)
  – Pylint
  – Integration Tests (Via twister) on emulation/simulation platforms
- Simulated Bluetooth Tests

- Planned
  - Footprint
  - Code coverage
  - Coding Guidelines
  - Static Analysis (Coverity)
  - Documentation coverage (APIs)

- PR template with checklist

- Minimal of 2 approvals
  - A collaborator from the same subsystem.
  - Alternately another maintainer of another subsystem
  - Approval by the assignee

- A minimum review period of 2 days, 4 hours for trivial changes (see *Give reviewers time to review before code merge*). Hotfixes can be merged at any time after CI passes.

- All required checks are passing

**Escalation Process**

- Contributors may object to change requests or decisions made by Maintainers.

- Process
  - Resolve in the PR among assignee, maintainers and reviewer
    - Assignee to act as moderator if applicable
4.2 Release Process

The Zephyr project releases on a time-based cycle, rather than a feature-driven one. Zephyr releases represent an aggregation of the work of many contributors, companies, and individuals from the community.

A time-based release process enables the Zephyr project to provide users with a balance of the latest technologies and features and excellent overall quality. A roughly 4-month release cycle allows the project to coordinate development of the features that have actually been implemented, allowing the project to maintain the quality of the overall release without delays because of one or two features that are not ready yet.

The Zephyr release model is loosely based on the Linux kernel model:

- Release tagging procedure:
  - linear mode on main branch,
  - release branches for maintenance after release tagging.

- Each release period will consist of a merge window period followed by one or more release candidates on which only stabilization changes, bug fixes, and documentation can be merged in.
  - Merge window mode: all changes are accepted (subject to approval from the respective maintainers.)
  - When the merge window is closed, the release owner lays a vN-rc1 tag and the tree enters the release candidate phase
  - CI sees the tag, builds and runs tests; QA analyses the report from the build and test run and gives an ACK/NAK to the build
  - The release owner, with QA and any other needed input, determines if the release candidate is a go for release
  - If it is a go for a release, the release owner lays a tag release vN at the same point

- Development on new features continues in topic branches. Once features are ready, they are submitted to mainline during the merge window period and after the release is tagged.
4.2.1 Merge Window

A relatively straightforward discipline is followed with regard to the merging of patches for each release. At the beginning of each development cycle, the “merge window” is said to be open. At that time, code which is deemed to be sufficiently stable (and which is accepted by the development community) is merged into the mainline tree. The bulk of changes for a new development cycle (and all of the major changes) will be merged during this time.

The merge window lasts for approximately two months. At the end of this time, the release owner will declare that the window is closed and release the first of the release candidates. For the codebase release which is destined to be 0.4.0, for example, the release which happens at the end of the merge window will be called 0.4.0-rc1. The -rc1 release is the signal that the time to merge new features has passed, and that the time to stabilize the next release of the code base has begun.

Over the next weeks, only patches which fix problems should be submitted to the mainline. On occasion, a more significant change will be allowed, but such occasions are rare and require a TSC approval (Change Control Board). As a general rule, if you miss the merge window for a given feature, the best thing to do is to wait for the next development cycle. (An occasional exception is made for drivers for previously unsupported hardware; if they do not touch any other in-tree code, they cannot cause regressions and should be safe to add at any time).

As fixes make their way into the mainline, the patch rate will slow over time. The mainline release owner releases new -rc drops once or twice a week; a normal series will get up to somewhere between -rc4 and -rc6 before the code base is considered to be sufficiently stable and the quality metrics have been achieved at which point the final 0.4.x release is made.

At that point, the whole process starts over again.

Here is the description of the various moderation levels:

- **Low:**
  - Major New Features
  - Bug Fixes
  - Refactoring
  - Structure/Directory Changes

- **Medium:**
  - Bug Fixes, all priorities
  - Enhancements
  - Minor “self-contained” New Features

- **High:**
  - Bug Fixes: P1 and P2
  - Documentation + Test Coverage

4.2.2 Release Quality Criteria

The current backlog of prioritized bugs shall be used as a quality metric to gate the final release. The following counts shall be used:

<table>
<thead>
<tr>
<th></th>
<th>High</th>
<th>Medium</th>
<th>Low</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table 4.2: Bug Count Release Thresholds</td>
<td>0</td>
<td>&lt;20</td>
<td>&lt;50</td>
</tr>
</tbody>
</table>
4.2.3 Releases

The following syntax should be used for releases and tags in Git:

- Release [Major].[Minor].[Patch Level]
- Release Candidate [Major].[Minor].[Patch Level]-rc[RC Number]
- Tagging:
  - v[Major].[Minor].[Patch Level]-rc[RC Number]
  - v[Major].[Minor].[Patch Level]
  - v[Major].[Minor].99 - A tag applied to main branch to signify that work on v[Major].[Minor+1] has started. For example, v1.7.99 will be tagged at the start of v1.8 process. The tag corresponds to VERSION_MAJOR/VERSION_MINOR/PATCHLEVEL macros as defined for a work-in-progress main branch version. Presence of this tag allows generation of sensible output for "git describe" on main branch, as typically used for automated builds and CI tools.

Long Term Support (LTS)

Long-term support releases are designed to be supported and maintained for an extended period and is the recommended release for products and the auditable branch used for certification.

An LTS release is defined as:

- Product focused
- Extended Stabilisation period: Allow for more testing and bug fixing
- Stable APIs
- Quality Driven Process
- Long Term: Maintained for an extended period of time (at least 2.5 years) overlapping previous LTS release for at least half a year.
**Product Focused**  Zephyr LTS is the recommended release for product makers with an extended support and maintenance which includes general stability and bug fixes, security fixes.

An LTS includes both mature and new features. API and feature maturity is documented and tracked. The footprint and scope of mature and stable APIs expands as we move from one LTS to the next giving users access to bleeding edge features and new hardware while keeping a stable foundation that evolves over time.

**Extended Stabilisation Period**  Zephyr LTS development cycle differs from regular releases and has an extended stabilization period. Feature freeze of regular releases happens 3-4 weeks before the scheduled release date. The stabilisation period for LTS is extended by 3 weeks with the feature freeze occurring 6-7 weeks before the anticipated release date. The time between code freeze and release date is extended in this case.

**Stable APIs**  Zephyr LTS provides a stable and long-lived foundation for developing products. To guarantee stability of the APIs and the implementation of such APIs it is required that any release software that makes the core of the OS went through the Zephyr API lifecycle and stabilised over at least 2 releases. This guarantees that we release many of the highlighted and core features with mature and well-established implementations with stable APIs that are supported during the lifetime of the release LTS.

- **API Freeze (LTS - 2)**
  - All stable APIs need to be frozen 2 releases before an LTS. APIs can be extended with additional features, but the core implementation is not modified. This is valid for the following subsystems for example:
    - Device Drivers (i2c.h, spi.h)...
    - Kernel (k_*):
    - OS services (logging, debugging, ..)
    - DTS: API and bindings stability
    - Kconfig
  - New APIs for experimental features can be added at any time as long as they are standalone and documented as experimental or unstable features/APIs.

- **Feature Freeze (LTS - 1)** - No new features or overhaul/restructuring of code covering major LTS features.
  - Kernel + Base OS
  - Additional advertised LTS features
  - Auxiliary features on top of and/or extending the base OS and advertised LTS features can be added at any time and should be marked as experimental if applicable

**Quality Driven Process**  The Zephyr project follows industry standards and processes with the goal of providing a quality oriented releases. This is achieved by providing the following products to track progress, integrity and quality of the software components provided by the project:

- Compliance with published coding guidelines, style guides and naming conventions and documentation of deviations.
- Regular static analysis on the complete tree using available commercial and open-source tools and documentation of deviations and false positives.
- Documented components and APIs
- Requirements Catalog
- Verification Plans
• Verification Reports
• Coverage Reports
• Requirements Traceability Matrix (RTM)
• SPDX License Reports

Each release is created with the above products to document the quality and the state of the software when it was released.

**Long Term Support and Maintenance**  A Zephyr LTS release is published every 2 years and is branched and maintained independently from the main tree for at least 2.5 years after it was released. Support and maintenance for an LTS release stops at least half a year after the following LTS release is published.

Changes and fixes flow in both directions. However, changes from main branch to an LTS branch will be limited to fixes that apply to both branches and for existing features only.

All fixes for an LTS branch that apply to the mainline tree shall be submitted to mainline tree as well.

**Auditable Code Base**

An auditable code base is to be established from a defined subset of Zephyr OS features and will be limited in scope. The LTS, development tree, and the auditable code bases shall be kept in sync after the audit branch is created, but with a more rigorous process in place for adding new features into the audit branch used for certification.

This process will be applied before new features move into the auditable code base.

The initial and subsequent certification targets will be decided by the Zephyr project governing board.

Processes to achieve selected certification will be determined by the Security and Safety Working Groups and coordinated with the TSC.

**4.2.4 Release Procedure**

This section documents the Release manager responsibilities so that it serves as a knowledge repository for Release managers.

**Milestones**

The following graphic shows the timeline of phases and milestones associated with each release:

This shows how the phases and milestones of one release overlap with those of the next release:
Table 4.3: Milestone Description

Release Checklist

Each release has a GitHub issue associated with it that contains the full checklist. After a release is complete, a checklist for the next release is created.

Tagging

The final release and each release candidate shall be tagged using the following steps:

**Note:** Tagging needs to be done via explicit git commands and not via GitHub’s release interface. The GitHub release interface does not generate annotated tags (it generates ‘lightweight’ tags regardless of release or pre-release). You should also upload your gpg public key to your GitHub account, since the instructions below involve creating signed tags. However, if you do not have a gpg public key you can...
Release Candidate

**Note:** This section uses tagging 1.11.0-rc1 as an example, replace with the appropriate release candidate version.

1. Update the version variables in the `VERSION` file located in the root of the Git repository to match the version for this release candidate. The `EXTRAVERSION` variable is used to identify the rc[RC Number] value for this candidate:

   ```
   EXTRAVERSION = rc1
   ```

2. Post a PR with the updated `VERSION` file using `release: Zephyr 1.11.0-rc1` as the commit subject. Merge the PR after successful CI.

3. Tag and push the version, using an annotated tag:

   ```
   $ git pull
   $ git tag -s -m "Zephyr 1.11.0-rc1" v1.11.0-rc1
   $ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0-rc1
   ```

4. Once the tag is pushed, a github action will create a draft release in Github with a shortlog since the last tag. The action will also create a SPDX manifest of the Zephyr tree and will add the file as an asset in the release.

   Go to the draft release that was created and edit as needed. If this step fails for a reason, it can be done manually following the steps below:

   1. Create a shortlog of changes between the previous release (use rc1..rc2 between release candidates):

      ```
      $ git shortlog v1.10.0..v1.11.0-rc1
      ```

   2. Find the new tag at the top of the releases page and edit the release with the Edit tag button with the following:

      - Name it Zephyr 1.11.0-rc1
      - Copy the shortlog into the release notes textbox (don't forget to quote it properly so it shows as unformatted text in Markdown)
      - Check the “This is a pre-release” checkbox

   5. Send an email to the mailing lists (announce and devel) with a link to the release

Final Release

**Note:** This section uses tagging 1.11.0 as an example, replace with the appropriate final release version.

When all final release criteria has been met and the final release notes have been approved and merged into the repository, the final release version will be set and repository tagged using the following procedure:

1. Update the version variables in the `VERSION` file located in the root of the Git repository. Set `EXTRAVERSION` variable to an empty string to indicate final release:

   ```
   EXTRAVERSION =
   ```

2. Post a PR with the updated `VERSION` file using `release: Zephyr 1.11.0` as the commit subject. Merge the PR after successful CI.
3. Tag and push the version, using two annotated tags:

   $ git pull
   $ git tag -s -m "Zephyr 1.11.0" v1.11.0
   $ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0

   # This is the tag that will represent the release on GitHub, so that
   # the file you can download is named `zephyr-v1.11.0.zip` and not
   # just `v1.11.0.zip`
   $ git tag -s -m "Zephyr 1.11.0" zephyr-v1.11.0
   $ git push git@github.com:zephyrproject-rtos/zephyr.git zephyr-v1.11.0

4. Find the new zephyr-v1.11.0 tag at the top of the releases page and edit the release with the Edit tag button with the following:

   • Name it Zephyr 1.11.0
   • Copy the full content of docs/releases/release-notes-1.11.rst into the release notes textbox

5. Send an email to the mailing lists (announce and devel) with a link to the release

Listing all closed GitHub issues

The release notes for a final release contain the list of GitHub issues that have been closed during the development process of that release.

In order to obtain the list of issues closed during the release development cycle you can do the following:

1. Look for the last release before the current one and find the day it was tagged:

   $ git show -s --format=%ci zephyr-v1.10.0
tag zephyr-v1.10.0
Tagger: Kumar Gala <kumar.gala@linaro.org>

   Zephyr 1.10.0
   2017-12-08 13:32:22 -0600

2. Use available release tools to list all the issues that have been closed between that date and the day of the release.

4.3 Feature Tracking

For feature tracking we use Github labels to classify new features and enhancements. The following is the description of each category:

**Enhancement** Changes to existing features that are not considered a bug and would not block a release. This is an incremental enhancement to a feature that already exists in Zephyr.

**Feature request** A request for the implementation or inclusion of a new unit of functionality that is not part of any release plans yet, that has not been vetted, and needs further discussion and details.

**Feature** A committed and planned unit of functionality with a detailed design and implementation proposal and an owner. Features must go through an RFC process and must be vetted and discussed in the TSC before a target milestone is set.

**Hardware Support** A request or plan to port an existing feature or enhancement to a particular hardware platform. This ranges from porting Zephyr itself to a new architecture, SoC or board to adding an implementation of a peripheral driver API for an existing hardware platform.

**Meta** A label to group other GitHub issues that are part of a single feature or unit of work.
The following workflow should be used to process features:

This is the formal way for asking for a new feature in Zephyr and indicating its importance to the project. Often, the requester may have a readiness and willingness to drive implementation of the feature in an upcoming release, and should assign the request to themselves. If not though, an owner will be assigned after evaluation by the TSC. A feature request can also have a companion RFC with more details on the feature and a proposed design or implementation.

* Label new features requests as `feature-request`
* The TSC discusses new `feature-request` items regularly and triages them. Items are examined for similarity with existing features, how they fit with the project goals and other timeline considerations. The priority is determined as follows:
  - High = Next milestone
  - Medium = As soon as possible
  - Low = Best effort
* After the initial discussion and triaging, the label is moved from `feature-request` to `feature` with the target milestone and an assignee.

All items marked as `feature-request` are non-binding and those without an assignee are open for grabs, meaning that they can be picked up and implemented by any project member or the community. You should contact an assigned owner if you’d like to discuss or contribute to that feature’s implementation.

### 4.3.1 Proposals and RFCs

Many changes, including bug fixes and documentation improvements can be implemented and reviewed via the normal GitHub pull request workflow.

Many changes however are “substantial” and need to go through a design process and produce a consensus among the project stakeholders.

The “RFC” (request for comments) process is intended to provide a consistent and controlled path for new features to enter the project.

Contributors and project stakeholders should consider using this process if they intend to make “substantial” changes to Zephyr or its documentation. Some examples that would benefit from an RFC are:

* A new feature that creates new API surface area, and would require a feature flag if introduced.
* The modification of an existing stable API
* The removal of features that already shipped as part of Zephyr.
* The introduction of new idiomatic usage or conventions, even if they do not include code changes to Zephyr itself.

The RFC process is a great opportunity to get more eyeballs on proposals coming from contributors before it becomes a part of Zephyr. Quite often, even proposals that seem “obvious” can be significantly improved once a wider group of interested people have a chance to weigh in.

The RFC process can also be helpful to encourage discussions about a proposed feature as it is being designed, and incorporate important constraints into the design while it’s easier to change, before the design has been fully implemented.

Some changes do not require an RFC:

* Rephrasing, reorganizing or refactoring
* Addition or removal of warnings
* Addition of new boards, SoCs or drivers to existing subsystems
* …
The process in itself consists in creating a GitHub issue with the **RFC label** that documents the proposal thoroughly. There is an **RFC template** included in the main Zephyr GitHub repository that serves as a guideline to write a new RFC.

As with Pull Requests, RFCs might require discussion in the context of one of the **Zephyr meetings** in order to move it forward in cases where there is either disagreement or not enough voiced opinions in order to proceed. Make sure to either label it appropriately or include it in the corresponding GitHub project in order for it to be examined during the next meeting.

### 4.3.2 Roadmap and Release Plans

Project roadmaps and release plans are both important tools for the project, but they have very different purposes and should not be confused. A **project roadmap** communicates the high-level overview of a project's strategy, while a release plan is a tactical document designed to capture and track the features planned for upcoming releases.

- The project roadmap communicates the why; a release plan details the what
- A release plan spans only a few months; a product roadmap might cover a year or more

#### Project Roadmap

The project roadmap should serve as a high-level, visual summary of the project's strategic objectives and expectations.

If built properly, the roadmap can be a valuable tool for several reasons. It can help the project present its plan in a compelling way to existing and new stakeholders, to help recruit new members and it can be a helpful resource the team and community can refer to throughout the project's development, to ensure they are still executing according to plan.

As such, the roadmap should contain only strategic-level details, major project themes, epics, and goals.

#### Release Plans

The release plan comes into play when the project roadmap's high-level strategy is translated into an actionable plan built on specific features, enhancements, and fixes that need to go into a specific release or milestone.

The release plan communicates those features and enhancements slated for your project's next release (or the next few releases). So it acts as more of a project plan, breaking the big ideas down into smaller projects the community and main stakeholders of the project can make progress on.

Items labeled as features are short or long term release items that shall have an assignee and a milestone set.

### 4.4 Code Flow and Branches

#### 4.4.1 Introduction

The zephyr Git repository has three types of branches:

- **main** Which contains the latest state of development
- **topic-** Topic branches that are used for shared development of a new feature
- **vx.y-branch** Branches which track maintenance releases based on a major release
Development in topic branches before features go to mainline allows teams to work independently on a subsystem or a feature, improves efficiency and turnaround time, and encourages collaboration and streamlines communication between developers.

Changes submitted to a development topic branch can evolve and improve incrementally in a branch, before they are submitted to the mainline tree for final integration.

By dedicating an isolated branch to complex features, it’s possible to initiate in-depth discussions around new additions before integrating them into the official project.

### 4.4.2 Roles and Responsibilities

Development topic branch owners have the following responsibilities:

- Use the infrastructure and tools provided by the project (GitHub, Git)
- Review changes coming from team members and request review from branch owners when submitting changes.
- Keep the branch in sync with upstream and update on a regular basis.
- Push changes frequently to upstream using the following methods:
  - GitHub pull requests: for example, when reviews have not been done in the local branch (one-man branch).
  - Merge requests: When a set of changes has been done in a local branch and has been reviewed and tested in a topic branch.

### 4.5 Modifying Contributions made by other developers

#### 4.5.1 Scenarios

Zephyr contributors and collaborators are encouraged to assist as reviewers in pull requests, so that patches may be approved and merged to Zephyr's main branch as part of the original pull requests. The authors of the pull requests are responsible for amending their original commits following the review process.

There are occasions, however, when a contributor might need to modify patches included in pull requests that are submitted by other Zephyr contributors. For instance, this is the case when:

- a developer cherry-picks commits submitted by other contributors into their own pull requests in order to:
  - integrate useful content which is part of a stale pull request, or
  - get content merged to the project’s main branch as part of a larger patch
- a developer pushes to a branch or pull request opened by another contributor in order to:
  - assist in updating pull requests in order to get the patches merged to the project’s main branch
  - drive stale pull requests to completion so they can be merged

#### 4.5.2 Accepted policies

A developer who intends to cherry-pick and potentially modify patches sent by another contributor shall:

- clarify in their pull request the reason for cherry-picking the patches, instead of assisting in getting the patches merged in their original pull request, and
- invite the original author of the patches to their pull request review.
A developer who intends to force-push to a branch or pull request of another Zephyr contributor shall clarify in the pull request the reason for pushing and for modifying the existing patches (e.g. stating that it is done to drive the pull request review to completion, when the pull request author is not able to do so).

**Note:** Developers should try to limit the above practice to pull requests identified as stale. Read about how to identify pull requests as stale in *development processes and tools*.

If the original patches are substantially modified, the developer can either:

- (preferably) reach out to the original author and request them to acknowledge that the modified patches may be merged while having the original sign-off line and author identity, or
- submit the modified patches as their own work (i.e. with their own sign-off line and author identity). In this case, the developer shall identify in the commit message(s) the original source the submitted work is based on (mentioning, for example, the original PR number).

**Note:** Contributors should uncheck the box “Allow Edits By Maintainers” to indicate that they do not wish their patches to be amended, inside their original branch or pull request, by other Zephyr developers.

### 4.6 Development Environment and Tools

#### 4.6.1 Code Review

GitHub is intended to provide a framework for reviewing every commit before it is accepted into the code base. Changes, in the form of Pull Requests (PR) are uploaded to GitHub but don’t actually become a part of the project until they’ve been reviewed, passed a series of checks (CI), and are approved by maintainers. GitHub is used to support the standard open source practice of submitting patches, which are then reviewed by the project members before being applied to the code base.

Pull requests should be appropriately labeled, and linked to any relevant bug or feature tracking issues.

The Zephyr project uses GitHub for code reviews and Git tree management. When submitting a change or an enhancement to any Zephyr component, a developer should use GitHub. GitHub automatically assigns a responsible reviewer on a component basis, as defined in the CODEOWNERS file stored with the code tree in the Zephyr project repository. A limited set of release managers are allowed to merge a pull request into the main branch once reviews are complete.

**Give reviewers time to review before code merge**

The Zephyr project is a global project that is not tied to a certain geography or timezone. We have developers and contributors from across the globe. When changes are proposed using pull request, we need to allow for a minimal review time to give developers and contributors the opportunity to review and comment on changes. There are different categories of changes and we know that some changes do require reviews by subject matter experts and owners of the subsystem being changed. Many changes fall under the “trivial” category that can be addressed with general reviews and do not need to be queued for a maintainer or code-owner review. Additionally, some changes might require further discussions and a decision by the TSC or the Security working group. To summarize the above, the diagram below proposes minimal review times for each category:

**Workflow**
An author of a change can suggest in his pull-request which category a change should belong to. A project maintainers or TSC member monitoring the inflow of changes can change the label of a pull request by adding a comment justifying why a change should belong to another category.

- The project will use the label system to categorize the pull requests.
- Changes should not be merged before the minimal time has expired.

### Categories/Labels

**Hotfix** Any change that is a fix to an issue that blocks developers from doing their daily work, for example CI breakage, Test breakage, Minor documentation fixes that impact the user experience. Such fixes can be merged at any time after they have passed CI checks. Depending on the fix, severity, and availability of someone to review them (other than the author) they can be merged with justification without review by one of the project owners.

**Trivial** Trivial changes are those that appear obvious enough and do not require maintainer or code-owner involvement. Such changes should not change the logic or the design of a subsystem or component. For example a trivial change can be:

- Documentation changes
- Configuration changes
- Minor Build System tweaks
- Minor optimization to code logic without changing the logic
• Test changes and fixes
• Sample modifications to support additional configuration or boards etc.

Maintainer  Any changes that touch the logic or the original design of a subsystem or component will need to be reviewed by the code owner or the designated subsystem maintainer. If the code changes is initiated by a contributor or developer other than the owner the pull request needs to be assigned to the code owner who will have to drive the pull request to a mergeable state by giving feedback to the author and asking for more reviews from other developers.

Security   Changes that appear to have an impact to the overall security of the system need to be reviewed by a security expert from the security working group.

TSC and Working Groups  Changes that introduce new features or functionality or change the way the overall system works need to be reviewed by the TSC or the responsible Working Group. For example for stable API changes, the proposal needs to be presented in the API meeting so that the relevant stakeholders are made aware of the change.

A Pull-Request should have an Assignee

• An assignee to a pull request should not be the same as the author of the pull-request
• An assignee to a pull request is responsible for driving the pull request to a mergeable state
• An assignee is responsible for dismissing stale reviews and seeking reviews from additional developers and contributors
• Pull requests should not be merged without an approval by the assignee.

Pull Request should not be merged by author without review

All pull requests need to be reviewed and should not be merged by the author without a review. The following exceptions apply:

• Hot fixes: Fixing CI issues, reverts, and system breakage
• Release related changes: Changing version file, applying tags and release related activities without any code changes.

Developers and contributors should always seek review, however there are cases when reviewers are not available and there is a need to get a code change into the tree as soon as possible.

Reviewers shall not ‘Request Changes’ without comments or justification

Any change requests (-1) on a pull request have to be justified. A reviewer should avoid blocking a pull-request with no justification. If a reviewer feels that a change should not be merged without their review, then: Request change of the category: for example:

• Trivial -> Maintainer
• Assign Pull Request to yourself, this will mean that a pull request should not be merged without your approval.
Pull Requests should have at least 2 approvals before they are merged

A pull-request shall be merged only with two positive reviews (approval). Beside the person merging the pull-request (merging != approval), two additional approvals are required to be able to merge a pull request. The person merging the request can merge without approving or approve and merge to get to the 2 approvals required.

Reviewers should keep track of pull requests they have provided feedback to

If a reviewer has requested changes in a pull request, he or she should monitor the state of the pull request and/or respond to mention requests to see if his feedback has been addressed. Failing to do so, negative reviews shall be dismissed by the assignee or an owner of the repository. Reviews will be dismissed following the criteria below:

- The feedback or concerns were visibly addressed by the author
- The reviewer did not revisit the pull request after 2 week and multiple pings by the author
- The review is unrelated to the code change or asking for unjustified structural changes such as:
  - Split the PR
  - Can you fix this unrelated code that happens to appear in the diff
  - Can you fix unrelated issues
  - Etc.

Closing Stale Issues and Pull Requests

- The Pull requests and issues sections on Github are NOT discussion forums. They are items that we need to execute and drive to closure. Use the mailing lists for discussions.
- In case of both issues and pull-requests the original poster needs to respond to questions and provide clarifications regarding the issue or the change. After one week without a response to a request, a second attempt to elicit a response from the contributor will be made. After one more week without a response the item may be closed (draft and DNM tagged pull requests are excluded).

4.6.2 Continuous Integration

All changes submitted to GitHub are subject to tests that are run on emulated platforms and architectures to identify breakage and regressions that can be immediately identified. Testing using Twister additionally performs build tests of all boards and platforms. Documentation changes are also verified through review and build testing to verify doc generation will be successful.

Any failures found during the CI test run will result in a negative review assigned automatically by the CI system. Developers are expected to fix issues and rework their patches and submit again.

The CI infrastructure currently runs the following tests:

- Run “checkpatch” for code style issues (can vote -1 on errors; see note)
- Gitlint: Git commit style based on project requirements
- License Check: Check for conflicting licenses
- Run “twister” script
  - Run kernel tests in QEMU (can vote -1 on errors)
  - Build various samples for different boards (can vote -1 on errors)
- Verify documentation builds correctly.
Note: “checkpatch” is a Perl script that uses regular expressions to extract information that requires a C language parser to process accurately. As such it sometimes issues false positives. Known cases include constructs like:

```c
static uint8_t __aligned(PAGE_SIZE) page_pool[PAGE_SIZE * POOL_PAGES];
IOPCTL_Type *base = config->base;
```

Both lines produce a diagnostic regarding spaces around the `*` operator: the first is misidentified as a pointer type declaration that would be correct as `PAGE_SIZE * POOL_PAGES` while the second is misidentified as a multiplication expression that would be correct as `IOPCTL_Type * base`.

Maintainers can override the `-1` in cases where the CI infrastructure gets the wrong answer.

### 4.6.3 Labeling issues and pull requests in GitHub

The project uses GitHub issues and pull requests (PRs) to track and manage daily and long-term work and contributions to the Zephyr project. We use GitHub labels to classify and organize these issues and PRs by area, type, priority, and more, making it easier to find and report on relevant items.

All GitHub issues or pull requests must be appropriately labeled. Issues and PRs often have multiple labels assigned, to help classify them in the different available categories. When reviewing a PR, if it has missing or incorrect labels, maintainers shall fix it.

This saves us all time when searching, reduces the chances of the PR or issue being forgotten, speeds up reviewing, avoids duplicate issue reports, etc.

These are the labels we currently have, grouped by type:

#### Area

<table>
<thead>
<tr>
<th>Labels</th>
<th>Area:*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applicable to</td>
<td>PRs and issues</td>
</tr>
<tr>
<td>Description</td>
<td>Indicates subsystems (e.g., Kernel, I2C, Memory Management), project functions (e.g., Debugging, Documentation, Process), or other categories (e.g., Coding Style, MISRA-C) affected by the bug or pull request.</td>
</tr>
</tbody>
</table>

An area maintainer should be able to filter by an area label and find all issues and PRs which relate to that area.

#### Platform

<table>
<thead>
<tr>
<th>Labels</th>
<th>Platform:*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applicable to</td>
<td>PRs and issues</td>
</tr>
<tr>
<td>Description</td>
<td>An issue or PR which affects only a particular platform</td>
</tr>
</tbody>
</table>
To be discussed in a meeting

<table>
<thead>
<tr>
<th>Labels</th>
<th>dev-review, TSC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applicable to</td>
<td>PRs and issues</td>
</tr>
<tr>
<td>Description</td>
<td>The issue is to be discussed in the following dev-review/TSC meeting if time permits</td>
</tr>
</tbody>
</table>

Stable API changes

<table>
<thead>
<tr>
<th>Labels</th>
<th>Stable API Change</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applicable to</td>
<td>PRs and issues</td>
</tr>
<tr>
<td>Description</td>
<td>The issue or PR describes a change to a stable API. See additional information in Introducing incompatible changes</td>
</tr>
</tbody>
</table>

Minimum PR review time

<table>
<thead>
<tr>
<th>Labels</th>
<th>Hot Fix, Trivial, Maintainer, Security Review, TSC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applicable to</td>
<td>PRs only</td>
</tr>
<tr>
<td>Description</td>
<td>Depending on the PR complexity, an indication of how long a merge should be held to ensure proper review. See review process</td>
</tr>
</tbody>
</table>

Issue priority labels

| Labels             | priority:{high|medium|low} |
|--------------------|-------------------------------|
| Applicable to      | Issues only                   |
| Description        | To classify the impact and importance of a bug or feature |

Note: Issue priorities are generally set or changed during the bug-triage or TSC meetings.

Miscellaneous labels

For both PRs and issues

<table>
<thead>
<tr>
<th>Bug</th>
<th>The issue is a bug, or the PR is fixing a bug</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coverity</td>
<td>A Coverity detected issue or its fix</td>
</tr>
<tr>
<td>Waiting for response</td>
<td>The Zephyr developers are waiting for the submitter to respond to a question, or address an issue.</td>
</tr>
<tr>
<td>Blocked</td>
<td>Blocked by another PR or issue</td>
</tr>
<tr>
<td>In progress</td>
<td>For PRs: is work in progress and should not be merged yet. For issues: Is being worked on</td>
</tr>
<tr>
<td>RFC</td>
<td>The author would like input from the community. For a PR it should be considered a draft</td>
</tr>
<tr>
<td>LTS</td>
<td>Long term release branch related</td>
</tr>
<tr>
<td>EXT</td>
<td>Related to an external component (in ext/)</td>
</tr>
</tbody>
</table>
### PR only labels

<table>
<thead>
<tr>
<th>Label</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNM</td>
<td>This PR should not be merged (Do Not Merge). For work in progress, GitHub “draft” PRs are preferred</td>
</tr>
<tr>
<td>Stale PR</td>
<td>PR which seems abandoned, and requires attention by the author</td>
</tr>
<tr>
<td>Needs review</td>
<td>The PR needs attention from the maintainers</td>
</tr>
<tr>
<td>Backport</td>
<td>The PR is a backport or should be backported</td>
</tr>
<tr>
<td>Licensing</td>
<td>The PR has licensing issues which require a licensing expert to review it</td>
</tr>
</tbody>
</table>

### Issue only labels

<table>
<thead>
<tr>
<th>Label</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regression</td>
<td>Something, which was working, but does not anymore (bug subtype)</td>
</tr>
<tr>
<td>Question</td>
<td>This issue is a question to the Zephyr developers</td>
</tr>
<tr>
<td>Enhancement</td>
<td>Changes/Updates/Additions to existing features</td>
</tr>
<tr>

Any issue must be classified and labeled as either Bug, Question, Enhancement, Feature, or Feature Request. More information on how feature requests are handled and become features can be found in Feature Tracking.

## 4.7 Bug Reporting

To maintain traceability and relation between proposals, changes, features, and issues, it is recommended to cross-reference source code commits with the relevant GitHub issues and vice versa. Any changes that originate from a tracked feature or issue should contain a reference to the feature by mentioning the corresponding issue or pull-request identifiers.

At any time it should be possible to establish the origin of a change and the reason behind it by following the references in the code.

### 4.7.1 Reporting a regression issue

It could happen that the issue being reported is identified as a regression, as the use case is known to be working on earlier commit or release. In this case, providing directly the guilty commit when submitting the bug gains a lot of time in the eventual bug fixing.

To identify the commit causing the regression, several methods could be used, but tree bisecting method is an efficient one that doesn't require deep code expertise and can be used by every one.

For this, `git bisect` is the recommended tool.

Recommendations on the process:

- Run `west update` on each bisection step.
- Once the bisection is over and a culprit identified, verify manually the result.
4.8 Communication and Collaboration

The Zephyr project mailing lists are used as the primary communication tool by project members, contributors, and the community. The mailing list is open for topics related to the project and should be used for collaboration among team members working on the same feature or subsystem or for discussing project direction and daily development of the code base. In general, bug reports and issues should be entered and tracked in the bug tracking system (GitHub Issues) and not broadcasted to the mailing list, the same applies to code reviews. Code should be submitted to GitHub using the appropriate tools.

4.9 Code Documentation

4.9.1 API Documentation

Well documented APIs enhance the experience for developers and are an essential requirement for defining an API's success. Doxygen is a general purpose documentation tool that the zephyr project uses for documenting APIs. It generates either an on-line documentation browser (in HTML) and/or provides input for other tools that is used to generate a reference manual from documented source files. In particular, doxygen's XML output is used as an input when producing the Zephyr project's online documentation.

4.9.2 Reference to Requirements

APIs for the most part document the implementation of requirements or advertised features and can be traced back to features. We use the API documentation as the main interface to trace implementation back to documented features. This is done using custom _doxygen_ tags that reference requirements maintained somewhere else in a requirement catalogue.

4.9.3 Test Documentation

To help understand what each test does and which functionality it tests we also document all test code using the same tools and in the same context and generate documentation for all unit and integration tests maintained in the same environment. Tests are documented using references to the APIs or functionality they validate by creating a link back to the APIs and by adding a reference to the original requirements.

4.9.4 Documentation Guidelines

Test Code

The Zephyr project uses several test methodologies, the most common being the Ztest framework. Test documentation should only be done on the entry test functions (usually prefixed with test_) and those that are called directly by the Ztest framework. Those tests are going to appear in test reports and using their name and identifier is the best way to identify them and trace back to them from requirements.

Test documentation should not interfere with the actual API documentation and needs to follow a new structure to avoid confusion. Using a consistent naming scheme and following a well-defined structure we will be able to group this documentation in its own module and identify it uniquely when parsing test data for traceability reports. Here are a few guidelines to be followed:

- All test code documentation should be grouped under the all_tests doxygen group
- All test documentation should be under doxygen groups that are prefixed with tests_

The custom doxygen @verify directive signifies that a test verifies a requirement:
To get coverage of how an implementation or a piece of code satisfies a requirements, we use the satisfy alias in doxygen:

```c
/**
 * @brief Give a semaphore.
 *
 * This routine gives @a sem, unless the semaphore is already at its maximum permitted count.
 *
 * @note Can be called by ISRs.
 *
 * @param sem Address of the semaphore.
 *
 * @satisfy{@req{015}}
 */
__syscall void k_sem_give(struct k_sem *sem);
```

To generate the matrix, you will first need to build the documentation, specifically you will need to build the doxygen XML output:

```
$ make doxygen
```

Parse the generated XML data from doxygen to generate the traceability matrix.

The Zephyr project defines a development process workflow using GitHub Issues to track feature, enhancement, and bug reports together with GitHub Pull Requests (PRs) for submitting and reviewing changes. Zephyr community members work together to review these Issues and PRs, managing feature enhancements and quality improvements of Zephyr through its regular releases, as outlined in the program management overview.

We can only manage the volume of Issues and PRs, by requiring timely reviews, feedback, and responses from the community and contributors, both for initial submissions and for follow-up questions and clarifications. Read about the project's development processes and tools and specifics about review timelines to learn about the project's goals and guidelines for our active developer community.
TSC Project Roles describes in detail the Zephyr project roles and associated permissions with respect to the development process workflow.

4.10 Terminology

- mainline: The main tree where the core functionality and core features are being developed.
- subsystem/feature branch: is a branch within the same repository. In our case, we will use the term branch also when referencing branches not in the same repository, which are a copy of a repository sharing the same history.
- upstream: A parent branch the source code is based on. This is the branch you pull from and push to, basically your upstream.
- LTS: Long Term Support
Chapter 5

Build and Configuration Systems

5.1 Build System (CMake)

CMake is used to build your application together with the Zephyr kernel. A CMake build is done in two stages. The first stage is called configuration. During configuration, the CMakeLists.txt build scripts are executed. After configuration is finished, CMake has an internal model of the Zephyr build, and can generate build scripts that are native to the host platform.

CMake supports generating scripts for several build systems, but only Ninja and Make are tested and supported by Zephyr. After configuration, you begin the build stage by executing the generated build scripts. These build scripts can recompile the application without involving CMake following most code changes. However, after certain changes, the configuration step must be executed again before building. The build scripts can detect some of these situations and reconfigure automatically, but there are cases when this must be done manually.

Zephyr uses CMake's concept of a 'target' to organize the build. A target can be an executable, a library, or a generated file. For application developers, the library target is the most important to understand. All source code that goes into a Zephyr build does so by being included in a library target, even application code.

Library targets have source code, that is added through CMakeLists.txt build scripts like this:

```
target_sources(app PRIVATE src/main.c)
```

In the above CMakeLists.txt, an existing library target named app is configured to include the source file src/main.c. The PRIVATE keyword indicates that we are modifying the internals of how the library is being built. Using the keyword PUBLIC would modify how other libraries that link with app are built. In this case, using PUBLIC would cause libraries that link with app to also include the source file src/main.c, behavior that we surely do not want. The PUBLIC keyword could however be useful when modifying the include paths of a target library.

5.1.1 Build and Configuration Phases

The Zephyr build process can be divided into two main phases: a configuration phase (driven by CMake) and a build phase (driven by Make or Ninja).

Configuration Phase

The configuration phase begins when the user invokes CMake to generate a build system, specifying a source application directory and a board target.
Zephyr Project Documentation, Release 3.0.99

Chapter 5. Build and Configuration Systems
CMake begins by processing the CMakeLists.txt file in the application directory, which refers to the CMakeLists.txt file in the Zephyr top-level directory, which in turn refers to CMakeLists.txt files throughout the build tree (directly and indirectly). Its primary output is a set of Makefiles or Ninja files to drive the build process, but the CMake scripts also do some processing of their own, which is explained here.

Note that paths beginning with build/ below refer to the build directory you create when running CMake.

**Devicetree**  
*.dts (devicetree source) and *.dtsi (devicetree source include) files are collected from the target's architecture, SoC, board, and application directories.

*.dtsi files are included by *.dts files via the C preprocessor (often abbreviated cpp, which should not be confused with C++). The C preprocessor is also used to merge in any devicetree *.overlay files, and to expand macros in *.dts, *.dtsi, and *.overlay files. The preprocessor output is placed in build/zephyr/zephyr.dts.pre.

The preprocessed devicetree sources are parsed by gen_defines.py to generate a build/zephyr/include/generated/devicetree_unfixed.h header with preprocessor macros.

Source code should access preprocessor macros generated from devicetree by including the devicetree.h header, which includes devicetree_unfixed.h.

gen_defines.py also writes the final devicetree to build/zephyr/zephyr.dts in the build directory. This file's contents may be useful for debugging.

If the devicetree compiler dtc is installed, it is run on build/zephyr/zephyr.dts to catch any extra warnings and errors generated by this tool. The output from dtc is unused otherwise, and this step is skipped if dtc is not installed.

The above is just a brief overview. For more information on devicetree, see *Devicetree Guide*.

**Devicetree fixups**  
Files named dts_fixup.h from the target's architecture, SoC, board, and application directories are concatenated into a single devicetree_fixups.h file. dts_fixup.h files are a legacy feature which should not be used in new code.

**Kconfig**  
Kconfig files define available configuration options for the target architecture, SoC, board, and application, as well as dependencies between options.

Kconfig configurations are stored in configuration files. The initial configuration is generated by merging configuration fragments from the board and application (e.g. prj.conf).

The output from Kconfig is an autoconf.h header with preprocessor assignments, and a .config file that acts both as a saved configuration and as configuration output (used by CMake).

Information from devicetree is available to Kconfig, through the functions defined in kconfigfunctions.py.

See the Kconfig section of the manual for more information.

**Build Phase**

The build phase begins when the user invokes make or ninja. Its ultimate output is a complete Zephyr application in a format suitable for loading/flashing on the desired target board (zephyr.elf, zephyr.hex, etc.) The build phase can be broken down, conceptually, into four stages: the pre-build, first-pass binary, final binary, and post-processing.

**Pre-build**  
Pre-build occurs before any source files are compiled, because during this phase header files used by the source files are generated.

**Offset generation**  
Access to high-level data structures and members is sometimes required when the definitions of those structures is not immediately accessible (e.g., assembly language). The generation of offsets.h (by gen_offset_header.py) facilitates this.
System call boilerplate  The `gen_syscall.py` and `parse_syscalls.py` scripts work together to bind potential system call functions with their implementations.

Intermediate binaries  Compilation proper begins with the first intermediate binary. Source files (C and assembly) are collected from various subsystems (which ones is decided during the configuration phase), and compiled into archives (with reference to header files in the tree, as well as those generated during the configuration phase and the pre-build stage(s)).

The exact number of intermediate binaries is decided during the configuration phase.

If memory protection is enabled, then:

Partition grouping  The `gen_app_partitions.py` script scans all the generated archives and outputs linker scripts to ensure that application partitions are properly grouped and aligned for the target's memory protection hardware.
Then `cpp` is used to combine linker script fragments from the target’s architecture/SoC, the kernel tree, optionally the partition output if memory protection is enabled, and any other fragments selected during the configuration process, into a `linker.cmd` file. The compiled archives are then linked with `ld` as specified in the `linker.cmd`.

**Unfixed size binary** The unfixed size intermediate binary is produced when **User Mode** is enabled or **Devicetree** is in use. It produces a binary where sizes are not fixed and thus it may be used by post-process steps that will impact the size of the final binary.

**Fixed size binary** The fixed size intermediate binary is produced when **User Mode** is enabled or when generated IRQ tables are used, **CONFIG_GEN_ISR_TABLES** is enabled. It produces a binary where sizes are fixed and thus the size must not change between the intermediate binary and the final binary.

**Intermediate binaries post-processing** The binaries from the previous stage are incomplete, with empty and/or placeholder sections that must be filled in by, essentially, reflection.

To complete the build procedure the following scripts are executed on the intermediate binaries to produce the missing pieces needed for the final binary.

When **User Mode** is enabled:

**Partition alignment** The `gen_app_partitions.py` script scans the unfixed size binary and generates an app shared memory aligned linker script snippet where the partitions are sorted in descending order.

When **Devicetree** is used:

**Device dependencies** The `gen_handles.py` script scans the unfixed size binary to determine relationships between devices that were recorded from devicetree data, and replaces the encoded relationships with values that are optimized to locate the devices actually present in the application.

When **CONFIG_GEN_ISR_TABLES is enabled**: The `gen_isr_tables.py` script scans the fixed size binary and creates an `isr_tables.c` source file with a hardware vector table and/or software IRQ table.

When **User Mode** is enabled:

---

5.1. Build System (CMake)

91
Kernel object hashing The `gen_kobject_list.py` scans the ELF DWARF debug data to find the address of the all kernel objects. This list is passed to `gperf`, which generates a perfect hash function and table of those addresses, then that output is optimized by `process_gperf.py`, using known properties of our special case.

When no intermediate binary post-processing is required then the first intermediate binary will be directly used as the final binary.

Final binary The binary from the previous stage is incomplete, with empty and/or placeholder sections that must be filled in by, essentially, reflection.

The link from the previous stage is repeated, this time with the missing pieces populated.

Post processing Finally, if necessary, the completed kernel is converted from ELF to the format expected by the loader and/or flash tool required by the target. This is accomplished in a straightforward manner with `objdump`.

5.1.2 Supporting Scripts and Tools

The following is a detailed description of the scripts used during the build process.

`scripts/gen_syscalls.py`

Script to generate system call invocation macros
This script parses the system call metadata JSON file emitted by parse_syscalls.py to create several files:

- A file containing weak aliases of any potentially unimplemented system calls, as well as the system call dispatch table, which maps system call type IDs to their handler functions.
- A header file defining the system call type IDs, as well as function prototypes for all system call handler functions.
- A directory containing header files. Each header corresponds to a header that was identified as containing system call declarations. These generated headers contain the inline invocation functions for each system call in that header.

**scripts/gen_handles.py**

Translate generic handles into ones optimized for the application.

Immutable device data includes information about dependencies, e.g. that a particular sensor is controlled through a specific I2C bus and that it signals event on a pin on a specific GPIO controller. This information is encoded in the first-pass binary using identifiers derived from the devicetree. This script extracts those identifiers and replaces them with ones optimized for use with the devices actually present.

For example the sensor might have a first-pass handle defined by its devicetree ordinal 52, with the I2C driver having ordinal 24 and the GPIO controller ordinal 14. The runtime ordinal is the index of the corresponding device in the static devicetree array, which might be 6, 5, and 3, respectively.

The output is a C source file that provides alternative definitions for the array contents referenced from the immutable device objects. In the final link these definitions supersede the ones in the driver-specific object file.
scripts/gen_kobject_list.py

Script to generate gperf tables of kernel object metadata

User mode threads making system calls reference kernel objects by memory address, as the kernel/driver APIs in Zephyr are the same for both user and supervisor contexts. It is necessary for the kernel to be able to validate accesses to kernel objects to make the following assertions:

- That the memory address points to a kernel object
- The kernel object is of the expected type for the API being invoked
- The kernel object is of the expected initialization state
- The calling thread has sufficient permissions on the object

For more details see the Kernel Objects section in the documentation.

The zephyr build generates an intermediate ELF binary, zephyr_prebuilt.elf, which this script scans looking for kernel objects by examining the DWARF debug information to look for instances of data structures that are considered kernel objects. For device drivers, the API struct pointer populated at build time is also examined to disambiguate between various device driver instances since they are all 'struct device'.

This script can generate five different output files:

- A gperf script to generate the hash table mapping kernel object memory addresses to kernel object metadata, used to track permissions, object type, initialization state, and any object-specific data.
- A header file containing generated macros for validating driver instances inside the system call handlers for the driver subsystem APIs.
- A code fragment included by kernel.h with one enum constant for each kernel object type and each driver instance.
- The inner cases of a switch/case C statement, included by kernel/userspace.c, mapping the kernel object types and driver instances to their human-readable representation in the otype_to_str() function.
- The inner cases of a switch/case C statement, included by kernel/userspace.c, mapping kernel object types to their sizes. This is used for allocating instances of them at runtime (CONFIG_DYNAMIC_OBJECTS) in the obj_size_get() function.

scripts/gen_offset_header.py

This script scans a specified object file and generates a header file that defined macros for the offsets of various found structure members (particularly symbols ending with _OFFSET or _SIZEOF), primarily intended for use in assembly code.

scripts/parse_syscalls.py

Script to scan Zephyr include directories and emit system call and subsystem metadata

System calls require a great deal of boilerplate code in order to implement completely. This script is the first step in the build system's process of auto-generating this code by doing a text scan of directories containing C or header files, and building up a database of system calls and their function call prototypes. This information is emitted to a generated JSON file for further processing.

This script also scans for struct definitions such as __subsystem and __net_socket, emitting a JSON dictionary mapping tags to all the struct declarations found that were tagged with them.

If the output JSON file already exists, its contents are checked against what information this script would have outputted; if the result is that the file would be unchanged, it is not modified to prevent unnecessary incremental builds.
arch/x86/gen_idt.py

Generate Interrupt Descriptor Table for x86 CPUs.

This script generates the interrupt descriptor table (IDT) for x86. Please consult the IA Architecture SW Developer Manual, volume 3, for more details on this data structure.

This script accepts as input the zephyr_prebuilt.elf binary, which is a link of the Zephyr kernel without various build-time generated data structures (such as the IDT) inserted into it. This kernel image has been properly padded such that inserting these data structures will not disturb the memory addresses of other symbols. From the kernel binary we read a special section “intList” which contains the desired interrupt routing configuration for the kernel, populated by instances of the IRQ_CONNECT() macro.

This script outputs three binary tables:

1. The interrupt descriptor table itself.
2. A bitfield indicating which vectors in the IDT are free for installation of dynamic interrupts at runtime.
3. An array which maps configured IRQ lines to their associated vector entries in the IDT, used to program the APIC at runtime.

arch/x86/gen_gdt.py

Generate a Global Descriptor Table (GDT) for x86 CPUs.

For additional detail on GDT and x86 memory management, please consult the IA Architecture SW Developer Manual, vol. 3.

This script accepts as input the zephyr_prebuilt.elf binary, which is a link of the Zephyr kernel without various build-time generated data structures (such as the GDT) inserted into it. This kernel image has been properly padded such that inserting these data structures will not disturb the memory addresses of other symbols.

The input kernel ELF binary is used to obtain the following information:

- Memory addresses of the Main and Double Fault TSS structures so GDT descriptors can be created for them
- Memory addresses of where the GDT lives in memory, so that this address can be populated in the GDT pseudo descriptor
- Whether userspace or HW stack protection are enabled in Kconfig

The output is a GDT whose contents depend on the kernel configuration. With no memory protection features enabled, we generate flat 32-bit code and data segments. If hardware-based stack overflow protection or userspace is enabled, we additionally create descriptors for the main and double-fault IA tasks, needed for userspace privilege elevation and double-fault handling. If userspace is enabled, we also create flat code/data segments for ring 3 execution.

scripts/gen_relocate_app.py

This script will relocate .text, .rodata, .data and .bss sections from required files and places it in the required memory region. This memory region and file are given to this python script in the form of a string.

Example of such a string would be:

```
SRAM2:COPY:/home/xyz/zephyr/samples/hello_world/src/main.c,\ 
SRAM1:COPY:/home/xyz/zephyr/samples/hello_world/src/main2.c, \ 
FLASH2:NOCOPY:/home/xyz/zephyr/samples/hello_world/src/main3.c
```
To invoke this script:

```
python3 gen_relocate_app.py -i input_string -o generated_linker -c generated_code
```

Configuration that needs to be sent to the python script.

- If the memory is like SRAM1/SRAM2/CCD/AON then place full object in the sections
- If the memory type is appended with _DATA / _TEXT/ _RODATA/ _BSS only the selected memory is placed in the required memory region. Others are ignored.
- COPY/NOCOPY defines whether the script should generate the relocation code in code_relocation.c or not

Multiple regions can be appended together like SRAM2_DATA_BSS this will place data and bss inside SRAM2.

**scripts/process_gperf.py**

gperf C file post-processor

We use gperf to build up a perfect hashtable of pointer values. The way gperf does this is to create a table ‘wordlist’ indexed by a string representation of a pointer address, and then doing memcmp() on a string passed in for comparison

We are exclusively working with 4-byte pointer values. This script adjusts the generated code so that we work with pointers directly and not strings. This saves a considerable amount of space.

**scripts/gen_app_partitions.py**

Script to generate a linker script organizing application memory partitions

Applications may declare build-time memory domain partitions with K_APPMEM_PARTITION_DEFINE, and assign globals to them using K_APP DMEM or K_APP_BMEM macros. For each of these partitions, we need to route all their data into appropriately-sized memory areas which meet the size/alignment constraints of the memory protection hardware.

This linker script is created very early in the build process, before the build attempts to link the kernel binary, as the linker script this tool generates is a necessary pre-condition for kernel linking. We extract the set of memory partitions to generate by looking for variables which have been assigned to input sections that follow a defined naming convention. We also allow entire libraries to be pulled in to assign their globals to a particular memory partition via command line directives.

This script takes as inputs:

- The base directory to look for compiled objects
- key/value pairs mapping static library files to what partitions their globals should end up in.

The output is a linker script fragment containing the definition of the app shared memory section, which is further divided, for each partition found, into data and BSS for each partition.

### 5.2 Configuration System (Kconfig)

The Zephyr kernel and subsystems can be configured at build time to adapt them for specific application and platform needs. Configuration is handled through Kconfig, which is the same configuration system used by the Linux kernel. The goal is to support configuration without having to change any source code.

Configuration options (often called *symbols*) are defined in *config* files, which also specify dependencies between symbols that determine what configurations are valid. Symbols can be grouped into menus and sub-menus to keep the interactive configuration interfaces organized.
The output from Kconfig is a header file `autoconf.h` with macros that can be tested at build time. Code for unused features can be compiled out to save space.

The following sections explain how to set Kconfig configuration options, go into detail on how Kconfig is used within the Zephyr project, and have some tips and best practices for writing Kconfig files.

### 5.2.1 Interactive Kconfig interfaces

There are two interactive configuration interfaces available for exploring the available Kconfig options and making temporary changes: `menuconfig` and `guiconfig`. `menuconfig` is a curses-based interface that runs in the terminal, while `guiconfig` is a graphical configuration interface.

**Note:** The configuration can also be changed by editing `zephyr/.config` in the application build directory by hand. Using one of the configuration interfaces is often handier, as they correctly handle dependencies between configuration symbols.

If you try to enable a symbol with unsatisfied dependencies in `zephyr/.config`, the assignment will be ignored and overwritten when re-configuring.

To make a setting permanent, you should set it in a `*.conf` file, as described in [Setting Kconfig configuration values](#).

**Tip:** Saving a minimal configuration file (with e.g. `D` in `menuconfig`) and inspecting it can be handy when making settings permanent. The minimal configuration file only lists symbols that differ from their default value.

To run one of the configuration interfaces, do this:

1. **Build your application as usual using either `west` or `cmake`:**
   
   **Using west:**
   ```bash
   west build -b <board>
   ```
   
   **Using CMake and ninja:**
   ```bash
   mkdir build && cd build
cmake -GNinja -DBOARD=<board> ..
ninja
   ```

2. **To run the terminal-based `menuconfig` interface, use either of these commands:**
   ```bash
   west build -t menuconfig
   ```
   ```bash
   ninja menuconfig
   ```

   **To run the graphical `guiconfig` interface, use either of these commands:**
   ```bash
   west build -t guiconfig
   ```
   ```bash
   ninja guiconfig
   ```

   **Note:** If you get an import error for `tkinter` when trying to run `guiconfig`, you are missing required packages. See [Install Linux Host Dependencies](#). The package you need is usually called something like `python3-tk/python3-tkinter`.

---

**5.2. Configuration System (Kconfig)**

97
tkinter is not included by default in many Python installations, despite being part of the standard library.

The two interfaces are shown below:

![Image of Zephyr Kernel Configuration]

**guiconfig** always shows the help text and other information related to the currently selected item in the bottom window pane. In the terminal interface, press `?` to view the same information.

**Note:** If you prefer to work in the **guiconfig** interface, then it's a good idea to check any changes to Kconfig files you make in **single-menu mode**, which is toggled via a checkbox at the top. Unlike full-tree mode, single-menu mode will distinguish between symbols defined with `config` and symbols defined with `menuconfig`, showing you what things would look like in the `menuconfig` interface.

3. Change configuration values in the `menuconfig` interface as follows:
   
   - Navigate the menu with the arrow keys. Common Vim key bindings are supported as well.
   - Use Space and Enter to enter menus and toggle values. Menus appear with `-->` next to them. Press ESC to return to the parent menu.

   Boolean configuration options are shown with `[ ]` brackets, while numeric and string-valued configuration symbols are shown with `( )` brackets. Symbol values that can’t be changed are shown as `--` or `*-`.

   **Note:** You can also press Y or N to set a boolean configuration symbol to the corresponding value.

   - Press `?` to display information about the currently selected symbol, including its help text. Press ESC or Q to return from the information display to the menu.

In the **guiconfig** interface, either click on the image next to the symbol to change its value, or double-click on the row with the symbol (this only works if the symbol has no children, as double-clicking a symbol with children open/closes its menu instead).

**guiconfig** also supports keyboard controls, which are similar to `menuconfig`. 
4. Pressing Q in the menuconfig interface will bring up the save-and-quit dialog (if there are changes to save):

Press Y to save the kernel configuration options to the default filename (`zephyr/.config`). You will typically save to the default filename unless you are experimenting with different configurations.

The guiconfig interface will also prompt for saving the configuration on exit if it has been modified.

**Note:** The configuration file used during the build is always `zephyr/.config`. If you have another saved configuration that you want to build with, copy it to `zephyr/.config`. Make sure to back up your original configuration file.

Also note that filenames starting with `.` are not listed by `ls` by default on Linux and macOS. Use the `-a` flag to see them.

Finding a symbol in the menu tree and navigating to it can be tedious. To jump directly to a symbol, press the `/` key (this also works in guiconfig). This brings up the following dialog, where you can search for symbols by name and jump to them. In guiconfig, you can also change symbol values directly within the dialog.

If you jump to a symbol that isn't currently visible (e.g., due to having unsatisfied dependencies), then show-all mode will be enabled. In show-all mode, all symbols are displayed, including currently invisible symbols. To turn off show-all mode, press A in menuconfig or Ctrl-A in guiconfig.

**Note:** Show-all mode can't be turned off if there are no visible items in the current menu.
Chapter 5. Build and Configuration Systems
To figure out why a symbol you jumped to isn't visible, inspect its dependencies, either by pressing '?' in menuconfig or in the information pane at the bottom in guiconfig. If you discover that the symbol depends on another symbol that isn't enabled, you can jump to that symbol in turn to see if it can be enabled.

**Note:** In menuconfig, you can press Ctrl-F to view the help of the currently selected item in the jump-to dialog without leaving the dialog.

For more information on menuconfig and guiconfig, see the Python docstrings at the top of menuconfig.py and guiconfig.py.

### 5.2.2 Setting Kconfig configuration values

The menuconfig and guiconfig interfaces can be used to test out configurations during application development. This page explains how to make settings permanent.

All Kconfig options can be searched in the Kconfig search page.

**Note:** Before making changes to Kconfig files, it's a good idea to also go through the Kconfig - Tips and Best Practices page.

#### Visible and invisible Kconfig symbols

When making Kconfig changes, it's important to understand the difference between visible and invisible symbols.

- A visible symbol is a symbol defined with a prompt. Visible symbols show up in the interactive configuration interfaces (hence visible), and can be set in configuration files.

  Here's an example of a visible symbol:

  ```c
  config FPU
    bool "Support floating point operations"
    depends on HAS_FPU
  ```

  The symbol is shown like this in menuconfig, where it can be toggled:

  ```
  [ ] Support floating point operations
  ```

- An invisible symbol is a symbol without a prompt. Invisible symbols are not shown in the interactive configuration interfaces, and users have no direct control over their value. They instead get their value from defaults or from other symbols.

  Here's an example or an invisible symbol:

  ```c
  config CPU_HAS_FPU
    bool
      help
      This symbol is y if the CPU has a hardware floating point unit.
  ```

  In this case, CPU_HAS_FPU is enabled through other symbols having select CPU_HAS_FPU.
Setting symbols in configuration files

Visible symbols can be configured by setting them in configuration files. The initial configuration is produced by merging a *_defconfig file for the board with application settings, usually from prj.conf. See The Initial Configuration below for more details.

Assignments in configuration files use this syntax:

```
CONFIG_<symbol name>=<value>
```

There should be no spaces around the equals sign.

bool symbols can be enabled or disabled by setting them to y or n, respectively. The FPU symbol from the example above could be enabled like this:

```
CONFIG_FPU=y
```

**Note:** A boolean symbol can also be set to n with a comment formatted like this:

```
# CONFIG_SOME_OTHER_BOOL is not set
```

This is the format you will see in the merged configuration in zephyr/.config.

This style is accepted for historical reasons: Kconfig configuration files can be parsed as makefiles (though Zephyr doesn't use this). Having n-valued symbols correspond to unset variables simplifies tests in Make.

Other symbol types are assigned like this:

```
CONFIG_SOME_STRING="cool value"
CONFIG_SOME_INT=123
```

Comments use a #:

```
# This is a comment
```

Assignments in configuration files are only respected if the dependencies for the symbol are satisfied. A warning is printed otherwise. To figure out what the dependencies of a symbol are, use one of the interactive configuration interfaces (you can jump directly to a symbol with /), or look up the symbol in the Kconfig search page.

The Initial Configuration

The initial configuration for an application comes from merging configuration settings from three sources:

1. A BOARD-specific configuration file stored in boards/<architecture>/<BOARD>/_defconfig
2. Any CMake cache entries prefix with CONFIG_
3. The application configuration

The application configuration can come from the sources below. By default, prj.conf is used.

1. If CONF_FILE is set, the configuration file(s) specified in it are merged and used as the application configuration. CONF_FILE can be set in various ways:
   1. In CMakeLists.txt, before calling find_package(Zephyr)
   2. By passing -DCONF_FILE=<conf file(s)>, either directly or via west
   3. From the CMake variable cache
2. Otherwise if CONF_FILE is set, and a single configuration file of the form prj_<build>.conf is used, then if file boards/<BOARD>_<build>.conf exists in same folder as file prj_<build>.conf, the result of merging prj_<build>.conf and boards/<BOARD>_<build>.conf is used.

3. Otherwise, prj_<BOARD>.conf is used if it exists in the application configuration directory.

4. Otherwise, if boards/<BOARD>.conf exists in the application configuration directory, the result of merging it with prj.conf is used.

5. Otherwise, if board revisions are used and boards/<BOARD>_<revision>.conf exists in the application configuration directory, the result of merging it with prj.conf and boards/<BOARD>.conf is used.

6. Otherwise, prj.conf is used if it exists in the application configuration directory.

All configuration files will be taken from the application's configuration directory except for files with an absolute path that are given with the CONF_FILE argument.

See Application Configuration Directory on how the application configuration directory is defined.

If a symbol is assigned both in <BOARD>_defconfig and in the application configuration, the value set in the application configuration takes precedence.

The merged configuration is saved to zephyr/.config in the build directory.

As long as zephyr/.config exists and is up-to-date (is newer than any BOARD and application configuration files), it will be used in preference to producing a new merged configuration. zephyr/.config is also the configuration that gets modified when making changes in the interactive configuration interfaces.

Configuring invisible Kconfig symbols

When making changes to the default configuration for a board, you might have to configure invisible symbols. This is done in boards/<architecture>/<BOARD>/Kconfig.defconfig, which is a regular Kconfig file.

**Note:** Assignments in .config files have no effect on invisible symbols, so this scheme is not just an organizational issue.

Assigning values in Kconfig.defconfig relies on defining a Kconfig symbol in multiple locations. As an example, say we want to set FOO_WIDTH below to 32:

```
config FOO_WIDTH
    int
```

To do this, we extend the definition of FOO_WIDTH as follows, in Kconfig.defconfig:

```
if BOARD_MY_BOARD
config FOO_WIDTH
    default 32
endif
```

**Note:** Since the type of the symbol (int) has already been given at the first definition location, it does not need to be repeated here. Only giving the type once at the “base” definition of the symbol is a good idea for reasons explained in Common Kconfig shorthands.

Default values in Kconfig.defconfig files have priority over default values given on the “base” definition of a symbol. Internally, this is implemented by including the Kconfig.defconfig files first. Kconfig
uses the first default with a satisfied condition, where an empty condition corresponds to if y (is always satisfied).

Note that conditions from surrounding top-level ifs are propagated to symbol properties, so the above default is equivalent to default 32 if BOARD_MY_BOARD.

**Warning:** When defining a symbol in multiple locations, dependencies are ORed together rather than ANDed together. It is not possible to make the dependencies of a symbol more restrictive by defining it in multiple locations.

For example, the direct dependencies of the symbol below becomes DEP1 || DEP2:

```c
config FOO
    ...
    depends on DEP1
config FOO
    ...
    depends on DEP2
```

When making changes to Kconfig.defconfig files, always check the symbol's direct dependencies in one of the interactive configuration interfaces afterwards. It is often necessary to repeat dependencies from the base definition of the symbol to avoid weakening a symbol's dependencies.

**Motivation for Kconfig.defconfig files**  One motivation for this configuration scheme is to avoid making fixed BOARD-specific settings configurable in the interactive configuration interfaces. If all board configuration were done via <BOARD>_defconfig, all symbols would have to be visible, as values given in <BOARD>_defconfig have no effect on invisible symbols.

Having fixed settings be user-configurable would clutter up the configuration interfaces and make them harder to understand, and would make it easier to accidentally create broken configurations.

When dealing with fixed board-specific settings, also consider whether they should be handled via devicetree instead.

**Configuring choices**  There are two ways to configure a Kconfig choice:

1. By setting one of the choice symbols to y in a configuration file.
   
   Setting one choice symbol to y automatically gives all other choice symbols the value n.

   If multiple choice symbols are set to y, only the last one set to y will be honored (the rest will get the value n). This allows a choice selection from a board defconfig file to be overridden from an application prj.conf file.

2. By changing the default of the choice in Kconfig.defconfig.
   
   As with symbols, changing the default for a choice is done by defining the choice in multiple locations. For this to work, the choice must have a name.

   As an example, assume that a choice has the following base definition (here, the name of the choice is FOO):

   ```c
   choice FOO
       bool "Foo choice"
       default B
   
   config A
       bool "A"
   ```
   (continues on next page)
To change the default symbol of FOO to A, you would add the following definition to Kconfig.

```c
choice FOO
default A
defconfig
```

The Kconfig.defconfig method should be used when the dependencies of the choice might not be satisfied. In that case, you're setting the default selection whenever the user makes the choice visible.

**More Kconfig resources** The Kconfig - Tips and Best Practices page has some tips for writing Kconfig files.

The kconfiglib.py docstring docstring (at the top of the file) goes over how symbol values are calculated in detail.

### 5.2.3 Kconfig - Tips and Best Practices

This page covers some Kconfig best practices and explains some Kconfig behaviors and features that might be cryptic or that are easily overlooked.

**Note:** The official Kconfig documentation is kconfig-language.rst and kconfig-macro-language.rst.

What to turn into Kconfig options

When deciding whether something belongs in Kconfig, it helps to distinguish between symbols that have prompts and symbols that don’t.

If a symbol has a prompt (e.g. bool "Enable foo"), then the user can change the symbol's value in the menuconfig or guiconfig interface (see Interactive Kconfig interfaces), or by manually editing configuration files. Conversely, a symbol without a prompt can never be changed directly by the user, not even by manually editing configuration files.

Only put a prompt on a symbol if it makes sense for the user to change its value.

Symbols without prompts are called hidden or invisible symbols, because they don’t show up in menuconfig and guiconfig. Symbols that have prompts can also be invisible, when their dependencies are not satisfied.

Symbols without prompts can’t be configured directly by the user (they derive their value from other symbols), so less restrictions apply to them. If some derived setting is easier to calculate in Kconfig than e.g. during the build, then do it in Kconfig, but keep the distinction between symbols with and without prompts in mind.

See the optional prompts section for a way to deal with settings that are fixed on some machines and configurable on other machines.

What not to turn into Kconfig options

In Zephyr, Kconfig configuration is done after selecting a target board. In general, it does not make sense to use Kconfig for a value that corresponds to a fixed machine-specific setting. Usually, such settings should be handled via devicetree instead.

In particular, avoid adding new Kconfig options of the following types:

Options that specify a device in the system by name For example, if you are writing an I2C device driver, avoid creating an option named MY_DEVICE_I2C_BUS_NAME for specifying the bus node your device is controlled by. See Device drivers that depend on other devices for alternatives.

Similarly, if your application depends on a hardware-specific PWM device to control an RGB LED, avoid creating an option like MY_PWM_DEVICE_NAME. See Applications that depend on board-specific devices for alternatives.
Options that specify fixed hardware configuration

For example, avoid Kconfig options specifying a GPIO pin.

An alternative applicable to device drivers is to define a GPIO specifier with type phandle-array in the device binding, and using the GPIO devicetree API from C. Similar advice applies to other cases where devicetree.h provides Hardware specific APIs for referring to other nodes in the system. Search the source code for drivers using these APIs for examples.

An application-specific devicetree binding to identify board specific properties may be appropriate. See tests/drivers/gpio/gpio_basic_api for an example.

For applications, see blinky-sample for a devicetree-based alternative.

select statements

The select statement is used to force one symbol to y whenever another symbol is y. For example, the following code forces CONSOLE to y whenever USB_CONSOLE is y:

```c
config CONSOLE
  bool "Console support"
...
config USB_CONSOLE
  bool "USB console support"
  select CONSOLE
```

This section covers some pitfalls and good uses for select.

select pitfalls

select might seem like a generally useful feature at first, but can cause configuration issues if overused.

For example, say that a new dependency is added to the CONSOLE symbol above, by a developer who is unaware of the USB_CONSOLE symbol (or simply forgot about it):

```c
config CONSOLE
  bool "Console support"
  depends on STRING_ROUTINES
...
config USB_CONSOLE
  bool "USB console support"
  select CONSOLE
  depends on STRING_ROUTINES
```

Enabling USB_CONSOLE now forces CONSOLE to y, even if STRING_ROUTINES is n.

To fix the problem, the STRING_ROUTINES dependency needs to be added to USB_CONSOLE as well:

```c
config USB_CONSOLE
  bool "USB console support"
  select CONSOLE
  depends on STRING_ROUTINES
...
config STRING_ROUTINES
  bool "Include string routines"
```

More insidious cases with dependencies inherited from if and menu statements are common.

An alternative attempt to solve the issue might be to turn the depends on into another select:

```c
config CONSOLE
  bool "Console support"
  select STRING_ROUTINES
```

(continues on next page)
In practice, this often amplifies the problem, because any dependencies added to STRING ROUTINES now need to be copied to both CONSOLE and USB CONSOLE.

In general, whenever the dependencies of a symbol are updated, the dependencies of all symbols that (directly or indirectly) select it have to be updated as well. This is very often overlooked in practice, even for the simplest case above.

Chains of symbols selecting each other should be avoided in particular, except for simple helper symbols, as covered below in Using select for helper symbols.

Liberal use of select also tends to make Kconfig files harder to read, both due to the extra dependencies and due to the non-local nature of select, which hides ways in which a symbol might get enabled.

**Alternatives to select** For the example in the previous section, a better solution is usually to turn the select into a depends on:

```c
config CONSOLE
 bool "Console support"
default y
```

This makes it impossible to generate an invalid configuration, and means that dependencies only ever have to be updated in a single spot.

An objection to using depends on here might be that configuration files that enable USB CONSOLE now also need to enable CONSOLE:

```
CONFIG_CONSOLE=y
CONFIG_USB_CONSOLE=y
```

This comes down to a trade-off, but if enabling CONSOLE is the norm, then a mitigation is to make CONSOLE default to y:

```c
config CONSOLE
 bool "Console support"
 default y
```

This gives just a single assignment in configuration files:

```
CONFIG_USB_CONSOLE=y
```

Note that configuration files that do not want CONSOLE enabled now have to explicitly disable it:

```
CONFIG_CONSOLE=n
```

**Using select for helper symbols** A good and safe use of select is for setting “helper” symbols that capture some condition. Such helper symbols should preferably have no prompt or dependencies.
For example, a helper symbol for indicating that a particular CPU/SoC has an FPU could be defined as follows:

```c
config CPU_HAS_FPU
  bool
  help
    If y, the CPU has an FPU
...
```

```c
config SOC_FOO
  bool "FOO SoC"
  select CPU_HAS_FPU
...
```

```c
config SOC_BAR
  bool "BAR SoC"
  select CPU_HAS_FPU
```

This makes it possible for other symbols to check for FPU support in a generic way, without having to look for particular architectures:

```c
config FPU
  bool "Support floating point operations"
  depends on CPU_HAS_FPU
```

The alternative would be to have dependencies like the following, possibly duplicated in several spots:

```c
config FPU
  bool "Support floating point operations"
  depends on SOC_FOO || SOC_BAR || ...
```

Invisible helper symbols can also be useful without `select`. For example, the following code defines a helper symbol that has the value `y` if the machine has some arbitrarily-defined “large” amount of memory:

```c
config LARGE_MEM
  def_bool MEM_SIZE >= 64
```

**Note:** This is short for the following:

```c
config LARGE_MEM
  bool
  default MEM_SIZE >= 64
```

**select recommendations** In summary, here are some recommended practices for `select`:

- Avoid selecting symbols with prompts or dependencies. Prefer `depends on`. If `depends on` causes annoying bloat in configuration files, consider adding a Kconfig default for the most common value.

  Rare exceptions might include cases where you're sure that the dependencies of the selecting and selected symbol will never drift out of sync, e.g. when dealing with two simple symbols defined close to one another within the same `if`.

  Common sense applies, but be aware that `select` often causes issues in practice. `depends on` is usually a cleaner and safer solution.
• Select simple helper symbols without prompts and dependencies however much you like. They're a great tool for simplifying Kconfig files.

(Lack of) conditional includes

if blocks add dependencies to each item within the if, as if depends on was used.

A common misunderstanding related to if is to think that the following code conditionally includes the file Kconfig.other:

```plaintext
if DEP
source "Kconfig.other"
endif
```

In reality, there are no conditional includes in Kconfig. if has no special meaning around a source.

**Note:** Conditional includes would be impossible to implement, because if conditions may contain (either directly or indirectly) forward references to symbols that haven't been defined yet.

Say that Kconfig.other above contains this definition:

```plaintext
config FOO
  bool "Support foo"
```

In this case, FOO will end up with this definition:

```plaintext
config FOO
  bool "Support foo"
  depends on DEP
```

Note that it is redundant to add depends on DEP to the definition of FOO in Kconfig.other, because the DEP dependency has already been added by if DEP.

In general, try to avoid adding redundant dependencies. They can make the structure of the Kconfig files harder to understand, and also make changes more error-prone, since it can be hard to spot that the same dependency is added twice.

“Stuck” symbols in menuconfig and guiconfig

There is a common subtle gotcha related to interdependent configuration symbols with prompts. Consider these symbols:

```plaintext
config FOO
  bool "Foo"

config STACK_SIZE
  hex "Stack size"
  default 0x200 if FOO
  default 0x100
```

Assume that the intention here is to use a larger stack whenever FOO is enabled, and that the configuration initially has FOO disabled. Also, remember that Zephyr creates an initial configuration in zephyr/.config in the build directory by merging configuration files (including e.g. prj.conf). This configuration file exists before menuconfig or guiconfig is run.

When first entering the configuration interface, the value of STACK_SIZE is 0x100, as expected. After enabling FOO, you might reasonably expect the value of STACK_SIZE to change to 0x200, but it stays as 0x100.
To understand what’s going on, remember that STACK_SIZE has a prompt, meaning it is user-configurable, and consider that all Kconfig has to go on from the initial configuration is this:

```
CONFIG_STACK_SIZE=0x100
```

Since Kconfig can’t know if the 0x100 value came from a default or was typed in by the user, it has to assume that it came from the user. Since STACK_SIZE is user-configurable, the value from the configuration file is respected, and any symbol defaults are ignored. This is why the value of STACK_SIZE appears to be “frozen” at 0x100 when toggling FOO.

The right fix depends on what the intention is. Here’s some different scenarios with suggestions:

- **If STACK_SIZE can always be derived automatically and does not need to be user-configurable, then just remove the prompt:**

  ```
  config STACK_SIZE
  hex
  default 0x200 if FOO
  default 0x100
  ```

  Symbols without prompts ignore any value from the saved configuration.

- **If STACK_SIZE should usually be user-configurable, but needs to be set to 0x200 when FOO is enabled, then disable its prompt when FOO is enabled, as described in optional prompts:**

  ```
  config STACK_SIZE
  hex "Stack size" if !FOO
  default 0x200 if FOO
  default 0x100
  ```

- **If STACK_SIZE should usually be derived automatically, but needs to be set to a custom value in rare circumstances, then add another option for making STACK_SIZE user-configurable:**

  ```
  config CUSTOM_STACK_SIZE
  bool "Use a custom stack size"
  help
  Enable this if you need to use a custom stack size. When disabled, a suitable stack size is calculated automatically.
  ```

  ```
  config STACK_SIZE
  hex "Stack size" if CUSTOM_STACK_SIZE
  default 0x200 if  FOO
  default 0x100
  ```

As long as CUSTOM_STACK_SIZE is disabled, STACK_SIZE will ignore the value from the saved configuration.

It is a good idea to try out changes in the menuconfig or guiconfig interface, to make sure that things behave the way you expect. This is especially true when making moderately complex changes like these.

### Assignments to promptless symbols in configuration files

Assignments to hidden (promptless, also called invisible) symbols in configuration files are always ignored. Hidden symbols get their value indirectly from other symbols, via e.g. default and select.

A common source of confusion is opening the output configuration file (zephyr/.config), seeing a bunch of assignments to hidden symbols, and assuming that those assignments must be respected when the configuration is read back in by Kconfig. In reality, all assignments to hidden symbols in zephyr/.config are ignored by Kconfig, like for other configuration files.

To understand why zephyr/.config still includes assignments to hidden symbols, it helps to realize that zephyr/.config serves two separate purposes:
1. It holds the saved configuration, and
2. it holds configuration output. `zephyr/.config` is parsed by the CMake files to let them query configuration settings, for example.

The assignments to hidden symbols in `zephyr/.config` are just configuration output. Kconfig itself ignores assignments to hidden symbols when calculating symbol values.

**Note:** A minimal configuration, which can be generated from within the `menuconfig` and `guiconfig` interfaces, could be considered closer to just a saved configuration, without the full configuration output.

**depends** on **and** string/int/hex symbols

**depends** on works not just for bool symbols, but also for string, int, and hex symbols (and for choices).

The Kconfig definitions below will hide the `FOO_DEVICE_FREQUENCY` symbol and disable any configuration output for it when `FOO_DEVICE` is disabled.

```c
config FOO_DEVICE
  bool "Foo device"

config FOO_DEVICE_FREQUENCY
  int "Foo device frequency"
  depends on FOO_DEVICE
```

In general, it’s a good idea to check that only relevant symbols are ever shown in the `menuconfig`/`guiconfig` interface. Having `FOO_DEVICE_FREQUENCY` show up when `FOO_DEVICE` is disabled (and possibly hidden) makes the relationship between the symbols harder to understand, even if code never looks at `FOO_DEVICE_FREQUENCY` when `FOO_DEVICE` is disabled.

**menuconfig symbols**

If the definition of a symbol `FOO` is immediately followed by other symbols that depend on `FOO`, then those symbols become children of `FOO`. If `FOO` is defined with `config FOO`, then the children are shown indented relative to `FOO`. Defining `FOO` with `menuconfig FOO` instead puts the children in a separate menu rooted at `FOO`.

**menuconfig** has no effect on evaluation. It’s just a display option.

**menuconfig** can cut down on the number of menus and make the menu structure easier to navigate. For example, say you have the following definitions:

```c
menu "Foo subsystem"

config FOO_SUBSYSTEM
  bool "Foo subsystem"

if FOO_SUBSYSTEM

config FOO_FEATURE_1
  bool "Foo feature 1"

config FOO_FEATURE_2
  bool "Foo feature 2"

config FOO_FREQUENCY
  int "Foo frequency"
```

(continues on next page)
... lots of other FOO-related symbols
endif # FOO_SUBSYSTEM
endmenu

In this case, it's probably better to get rid of the menu and turn FOO_SUBSYSTEM into a menuconfig symbol:

```
menuconfig FOO_SUBSYSTEM
  bool "Foo subsystem"

if FOO_SUBSYSTEM
  config FOO_FEATURE_1
    bool "Foo feature 1"

  config FOO_FEATURE_2
    bool "Foo feature 2"

  config FOO_FREQUENCY
    int "Foo frequency"

... lots of other FOO-related symbols
endif # FOO_SUBSYSTEM
```

In the menuconfig interface, this will be displayed as follows:

```
[*] Foo subsystem --->
```

Note that making a symbol without children a menuconfig is meaningless. It should be avoided, because it looks identical to a symbol with all children invisible:

```
[*] I have no children ----
[*] All my children are invisible ----
```

### Checking changes in menuconfig/guiconfig

When adding new symbols or making other changes to Kconfig files, it is a good idea to look up the symbols in menuconfig or guiconfig afterwards. To get to a symbol quickly, use the jump-to feature (press `/`).

Here are some things to check:

- Are the symbols placed in a good spot? Check that they appear in a menu where they make sense, close to related symbols.
  
  If one symbol depends on another, then it's often a good idea to place it right after the symbol it depends on. It will then be shown indented relative to the symbol it depends on in the menuconfig interface, and in a separate menu rooted at the symbol in guiconfig. This also works if several symbols are placed after the symbol they depend on.

- Is it easy to guess what the symbols do from their prompts?

- If many symbols are added, do all combinations of values they can be set to make sense?
  
  For example, if two symbols FOO_SUPPORT and NO_FOO_SUPPORT are added, and both can be enabled at the same time, then that makes a nonsensical configuration. In this case, it's probably better to
have a single FOO_SUPPORT symbol.

- Are there any duplicated dependencies?
  This can be checked by selecting a symbol and pressing ? to view the symbol information. If there are duplicated dependencies, then use the Included via ... path shown in the symbol information to figure out where they come from.

**Checking changes with scripts/kconfig/lint.py**

After you make Kconfig changes, you can use the scripts/kconfig/lint.py script to check for some potential issues, like unused symbols and symbols that are impossible to enable. Use --help to see available options.

Some checks are necessarily a bit heuristic, so a symbol being flagged by a check does not necessarily mean there's a problem. If a check returns a false positive e.g. due to token pasting in C (CONFIG_FOO_##index##_BAR), just ignore it.

When investigating an unknown symbol FOO_BAR, it is a good idea to run git grep FOO_BAR to look for references. It is also a good idea to search for some components of the symbol name with e.g. git grep FOO and git grep BAR, as it can help uncover token pasting.

**Style recommendations and shorthands**

This section gives some style recommendations and explains some common Kconfig shorthands.

**Factoring out common dependencies**  If a sequence of symbols/choices share a common dependency, the dependency can be factored out with an if.

As an example, consider the following code:

```bash
config FOO
    bool "Foo"
    depends on DEP

config BAR
    bool "Bar"
    depends on DEP

choice
    prompt "Choice"
    depends on DEP

config BAZ
    bool "Baz"

config QAZ
    bool "Qaz"

endchoice
```

Here, the DEP dependency can be factored out like this:

```bash
if DEP

config FOO
    bool "Foo"
```

(continues on next page)
config BAR
    bool "Bar"

choice
    prompt "Choice"

config BAZ
    bool "Baz"

config QAZ
    bool "Qaz"

endchoice

endif # DEP

Note: Internally, the second version of the code is transformed into the first.

If a sequence of symbols/choices with shared dependencies are all in the same menu, the dependency can be put on the menu itself:

menu "Foo features"
    depends on FOO_SUPPORT

config FOO_FEATURE_1
    bool "Foo feature 1"

config FOO_FEATURE_2
    bool "Foo feature 2"

endmenu

If FOO_SUPPORT is n, the entire menu disappears.

Redundant defaults  bool symbols implicitly default to n, and string symbols implicitly default to the empty string. Therefore, default n and default "" are (almost) always redundant.

The recommended style in Zephyr is to skip redundant defaults for bool and string symbols. That also generates clearer documentation: (Implicitly defaults to n instead of n if <dependencies, possibly inherited>).

Note: The one case where default n/default "" is not redundant is when defining a symbol in multiple locations and wanting to override e.g. a default y on a later definition.

Defaults should always be given for int and hex symbols, however, as they implicitly default to the empty string. This is partly for compatibility with the C Kconfig tools, though an implicit 0 default might be less likely to be what was intended compared to other symbol types as well.

Common Kconfig shorthands  Kconfig has two shorthands that deal with prompts and defaults.

• <type> "prompt" is a shorthand for giving a symbol/choice a type and a prompt at the same time. These two definitions are equal:
The first style, with the shorthand, is preferred in Zephyr.

- `def_<type> <value>` is a shorthand for giving a type and a value at the same time. These two definitions are equal:

```plaintext
config FOO
    def_bool BAR && BAZ

config FOO
    bool
default BAR && BAZ
```

Using both the `<type> "prompt"` and the `def_<type> <value>` shorthand in the same definition is redundant, since it gives the type twice.

The `def_<type> <value>` shorthand is generally only useful for symbols without prompts, and somewhat obscure.

**Note:** For a symbol defined in multiple locations (e.g., in a `Kconfig.defconfig` file in Zephyr), it is best to only give the symbol type for the “base” definition of the symbol, and to use `default` (instead of `def_<type> value`) for the remaining definitions. That way, if the base definition of the symbol is removed, the symbol ends up without a type, which generates a warning that points to the other definitions. That makes the extra definitions easier to discover and remove.

**Prompt strings** For a Kconfig symbol that enables a driver/subsystem FOO, consider having just “Foo” as the prompt, instead of “Enable Foo support” or the like. It will usually be clear in the context of an option that can be toggled on/off, and makes things consistent.

**Header comments and other nits** A few formatting nits, to help keep things consistent:

- Use this format for any header comments at the top of Kconfig files:

  ```plaintext
  # <Overview of symbols defined in the file, preferably in plain English>
  (Blank line)
  # Copyright (c) 2019 ...
  # SPDX-License-Identifier: <License>
  (Blank line)
  (Kconfig definitions)
  ```

- Format comments as `# Comment` rather than `#Comment`
- Put a blank line before/after each top-level `if` and `endif`
- Use a single tab for each indentation
- Indent help text with two extra spaces

**Lesser-known/used Kconfig features**

This section lists some more obscure Kconfig behaviors and features that might still come in handy.
**The imply statement**  The imply statement is similar to select, but respects dependencies and doesn’t force a value. For example, the following code could be used to enable USB keyboard support by default on the FOO SoC, while still allowing the user to turn it off:

```plaintext
config SOC_FOO
  bool "FOO SoC"
  imply USB_KEYBOARD
...

config USB_KEYBOARD
  bool "USB keyboard support"
```
imply acts like a suggestion, whereas select forces a value.

**Optional prompts**  A condition can be put on a symbol's prompt to make it optionally configurable by the user. For example, a value MASK that's hardcoded to 0xFF on some boards and configurable on others could be expressed as follows:

```plaintext
config MASK
  hex "Bitmask" if HAS_CONFIGURABLE_MASK
  default 0xFF
```

**Note:** This is short for the following:

```plaintext
config MASK
  hex
  prompt "Bitmask" if HAS_CONFIGURABLE_MASK
  default 0xFF
```
The HAS_CONFIGURABLE_MASK helper symbol would get selected by boards to indicate that MASK is configurable. When MASK is configurable, it will also default to 0xFF.

**Optional choices**  Defining a choice with the optional keyword allows the whole choice to be toggled off to select none of the symbols:

```plaintext
choice
  prompt "Use legacy protocol"
  optional

config LEGACY_PROTOCOL_1
  bool "Legacy protocol 1"

config LEGACY_PROTOCOL_2
  bool "Legacy protocol 2"
endchoice
```
In the menuconfig interface, this will be displayed e.g. as [*] Use legacy protocol (Legacy protocol 1) --->, where the choice can be toggled off to enable neither of the symbols.

**visible if conditions**  Putting a visible if condition on a menu hides the menu and all the symbols within it, while still allowing symbol default values to kick in.

As a motivating example, consider the following code:
menu "Foo subsystem"
    depends on HAS_CONFIGURABLE_FOO

config FOO_SETTING_1
    int "Foo setting 1"
    default 1

config FOO_SETTING_2
    int "Foo setting 2"
    default 2

demenu

When HAS_CONFIGURABLE_FOO is n, no configuration output is generated for FOO_SETTING_1 and FOO_SETTING_2, as the code above is logically equivalent to the following code:

config FOO_SETTING_1
    int "Foo setting 1"
    default 1
    depends on HAS_CONFIGURABLE_FOO

config FOO_SETTING_2
    int "Foo setting 2"
    default 2
    depends on HAS_CONFIGURABLE_FOO

If we want the symbols to still get their default values even when HAS_CONFIGURABLE_FOO is n, but not be configurable by the user, then we can use visible if instead:

menu "Foo subsystem"
    visible if HAS_CONFIGURABLE_FOO

config FOO_SETTING_1
    int "Foo setting 1"
    default 1

config FOO_SETTING_2
    int "Foo setting 2"
    default 2

demenu

This is logically equivalent to the following:

config FOO_SETTING_1
    int "Foo setting 1" if HAS_CONFIGURABLE_FOO
    default 1

config FOO_SETTING_2
    int "Foo setting 2" if HAS_CONFIGURABLE_FOO
    default 2

Note: See the optional prompts section for the meaning of the conditions on the prompts.

When HAS_CONFIGURABLE is n, we now get the following configuration output for the symbols, instead of no output:
Other resources

The *Intro to symbol values* section in the Kconfiglib docstring goes over how symbols values are calculated in more detail.

### 5.2.4 Custom Kconfig Preprocessor Functions

Kconfiglib supports custom Kconfig preprocessor functions written in Python. These functions are defined in `scripts/kconfig/kconfigfunctions.py`.

**Note:** The official Kconfig preprocessor documentation can be found [here](#).

Most of the custom preprocessor functions are used to get devicetree information into Kconfig. For example, the default value of a Kconfig symbol can be fetched from a devicetree `reg` property.

#### Devicetree-related Functions

The functions listed below are used to get devicetree information into Kconfig. See the Python docstrings in `scripts/kconfig/kconfigfunctions.py` for detailed documentation.

The `*_int` version of each function returns the value as a decimal integer, while the `*_hex` version returns a hexadecimal value starting with `0x`.

- `$\text{dt\_chosen\_reg\_addr\_int}(\text{<property in /chosen>},[,\text{<index>},\text{<unit>})}$
- `$\text{dt\_chosen\_reg\_addr\_hex}(\text{<property in /chosen>},[,\text{<index>},\text{<unit>})}$
- `$\text{dt\_chosen\_reg\_size\_int}(\text{<property in /chosen>},[,\text{<index>},\text{<unit>})}$
- `$\text{dt\_chosen\_reg\_size\_hex}(\text{<property in /chosen>},[,\text{<index>},\text{<unit>})}$
- `$\text{dt\_node\_reg\_addr\_int}(\text{<node path>},[,\text{<index>},\text{<unit>})}$
- `$\text{dt\_node\_reg\_addr\_hex}(\text{<node path>},[,\text{<index>},\text{<unit>})}$
- `$\text{dt\_node\_reg\_size\_int}(\text{<node path>},[,\text{<index>},\text{<unit>})}$
- `$\text{dt\_node\_reg\_size\_hex}(\text{<node path>},[,\text{<index>},\text{<unit>})}$
- `$\text{dt\_compat\_enabled}(\text{<compatible string>})$
- `$\text{dt\_chosen\_enabled}(\text{<property in /chosen>})$
- `$\text{dt\_node\_has\_bool\_prop}(\text{<node path>},\text{<prop>})$
- `$\text{dt\_node\_has\_prop}(\text{<node path>},\text{<prop>})$

#### Example Usage

Assume that the devicetree for some board looks like this:

```plaintext
{}
  soc {
    #address-cells = <1>;
    #size-cells = <1>;

    spi0: spi@00140000 {
      compatible = "sifive,spi0";
      reg = <0x00140000 0x0100 0x20010000 0x3c09000>;
      reg-names = "control", "mem";
    }
```

(continues on next page)
The second entry in `reg` in `spi@1001400 (<0x20010000 0x3c0900>)` corresponds to `mem`, and has the address `0x20010000`. This address can be inserted into Kconfig as follows:

```c
config FLASH_BASE_ADDRESS
default $(dt_node_reg_addr_hex,/soc/spi@1001400,1)
```

After preprocessor expansion, this turns into the definition below:

```c
config FLASH_BASE_ADDRESS
default 0x20010000
```

### 5.2.5 Kconfig extensions

Zephyr uses the Kconfiglib implementation of Kconfig, which includes some Kconfig extensions:

- Environment variables in `source` statements are expanded directly, meaning no “bounce” symbols with `option env="ENV_VAR"` need to be defined.

**Note:** `option env` has been removed from the C tools as of Linux 4.18 as well.

The recommended syntax for referencing environment variables is `$F00` rather than `F00`. This uses the new Kconfig preprocessor. The `$F00` syntax for expanding environment variables is only supported for backwards compatibility.

- The `source` statement supports glob patterns and includes each matching file. A pattern is required to match at least one file.

Consider the following example:

```c
source "foo/bar/*/Kconfig"
```

If the pattern `foo/bar/*/Kconfig` matches the files `foo/bar/baz/Kconfig` and `foo/bar/qaz/Kconfig`, the statement above is equivalent to the following two `source` statements:

```c
source "foo/bar/baz/Kconfig"
source "foo/bar/qaz/Kconfig"
```

If no files match the pattern, an error is generated.

The wildcard patterns accepted are the same as for the Python `glob` module.

For cases where it’s okay for a pattern to match no files (or for a plain filename to not exist), a separate `osource` (optional `source`) statement is available. `osource` is a no-op if no file matches.

**Note:** `source` and `osource` are analogous to `include` and `-include` in Make.

- An `rsource` statement is available for including files specified with a relative path. The path is relative to the directory of the Kconfig file that contains the `rsource` statement.

As an example, assume that `foo/Kconfig` is the top-level Kconfig file, and that `foo/bar/Kconfig` has the following statements:
This will include the two files foo/qaz/Kconfig1 and foo/bar/qaz/Kconfig2.

`rsource` can be used to create `Kconfig` “subtrees” that can be moved around freely.

`rsource` also supports glob patterns.

A drawback of `rsource` is that it can make it harder to figure out where a file gets included, so only use it if you need it.

• An `orsource` statement is available that combines `osource` and `rsource`.

For example, the following statement will include `Kconfig1` and `Kconfig2` from the current directory (if they exist):

```bash
orsource "Kconfig[12]"
```

• `def_int`, `def_hex`, and `def_string` keywords are available, analogous to `def_bool`. These set the type and add a default at the same time.

Users interested in optimizing their configuration for security should refer to the Zephyr Security Guide’s section on the `Hardening Tool`. 
Chapter 6

Application Development

Note: In this document, we'll assume your application directory is <home>/app, and that its build directory is <home>/app/build. (These terms are defined in the following Overview.) On Linux/macOS, <home> is equivalent to ~, whereas on Windows it's %userprofile%.

6.1 Overview

Zephyr's build system is based on CMake.

The build system is application-centric, and requires Zephyr-based applications to initiate building the kernel source tree. The application build controls the configuration and build process of both the application and Zephyr itself, compiling them into a single binary.

Zephyr's base directory hosts Zephyr's own source code, its kernel configuration options, and its build definitions.

The files in the application directory link Zephyr with the application. This directory contains all application-specific files, such as configuration options and source code.

An application in its simplest form has the following contents:

```
<home>/app
  CMakeLists.txt
  prj.conf
  src
    main.c
```

These contents are:

- **CMakeLists.txt**: This file tells the build system where to find the other application files, and links the application directory with Zephyr's CMake build system. This link provides features supported by Zephyr's build system, such as board-specific kernel configuration files, the ability to run and debug compiled binaries on real or emulated hardware, and more.

- **Kernel configuration files**: An application typically provides a Kconfig configuration file (usually called prj.conf) that specifies application-specific values for one or more kernel configuration options. These application settings are merged with board-specific settings to produce a kernel configuration.

  See [Kconfig Configuration](#) below for more information.
• **Application source code files**: An application typically provides one or more application-specific files, written in C or assembly language. These files are usually located in a sub-directory called `src`.

Once an application has been defined, you can use CMake to create project files for building it from a directory where you want to host these files. This is known as the **build directory**. Application build artifacts are always generated in a build directory; Zephyr does not support “in-tree” builds.

The following sections describe how to create, build, and run Zephyr applications, followed by more detailed reference material.

### 6.2 Source Tree Structure

Understanding the Zephyr source tree can be helpful in locating the code associated with a particular Zephyr feature.

At the top of the tree there are several files that are of importance:

**CMakeLists.txt** The top-level file for the CMake build system, containing a lot of the logic required to build Zephyr.

**Kconfig** The top-level Kconfig file, which refers to the file `Kconfig.zephyr` also found at the top-level directory.

*See [the Kconfig section of the manual](https://docs.zephyrproject.org) for detailed Kconfig documentation.*

**west.yml** The *West (Zephyr’s meta-tool)* manifest, listing the external repositories managed by the west command-line tool.

The Zephyr source tree also contains the following top-level directories, each of which may have one or more additional levels of subdirectories which are not described here.

**arch** Architecture-specific kernel and system-on-chip (SoC) code. Each supported architecture (for example, x86 and ARM) has its own subdirectory, which contains additional subdirectories for the following areas:

- architecture-specific kernel source files
- architecture-specific kernel include files for private APIs

**soc** SoC related code and configuration files.

**boards** Board related code and configuration files.

**doc** Zephyr technical documentation source files and tools used to generate the [https://docs.zephyrproject.org](https://docs.zephyrproject.org) web content.

**drivers** Device driver code.

**dts devicetree** source files used to describe non-discoverable board-specific hardware details.

**include** Include files for all public APIs, except those defined under `lib`.

**kernel** Architecture-independent kernel code.

**lib** Library code, including the minimal standard C library.

**misc** Miscellaneous code that doesn’t belong to any of the other top-level directories.

**samples** Sample applications that demonstrate the use of Zephyr features.

**scripts** Various programs and other files used to build and test Zephyr applications.

**cmake** Additional build scripts needed to build Zephyr.

**subsys** Subsystems of Zephyr, including:

- USB device stack code.
• Networking code, including the Bluetooth stack and networking stacks.
• File system code.
• Bluetooth host and controller
tests Test code and benchmarks for Zephyr features.
share Additional architecture independent data. Currently containing Zephyr CMake package.

6.3 Example standalone application

A reference standalone application contained in its own Git repository can be found in the Example Application repository. It can be used as a reference on how to structure out-of-tree, Zephyr-based applications using the T2 star topology. It also demonstrates the out-of-tree use of features commonly used in applications such as:
• Custom boards
• Custom devicetree bindings
• Custom drivers
• Continuous Integration (CI) setup

6.4 Creating an Application

Follow these steps to create a new application directory. (Refer to the Example Application repository for a reference standalone application in its own Git repository or to samples-and-demos for existing applications provided as part of Zephyr.)

1. Create an application directory on your workstation computer, outside of the Zephyr base directory. Usually you’ll want to create it somewhere under your user’s home directory.

   For example, in a Unix shell or Windows cmd.exe prompt, navigate to where you want to create your application, then enter:

   ```bash
   mkdir app
   ```

   **Warning:** Building Zephyr or creating an application in a directory with spaces anywhere on the path is not supported. So the Windows path C:\Users\YourName\app will work, but C:\Users\Your Name\app will not.

2. It’s recommended to place all application source code in a subdirectory named src. This makes it easier to distinguish between project files and sources.

   Continuing the previous example, enter:

   ```bash
   cd app
   mkdir src
   ```

3. Place your application source code in the src sub-directory. For this example, we’ll assume you created a file named src/main.c.

4. Create a file named CMakeLists.txt in the app directory with the following contents:
cmake_minimum_required(VERSION 3.20.0)
find_package(Zephyr)
project(my_zephyr_app)
target_sources(app PRIVATE src/main.c)

CMake_minimum_required() is required to be in your CMakeLists.txt by CMake. It is also invoked by the Zephyr package. The most recent of the two versions will be enforced by CMake.

find_package(Zephyr) pulls in the Zephyr build system, which creates a CMake target named app (see Zephyr CMake Package). Adding sources to this target is how you include them in the build. The Zephyr package will define Zephyr-Kernel as a CMake project and enable support for the C, CXX, ASM languages.

project(my_zephyr_app) is required for defining your application project. This must be called after find_package(Zephyr) to avoid interference with Zephyr's project(Zephyr-Kernel).

target_sources(app PRIVATE src/main.c) is to add your source file to the app target. This must come after find_package(Zephyr) which defines the target.

5. Set Kconfig configuration options. See Kconfig Configuration.

6. Configure any devicetree overlays needed by your application. See Set devicetree overlays.

Note: include($ENV{ZEPHYR_BASE}/cmake/app/boilerplate.cmake NO_POLICY_SCOPE) is still supported for backward compatibility with older applications. Including boilerplate.cmake directly in the sample still requires using Zephyr Environment Scripts before building the application.

6.5 Important Build System Variables

You can control the Zephyr build system using many variables. This section describes the most important ones that every Zephyr developer should know about.

Note: The variables BOARD, CONF_FILE, and DTC_OVERLAY_FILE can be supplied to the build system in 3 ways (in order of precedence):

- As a parameter to the west build or cmake invocation via the -D command-line switch. If you have multiple overlay files, you should use quotations, "file1.overlay;file2.overlay"
- As Environment Variables.
- As a set(<VARIABLE> <VALUE>) statement in your CMakeLists.txt

- ZEPHYR_BASE: Zephyr base variable used by the build system. find_package(Zephyr) will automatically set this as a cached CMake variable. But ZEPHYR_BASE can also be set as an environment variable in order to force CMake to use a specific Zephyr installation.
- BOARD: Selects the board that the application's build will use for the default configuration. See boards for built-in boards, and Board Porting Guide for information on adding board support.
- CONF_FILE: Indicates the name of one or more Kconfig configuration fragment files. Multiple file-names can be separated with either spaces or semicolons. Each file includes Kconfig configuration values that override the default configuration values.

See The Initial Configuration for more information.
• OVERLAY_CONFIG: Additional Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. This can be useful in order to leave CONF_FILE at its default value, but “mix in” some additional configuration options.

• DTC_OVERLAY_FILE: One or more devicetree overlay files to use. Multiple files can be separated with semicolons. See Set devicetree overlays for examples and Introduction to devicetree for information about devicetree and Zephyr.

• SHIELD: see Shields

• ZEPHYR_MODULES: A CMake list containing absolute paths of additional directories with source code, Kconfig, etc. that should be used in the application build. See Modules (External projects) for details. If you set this variable, it must be a complete list of all modules to use, as the build system will not automatically pick up any modules from west.

• ZEPHYR_EXTRA_MODULES: Like ZEPHYR_MODULES, except these will be added to the list of modules found via west, instead of replacing it.

Note: You can use a Zephyr Build Configuration CMake package to share common settings for these variables.

6.6 Application CMakeLists.txt

Every application must have a CMakeLists.txt file. This file is the entry point, or top level, of the build system. The final zephyr.elf image contains both the application and the kernel libraries.

This section describes some of what you can do in your CMakeLists.txt. Make sure to follow these steps in order.

1. If you only want to build for one board, add the name of the board configuration for your application on a new line. For example:

   ```cmake
   set(BOARD qemu_x86)
   ```

   Refer to boards for more information on available boards.

   The Zephyr build system determines a value for BOARD by checking the following, in order (when a BOARD value is found, CMake stops looking further down the list):

   • Any previously used value as determined by the CMake cache takes highest precedence. This ensures you don’t try to run a build with a different BOARD value than you set during the build configuration step.

   • Any value given on the CMake command line (directly or indirectly via west build) using -DBOARD=YOUR_BOARD will be checked for and used next.

   • If an environment variable BOARD is set, its value will then be used.

   • Finally, if you set BOARD in your application CMakeLists.txt as described in this step, this value will be used.

2. If your application uses a configuration file or files other than the usual prj.conf (or prj.YOUR_BOARD.conf, where YOUR_BOARD is a board name), add lines setting the CONF_FILE variable to these files appropriately. If multiple filenames are given, separate them by a single space or semicolon. CMake lists can be used to build up configuration fragment files in a modular way when you want to avoid setting CONF_FILE in a single place. For example:

   ```cmake
   set(CONF_FILE "fragment_file1.conf")
   list(APPEND CONF_FILE "fragment_file2.conf")
   ```

   See The Initial Configuration for more information.
3. If your application uses devicetree overlays, you may need to set `DTC_OVERLAY_FILE`. See `Set devicetree overlays`.

4. If your application has its own kernel configuration options, create a `Kconfig` file in the same directory as your application's `CMakeLists.txt`.

See `the Kconfig section of the manual` for detailed `Kconfig` documentation.

An (unlikely) advanced use case would be if your application has its own unique configuration options that are set differently depending on the build configuration.

If you just want to set application specific values for existing Zephyr configuration options, refer to the `CONF_FILE` description above.

Structure your `Kconfig` file like this:

```c
# SPDX-License-Identifier: Apache-2.0

mainmenu "Your Application Name"

# Your application configuration options go here

# Sources Kconfig.zephyr in the Zephyr root directory.
#
# Note: All 'source' statements work relative to the Zephyr root directory (due to the $srctree environment variable being set to $ZEPHYR_BASE). If you want # to 'source' relative to the current Kconfig file instead, use 'rsource' (or a # path relative to the Zephyr root).
source "Kconfig.zephyr"
```

**Note:** Environment variables in `source` statements are expanded directly, so you do not need to define an option `env="ZEPHYR_BASE"` `Kconfig` “bounce” symbol. If you use such a symbol, it must have the same name as the environment variable.

See `Kconfig extensions` for more information.

The `Kconfig` file is automatically detected when placed in the application directory, but it is also possible for it to be found elsewhere if the CMake variable `KCONFIG_ROOT` is set with an absolute path.

5. Specify that the application requires Zephyr on a new line, after any lines added from the steps above:

```c
find_package(Zephyr)
project(my_zephyr_app)
```

**Note:** `find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})` can be used if enforcing a specific Zephyr installation by explicitly setting the `ZEPHYR_BASE` environment variable should be supported. All samples in Zephyr supports the `ZEPHYR_BASE` environment variable.

6. Now add any application source files to the ‘app’ target library, each on their own line, like so:

```c
target_sources(app PRIVATE src/main.c)
```

Below is a simple example `CMakeList.txt`:

```c
set(BOARD qemu_x86)
find_package(Zephyr)
(continues on next page)```
The Cmake property HEX_FILES_TO_MERGE leverages the application configuration provided by Kconfig and CMake to let you merge externally built hex files with the hex file generated when building the Zephyr application. For example:

```cmake
set_property(GLOBAL APPEND PROPERTY HEX_FILES_TO_MERGE
c{app_bootloader_hex}
c{PROJECT_BINARY_DIR}/${KERNEL_HEX_NAME}
c{app_provision_hex})
```

### 6.7 CMakeCache.txt

CMake uses a CMakeCache.txt file as persistent key/value string storage used to cache values between runs, including compile and build options and paths to library dependencies. This cache file is created when CMake is run in an empty build folder.

For more details about the CMakeCache.txt file see the official CMake documentation running cmake.

### 6.8 Application Configuration

#### 6.8.1 Application Configuration Directory

Zephyr will use configuration files from the application’s configuration directory except for files with an absolute path provided by the arguments described earlier, for example CONF_FILE, OVERLAY_CONFIG, and DTC_OVERLAY_FILE.

The application configuration directory is defined by the APPLICATION_CONFIG_DIR variable.

APPLICATION_CONFIG_DIR will be set by one of the sources below with the highest priority listed first.

1. If APPLICATION_CONFIG_DIR is specified by the user with -DAPPLICATION_CONFIG_DIR=<path> or in a CMake file before `find_package(Zephyr)` then this folder is used a the application’s configuration directory.
2. The application’s source directory.

#### 6.8.2 Kconfig Configuration

Application configuration options are usually set in prj.conf in the application directory. For example, C++ support could be enabled with this assignment:

```cmake
CONFIG_CPLUSPLUS=y
```

Looking at existing samples is a good way to get started.

See Setting Kconfig configuration values for detailed documentation on setting Kconfig configuration values. The *Initial Configuration* section on the same page explains how the initial configuration is derived. See kconfig-search for a complete list of configuration options. See Hardening Tool for security information related with Kconfig options.

The other pages in the *Kconfig section of the manual* are also worth going through, especially if you planning to add new configuration options.
6.9 Experimental features

Zephyr is a project under constant development and thus there are features that are still in early stages of their development cycle. Such features will be marked [EXPERIMENTAL] in their Kconfig title.

The CONFIG_WARN_EXPERIMENTAL setting can be used to enable warnings at CMake configure time if any experimental feature is enabled.

```plaintext
CONFIG_WARN_EXPERIMENTAL=y
```

For example, if option CONFIG_FOO is experimental, then enabling it and CONFIG_WARN_EXPERIMENTAL will print the following warning at CMake configure time when you build an application:

```plaintext
warning: Experimental symbol FOO is enabled.
```

6.9.1 Devicetree Overlays

See Set devicetree overlays.

6.10 Application-Specific Code

Application-specific source code files are normally added to the application’s src directory. If the application adds a large number of files the developer can group them into sub-directories under src, to whatever depth is needed.

Application-specific source code should not use symbol name prefixes that have been reserved by the kernel for its own use. For more information, see Naming Conventions.

6.10.1 Third-party Library Code

It is possible to build library code outside the application’s src directory but it is important that both application and library code targets the same Application Binary Interface (ABI). On most architectures there are compiler flags that control the ABI targeted, making it important that both libraries and applications have certain compiler flags in common. It may also be useful for glue code to have access to Zephyr kernel header files.

To make it easier to integrate third-party components, the Zephyr build system has defined CMake functions that give application build scripts access to the zephyr compiler options. The functions are documented and defined in cmake/extensions.cmake and follow the naming convention zephyr_get_<type>_<format>.

The following variables will often need to be exported to the third-party build system.

- **CMAKE_C_COMPILER**, **CMAKE_AR**.
- **ARCH** and **BOARD**, together with several variables that identify the Zephyr kernel version.

samples/application_development/external_lib is a sample project that demonstrates some of these features.

6.11 Building an Application

The Zephyr build system compiles and links all components of an application into a single application image that can be run on simulated hardware or real hardware.
Like any other CMake-based system, the build process takes place in two stages. First, build files (also known as a buildsystem) are generated using the `cmake` command-line tool while specifying a generator. This generator determines the native build tool the buildsystem will use in the second stage. The second stage runs the native build tool to actually build the source files and generate an image. To learn more about these concepts refer to the CMake introduction in the official CMake documentation.

Although the default build tool in Zephyr is `west`, Zephyr’s meta-tool, which invokes `cmake` and the underlying build tool (ninja or make) behind the scenes, you can also choose to invoke `cmake` directly if you prefer. On Linux and macOS you can choose between the `make` and `ninja` generators (i.e. build tools), whereas on Windows you need to use `ninja`, since `make` is not supported on this platform. For simplicity we will use `ninja` throughout this guide, and if you choose to use `west build` to build your application know that it will default to `ninja` under the hood.

As an example, let’s build the Hello World sample for the `reel_board`:

Using west:

```bash
west build -b reel_board samples/hello_world
```

Using CMake and ninja:

```bash
# Use cmake to configure a Ninja-based buildsystem:
cmake -B build -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -C build
```

On Linux and macOS, you can also build with `make` instead of `ninja`:

Using west:

- to use `make` just once, add `-- -G"Unix Makefiles"` to the west build command line; see the `west build` documentation for an example.
- to use `make` by default from now on, run `west config build.generator "Unix Makefiles"`.

Using CMake directly:

```bash
# Use cmake to configure a Make-based buildsystem:
cmake -B build -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
made -C build
```

### 6.11.1 Basics

**Note:** In the below example, `west` is used outside of a west workspace. For this to work, you must set the `ZEPHYR_BASE` environment variable to the path of your zephyr git repository, using one of the methods on the Environment Variables page.

1. Navigate to the application directory `<home>/app`.

2. Enter the following commands to build the application’s `zephyr.elf` image for the board specified in the command-line parameters:

Using west:

```bash
west build -b <board>
```

Using CMake and ninja:
If desired, you can build the application using the configuration settings specified in an alternate .conf file using the CONF_FILE parameter. These settings will override the settings in the application’s .config file or its default .conf file. For example:

Using west:

```
west build -b <board> -- -DCONF_FILE=prj.alternate.conf
```

Using CMake and ninja:

```
mkdir build && cd build
cmake -GNinja -DBOARD=<board> -DCONF_FILE=prj.alternate.conf ..
ninja
```

As described in the previous section, you can instead choose to permanently set the board and configuration settings by either exporting BOARD and CONF_FILE environment variables or by setting their values in your CMakeLists.txt using set() statements. Additionally, west allows you to set a default board.

### 6.11.2 Build Directory Contents

When using the Ninja generator a build directory looks like this:

```
<home>/app/build
|-- build.ninja
|  -- CMakeCache.txt
|  -- CMakeFiles
|  -- cmake_install.cmake
|  -- rules.ninja
|  -- zephyr
```

The most notable files in the build directory are:

- **build.ninja**, which can be invoked to build the application.
  
- A **zephyr** directory, which is the working directory of the generated build system, and where most generated files are created and stored.

After running ninja, the following build output files will be written to the zephyr sub-directory of the build directory. (This is **not the Zephyr base directory**, which contains the Zephyr source code etc. and is described above.)

- **.config**, which contains the configuration settings used to build the application.

  **Note:** The previous version of .config is saved to .config.old whenever the configuration is updated. This is for convenience, as comparing the old and new versions can be handy.

- Various object files (.o files and .a files) containing compiled kernel and application code.

- **zephyr.elf**, which contains the final combined application and kernel binary. Other binary output formats, such as .hex and .bin, are also supported.
6.11.3 Rebuilding an Application

Application development is usually fastest when changes are continually tested. Frequently rebuilding your application makes debugging less painful as the application becomes more complex. It’s usually a good idea to rebuild and test after any major changes to the application’s source files, CMakeLists.txt files, or configuration settings.

**Important:** The Zephyr build system rebuilds only the parts of the application image potentially affected by the changes. Consequently, rebuilding an application is often significantly faster than building it the first time.

Sometimes the build system doesn’t rebuild the application correctly because it fails to recompile one or more necessary files. You can force the build system to rebuild the entire application from scratch with the following procedure:

1. Open a terminal console on your host computer, and navigate to the build directory `<home>/app/build`.
2. Enter one of the following commands, depending on whether you want to use west or cmake directly to delete the application’s generated files, except for the `.config` file that contains the application’s current configuration information.
   
   ```
   west build -t clean
   
   or
   
   ninja clean
   ```

   Alternatively, enter one of the following commands to delete all generated files, including the `.config` files that contain the application’s current configuration information for those board types.

   ```
   west build -t pristine
   
   or
   
   ninja pristine
   ```

   If you use west, you can take advantage of its capability to automatically `make the build folder pristine` whenever it is required.

3. Rebuild the application normally following the steps specified in *Building an Application* above.

6.11.4 Building for a board revision

The Zephyr build system has support for specifying multiple hardware revisions of a single board with small variations. Using revisions allows the board support files to make minor adjustments to a board configuration without duplicating all the files described in *Create your board directory* for each revision.

To build for a particular revision, use `<board>@<revision>` instead of plain `<board>`. For example:

Using west:

```
west build -b <board>@<revision>
```

Using CMake and ninja:

```
mkdir build && cd build
cmake -GNinja -DBOARD=<board>@<revision> ..
ninja
```
Check your board's documentation for details on whether it has multiple revisions, and what revisions are supported.

When targeting a board revision, the active revision will be printed at CMake configure time, like this:

```
-- Board: plank, Revision: 1.5.0
```

### 6.12 Run an Application

An application image can be run on a real board or emulated hardware.

#### 6.12.1 Running on a Board

Most boards supported by Zephyr let you flash a compiled binary using the `flash` target to copy the binary to the board and run it. Follow these instructions to flash and run an application on real hardware:

1. Build your application, as described in *Building an Application*.
2. Make sure your board is attached to your host computer. Usually, you'll do this via USB.
3. Run one of these console commands from the build directory, `<home>/app/build`, to flash the compiled Zephyr image and run it on your board:

   ```
   west flash
   
   or
   
   ninja flash
   ```

The Zephyr build system integrates with the board support files to use hardware-specific tools to flash the Zephyr binary to your hardware, then run it.

Each time you run the flash command, your application is rebuilt and flashed again.

In cases where board support is incomplete, flashing via the Zephyr build system may not be supported. If you receive an error message about flash support being unavailable, consult your board's documentation for additional information on how to flash your board.

**Note:** When developing on Linux, it's common to need to install board-specific udev rules to enable USB device access to your board as a non-root user. If flashing fails, consult your board's documentation to see if this is necessary.

#### 6.12.2 Running in an Emulator

The kernel has built-in emulator support for QEMU (on Linux/macOS only, this is not yet supported on Windows). It allows you to run and test an application virtually, before (or in lieu of) loading and running it on actual target hardware. Follow these instructions to run an application via QEMU:

1. Build your application for one of the QEMU boards, as described in *Building an Application*.
   
   For example, you could set `BOARD` to:
   
   - `qemu_x86` to emulate running on an x86-based board
   - `qemu_cortex_m3` to emulate running on an ARM Cortex M3-based board

2. Run one of these console commands from the build directory, `<home>/app/build`, to run the Zephyr binary in QEMU:
Zephyr Project Documentation, Release 3.0.99

west build -t run

or

ninja run

3. Press Ctrl A, X to stop the application from running in QEMU.

The application stops running and the terminal console prompt redisplays.

Each time you execute the run command, your application is rebuilt and run again.

Note: If the (Linux only) Zephyr SDK is installed, the run target will use the SDK's QEMU binary by default. To use another version of QEMU, set the environment variable QEMU_BIN_PATH to the path of the QEMU binary you want to use instead.

Note: You can choose a specific emulator by appending _<emulator> to your target name, for example west build -t run_qemu or ninja run_qemu for QEMU.

6.13 Application Debugging

This section is a quick hands-on reference to start debugging your application with QEMU. Most content in this section is already covered in QEMU and GNU.Debugger reference manuals.

In this quick reference, you'll find shortcuts, specific environmental variables, and parameters that can help you to quickly set up your debugging environment.

The simplest way to debug an application running in QEMU is using the GNU Debugger and setting a local GDB server in your development system through QEMU.

You will need an Executable and Linkable Format (ELF) binary image for debugging purposes. The build system generates the image in the build directory. By default, the kernel binary name is zephyr.elf. The name can be changed using a Kconfig option.

We will use the standard 1234 TCP port to open a GDB (GNU Debugger) server instance. This port number can be changed for a port that best suits the development environment.

You can run QEMU to listen for a “gdb connection” before it starts executing any code to debug it.

qemu -s -S <image>

will setup Qemu to listen on port 1234 and wait for a GDB connection to it.

The options used above have the following meaning:

- -s Do not start CPU at startup; rather, you must type ‘c’ in the monitor.
- -S Shorthand for -gdb tcp::1234: open a GDB server on TCP port 1234.

To debug with QEMU and to start a GDB server and wait for a remote connect, run either of the following inside the build directory of an application:

ninja debugserver

The build system will start a QEMU instance with the CPU halted at startup and with a GDB server instance listening at the TCP port 1234.

Using a local GDB configuration .gdbinit can help initialize your GDB instance on every run. In this example, the initialization file points to the GDB server instance. It configures a connection to a remote
target at the local host on the TCP port 1234. The initialization sets the kernel's root directory as a reference.

The .gdbinit file contains the following lines:

```
target remote localhost:1234
dir ZEPHYR_BASE
```

**Note:** Substitute the correct `ZEPHYR_BASE` for your system.

Execute the application to debug from the same directory that you chose for the .gdbinit file. The command can include the `--tui` option to enable the use of a terminal user interface. The following commands connects to the GDB server using gdb. The command loads the symbol table from the elf binary file. In this example, the elf binary file name corresponds to `zephyr.elf` file:

```
....../path/to/gdb --tui zephyr.elf
```

**Note:** The GDB version on the development system might not support the `--tui` option. Please make sure you use the GDB binary from the SDK which corresponds to the toolchain that has been used to build the binary.

If you are not using a .gdbinit file, issue the following command inside GDB to connect to the remote GDB server on port 1234:

```
(gdb) target remote localhost:1234
```

Finally, the command below connects to the GDB server using the Data Displayer Debugger (ddd). The command loads the symbol table from the elf binary file, in this instance, the `zephyr.elf` file.

The DDD (Data Displayer Debugger) may not be installed in your development system by default. Follow your system instructions to install it. For example, use `sudo apt-get install ddd` on an Ubuntu system.

```
ddd --gdb --debugger "gdb zephyr.elf"
```

Both commands execute the GDB (GNU Debugger). The command name might change depending on the toolchain you are using and your cross-development tools.

### 6.14 Custom Board, Devicetree and SOC Definitions

In cases where the board or platform you are developing for is not yet supported by Zephyr, you can add board, Devicetree and SOC definitions to your application without having to add them to the Zephyr tree.

The structure needed to support out-of-tree board and SOC development is similar to how boards and SOCs are maintained in the Zephyr tree. By using this structure, it will be much easier to upstream your platform related work into the Zephyr tree after your initial development is done.

Add the custom board to your application or a dedicated repository using the following structure:
where the `boards` directory hosts the board you are building for:

```
- [boards]
  - [x86]
    - [my_custom_board]
      - [doc]
      - [img]
      - [support]
  - [src]
```

and the `soc` directory hosts any SOC code. You can also have boards that are supported by a SOC that is available in the Zephyr tree.

### 6.14.1 Boards

Use the proper architecture folder name (e.g., `x86`, `arm`, etc.) under `boards` for `my_custom_board`. (See `boards` for a list of board architectures.)

Documentation (under `doc/`) and support files (under `support/`) are optional, but will be needed when submitting to Zephyr.

The contents of `my_custom_board` should follow the same guidelines for any Zephyr board, and provide the following files:

- `my_custom_board_defconfig`
- `my_custom_board.dts`
- `my_custom_board.yaml`
- `board.cmake`
- `board.h`
- `CMakeLists.txt`
- `doc/`
- `dts_fixup.h`
- `Kconfig.board`
- `Kconfig.defconfig`
- `pinmux.c`
- `support/`

Once the board structure is in place, you can build your application targeting this board by specifying the location of your custom board information with the `-DBOARD_ROOT` parameter to the CMake build system:

Using west:

```bash
west build -b <board name> -- -DBOARD_ROOT=<path to boards>
```

Using CMake and ninja:

```bash
cmake -B build -GNinja -DBOARD=<board name> -DBOARD_ROOT=<path to boards> .
ninja -C build
```

This will use your custom board configuration and will generate the Zephyr binary into your application directory.

You can also define the `BOARD_ROOT` variable in the application `CMakeLists.txt` file. Make sure to do so before pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`. When

**Note:** When specifying `BOARD_ROOT` in a `CMakeLists.txt`, then an absolute path must be provided, for example `list(APPEND BOARD_ROOT '${CMAKE_CURRENT_SOURCE_DIR}/<extra-board-root>'`). When
using \(-DBOARD\_ROOT=<board\_root>\) both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

### 6.14.2 SOC Definitions

Similar to board support, the structure is similar to how SOCs are maintained in the Zephyr tree, for example:

```
  soc
    \|-- arm
    |   \-- st_stm32
          |   \-- common
          |       \-- stm3210
```

The file `soc/Kconfig` will create the top-level \texttt{SoC/CPU/Configuration Selection} menu in \texttt{Kconfig}.

Out of tree SoC definitions can be added to this menu using the `SOC\_ROOT` CMake variable. This variable contains a semicolon-separated list of directories which contain SoC support files.

Following the structure above, the following files can be added to load more SoCs into the menu:

```
  soc
    \|-- arm
    |   \-- st_stm32
        \-- Kconfig
        \-- Kconfig.soc
        \-- Kconfig.defconfig
```

The \texttt{Kconfig} files above may describe the SoC or load additional SoC \texttt{Kconfig} files.

An example of loading \texttt{stm31l0} specific \texttt{Kconfig} files in this structure:

```
  soc
    \|-- arm
    |   \-- st_stm32
        \-- Kconfig.soc
            \-- stm32l0
                \-- Kconfig.series
```

can be done with the following content in `st_stm32/Kconfig.soc`:

```
rsource "/Kconfig.series"
```

Once the SOC structure is in place, you can build your application targeting this platform by specifying the location of your custom platform information with the `DSOC\_ROOT` parameter to the CMake build system:

**Using west:**

```
w west build -b <board\ name> -- DSOC\_ROOT=<path to soc> -DBOARD\_ROOT=<path to boards>
```

**Using CMake and ninja:**

```
cmake -B build -GNinja -DBOARD=<board \ name> -DSOC\_ROOT=<path to soc> -DBOARD\_ROOT= <path to boards>
ninja -C build
```

This will use your custom platform configurations and will generate the Zephyr binary into your application directory.
See Build settings for information on setting SOC_ROOT in a module's zephyr/module.yml file.

Or you can define the SOC_ROOT variable in the application CMakeLists.txt file. Make sure to do so before pulling in the Zephyr boilerplate with find_package(Zephyr ...).

**Note:** When specifying SOC_ROOT in a CMakeLists.txt, then an absolute path must be provided, for example list(APPEND SOC_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-soc-root>). When using -DSOC_ROOT=<soc-root> both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

### 6.14.3 Devicetree Definitions

Devicetree directory trees are found in APPLICATION_SOURCE_DIR, BOARD_DIR, and ZEPHYR_BASE, but additional trees, or DTS_ROOTs, can be added by creating this directory tree:

```markdown
include/
dts/common/
dts/arm/
dts/
dts/bindings/
```

Where ‘arm’ is changed to the appropriate architecture. Each directory is optional. The binding directory contains bindings and the other directories contain files that can be included from DT sources.

Once the directory structure is in place, you can use it by specifying its location through the DTS_ROOT CMake Cache variable:

Using west:

```
west build -b <board name> -- -DDTS_ROOT=<path to dts root>
```

Using CMake and ninja:

```
cmake -B build -GNinja -DBOARD=<board name> -DDTS_ROOT=<path to dts root> .
ninja -C build
```

You can also define the variable in the application CMakeLists.txt file. Make sure to do so before pulling in the Zephyr boilerplate with find_package(Zephyr ...).

**Note:** When specifying DTS_ROOT in a CMakeLists.txt, then an absolute path must be provided, for example list(APPEND DTS_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-dts-root>). When using -DDTS_ROOT=<dts-root> both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Devicetree source are passed through the C preprocessor, so you can include files that can be located in a DTS_ROOT directory. By convention devicetree include files have a .dtsi extension.

You can also use the preprocessor to control the content of a devicetree file, by specifying directives through the DTS_EXTRA_CPPFLAGS CMake Cache variable:

Using west:

```
w west build -b <board name> -- -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_FEATURE
```

Using CMake and ninja:
6.15 Debug with Eclipse

6.15.1 Overview

CMake supports generating a project description file that can be imported into the Eclipse Integrated Development Environment (IDE) and used for graphical debugging.

The GNU MCU Eclipse plug-ins provide a mechanism to debug ARM projects in Eclipse with pyOCD, Segger J-Link, and OpenOCD debugging tools.

The following tutorial demonstrates how to debug a Zephyr application in Eclipse with pyOCD in Windows. It assumes you have already installed the GCC ARM Embedded toolchain and pyOCD.

6.15.2 Set Up the Eclipse Development Environment

1. Download and install Eclipse IDE for C/C++ Developers.
2. In Eclipse, install the GNU MCU Eclipse plug-ins by opening the menu Window->Eclipse Marketplace..., searching for GNU MCU Eclipse, and clicking Install on the matching result.
3. Configure the path to the pyOCD GDB server by opening the menu Window->Preferences, navigating to MCU, and setting the Global pyOCD Path.

6.15.3 Generate and Import an Eclipse Project

1. Set up a GNU Arm Embedded toolchain as described in 3rd Party Toolchains.
2. Navigate to a folder outside of the Zephyr tree to build your application.

```bash
# On Windows
cd %userprofile%
```

**Note:** If the build directory is a subdirectory of the source directory, as is usually done in Zephyr, CMake will warn:

“The build directory is a subdirectory of the source directory.
This is not supported well by Eclipse. It is strongly recommended to use a build directory which is a sibling of the source directory.”

3. Configure your application with CMake and build it with ninja. Note the different CMake generator specified by the -G"Eclipse CDT4 - Ninja" argument. This will generate an Eclipse project description file, .project, in addition to the usual ninja build files.

Using west:

```bash
west build -b frdm_k64f %ZEPHYR_BASE%/samples/synchronization -- -G"Eclipse CDT4
-- Ninja"
```

Using CMake and ninja:

```bash
cmake -B build -GNinja -DBOARD=<board name> -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_˓FEATURE.
ninja -C build
```
cmake -B build -GNinja -DBOARD=frdm_k64f -G"Eclipse CDT4 - Ninja" %ZEPHYR_BASE%\amples\synchronization
ninja -C build

4. In Eclipse, import your generated project by opening the menu File->Import... and selecting the option Existing Projects into Workspace. Browse to your application build directory in the choice, Select root directory:. Check the box for your project in the list of projects found and click the Finish button.

6.15.4 Create a Debugger Configuration

1. Open the menu Run->Debug Configurations....
2. Select GDB PyOCD Debugging, click the New button, and configure the following options:
   - In the Main tab:
     - Project: my_zephyr_app@build
     - C/C++ Application: zephyr/zephyr.elf
   - In the Debugger tab:
     - pyOCD Setup
       - Executable path: $pyocd_path$/pyocd_executable
       - Uncheck “Allocate console for semihosting”
     - Board Setup
       - Bus speed: 8000000 Hz
       - Uncheck “Enable semihosting”
     - GDB Client Setup
       - Executable path example (use your GNUARMEMB_TOOLCHAIN_PATH): C:\gcc-arm-none-eabi-6_2017-q2-update\bin\arm-none-eabi-gdb.exe
   - In the SVD Path tab:
     - File path: <workspace top>\modules\hal\nxp\mcux\devices\MK64F12\MK64F12.xml

   Note: This is optional. It provides the SoC’s memory-mapped register addresses and bitfields to the debugger.

3. Click the Debug button to start debugging.

6.15.5 RTOS Awareness

Support for Zephyr RTOS awareness is implemented in pyOCD v0.11.0 and later. It is compatible with GDB PyOCD Debugging in Eclipse, but you must enable CONFIG_DEBUG_THREAD_INFO=y in your application.
Chapter 7

API Reference

7.1 API Status and Guidelines

7.1.1 API Overview

The table lists Zephyr’s APIs and information about them, including their current stability level.

#### 7.1.2 API Lifecycle

Developers using Zephyr’s APIs need to know how long they can trust that a given API will not change in future releases. At the same time, developers maintaining and extending Zephyr’s APIs need to be able to introduce new APIs that aren’t yet fully proven, and to potentially retire old APIs when they’re no longer optimal or supported by the underlying platforms.

An up-to-date table of all APIs and their maturity level can be found in the [API Overview](#) page.

**Experimental**

Experimental APIs denote that a feature was introduced recently, and may change or be removed in future versions. Try it out and provide feedback to the community via the [Developer mailing list](#).

The following requirements apply to all new APIs:

- Documentation of the API (usage) explaining its design and assumptions, how it is to be used, current implementation limitations, and future potential, if appropriate.
- The API introduction should be accompanied by at least one implementation of said API (in the case of peripheral APIs, this corresponds to one driver)
- At least one sample using the new API (may only build on one single board)
Peripheral APIs (Hardware Related)  When introducing an API (public header file with documentation) for a new peripheral or driver subsystem, review of the API is enforced and is driven by the API working group consisting of representatives from different vendors.

The API shall be promoted to unstable when it has at least two implementations on different hardware platforms.

Unstable

The API is in the process of settling, but has not yet had sufficient real-world testing to be considered stable. The API is considered generic in nature and can be used on different hardware platforms.

Note: Changes will not be announced.

Peripheral APIs (Hardware Related)  The API shall be promoted from experimental to unstable when it has at least two implementations on different hardware platforms.

Hardware Agnostic APIs  For hardware agnostic APIs, multiple applications using it are required to promote an API from experimental to unstable.

Stable

The API has proven satisfactory, but cleanup in the underlying code may cause minor changes. Backwards-compatibility will be maintained if reasonable.

An API can be declared stable after fulfilling the following requirements:

- Test cases for the new API with 100% coverage
- Complete documentation in code. All public interfaces shall be documented and available in online documentation.
- The API has been in-use and was available in at least 2 development releases
Stable APIs can get backward compatible updates, bug fixes and security fixes at any time. In order to declare an API stable, the following steps need to be followed:

1. A Pull Request must be opened that changes the corresponding entry in the API Overview table
2. An email must be sent to the devel mailing list announcing the API upgrade request
3. The Pull Request must be submitted for discussion in the next Zephyr API meeting where, barring any objections, the Pull Request will be merged

Introducing incompatible changes A stable API, as described above strives to remain backwards-compatible through its life-cycle. There are however cases where fulfilling this objective prevents technical progress or is simply unfeasible without unreasonable burden on the maintenance of the API and its implementation(s).

An incompatible change is defined as one that forces users to modify their existing code in order to maintain the current behavior of their application. The need for recompilation of applications (without changing the application itself) is not considered an incompatible change.

In order to restrict and control the introduction of a change that breaks the promise of backwards compatibility the following steps must be followed whenever such a change is considered necessary in order to accept it in the project:

1. An RFC issue must be opened on GitHub with the following content:

   Title: RFC: API Change: <subsystem>
   Contents:
   - Problem Description:
   - Background information on why the change is required
   - Proposed Change (detailed):
   - Brief description of the API change
   - Detailed RFC:
   - Function call changes
   - Device Tree changes (source and bindings)
   - Kconfig option changes
   - Dependencies:
   - Impact to users of the API, including the steps required to adapt out-of-tree users of the API to the change

   Instead of a written description of the changes, the RFC issue may link to a Pull Request containing those changes in code form.

2. The RFC issue must be labeled with the GitHub Stable API Change label
3. The RFC issue must be submitted for discussion in the next Zephyr API meeting
4. An email must be sent to the devel mailing list with a subject identical to the RFC issue title and that links to the RFC issue

The RFC will then receive feedback through issue comments and will also be discussed in the Zephyr API meeting, where the stakeholders and the community at large will have a chance to discuss it in detail.

Finally, and if not done as part of the first step, a Pull Request must be opened on GitHub. It is left to the person proposing the change to decide whether to introduce both the RFC and the Pull Request at the same time or to wait until the RFC has gathered consensus enough so that the implementation can proceed with confidence that it will be accepted. The Pull Request must include the following:

- A title that matches the RFC issue
- A link to the RFC issue
- The actual changes to the API
  - Changes to the API header file
  - Changes to the API implementation(s)
– Changes to the relevant API documentation
– Changes to Device Tree source and bindings

• The changes required to adapt in-tree users of the API to the change. Depending on the scope of this task this might require additional help from the corresponding maintainers

• An entry in the “API Changes” section of the release notes for the next upcoming release

• The labels API, Stable API Change and Release Notes, as well as any others that are applicable

Once the steps above have been completed, the outcome of the proposal will depend on the approval of the actual Pull Request by the maintainer of the corresponding subsystem. As with any other Pull Request, the author can request for it to be discussed and ultimately even voted on in the Zephyr TSC meeting. If the Pull Request is merged then an email must be sent to the devel and user mailing lists informing them of the change.

**Note:** Incompatible changes will be announced in the “API Changes” section of the release notes.

### Deprecated

**Note:** Unstable APIs can be removed without deprecation at any time. Deprecation and removal of APIs will be announced in the “API Changes” section of the release notes.

The following are the requirements for deprecating an existing API:

• Deprecation Time (stable APIs): 2 Releases The API needs to be marked as deprecated in at least two full releases. For example, if an API was first deprecated in release 1.14, it will be ready to be removed in 1.16 at the earliest. There may be special circumstances, determined by the API working group, where an API is deprecated sooner.

• What is required when deprecating:
  – Mark as deprecated. This can be done by using the compiler itself (\_\_deprecated for function declarations and \_\_DEPRECATED\_MACRO for macro definitions), or by introducing a Kconfig option (typically one that contains the DEPRECATED word in it) that, when enabled, reverts the APIs back to their previous form
  – Document the deprecation
  – Include the deprecation in the “API Changes” of the release notes for the next upcoming release
  – Code using the deprecated API needs to be modified to remove usage of said API
  – The change needs to be atomic and bisectable
  – Create a GitHub issue to track the removal of the deprecated API, and add it to the roadmap targeting the appropriate release (in the example above, 1.16).

During the deprecation waiting period, the API will be in the deprecated state. The Zephyr maintainers will track usage of deprecated APIs on docs.zephyrproject.org and support developers migrating their code. Zephyr will continue to provide warnings:

• API documentation will inform users that the API is deprecated.
• Attempts to use a deprecated API at build time will log a warning to the console.

### Retired

In this phase, the API is removed.
The target removal date is 2 releases after deprecation is announced. The Zephyr maintainers will decide when to actually remove the API; this will depend on how many developers have successfully migrated from the deprecated API, and on how urgently the API needs to be removed.

If it’s OK to remove the API, it will be removed. The maintainers will remove the corresponding documentation, and communicate the removal in the usual ways: the release notes, mailing lists, Github issues and pull-requests.

If it’s not OK to remove the API, the maintainers will continue to support migration and update the roadmap with the aim to remove the API in the next release.

### 7.1.3 API Design Guidelines

Zephyr development and evolution is a group effort, and to simplify maintenance and enhancements there are some general policies that should be followed when developing a new capability or interface.

#### Using Callbacks

Many APIs involve passing a callback as a parameter or as a member of a configuration structure. The following policies should be followed when specifying the signature of a callback:

- The first parameter should be a pointer to the object most closely associated with the callback. In the case of device drivers this would be `struct device *dev`. For library functions it may be a pointer to another object that was referenced when the callback was provided.

- The next parameter(s) should be additional information specific to the callback invocation, such as a channel identifier, new status value, and/or a message pointer followed by the message length.

- The final parameter should be a `void *user_data` pointer carrying context that allows a shared callback function to locate additional material necessary to process the callback.

An exception to providing `user_data` as the last parameter may be allowed when the callback itself was provided through a structure that will be embedded in another structure. An example of such a case is `gpio_callback`, normally defined within a data structure specific to the code that also defines the callback function. In those cases further context can accessed by the callback indirectly by `CONTAINER_OF`.

#### Examples

- The requirements of `k_timer_expiry_t` invoked when a system timer alarm fires are satisfied by:

  ```c
  void handle_timeout(struct k_timer *timer)
  { ... }
  ```

  The assumption here, as with `gpio_callback`, is that the timer is embedded in a structure reachable from `CONTAINER_OF` that can provide additional context to the callback.

- The requirements of `counter_alarm_callback_t` invoked when a counter device alarm fires are satisfied by:

  ```c
  void handle_alarm(const struct device *dev,
  uint8_t chan_id,
  uint32_t ticks,
  void *user_data)
  { ... }
  ```

  This provides more complete useful information, including which counter channel timed-out and the counter value at which the timeout occurred, as well as user context which may or may not be the `counter_alarm_cfg` used to register the callback, depending on user needs.
Conditional Data and APIs

APIs and libraries may provide features that are expensive in RAM or code size but are optional in the sense that some applications can be implemented without them. Examples of such feature include capturing a timestamp or providing an alternative interface. The developer in coordination with the community must determine whether enabling the features is to be controllable through a Kconfig option.

In the case where a feature is determined to be optional the following practices should be followed.

- Any data that is accessed only when the feature is enabled should be conditionally included via `#ifdef CONFIG_MYFEATURE` in the structure or union declaration. This reduces memory use for applications that don't need the capability.
- Function declarations that are available only when the option is enabled should be provided unconditionally. Add a note in the description that the function is available only when the specified feature is enabled, referencing the required Kconfig symbol by name. In the cases where the function is used but not enabled the definition of the function shall be excluded from compilation, so references to the unsupported API will result in a link-time error.
- Where code specific to the feature is isolated in a source file that has no other content that file should be conditionally included in `CMakeLists.txt`:

```
zephyr_sources_ifdef(CONFIG_MYFEATURE foofuncs.c)
```

- Where code specific to the feature is part of a source file that has other content the feature-specific code should be conditionally processed using `#ifdef CONFIG_MYFEATURE`.

The Kconfig flag used to enable the feature should be added to the `PREDEFINED` variable in `doc/zephyr.doxyfile.in` to ensure the conditional API and functions appear in generated documentation.

Return Codes

Implementations of an API, for example an API for accessing a peripheral might implement only a subset of the functions that is required for minimal operation. A distinction is needed between APIs that are not supported and those that are not implemented or optional:

- APIs that are supported but not implemented shall return `-ENOSYS`.
- Optional APIs that are not supported by the hardware should be implemented and the return code in this case shall be `-ENOTSUP`.
- When an API is implemented, but the particular combination of options requested in the call cannot be satisfied by the implementation the call shall return `-ENOTSUP`. (For example, a request for a level-triggered GPIO interrupt on hardware that supports only edge-triggered interrupts)

7.1.4 API Terminology

The following terms may be used as shorthand API tags to indicate the allowed calling context (thread, ISR, pre-kernel), the effect of a call on the current thread state, and other behavioral characteristics.

- `reschedule` if executing the function reaches a reschedule point
- `sleep` if executing the function can cause the invoking thread to sleep
- `no-wait` if a parameter to the function can prevent the invoking thread from trying to sleep
- `isr-ok` if the function can be safely called and will have its specified effect whether invoked from interrupt or thread context
- `pre-kernel-ok` if the function can be safely called before the kernel has been fully initialized and will have its specified effect when invoked from that context.
async if the function may return before the operation it initializes is complete (i.e. function return and
operation completion are asynchronous)

supervisor if the calling thread must have supervisor privileges to execute the function

Details on the behavioral impact of each attribute are in the following sections.

reschedule

The reschedule attribute is used on a function that can reach a reschedule point within its execution.

Details The significance of this attribute is that when a rescheduling function is invoked by a thread
it is possible for that thread to be suspended as a consequence of a higher-priority thread being made
ready. Whether the suspension actually occurs depends on the operation associated with the reschedule
point and the relative priorities of the invoking thread and the head of the ready queue.

Note that in the case of timeslicing, or reschedule points executed from interrupts, any thread may be
suspended in any function.

Functions that are not reschedule may be invoked from either thread or interrupt context.

Functions that are reschedule may be invoked from thread context.

Functions that are reschedule but not sleep may be invoked from interrupt context.

sleep

The sleep attribute is used on a function that can cause the invoking thread to sleep.

Explanation This attribute is of relevance specifically when considering applications that use only non-
preemptible threads, because the kernel will not replace a running cooperative-only thread at a resched-
ule point unless that thread has explicitly invoked an operation that caused it to sleep.

This attribute does not imply the function will sleep unconditionally, but that the operation may require
an invoking thread that would have to suspend, wait, or invoke k_yield() before it can complete its
operation. This behavior may be mediated by no-wait.

Functions that are sleep are implicitly reschedule.

Functions that are sleep may be invoked from thread context.

Functions that are sleep may be invoked from interrupt and pre-kernel contexts if and only if invoked in
no-wait mode.

no-wait

The no-wait attribute is used on a function that is also sleep to indicate that a parameter to the function
can force an execution path that will not cause the invoking thread to sleep.

Explanation The paradigmatic case of a no-wait function is a function that takes a timeout, to which
K_NO_WAIT can be passed. The semantics of this special timeout value are to execute the function's
operation as long as it can be completed immediately, and to return an error code rather than sleep if it
cannot.

It is use of the no-wait feature that allows functions like k_sem_take() to be invoked from ISRs, since it
is not permitted to sleep in interrupt context.

A function with a no-wait path does not imply that taking that path guarantees the function is syn-
chronous.
Functions with this attribute may be invoked from interrupt and pre-kernel contexts only when the parameter selects the no-wait path.

isr-ok

The isr-ok attribute is used on a function to indicate that it works whether it is being invoked from interrupt or thread context.

**Explanation**  Any function that is not sleep is inherently isr-ok. Functions that are sleep are isr-ok if the implementation ensures that the documented behavior is implemented even if called from an interrupt context. This may be achieved by having the implementation detect the calling context and transfer the operation that would sleep to a thread, or by documenting that when invoked from a non-thread context the function will return a specific error (generally -EWOULDBLOCK).

Note that a function that is no-wait is safe to call from interrupt context only when the no-wait path is selected. isr-ok functions need not provide a no-wait path.

pre-kernel-ok

The pre-kernel-ok attribute is used on a function to indicate that it works as documented even when invoked before the kernel main thread has been started.

**Explanation**  This attribute is similar to isr-ok in function, but is intended for use by any API that is expected to be called in DEVICE_DEFINE() or SYS_INIT() calls that may be invoked with PRE_KERNEL_1 or PRE_KERNEL_2 initialization levels.

Generally a function that is pre-kernel-ok checks k_is_pre_kernel() when determining whether it can fulfill its required behavior. In many cases it would also check k_is_in_isr() so it can be isr-ok as well.

async

A function is async (i.e. asynchronous) if it may return before the operation it initiates has completed. An asynchronous function will generally provide a mechanism by which operation completion is reported, e.g. a callback or event.

A function that is not asynchronous is synchronous, i.e. the operation will always be complete when the function returns. As most functions are synchronous this behavior does not have a distinct attribute to identify it.

**Explanation**  Be aware that async is orthogonal to context-switching. Some APIs may provide completion information through a callback, but may suspend while waiting for the resource necessary to initiate the operation; an example is spi_transceive_async().

If a function is both no-wait and async then selecting the no-wait path only guarantees that the function will not sleep. It does not affect whether the operation will be completed before the function returns.

supervisor

The supervisor attribute is relevant only in user-mode applications, and indicates that the function cannot be invoked from user mode.
7.2 Audio

7.2.1 Audio Codec

Overview

The Audio Codec API provides access to digital audio codecs.

Configuration Options

Related configuration options:
- CONFIG_AUDIO_CODEC

API Reference

`group audio_codec_interface`

Abstraction for audio codecs.

Enums

`enum audio_pcm_rate_t`

PCM audio sample rates

Values:

- enumerator AUDIO_PCM_RATE_8K = 8000
- enumerator AUDIO_PCM_RATE_16K = 16000
- enumerator AUDIO_PCM_RATE_24K = 24000
- enumerator AUDIO_PCM_RATE_32K = 32000
- enumerator AUDIO_PCM_RATE_44P1K = 44100
- enumerator AUDIO_PCM_RATE_48K = 48000
- enumerator AUDIO_PCM_RATE_96K = 96000
- enumerator AUDIO_PCM_RATE_192K = 192000

`enum audio_pcm_width_t`

PCM audio sample bit widths
Values:

enumerator AUDIO_PCM_WIDTH_16_BITS = 16
enumerator AUDIO_PCM_WIDTH_20_BITS = 20
enumerator AUDIO_PCM_WIDTH_24_BITS = 24
enumerator AUDIO_PCM_WIDTH_32_BITS = 32

define enum audio_dai_type_t
    Digital Audio Interface (DAI) type
    Values:
    enumerator AUDIO_DAI_TYPE_I2S
    enumerator AUDIO_DAI_TYPE_INVALID

define enum audio_property_t
    Codec properties that can be set by audio_codec_set_property()
    Values:
    enumerator AUDIO_PROPERTY_OUTPUT_VOLUME
    enumerator AUDIO_PROPERTY_OUTPUT_MUTE

define enum audio_channel_t
    Audio channel identifiers to use in audio_codec_set_property()
    Values:
    enumerator AUDIO_CHANNEL_FRONT_LEFT
    enumerator AUDIO_CHANNEL_FRONT_RIGHT
    enumerator AUDIO_CHANNEL_LFE
    enumerator AUDIO_CHANNEL_FRONT_CENTER
    enumerator AUDIO_CHANNEL_REAR_LEFT
enumerator AUDIO_CHANNEL_REAR_RIGHT
enumerator AUDIO_CHANNEL_REAR_CENTER
enumerator AUDIO_CHANNEL_SIDE_LEFT
enumerator AUDIO_CHANNEL_SIDE_RIGHT
enumerator AUDIO_CHANNEL_ALL

Functions

static inline int audio_codec_configure(const struct device *dev, struct audio_codec_cfg *cfg)
Configure the audio codec.
Configure the audio codec device according to the configuration parameters provided as input

Parameters
• dev – Pointer to the device structure for codec driver instance.
• cfg – Pointer to the structure containing the codec configuration.

Returns 0 on success, negative error code on failure

static inline void audio_codec_start_output(const struct device *dev)
Set codec to start output audio playback.
Setup the audio codec device to start the audio playback

Parameters
• dev – Pointer to the device structure for codec driver instance.

static inline void audio_codec_stop_output(const struct device *dev)
Set codec to stop output audio playback.
Setup the audio codec device to stop the audio playback

Parameters
• dev – Pointer to the device structure for codec driver instance.

static inline int audio_codec_set_property(const struct device *dev, audio_property_t property,
audio_channel_t channel, audio_property_value_t val)
Set a codec property defined by audio_property_t.
Set a property such as volume level, clock configuration etc.

Parameters
• dev – Pointer to the device structure for codec driver instance.
• property – The codec property to set
• channel – The audio channel for which the property has to be set
• val – pointer to a property value of type audio_codec_property_value_t

Returns 0 on success, negative error code on failure
static inline int audio_codec_apply_properties(const struct device *dev)
    Atomically apply any cached properties.
    Following one or more invocations of audio_codec_set_property, that may have been cached
    by the driver, audio_codec_apply_properties can be invoked to apply all the properties as
    atomic as possible

    Parameters
    • dev – Pointer to the device structure for codec driver instance.

    Returns 0 on success, negative error code on failure

union audio_dai_cfg_t
    #include <codec.h> Digital Audio Interface Configuration Configuration is dependent on DAI
    type

Public Members

struct i2s_config i2s

struct audio_codec_cfg
    #include <codec.h> Codec configuration parameters

union audio_property_value_t
    #include <codec.h> Codec property values

Public Members

int vol

bool mute

7.2.2 Audio DMIC

Overview

The audio DMIC interface provides access to digital microphones.

Configuration Options

Related configuration options:
    • CONFIG_AUDIO_DMIC

API Reference

group audio_dmic_interface
    Abstraction for digital microphones.
 Enums

 enum dmic_state
   DMIC driver states
   Values:
   
   enumerator DMIC_STATE_UNINIT

   enumerator DMIC_STATE_INITIALIZED

   enumerator DMIC_STATE_CONFIGURED

   enumerator DMIC_STATE_ACTIVE

   enumerator DMIC_STATE_PAUSED

 enum dmic_trigger
   DMIC driver trigger commands
   Values:
   
   enumerator DMIC_TRIGGER_STOP

   enumerator DMIC_TRIGGER_START

   enumerator DMIC_TRIGGER_PAUSE

   enumerator DMIC_TRIGGER_RELEASE

   enumerator DMIC_TRIGGER_RESET

 enum pdm_lr
   PDM Channels LEFT / RIGHT
   Values:
   
   enumerator PDM_CHAN_LEFT

   enumerator PDM_CHAN_RIGHT
Functions

static inline uint32_t dmic_build_channel_map(uint8_t channel, uint8_t pdm, enum pdm_lr lr)
Build the channel map to populate struct pdm_chan_cfg

Returns the map of PDM controller and LEFT/RIGHT channel shifted to the bit position corresponding to the input logical channel value

Parameters
• channel – The logical channel number
• pdm – The PDM hardware controller number
• lr – LEFT/RIGHT channel within the chosen PDM hardware controller

static inline void dmic_parse_channel_map(uint32_t channel_map_lo, uint32_t channel_map_hi, uint8_t channel, uint8_t *pdm, enum pdm_lr *lr)
Helper function to parse the channel map in pdm_chan_cfg

Returns the PDM controller and LEFT/RIGHT channel corresponding to the channel map and the logical channel provided as input

Parameters
• channel_map_lo – Lower order/significant bits of the channel map
• channel_map_hi – Higher order/significant bits of the channel map
• channel – The logical channel number
• pdm – Pointer to the PDM hardware controller number
• lr – Pointer to the LEFT/RIGHT channel within the PDM controller

static inline uint32_t dmic_build_clk_skew_map(uint8_t pdm, uint8_t skew)
Build a bit map of clock skew values for each PDM channel

Returns the bit-map of clock skew value shifted to the bit position corresponding to the input PDM controller value

Parameters
• pdm – The PDM hardware controller number
• skew – The skew to apply for the clock output from the PDM controller

static inline int dmic_configure(const struct device *dev, struct dmic_cfg *cfg)
Configure the DMIC driver and controller(s)

Configures the DMIC driver device according to the number of channels, channel mapping, PDM I/O configuration, PCM stream configuration, etc.

Parameters
• dev – Pointer to the device structure for DMIC driver instance
• cfg – Pointer to the structure containing the DMIC configuration

Returns 0 on success, a negative error code on failure

static inline int dmic_trigger(const struct device *dev, enum dmic_trigger cmd)
Send a command to the DMIC driver

Sends a command to the driver to perform a specific action

Parameters
• dev – Pointer to the device structure for DMIC driver instance
• cmd – The command to be sent to the driver instance

Returns 0 on success, a negative error code on failure

static inline int dmic_read(const struct device *dev, uint8_t stream, void **buffer, size_t *size, int32_t timeout)
Read received decimated PCM data stream
Optionally waits for audio to be received and provides the received audio buffer from the requested stream

Parameters
• dev – Pointer to the device structure for DMIC driver instance
• stream – Stream identifier
• buffer – Pointer to the received buffer address
• size – Pointer to the received buffer size
• timeout – Timeout in milliseconds to wait in case audio is not yet received, or SYS_FOREVER_MS

Returns 0 on success, a negative error code on failure

struct pdm_io_cfg
#include <dmic.h> PDM Input/Output signal configuration

struct pcm_stream_cfg
#include <dmic.h> Configuration of the PCM streams to be output by the PDM hardware

struct pdm_chan_cfg
#include <dmic.h> Mapping/ordering of the PDM channels to logical PCM output channel

struct dmic_cfg
#include <dmic.h> Input configuration structure for the DMIC configuration API

7.2.3 I2S

Overview

The I2S (Inter-IC Sound) API provides support for the standard I2S interface as well as common non-standard extensions such as PCM Short/Long Frame Sync and Left/Right Justified Data Formats.

Configuration Options

Related configuration options:
• CONFIG_I2S

API Reference

group i2s_interface
I2S (Inter-IC Sound) Interface.

The I2S API provides support for the standard I2S interface standard as well as common non-standard extensions such as PCM Short/Long Frame Sync, Left/Right Justified Data Format.
Defines

I2S_FMT_DATA_FORMAT_SHIFT
Data Format bit field position.

I2S_FMT_DATA_FORMAT_MASK
Data Format bit field mask.

I2S_FMT_DATA_FORMAT_I2S
Standard I2S Data Format.
Serial data is transmitted in two's complement with the MSB first. Both Word Select (WS) and Serial Data (SD) signals are sampled on the rising edge of the clock signal (SCK). The MSB is always sent one clock period after the WS changes. Left channel data are sent first indicated by WS = 0, followed by right channel data indicated by WS = 1.

I2S_FMT_DATA_FORMAT_PCM_SHORT
PCM Short Frame Sync Data Format.
Serial data is transmitted in two's complement with the MSB first. Both Word Select (WS) and Serial Data (SD) signals are sampled on the falling edge of the clock signal (SCK). The falling edge of the frame sync signal (WS) indicates the start of the PCM word. The frame sync is one clock cycle long. An arbitrary number of data words can be sent in one frame.

I2S_FMT_DATA_FORMAT_PCM_LONG
PCM Long Frame Sync Data Format.
Serial data is transmitted in two's complement with the MSB first. Both Word Select (WS) and Serial Data (SD) signals are sampled on the falling edge of the clock signal (SCK). The rising edge of the frame sync signal (WS) indicates the start of the PCM word. The frame sync has an arbitrary length, however it has to fall before the start of the next frame. An arbitrary number of data words can be sent in one frame.
I2S_FMT_DATA_FORMAT_LEFT_JUSTIFIED

Left Justified Data Format.

Serial data is transmitted in two's complement with the MSB first. Both Word Select (WS) and Serial Data (SD) signals are sampled on the rising edge of the clock signal (SCK). The bits within the data word are left justified such that the MSB is always sent in the clock period following the WS transition. Left channel data are sent first indicated by WS = 1, followed by right channel data indicated by WS = 0.

```
<table>
<thead>
<tr>
<th>SCK</th>
<th>WS</th>
<th>SD</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

I2S_FMT_DATA_FORMAT_RIGHT_JUSTIFIED

Right Justified Data Format.

Serial data is transmitted in two's complement with the MSB first. Both Word Select (WS) and Serial Data (SD) signals are sampled on the rising edge of the clock signal (SCK). The bits within the data word are right justified such that the LSB is always sent in the clock period preceding the WS transition. Left channel data are sent first indicated by WS = 1, followed by right channel data indicated by WS = 0.

```
<table>
<thead>
<tr>
<th>SCK</th>
<th>WS</th>
<th>SD</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

I2S_FMT_DATA_ORDER_MSB
Send MSB first

I2S_FMT_DATA_ORDER_LSB
Send LSB first

I2S_FMT_DATA_ORDER_INV
Invert bit ordering, send LSB first

I2S_FMT_CLK_FORMAT_SHIFT
Data Format bit field position.

I2S_FMT_CLK_FORMAT_MASK
Data Format bit field mask.
I2S_FMT_BIT_CLK_INV
Invert bit clock

I2S_FMT_FRAME_CLK_INV
Invert frame clock

I2S_FMT_CLK_NF_NB
NF represents “Normal Frame” whereas IF represents “Inverted Frame” NB represents “Normal Bit Clk” whereas IB represents “Inverted Bit clk”

I2S_FMT_CLK_IF_NB

I2S_FMT_CLK_IF_IB

I2S_FMT_CLK_IF_IB

I2S_OPT_BIT_CLK_CONT
Run bit clock continuously

I2S_OPT_BIT_CLK_GATED
Run bit clock when sending data only

I2S_OPT_BIT_CLK_MASTER
I2S driver is bit clock master

I2S_OPT_BIT_CLK_SLAVE
I2S driver is bit clock slave

I2S_OPT_FRAME_CLK_MASTER
I2S driver is frame clock master

I2S_OPT_FRAME_CLK_SLAVE
I2S driver is frame clock slave

I2S_OPT_LOOPBACK
Loop back mode.
In loop back mode RX input will be connected internally to TX output. This is used primarily for testing.

I2S_OPT_PINGPONG
Ping pong mode.
In ping pong mode TX output will keep alternating between a ping buffer and a pong buffer. This is normally used in audio streams when one buffer is being populated while the other is being played (DMAed) and vice versa. So, in this mode, 2 sets of buffers fixed in size are used. Static Arrays are used to achieve this and hence they are never freed.
**Typedefs**

typedef uint8_t i2s_fmt_t

typedef uint8_t i2s_opt_t

** Enums **

eenum i2s_dir
   I2C Direction.
   *Values:*

   - enumerator I2S_DIR_RX
     Receive data
   
   - enumerator I2S_DIR_TX
     Transmit data
   
   - enumerator I2S_DIR_BOTH
     Both receive and transmit data

eneenum i2s_state
   Interface state
   *Values:*

   - enumerator I2S_STATE_NOT_READY
     The interface is not ready.
     
     The interface was initialized but is not yet ready to receive / transmit data. Call i2s_configure() to configure interface and change its state to READY.

   - enumerator I2S_STATE_READY
     The interface is ready to receive / transmit data.
   
   - enumerator I2S_STATE_RUNNING
     The interface is receiving / transmitting data.
   
   - enumerator I2S_STATE_STOPPING
     The interface is draining its transmit queue.

   - enumerator I2S_STATE_ERROR
     TX buffer underrun or RX buffer overrun has occurred.

eenum i2s_trigger_cmd
   Trigger command
   *Values:*

enumerator I2S_TRIGGER_START
Start the transmission / reception of data.

If I2S_DIR_TX is set some data has to be queued for transmission by the i2s_write() function. This trigger can be used in READY state only and changes the interface state to RUNNING.

enumerator I2S_TRIGGER_STOP
Stop the transmission / reception of data.

Stop the transmission / reception of data at the end of the current memory block. This trigger can be used in RUNNING state only and at first changes the interface state to STOPPING. When the current TX / RX block is transmitted / received the state is changed to READY. Subsequent START trigger will resume transmission / reception where it stopped.

enumerator I2S_TRIGGER_DRAIN
Empty the transmit queue.

Send all data in the transmit queue and stop the transmission. If the trigger is applied to the RX queue it has the same effect as I2S_TRIGGER_STOP. This trigger can be used in RUNNING state only and at first changes the interface state to STOPPING. When all TX blocks are transmitted the state is changed to READY.

enumerator I2S_TRIGGER_DROP
Discard the transmit / receive queue.

Stop the transmission / reception immediately and discard the contents of the respective queue. This trigger can be used in any state other than NOT_READY and changes the interface state to READY.

enumerator I2S_TRIGGER_PREPARE
Prepare the queues after underrun/overrun error has occurred.

This trigger can be used in ERROR state only and changes the interface state to READY.

Functions

```c
int i2s_configure(const struct device *dev, enum i2s_dir dir, const struct i2s_config *cfg)
```

Configure operation of a host I2S controller.

The dir parameter specifies if Transmit (TX) or Receive (RX) direction will be configured by data provided via cfg parameter.
The function can be called in NOT_READY or READY state only. If executed successfully the function will change the interface state to READY.

If the function is called with the parameter `cfg->frame_clk_freq` set to 0 the interface state will be changed to NOT_READY.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `dir` – Stream direction: RX, TX, or both, as defined by `I2S_DIR_*`. The `I2S_DIR_BOTH` value may not be supported by some drivers. For those, the RX and TX streams need to be configured separately.
- `cfg` – Pointer to the structure containing configuration parameters.

**Return values**

- 0 – If successful.
- -EINVAL – Invalid argument.
- -ENOSYS – `I2S_DIR_BOTH` value is not supported.

```c
static inline const struct i2s_config *i2s_config_get(const struct device *dev, enum i2s_dir dir)
```

Fetch configuration information of a host I2S controller.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance
- `dir` – Stream direction: RX or TX as defined by `I2S_DIR_*`

**Return values**

- Pointer to the structure containing configuration parameters, or
- NULL if un-configured

```c
static inline int i2s_read(const struct device *dev, void **mem_block, size_t *size)
```

Read data from the RX queue.

Data received by the I2S interface is stored in the RX queue consisting of memory blocks preallocated by this function from `rx_mem_slab` (as defined by `i2s_configure`). Ownership of the RX memory block is passed on to the user application which has to release it.

The data is read in chunks equal to the size of the memory block. If the interface is in READY state the number of bytes read can be smaller.

If there is no data in the RX queue the function will block waiting for the next RX memory block to fill in. This operation can timeout as defined by `i2s_configure`. If the timeout value is set to `K_NO_WAIT` the function is non-blocking.

Reading from the RX queue is possible in any state other than NOT_READY. If the interface is in the ERROR state it is still possible to read all the valid data stored in RX queue. Afterwards the function will return -EIO error.

**Parameters**

- `dev` – Pointer to the device structure for the driver instance.
- `mem_block` – Pointer to the RX memory block containing received data.
- `size` – Pointer to the variable storing the number of bytes read.

**Return values**

- 0 – If successful.
- -EIO – The interface is in NOT_READY or ERROR state and there are no more data blocks in the RX queue.
- -EBUSY – Returned without waiting.
- -EAGAIN – Waiting period timed out.
int i2s_buf_read(const struct device *dev, void *buf, size_t *size)
    Read data from the RX queue into a provided buffer.

Data received by the I2S interface is stored in the RX queue consisting of memory blocks preallocated by this function from rx_mem_slab (as defined by i2s_configure). Calling this function removes one block from the queue which is copied into the provided buffer and then freed.

The provided buffer must be large enough to contain a full memory block of data, which is parameterized for the channel via i2s_configure().

This function is otherwise equivalent to i2s_read().

Parameters
- dev – Pointer to the device structure for the driver instance.
- buf – Destination buffer for read data, which must be at least the as large as the configured memory block size for the RX channel.
- size – Pointer to the variable storing the number of bytes read.

Return values
- 0 – If successful.
- -EIO – The interface is in NOT_READY or ERROR state and there are no more data blocks in the RX queue.
- -EBUSY – Returned without waiting.
- -EAGAIN – Waiting period timed out.

static inline int i2s_write(const struct device *dev, void *mem_block, size_t size)
    Write data to the TX queue.

Data to be sent by the I2S interface is stored first in the TX queue. TX queue consists of memory blocks preallocated by the user from tx_mem_slab (as defined by i2s_configure). This function takes ownership of the memory block and will release it when all data are transmitted.

If there are no free slots in the TX queue the function will block waiting for the next TX memory block to be send and removed from the queue. This operation can timeout as defined by i2s_configure. If the timeout value is set to K_NO_WAIT the function is non-blocking.

Writing to the TX queue is only possible if the interface is in READY or RUNNING state.

Parameters
- dev – Pointer to the device structure for the driver instance.
- mem_block – Pointer to the TX memory block containing data to be sent.
- size – Number of bytes to write. This value has to be equal or smaller than the size of the memory block.

Return values
- 0 – If successful.
- -EIO – The interface is not in READY or RUNNING state.
- -EBUSY – Returned without waiting.
- -EAGAIN – Waiting period timed out.

int i2s_buf_write(const struct device *dev, void *buf, size_t size)
    Write data to the TX queue from a provided buffer.

This function acquires a memory block from the I2S channel TX queue and copies the provided data buffer into it. It is otherwise equivalent to i2s_write().

7.2. Audio
Parameters

- \texttt{dev} – Pointer to the device structure for the driver instance.
- \texttt{buf} – Pointer to a buffer containing the data to transmit.
- \texttt{size} – Number of bytes to write. This value has to be equal or smaller than the size of the channel's TX memory block configuration.

Return values

- 0 – If successful.
- -EIO – The interface is not in READY or RUNNING state.
- -EBUSY – Returned without waiting.
- -EAGAIN – Waiting period timed out.
- -ENOMEM – No memory in TX slab queue.
- -EINVAL – Size parameter larger than TX queue memory block.

\begin{verbatim}
int i2s_trigger(const struct device *dev, enum i2s_dir dir, enum i2s_trigger_cmd cmd)
    Send a trigger command.
\end{verbatim}

Parameters

- \texttt{dev} – Pointer to the device structure for the driver instance.
- \texttt{dir} – Stream direction: RX, TX, or both, as defined by I2S_DIR_*. The I2S_DIR_BOTH value may not be supported by some drivers. For those, triggering need to be done separately for the RX and TX streams.
- \texttt{cmd} – Trigger command.

Return values

- 0 – If successful.
- -EINVAL – Invalid argument.
- -EIO – The trigger cannot be executed in the current state or a DMA channel cannot be allocated.
- -ENOMEM – RX/TX memory block not available.
- -ENOSYS – I2S_DIR_BOTH value is not supported.

\begin{verbatim}
struct i2s_config
    #include <i2s.h> Interface configuration options.

Memory slab pointed to by the mem_slab field has to be defined and initialized by the user. For I2S driver to function correctly number of memory blocks in a slab has to be at least 2 per queue. Size of the memory block should be multiple of frame_size where frame_size = (channels * word_size_bytes). As an example 16 bit word will occupy 2 bytes, 24 or 32 bit word will occupy 4 bytes.

Please check Zephyr Kernel Primer for more information on memory slabs.
\end{verbatim}

Remark

When I2S data format is selected parameter channels is ignored, number of words in a frame is always 2.

\begin{verbatim}
Param word_size Number of bits representing one data word.
\end{verbatim}
Param channels  Number of words per frame.
Param format  Data stream format as defined by I2S_FMT_* constants.
Param options  Configuration options as defined by I2S_OPT_* constants.
Param frame_clk_freq  Frame clock (WS) frequency, this is sampling rate.
Param mem_slab  memory slab to store RX/TX data.
Param block_size  Size of one RX/TX memory block (buffer) in bytes.
Param timeout  Read/Write timeout. Number of milliseconds to wait in case TX queue is full or RX queue is empty, or 0, or SYS_FOREVER_MS.

7.3 Asynchronous Notifications

Zephyr APIs often include async functions where an operation is initiated and the application needs to be informed when it completes, and whether it succeeded. Using k_poll() is often a good method, but some application architectures may be more suited to a callback notification, and operations like enabling clocks and power rails may need to be invoked before kernel functions are available so a busy-wait for completion may be needed.

This API is intended to be embedded within specific subsystems such as On-Off Manager and other APIs that support async transactions. The subsystem wrappers are responsible for extracting operation-specific data from requests that include a notification element, and for invoking callbacks with the parameters required by the API.

A limitation is that this API is not suitable for System Calls because:

• sys_notify is not a kernel object;
• copying the notification content from userspace will break use of CONTAINER_OF in the implementing function;
• neither the spin-wait nor callback notification methods can be accepted from userspace callers.

Where a notification is required for an asynchronous operation invoked from a user mode thread the subsystem or driver should provide a syscall API that uses k_poll_signal for notification.

7.3.1 API Reference

group sys_notify.Apis

Typedefs

typedef void (*sys_notify_generic_callback)()

Generic signature used to notify of result completion by callback.

Functions with this role may be invoked from any context including pre-kernel, ISR, or cooperative or pre-emptible threads. Compatible functions must be isr-ok and not sleep.

Parameters that should generally be passed to such functions include:

• a pointer to a specific client request structure, i.e. the one that contains the sys_notify structure.
• the result of the operation, either as passed to `sys_notify_finalize()` or extracted afterwards using `sys_notify_fetch_result()`. Expected values are service-specific, but the value shall be non-negative if the operation succeeded, and negative if the operation failed.

Functions

```c
static inline uint32_t sys_notify_get_method(const struct sys_notify *notify)

int sys_notify_validate(struct sys_notify *notify)
Validate and initialize the notify structure.

This should be invoked at the start of any service-specific configuration validation. It ensures that the basic asynchronous notification configuration is consistent, and clears the result.

Note that this function does not validate extension bits (zeroed by async notify API init functions like `sys_notify_init_callback()`). It may fail to recognize that an uninitialized structure has been passed because only method bits of flags are tested against method settings. To reduce the chance of accepting an uninitialized operation service validation of structures that contain an `sys_notify` instance should confirm that the extension bits are set or cleared as expected.

Return values
• 0 – on successful validation and reinitialization
• -EINVAL – if the configuration is not valid.
```

```c
sys_notify_generic_callback sys_notify_finalize(struct sys_notify *notify, int res)
Record and signal the operation completion.

Parameters
• notify – pointer to the notification state structure.
• res – the result of the operation. Expected values are service-specific, but the value shall be non-negative if the operation succeeded, and negative if the operation failed.

Returns If the notification is to be done by callback this returns the generic version of the function to be invoked. The caller must immediately invoke that function with whatever arguments are expected by the callback. If notification is by spin-wait or signal, the notification has been completed by the point this function returns, and a null pointer is returned.
```

```c
static inline int sys_notify_fetch_result(const struct sys_notify *notify, int *result)
Check for and read the result of an asynchronous operation.

Parameters
• notify – pointer to the object used to specify asynchronous function behavior and store completion information.
• result – pointer to storage for the result of the operation. The result is stored only if the operation has completed.

Return values
• 0 – if the operation has completed.
• -EAGAIN – if the operation has not completed.
```

```c
static inline void sys_notify_init_spinwait(struct sys_notify *notify)
Initialize a notify object for spin-wait notification.

Clients that use this initialization receive no asynchronous notification, and instead must periodically check for completion using `sys_notify_fetch_result()`.
```
On completion of the operation the client object must be reinitialized before it can be re-used.

**Parameters**

- **notify** – pointer to the notification configuration object.

```c
static inline void sys_notify_init_signal(struct sys_notify *notify, struct k_poll_signal *sigp)
```

Initialize a notify object for (k_poll) signal notification.

Clients that use this initialization will be notified of the completion of operations through the provided signal.

On completion of the operation the client object must be reinitialized before it can be re-used.

**Note:** This capability is available only when CONFIG_POLL is selected.

**Parameters**

- **notify** – pointer to the notification configuration object.
- **sigp** – pointer to the signal to use for notification. The value must not be null. The signal must be reset before the client object is passed to the on-off service API.

```c
static inline void sys_notify_init_callback(struct sys_notify *notify, sys_notify_generic_callback handler)
```

Initialize a notify object for callback notification.

Clients that use this initialization will be notified of the completion of operations through the provided callback. Note that callbacks may be invoked from various contexts depending on the specific service; see `sys_notify_generic_callback`.

On completion of the operation the client object must be reinitialized before it can be re-used.

**Parameters**

- **notify** – pointer to the notification configuration object.
- **handler** – a function pointer to use for notification.

```c
static inline bool sys_notify_uses_callback(const struct sys_notify *notify)
```

Detect whether a particular notification uses a callback.

The generic handler does not capture the signature expected by the callback, and the translation to a service-specific callback must be provided by the service. This check allows abstracted services to reject callback notification requests when the service doesn't provide a translation function.

**Returns** true if and only if a callback is to be used for notification.

---

`struct sys_notify`

```c
#include <notify.h>
```

State associated with notification for an asynchronous operation.

Objects of this type are allocated by a client, which must use an initialization function (e.g. `sys_notify_init_signal()`) to configure them. Generally the structure is a member of a service-specific client structure, such as `onoff_client`.

Control of the containing object transfers to the service provider when a pointer to the object is passed to a service function that is documented to take control of the object, such as `onoff_service_request()`. While the service provider controls the object the client must not change any object fields. Control reverts to the client:

- if the call to the service API returns an error;
- when operation completion is posted. This may occur before the call to the service API returns.

### 7.3. Asynchronous Notifications
Operation completion is technically posted when the flags field is updated so that `sys_notify_fetch_result()` returns success. This will happen before the signal is posted or callback is invoked. Note that although the manager will no longer reference the `sys_notify` object past this point, the containing object may have state that will be referenced within the callback. Where callbacks are used control of the containing object does not revert to the client until the callback has been invoked. (Re-use within the callback is explicitly permitted.)

After control has reverted to the client the notify object must be reinitialized for the next operation.

The content of this structure is not public API to clients: all configuration and inspection should be done with functions like `sys_notify_init_callback()` and `sys_notify_fetch_result()`. However, services that use this structure may access certain fields directly.

```c
union method
#include <notify.h>

Public Members

struct k_poll_signal *signal

    sys_notify_generic_callback callback
```

### 7.4 Bluetooth

#### 7.4.1 Connection Management

The Zephyr Bluetooth stack uses an abstraction called `bt_conn` to represent connections to other devices. The internals of this struct are not exposed to the application, but a limited amount of information (such as the remote address) can be acquired using the `bt_conn_get_info()` API. Connection objects are reference counted, and the application is expected to use the `bt_conn_ref()` API whenever storing a connection pointer for a longer period of time, since this ensures that the object remains valid (even if the connection would get disconnected). Similarly the `bt_conn_unref()` API is to be used when releasing a reference to a connection.

An application may track connections by registering a `bt_conn_cb` struct using the `bt_conn_cb_register()` or `BT_CONN_CB_DEFINE` APIs. This struct lets the application define callbacks for connection & disconnection events, as well as other events related to a connection such as a change in the security level or the connection parameters. When acting as a central the application will also get hold of the connection object through the return value of the `bt_conn_create_le()` API.

**API Reference**

*group* `bt_conn`

  Connection management.

  **Defines**

  `BT_LE_CONN_PARAM_INIT(int_min, int_max, lat, to)`

  Initialize connection parameters.

  **Parameters**
```
• int_min – Minimum Connection Interval (N * 1.25 ms)
• int_max – Maximum Connection Interval (N * 1.25 ms)
• lat – Connection Latency
• to – Supervision Timeout (N * 10 ms)

BT_LE_CONN_PARAM(int_min, int_max, lat, to)
Helper to declare connection parameters inline

Parameters
• int_min – Minimum Connection Interval (N * 1.25 ms)
• int_max – Maximum Connection Interval (N * 1.25 ms)
• lat – Connection Latency
• to – Supervision Timeout (N * 10 ms)
```

```
BT_LE_CONN_PARAM_DEFAULT
Default LE connection parameters: Connection Interval: 30-50 ms Latency: 0 Timeout: 4 s
```

```
BT_CONN_LE_PHY_PARAM_INIT(_pref_tx_phy, _pref_rx_phy)
Initialize PHY parameters

Parameters
• _pref_tx_phy – Bitmask of preferred transmit PHYs.
• _pref_rx_phy – Bitmask of preferred receive PHYs.
```

```
BT_CONN_LE_PHY_PARAM(_pref_tx_phy, _pref_rx_phy)
Helper to declare PHY parameters inline

Parameters
• _pref_tx_phy – Bitmask of preferred transmit PHYs.
• _pref_rx_phy – Bitmask of preferred receive PHYs.
```

```
BT_CONN_LE_PHY_PARAM_1M
Only LE 1M PHY
```

```
BT_CONN_LE_PHY_PARAM_2M
Only LE 2M PHY
```

```
BT_CONN_LE_PHY_PARAM_CODED
Only LE Coded PHY.
```

```
BT_CONN_LE_PHY_PARAM_ALL
All LE PHYs.
```

```
BT_CONN_LE_DATA_LEN_PARAM_INIT(_tx_max_len, _tx_max_time)
Initialize transmit data length parameters

Parameters
• _tx_max_len – Maximum Link Layer transmission payload size in bytes.
• _tx_max_time – Maximum Link Layer transmission payload time in us.
```

```
BT_CONN_LE_DATA_LEN_PARAM(_tx_max_len, _tx_max_time)
Helper to declare transmit data length parameters inline

Parameters
• _tx_max_len – Maximum Link Layer transmission payload size in bytes.
```

7.4. Bluetooth
• `_tx_max_time` – Maximum Link Layer transmission payload time in us.

`BT_LE_DATA_LEN_PARAM_DEFAULT`
Default LE data length parameters.

`BT_LE_DATA_LEN_PARAM_MAX`
Maximum LE data length parameters.

`BT_CONN_INTERVAL_TO_MS(interval)`

`BT_CONN_ROLE_MASTER`
Connection role (central or peripheral)

`BT_CONN_ROLE_SLAVE`

`BT_CONN_LE_CREATE_PARAM_INIT(_options, _interval, _window)`
Initialize create connection parameters.

**Parameters**

• `_options` – Create connection options.
• `_interval` – Create connection scan interval (N * 0.625 ms).
• `_window` – Create connection scan window (N * 0.625 ms).

`BT_CONN_LE_CREATE_PARAM(_options, _interval, _window)`
Helper to declare create connection parameters inline

**Parameters**

• `_options` – Create connection options.
• `_interval` – Create connection scan interval (N * 0.625 ms).
• `_window` – Create connection scan window (N * 0.625 ms).

`BT_CONN_LE_CREATE_CONN`
Default LE create connection parameters. Scan continuously by setting scan interval equal to scan window.

`BT_CONN_LE_CREATE_CONN_AUTO`
Default LE create connection using filter accept list parameters. Scan window: 30 ms. Scan interval: 60 ms.

`BT_CONN_CB_DEFINE(_name)`
Register a callback structure for connection events.

**Parameters**

• `_name` – Name of callback structure.

`BT_PASSKEY_INVALID`
Special passkey value that can be used to disable a previously set fixed passkey.

`BT_BR_CONN_PARAM_INIT(role_switch)`
Initialize BR/EDR connection parameters.

**Parameters**

• `role_switch` – True if role switch is allowed

`BT_BR_CONN_PARAM(role_switch)`
Helper to declare BR/EDR connection parameters inline
Parameters

- role_switch – True if role switch is allowed

BT_BR_CONN_PARAM_DEFAULT
Default BR/EDR connection parameters: Role switch allowed

Enums

enum [anonymous]
Connection PHY options

Values:

enumerator BT_CONN_LE_PHY_OPT_NONE = 0
Convenience value when no options are specified.

enumerator BT_CONN_LE_PHY_OPT_CODED_S2 = BIT(0)
LE Coded using S=2 coding preferred when transmitting.

enumerator BT_CONN_LE_PHY_OPT_CODED_S8 = BIT(1)
LE Coded using S=8 coding preferred when transmitting.

enum [anonymous]
Connection Type

Values:

enumerator BT_CONN_TYPE_LE = BIT(0)
LE Connection Type

enumerator BT_CONN_TYPE_BR = BIT(1)
BR/EDR Connection Type

enumerator BT_CONN_TYPE_SCO = BIT(2)
SCO Connection Type

enumerator BT_CONN_TYPE_ISO = BIT(3)
ISO Connection Type

enumerator BT_CONN_TYPE_ALL = BT_CONN_TYPE_LE | BT_CONN_TYPE_BR | BT_CONN_TYPE_SCO | BT_CONN_TYPE_ISO
All Connection Type

enum [anonymous]
Values:

enumerator BT_CONN_ROLE_CENTRAL = 0

enumerator BT_CONN_ROLE_PERIPHERAL = 1

enum bt_conn_le_tx_power_phy

Values:
enumerator BT_CONN_LE_TX_POWER_PHY_NONE
    Convenience macro for when no PHY is set.

enumerator BT_CONN_LE_TX_POWER_PHY_1M
    LE 1M PHY

enumerator BT_CONN_LE_TX_POWER_PHY_2M
    LE 2M PHY

enumerator BT_CONN_LE_TX_POWER_PHY_CODED_S8
    LE Coded PHY using S=8 coding.

enumerator BT_CONN_LE_TX_POWER_PHY_CODED_S2
    LE Coded PHY using S=2 coding.

enum [anonymous]
    Values:

enumerator BT_CONN_LE_OPT_NONE = 0
    Convenience value when no options are specified.

enumerator BT_CONN_LE_OPT_CODED = BIT(0)
    Enable LE Coded PHY.

    Enable scanning on the LE Coded PHY.

enumerator BT_CONN_LE_OPT_NO_1M = BIT(1)
    Disable 1M PHY.

    Disable scanning on the LE 1M PHY.

    @note Requires @ref BT_CONN_LE_OPT_CODED.

enum bt_security_t
    Security level.
    Values:

enumerator BT_SECURITY_L0
    Level 0: Only for BR/EDR special cases, like SDP

enumerator BT_SECURITY_L1
    Level 1: No encryption and no authentication.

enumerator BT_SECURITY_L2
    Level 2: Encryption and no authentication (no MITM).

enumerator BT_SECURITY_L3
    Level 3: Encryption and authentication (MITM).

enumerator BT_SECURITY_L4
    Level 4: Authenticated Secure Connections and 128-bit key.
enumerator BT_SECURITY_FORCE_PAIR = BIT(7)
    Bit to force new pairing procedure, bit-wise OR with requested security level.

enum bt_security_err
    Values:

    enumerator BT_SECURITY_ERR_SUCCESS
        Security procedure successful.

    enumerator BT_SECURITY_ERR_AUTH_FAIL
        Authentication failed.

    enumerator BT_SECURITY_ERR_PIN_OR_KEY_MISSING
        PIN or encryption key is missing.

    enumerator BT_SECURITY_ERR_OOB_NOT_AVAILABLE
        OOB data is not available.

    enumerator BT_SECURITY_ERR_AUTH_REQUIREMENT
        The requested security level could not be reached.

    enumerator BT_SECURITY_ERR_PAIR_NOT_SUPPORTED
        Pairing is not supported.

    enumerator BT_SECURITY_ERR_PAIR_NOT_ALLOWED
        Pairing is not allowed.

    enumerator BT_SECURITY_ERR_INVALID_PARAM
        Invalid parameters.

    enumerator BT_SECURITY_ERR_KEY_REJECTED
        Distributed Key Rejected.

    enumerator BT_SECURITY_ERR_UNSPECIFIED
        Pairing failed but the exact reason could not be specified.

Functions

struct bt_conn *bt_conn_ref(struct bt_conn *conn)
    Increment a connection's reference count.
    Increment the reference count of a connection object.

    Note: Will return NULL if the reference count is zero.

Parameters

    • conn – Connection object.

Returns Connection object with incremented reference count, or NULL if the reference count is zero.

void bt_conn_unref(struct bt_conn *conn)
    Decrement a connection's reference count.
Decrement the reference count of a connection object.

**Parameters**
- conn – Connection object.

```c
void bt_conn_foreach(int type, void (*func)(struct bt_conn *conn, void *data), void *data)
```
Iterate through all existing connections.

**Parameters**
- type – Connection Type
- func – Function to call for each connection.
- data – Data to pass to the callback function.

```c
struct bt_conn *bt_conn_lookup_addr_le(uint8_t id, const bt_addr_le_t *peer)
```
Look up an existing connection by address.

Look up an existing connection based on the remote address.
The caller gets a new reference to the connection object which must be released with `bt_conn_unref()` once done using the object.

**Parameters**
- id – Local identity (in most cases BT_ID_DEFAULT).
- peer – Remote address.

**Returns** Connection object or NULL if not found.

```c
const bt_addr_le_t *bt_conn_get_dst(const struct bt_conn *conn)
```
Get destination (peer) address of a connection.

**Parameters**
- conn – Connection object.

**Returns** Destination address.

```c
uint8_t bt_conn_index(struct bt_conn *conn)
```
Get array index of a connection.

This function is used to map `bt_conn` to index of an array of connections. The array has CONFIG_BT_MAX_CONN elements.

**Parameters**
- conn – Connection object.

**Returns** Index of the connection object. The range of the returned value is 0..CONFIG_BT_MAX_CONN-1

```c
int bt_conn_get_info(const struct bt_conn *conn, struct bt_conn_info *info)
```
Get connection info.

**Parameters**
- conn – Connection object.
- info – Connection info object.

**Returns** Zero on success or (negative) error code on failure.

```c
int bt_conn_get_remote_info(struct bt_conn *conn, struct bt_conn_remote_info *remote_info)
```
Get connection info for the remote device.

**Note:** In order to retrieve the remote version (version, manufacturer and subversion) CONFIG_BT_REMOTE_VERSION must be enabled
Note: The remote information is exchanged directly after the connection has been established. The application can be notified about when the remote information is available through the remote_info_available callback.

Parameters
- `conn` – Connection object.
- `remote_info` – Connection remote info object.

Returns Zero on success or (negative) error code on failure.

Returns -EBUSY The remote information is not yet available.

```c
int bt_conn_le_get_tx_power_level(struct bt_conn *conn, struct bt_conn_le_tx_power *tx_power_level)
```

Get connection transmit power level.

Parameters
- `conn` – Connection object.
- `tx_power_level` – Transmit power level descriptor.

Returns Zero on success or (negative) error code on failure.

Returns -ENOBUFS HCI command buffer is not available.

```c
int bt_conn_le_param_update(struct bt_conn *conn, const struct bt_le_conn_param *param)
```

Update the connection parameters.

If the local device is in the peripheral role then updating the connection parameters will be delayed. This delay can be configured by through the CONFIG_BT_CONN_PARAM_UPDATE_TIMEOUT option.

Parameters
- `conn` – Connection object.
- `param` – Updated connection parameters.

Returns Zero on success or (negative) error code on failure.

```c
int bt_conn_le_data_len_update(struct bt_conn *conn, const struct bt_conn_le_data_len_param *param)
```

Update the connection transmit data length parameters.

Parameters
- `conn` – Connection object.
- `param` – Updated data length parameters.

Returns Zero on success or (negative) error code on failure.

```c
int bt_conn_le_phy_update(struct bt_conn *conn, const struct bt_conn_le_phy_param *param)
```

Update the preferred transmit and receive PHYs of the connection. Use `BT_GAP_LE_PHY_NONE` to indicate no preference.

Parameters
- `conn` – Connection object.
- `param` – Updated connection parameters.

Returns Zero on success or (negative) error code on failure.
int bt_conn_disconnect(struct bt_conn *conn, uint8_t reason)
Disconnect from a remote device or cancel pending connection.

Disconnect an active connection with the specified reason code or cancel pending outgoing connection.

The disconnect reason for a normal disconnect should be: BT_HCI_ERR_REMOTE_USER_TERM_CONN.

The following disconnect reasons are accepted:
- BT_HCI_ERR_AUTH_FAIL
- BT_HCI_ERR_REMOTE_USER_TERM_CONN
- BT_HCI_ERR_REMOTE_LOW_RESOURCES
- BT_HCI_ERR_REMOTE_POWER_OFF
- BT_HCI_ERR_UNSUPP_REMOTE_FEATURE
- BT_HCI_ERR_PAIRING_NOT_SUPPORTED
- BT_HCI_ERR_UNACCEPT_CONN_PARAM

Parameters
- conn – Connection to disconnect.
- reason – Reason code for the disconnection.

Returns
Zero on success or (negative) error code on failure.

int bt_conn_le_create(const bt_addr_le_t *peer, const struct bt_conn_le_create_param *create_param, const struct bt_le_conn_param *conn_param, struct bt_conn **conn)
Initiate an LE connection to a remote device.

Allows initiate new LE link to remote peer using its address.

The caller gets a new reference to the connection object which must be released with bt_conn_unref() once done using the object.

This uses the General Connection Establishment procedure.

The application must disable explicit scanning before initiating a new LE connection.

Parameters

Returns
Zero on success or (negative) error code on failure.

int bt_conn_le_create_auto(const struct bt_conn_le_create_param *create_param, const struct bt_le_conn_param *conn_param)
Automatically connect to remote devices in the filter accept list.

This uses the Auto Connection Establishment procedure. The procedure will continue until a single connection is established or the procedure is stopped through bt_conn_create_auto_stop.

To establish connections to all devices in the the filter accept list the procedure should be started again in the connected callback after a new connection has been established.

Parameters
- create_param – Create connection parameters
• conn_param – Initial connection parameters.

**Returns** Zero on success or (negative) error code on failure.

int bt_conn_create_auto_stop(void)
Stop automatic connect creation.

**Returns** Zero on success or (negative) error code on failure.

int bt_le_set_auto_conn(const bt_addr_le_t *addr, const struct bt_le_conn_param *param)
Automatically connect to remote device if it’s in range.

This function enables/disables automatic connection initiation. Every time the device loses the connection with peer, this connection will be re-established if connectable advertisement from peer is received.

**Note:** Auto connect is disabled during explicit scanning.

**Parameters**

• addr – Remote Bluetooth address.

• param – If non-NULL, auto connect is enabled with the given parameters. If NULL, auto connect is disabled.

**Returns** Zero on success or error code otherwise.

int bt_conn_set_security(struct bt_conn *conn, bt_security_t sec)
Set security level for a connection.

This function enable security (encryption) for a connection. If the device has bond information for the peer with sufficiently strong key encryption will be enabled. If the connection is already encrypted with sufficiently strong key this function does nothing.

If the device has no bond information for the peer and is not already paired then the pairing procedure will be initiated. If the device has bond information or is already paired and the keys are too weak then the pairing procedure will be initiated.

This function may return error if required level of security is not possible to achieve due to local or remote device limitation (e.g., input output capabilities), or if the maximum number of paired devices has been reached.

This function may return error if the pairing procedure has already been initiated by the local device or the peer device.

**Note:** When CONFIG_BT_SMP_SC_ONLY is enabled then the security level will always be level 4.

**Note:** When CONFIG_BT_SMP_OOB_LEGACY_PAIR_ONLY is enabled then the security level will always be level 3.

**Parameters**

• conn – Connection object.

• sec – Requested security level.

**Returns** 0 on success or negative error
bt_security_t bt_conn_get_security(struct bt_conn *conn)
Get security level for a connection.

Returns Connection security level

uint8_t bt_conn_enc_key_size(struct bt_conn *conn)
Get encryption key size.
This function gets encryption key size. If there is no security (encryption) enabled 0 will be returned.

Parameters
• conn – Existing connection object.

Returns Encryption key size.

void bt_conn_cb_register(struct bt_conn_cb *cb)
Register connection callbacks.
Register callbacks to monitor the state of connections.

Parameters
• cb – Callback struct. Must point to memory that remains valid.

void bt_set_bondable(bool enable)
Enable/disable bonding.
Set/clear the Bonding flag in the Authentication Requirements of SMP Pairing Request/Response data. The initial value of this flag depends on BT_BONDABLE Kconfig setting. For the vast majority of applications calling this function shouldn't be needed.

Parameters
• enable – Value allowing/disallowing to be bondable.

void bt_set_oob_data_flag(bool enable)
Allow/disallow remote OOB data to be used for pairing.
Set/clear the OOB data flag for SMP Pairing Request/Response data. The initial value of this flag depends on BT_OOB_DATA_PRESENT Kconfig setting.

Parameters
• enable – Value allowing/disallowing remote OOB data.

int bt_le_oob_set_legacy_tk(struct bt_conn *conn, const uint8_t *tk)
Set OOB Temporary Key to be used for pairing.
This function allows to set OOB data for the LE legacy pairing procedure. The function should only be called in response to the oob_data_request() callback provided that the legacy method is user pairing.

Parameters
• conn – Connection object
• tk – Pointer to 16 byte long TK array

Returns Zero on success or -EINVAL if NULL

int bt_le_oob_set_sc_data(struct bt_conn *conn, const struct bt_le_oob_sc_data *oobd_local, const struct bt_le_oob_sc_data *oobd_remote)
Set OOB data during LE Secure Connections (SC) pairing procedure.
This function allows to set OOB data during the LE SC pairing procedure. The function should only be called in response to the oob_data_request() callback provided that LE SC method is used for pairing.
The user should submit OOB data according to the information received in the callback. This may yield three different configurations: with only local OOB data present, with only remote OOB data present or with both local and remote OOB data present.

**Parameters**

- `conn` – Connection object
- `oobd_local` – Local OOB data or NULL if not present
- `oobd_remote` – Remote OOB data or NULL if not present

**Returns** Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
int bt_le_oob_get_sc_data(struct bt_conn *conn, const struct bt_le_oob_sc_data **oobd_local, const struct bt_le_oob_sc_data **oobd_remote)
```

Get OOB data used for LE Secure Connections (SC) pairing procedure.

This function allows to get OOB data during the LE SC pairing procedure that were set by the `bt_le_oob_set_sc_data()` API.

**Note:** The OOB data will only be available as long as the connection object associated with it is valid.

**Parameters**

- `conn` – Connection object
- `oobd_local` – Local OOB data or NULL if not set
- `oobd_remote` – Remote OOB data or NULL if not set

**Returns** Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
int bt_passkey_set(unsigned int passkey)
```

Set a fixed passkey to be used for pairing.

This API is only available when the `CONFIG_BT_FIXED_PASSKEY` configuration option has been enabled.

Sets a fixed passkey to be used for pairing. If set, the `pairing_confim()` callback will be called for all incoming pairings.

**Parameters**

- `passkey` – A valid passkey (0 - 999999) or BT_PASSKEY_INVALID to disable a previously set fixed passkey.

**Returns** 0 on success or a negative error code on failure.

```c
int bt_conn_auth_cb_register(const struct bt_conn_auth_cb *cb)
```

Register authentication callbacks.

Register callbacks to handle authenticated pairing. Passing NULL unregisters a previous callbacks structure.

**Parameters**

- `cb` – Callback struct.

**Returns** Zero on success or negative error code otherwise

```c
int bt_conn_auth_passkey_entry(struct bt_conn *conn, unsigned int passkey)
```

Reply with entered passkey.
This function should be called only after passkey_entry callback from `bt_conn_auth_cb` structure was called.

**Parameters**
- `conn` – Connection object.
- `passkey` – Entered passkey.

**Returns**
Zero on success or negative error code otherwise

```c
int bt_conn_auth_cancel(struct bt_conn *conn)
```
Cancel ongoing authenticated pairing.

This function allows to cancel ongoing authenticated pairing.

**Parameters**
- `conn` – Connection object.

**Returns**
Zero on success or negative error code otherwise

```c
int bt_conn_auth_passkey_confirm(struct bt_conn *conn)
```
Reply if passkey was confirmed to match by user.

This function should be called only after passkey_confirm callback from `bt_conn_auth_cb` structure was called.

**Parameters**
- `conn` – Connection object.

**Returns**
Zero on success or negative error code otherwise

```c
int bt_conn_auth_pairing_confirm(struct bt_conn *conn)
```
Reply if incoming pairing was confirmed by user.

This function should be called only after pairing_confirm callback from `bt_conn_auth_cb` structure was called if user confirmed incoming pairing.

**Parameters**
- `conn` – Connection object.

**Returns**
Zero on success or negative error code otherwise

```c
int bt_conn_auth_pincode_entry(struct bt_conn *conn, const char *pin)
```
Reply with entered PIN code.

This function should be called only after PIN code callback from `bt_conn_auth_cb` structure was called. It's for legacy 2.0 devices.

**Parameters**
- `conn` – Connection object.
- `pin` – Entered PIN code.

**Returns**
Zero on success or negative error code otherwise

```c
struct bt_conn *bt_conn_create_br(const bt_addr_t *peer, const struct bt_br_conn_param *param)
```
Initiate an BR/EDR connection to a remote device.

Allows initiate new BR/EDR link to remote peer using its address.

The caller gets a new reference to the connection object which must be released with `bt_conn_unref()` once done using the object.

**Parameters**
- `peer` – Remote address.
- `param` – Initial connection parameters.
Returns Valid connection object on success or NULL otherwise.

struct bt_conn *bt_conn_create_sco(const bt_addr_t *peer)
Initiate an SCO connection to a remote device.
Allows initiate new SCO link to remote peer using its address.
The caller gets a new reference to the connection object which must be released with
bt_conn_unref() once done using the object.

Parameters
• peer – Remote address.

Returns Valid connection object on success or NULL otherwise.

struct bt_le_conn_param
#include <conn.h> Connection parameters for LE connections

struct bt_conn_le_phy_info
#include <conn.h> Connection PHY information for LE connections

Public Members

uint8_t rx_phy
Connection transmit PHY

Public Members

uint8_t phy
   Input: 1M, 2M, Coded S2 or Coded S8

int8_t current_level
   Output: current transmit power level

int8_t max_level
   Output: maximum transmit power level

Public Members

uint32_t options
   Bit-field of create connection options.

uint16_t interval
   Scan interval (N * 0.625 ms)

uint16_t window
   Scan window (N * 0.625 ms)

uint16_t interval_coded
   Scan interval LE Coded PHY (N * 0.625 MS)
   Set zero to use same as LE 1M PHY scan interval

uint16_t window_coded
   Scan window LE Coded PHY (N * 0.625 MS)
   Set zero to use same as LE 1M PHY scan window.

uint16_t timeout
   Connection initiation timeout (N * 10 MS)
```
Set zero to use the default CONFIG_BT_CREATE_CONN_TIMEOUT timeout.

**Note:** Unused in `bt_conn_le_create_auto`

```c
struct bt_conn_cb

#include <conn.h> Connection callback structure.

This structure is used for tracking the state of a connection. It is registered with the help of the `bt_conn_cb_register()` API. It's permissible to register multiple instances of this `bt_conn_cb` type, in case different modules of an application are interested in tracking the connection state. If a callback is not of interest for an instance, it may be set to NULL and will as a consequence not be used for that instance.

**Public Members**

```c
void (*connected)(struct bt_conn *conn, uint8_t err)
```

A new connection has been established.

This callback notifies the application of a new connection. In case the `err` parameter is non-zero it means that the connection establishment failed.

`err` can mean either of the following:

- `BT_HCI_ERR_UNKNOWN_CONN_ID` Creating the connection started by `bt_conn_le_create` was canceled either by the user through `bt_conn_disconnect` or by the timeout in the host through `bt_conn_le_create_param` timeout parameter, which defaults to `CONFIG_BT_CREATE_CONN_TIMEOUT` seconds.
- `BT_HCI_ERR_ADV_TIMEOUT` High duty cycle directed connectable advertiser started by `bt_le_adv_start` failed to be connected within the timeout.

**Note:** If the connection was established from an advertising set then the advertising set cannot be restarted directly from this callback. Instead use the connected callback of the advertising set.

```c
Param conn New connection object.
Param err HCI error. Zero for success, non-zero otherwise.
```

```c
void (*disconnected)(struct bt_conn *conn, uint8_t reason)
```

A connection has been disconnected.

This callback notifies the application that a connection has been disconnected.

When this callback is called the stack still has one reference to the connection object. If the application in this callback tries to start either a connectable advertiser or create a new connection this might fail because there are no free connection objects available. To avoid this issue it is recommended to either start connectable advertise or create a new connection using `k_work_submit` or increase `CONFIG_BT_MAX_CONN`.

```c
Param conn Connection object.
Param reason BT_HCI_ERR_* reason for the disconnection.
```

```c
bool (*le_param_req)(struct bt_conn *conn, struct bt_le_conn_param *param)
```

LE connection parameter update request.

This callback notifies the application that a remote device is requesting to update the connection parameters. The application accepts the parameters by returning true, or rejects them by returning false. Before accepting, the application may also adjust the parameters to better suit its needs.
It is recommended for an application to have just one of these callbacks for simplicity. However, if an application registers multiple it needs to manage the potentially different requirements for each callback. Each callback gets the parameters as returned by previous callbacks, i.e. they are not necessarily the same ones as the remote originally sent.

If the application does not have this callback then the default is to accept the parameters.

**Param conn**  Connection object.
**Param param**  Proposed connection parameters.
**Return**  true to accept the parameters, or false to reject them.

```c
void (*le_param_updated)(struct bt_conn *conn, uint16_t interval, uint16_t latency, uint16_t timeout)
```

The parameters for an LE connection have been updated.

This callback notifies the application that the connection parameters for an LE connection have been updated.

**Param conn**  Connection object.
**Param interval**  Connection interval.
**Param latency**  Connection latency.
**Param timeout**  Connection supervision timeout.

```c
void (*identity_resolved)(struct bt_conn *conn, const bt_addr_le_t *rpa, const bt_addr_le_t *identity)
```

Remote Identity Address has been resolved.

This callback notifies the application that a remote Identity Address has been resolved.

**Param conn**  Connection object.
**Param rpa**  Resolvable Private Address.
**Param identity**  Identity Address.

```c
void (*security_changed)(struct bt_conn *conn, bt_security_t level, enum bt_security_err err)
```

The security level of a connection has changed.

This callback notifies the application that the security of a connection has changed.

The security level of the connection can either have been increased or remain unchanged. An increased security level means that the pairing procedure has been performed or the bond information from a previous connection has been applied. If the security level remains unchanged this means that the encryption key has been refreshed for the connection.

**Param conn**  Connection object.
**Param level**  New security level of the connection.
**Param err**  Security error. Zero for success, non-zero otherwise.

```c
void (*remote_info_available)(struct bt_conn *conn, struct bt_conn_remote_info *remote_info)
```

Remote information procedures has completed.

This callback notifies the application that the remote information has been retrieved from the remote peer.

**Param conn**  Connection object.
**Param remote_info**  Connection information of remote device.

```c
void (*le_phy_updated)(struct bt_conn *conn, struct bt_conn_le_phy_info *param)
```

The PHY of the connection has changed.

This callback notifies the application that the PHY of the connection has changed.

**Param conn**  Connection object.
**Param info**  Connection LE PHY information.
void (*le_data_len_updated)(struct bt_conn *conn, struct bt_conn_le_data_len_info *info)

The data length parameters of the connection has changed.

This callback notifies the application that the maximum Link Layer payload length or transmission time has changed.

**Param conn** Connection object.

**Param info** Connection data length information.

```c
struct bt_conn_oob_info
#include <conn.h> Info Structure for OOB pairing
```

**Public Types**

7.4. Bluetooth 189
### Public Members

#### `enum bt_security_err (*pairing_accept)(struct bt_conn *conn, const struct bt_conn_pairing_feat *const feat)`

Query to proceed incoming pairing or not.

On any incoming pairing req/rsp this callback will be called for the application to decide whether to allow for the pairing to continue.

The pairing info received from the peer is passed to assist making the decision.

As this callback is synchronous the application should return a response value immediately. Otherwise it may affect the timing during pairing. Hence, this information should not be conveyed to the user to take action.

The remaining callbacks are not affected by this, but do notice that other callbacks can be called during the pairing. Eg. if pairing_confirm is registered both will be called for Just-Works pairings.

This callback may be unregistered in which case pairing continues as if the Kconfig flag was not set.

This callback is not called for BR/EDR Secure Simple Pairing (SSP).

**Param conn** Connection where pairing is initiated.

**Param feat** Pairing req/rsp info.

#### `void (*passkey_display)(struct bt_conn *conn, unsigned int passkey)`

Display a passkey to the user.

When called the application is expected to display the given passkey to the user, with the expectation that the passkey will then be entered on the peer device. The passkey will be in the range of 0 - 999999, and is expected to be padded with zeroes so that six digits are always shown. E.g. the value 37 should be shown as 000037.

This callback may be set to NULL, which means that the local device lacks the ability do display a passkey. If set to non-NULL the cancel callback must also be provided, since this is the only way the application can find out that it should stop displaying the passkey.

**Param conn** Connection where pairing is currently active.

**Param passkey** Passkey to show to the user.

#### `void (*passkey_entry)(struct bt_conn *conn)`

Request the user to enter a passkey.

When called the user is expected to enter a passkey. The passkey must be in the range of 0 - 999999, and should be expected to be zero-padded, as that's how the peer device will typically be showing it (e.g. 37 would be shown as 000037).
Once the user has entered the passkey its value should be given to the stack using the
\texttt{bt\_conn\_auth\_passkey\_entry()} API.

This callback may be set to NULL, which means that the local device lacks the ability to
enter a passkey. If set to non-NULL the cancel callback must also be provided, since this is
the only way the application can find out that it should stop requesting the user to enter
a passkey.

\textbf{Param conn}  \hspace{1em} Connection where pairing is currently active.

\begin{verbatim}
void (*passkey_confirm)(struct bt_conn *conn, unsigned int passkey)
Request the user to confirm a passkey.
\end{verbatim}

When called the user is expected to confirm that the given passkey is also shown on the
peer device. The passkey will be in the range of 0 - 999999, and should be zero-padded
to always be six digits (e.g. 37 would be shown as 000037).

Once the user has confirmed the passkey to match, the \texttt{bt\_conn\_auth\_passkey\_confirm()} API should be called. If the user concluded that the passkey doesn't match the
\texttt{bt\_conn\_auth\_cancel()} API should be called.

This callback may be set to NULL, which means that the local device lacks the ability to
confirm a passkey. If set to non-NULL the cancel callback must also be provided, since
this is the only way the application can find out that it should stop requesting the user to
confirm a passkey.

\textbf{Param conn}  \hspace{1em} Connection where pairing is currently active.

\textbf{Param passkey}  \hspace{1em} Passkey to be confirmed.

\begin{verbatim}
void (*oob_data_request)(struct bt_conn *conn, struct bt_conn_oob_info *info)
Request the user to provide Out of Band (OOB) data.
\end{verbatim}

When called the user is expected to provide OOB data. The required data are indicated
by the information structure.

For LE Secure Connections OOB pairing, the user should provide local OOB data, remote
OOB data or both depending on their availability. Their value should be given to the stack
using the \texttt{bt\_le\_oob\_set\_sc\_data()} API.

This callback must be set to non-NULL in order to support OOB pairing.

\textbf{Param conn}  \hspace{1em} Connection where pairing is currently active.

\textbf{Param info}  \hspace{1em} OOB pairing information.

\begin{verbatim}
void (*cancel)(struct bt_conn *conn)
Cancel the ongoing user request.
\end{verbatim}

This callback will be called to notify the application that it should cancel any previous
user request (passkey display, entry or confirmation).

This may be set to NULL, but must always be provided whenever the passkey_display,
passkey_entry passkey_confirm or pairing_confirm callback has been provided.

\textbf{Param conn}  \hspace{1em} Connection where pairing is currently active.

\begin{verbatim}
void (*pairing_confirm)(struct bt_conn *conn)
Request confirmation for an incoming pairing.
\end{verbatim}

This callback will be called to confirm an incoming pairing request where none of the
other user callbacks is applicable.

If the user decides to accept the pairing the \texttt{bt\_conn\_auth\_pairing\_confirm()} API should
be called. If the user decides to reject the pairing the \texttt{bt\_conn\_auth\_cancel()} API should
be called.

This callback may be set to NULL, which means that the local device lacks the ability to
confirm a pairing request. If set to non-NULL the cancel callback must also be provided,
since this is the only way the application can find out that it should stop requesting the
user to confirm a pairing request.

**Param conn**  Connection where pairing is currently active.

```c
void (*pincode_entry)(struct bt_conn *conn, bool highsec)
```
Request the user to enter a passkey.

This callback will be called for a BR/EDR (Bluetooth Classic) connection where pairing
is being performed. Once called the user is expected to enter a PIN code with a length
between 1 and 16 digits. If the `highsec` parameter is set to true the PIN code must be 16
digits long.

Once entered, the PIN code should be given to the stack using the
`bt_conn_auth_pincode_entry()` API.

This callback may be set to NULL, however in that case pairing over BR/EDR will not be
possible. If provided, the cancel callback must be provided as well.

**Param conn**  Connection where pairing is currently active.

**Param highsec**  true if 16 digit PIN is required.

```c
void (*pairing_complete)(struct bt_conn *conn, bool bonded)
```
notify that pairing procedure was complete.

This callback notifies the application that the pairing procedure has been completed.

**Param conn**  Connection object.

**Param bonded**  Bond information has been distributed during the pairing proce-
dure.

```c
void (*pairing_failed)(struct bt_conn *conn, enum bt_security_err reason)
```
notify that pairing process has failed.

**Param conn**  Connection object.

**Param reason**  Pairing failed reason

```c
void (*bond_deleted)(uint8_t id, const bt_addr_le_t *peer)
```
Notify that bond has been deleted.

This callback notifies the application that the bond information for the remote peer has
been deleted

**Param id**  Which local identity had the bond.

**Param peer**  Remote address.

```c
struct bt_br_conn_param
#include <conn.h>  Connection parameters for BR/EDR connections
```

### 7.4.2 Bluetooth Controller

**API Reference**

**group bt_ctrl**

Bluetooth Controller.

**Functions**

```c
void bt_ctrl_set_public_addr(const uint8_t *addr)
```
Set public address for controller.

Should be called before `bt_enable()`.
7.4.3 Cryptography

API Reference

```c
int bt_rand(void *buf, size_t len)
```
Generate random data.

A random number generation helper which utilizes the Bluetooth controller's own RNG.

**Parameters**
- `buf` – Buffer to insert the random data
- `len` – Length of random data to generate

**Returns** Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error

```c
int bt_encrypt_le(const uint8_t key[16], const uint8_t plaintext[16], uint8_t enc_data[16])
```
AES encrypt little-endian data.

An AES encrypt helper is used to request the Bluetooth controller's own hardware to encrypt the plaintext using the key and returns the encrypted data.

**Parameters**
- `key` – 128 bit LS byte first key for the encryption of the plaintext
- `plaintext` – 128 bit LS byte first plaintext data block to be encrypted
- `enc_data` – 128 bit LS byte first encrypted data block

**Returns** Zero on success or error code otherwise.

```c
int bt_encrypt_be(const uint8_t key[16], const uint8_t plaintext[16], uint8_t enc_data[16])
```
AES encrypt big-endian data.

An AES encrypt helper is used to request the Bluetooth controller's own hardware to encrypt the plaintext using the key and returns the encrypted data.

**Parameters**
- `key` – 128 bit MS byte first key for the encryption of the plaintext
- `plaintext` – 128 bit MS byte first plaintext data block to be encrypted
- `enc_data` – 128 bit MS byte first encrypted data block

**Returns** Zero on success or error code otherwise.

```c
int bt_ccm_decrypt(const uint8_t key[16], uint8_t nonce[13], const uint8_t *enc_data, size_t len, const uint8_t *aad, size_t aad_len, uint8_t *plaintext, size_t mic_size)
```
Decrypt big-endian data with AES-CCM.

Assumes that the MIC follows directly after the encrypted data.

7.4. Bluetooth
Parameters

- **key** – 128 bit MS byte first key
- **nonce** – 13 byte MS byte first nonce
- **enc_data** – Encrypted data
- **len** – Length of the encrypted data
- **aad** – Additional input data
- **aad_len** – Additional input data length
- **plaintext** – Plaintext buffer to place result in
- **mic_size** – Size of the trailing MIC (in bytes)

Return values

- 0 – Successfully decrypted the data.
- -EINVAL – Invalid parameters.
- -EBADMSG – Authentication failed.

```c
int bt_ccm_encrypt(const uint8_t key[16], uint8_t nonce[13], const uint8_t *plaintext, size_t len, const uint8_t *aad, size_t aad_len, uint8_t *enc_data, size_t mic_size)
```

Encrypt big-endian data with AES-CCM.

Encrypts and generates a MIC from `plaintext` with AES-CCM, as described in [https://tools.ietf.org/html/rfc3610](https://tools.ietf.org/html/rfc3610).

Places the MIC directly after the encrypted data.

Parameters

- **key** – 128 bit MS byte first key
- **nonce** – 13 byte MS byte first nonce
- **plaintext** – Plaintext buffer to encrypt
- **len** – Length of the encrypted data
- **aad** – Additional input data
- **aad_len** – Additional input data length
- **enc_data** – Buffer to place encrypted data in
- **mic_size** – Size of the trailing MIC (in bytes)

Return values

- 0 – Successfully encrypted the data.
- -EINVAL – Invalid parameters.

### 7.4.4 Data Buffers

**API Reference**

```c
group bt_buf
    Data buffers.
```
Defines

BT_BUF_RESERVE

BT_BUF_SIZE(size)
   Helper to include reserved HCI data in buffer calculations

BT_BUF_ACL_SIZE(size)
   Helper to calculate needed buffer size for HCI ACL packets

BT_BUF_EVT_SIZE(size)
   Helper to calculate needed buffer size for HCI Event packets.

BT_BUF_CMD_SIZE(size)
   Helper to calculate needed buffer size for HCI Command packets.

BT_BUF_ISO_SIZE(size)
   Helper to calculate needed buffer size for HCI ISO packets.

BT_BUF_ACL_RX_SIZE
   Data size needed for HCI ACL RX buffers

BT_BUF_EVT_RX_SIZE
   Data size needed for HCI Event RX buffers

BT_BUF_ISO_RX_SIZE

BT_BUF_ISO_RX_COUNT

BT_BUF_RX_SIZE
   Data size needed for HCI ACL, HCI ISO or Event RX buffers

BT_BUF_RX_COUNT
   Buffer count needed for HCI ACL, HCI ISO or Event RX buffers

BT_BUF_CMD_TX_SIZE
   Data size needed for HCI Command buffers.

Enums

enum bt_buf_type
   Possible types of buffers passed around the Bluetooth stack
   Values:

   enumerator BT_BUF_CMD
      HCI command

   enumerator BT_BUF_EVT
      HCI event

   enumerator BT_BUF_ACL_OUT
      Outgoing ACL data

7.4. Bluetooth
enumerator BT_BUF_ACL_IN
   Incoming ACL data

enumerator BT_BUF_ISO_OUT
   Outgoing ISO data

enumerator BT_BUF_ISO_IN
   Incoming ISO data

enumerator BT_BUF_H4
   H:4 data

Functions

struct net_buf *bt_buf_get_rx(enum bt_buf_type type, k_timeout_t timeout)
Allocate a buffer for incoming data
This will set the buffer type so bt_buf_set_type() does not need to be explicitly called before bt_recv_prio().

Parameters

• type – Type of buffer. Only BT_BUF_EVT and BT_BUF_ACL_IN are allowed.
• timeout – Non-negative waiting period to obtain a buffer or one of the special values K_NO_WAIT and K_FOREVER.

Returns A new buffer.

struct net_buf *bt_buf_get_tx(enum bt_buf_type type, k_timeout_t timeout, const void *data, size_t size)
Allocate a buffer for outgoing data
This will set the buffer type so bt_buf_set_type() does not need to be explicitly called before bt_send().

Parameters

• type – Type of buffer. Only BT_BUF_CMD, BT_BUF_ACL_OUT or BT_BUF_H4, when operating on H:4 mode, are allowed.
• timeout – Non-negative waiting period to obtain a buffer or one of the special values K_NO_WAIT and K_FOREVER.
• data – Initial data to append to buffer.
• size – Initial data size.

Returns A new buffer.

struct net_buf *bt_buf_get_cmd_complete(k_timeout_t timeout)
Allocate a buffer for an HCI Command Complete/Status Event
This will set the buffer type so bt_buf_set_type() does not need to be explicitly called before bt_recv_prio().

Parameters

• timeout – Non-negative waiting period to obtain a buffer or one of the special values K_NO_WAIT and K_FOREVER.

Returns A new buffer.
struct net_buf *bt_buf_get_evt(uint8_t evt, bool discardable, k_timeout_t timeout)

Allocate a buffer for an HCI Event

This will set the buffer type so bt_buf_set_type() does not need to be explicitly called before bt_recv_prio() or bt_recv().

Parameters

• evt – HCI event code
• discardable – Whether the driver considers the event discardable.
• timeout – Non-negative waiting period to obtain a buffer or one of the special values K_NO_WAIT and K_FOREVER.

Returns A new buffer.

static inline void bt_buf_set_type(struct net_buf *buf, enum bt_buf_type type)

Set the buffer type

Parameters

• buf – Bluetooth buffer
• type – The BT_* type to set the buffer to

static inline enum bt_buf_type bt_buf_get_type(struct net_buf *buf)

Get the buffer type

Parameters

• buf – Bluetooth buffer

Returns The BT_* type to of the buffer

struct bt_buf_data
#include <buf.h> This is a base type for bt_buf user data.

7.4.5 Generic Access Profile (GAP)

API Reference

group bt_gap

Generic Access Profile.

Defines

BT_ID_DEFAULT

Convenience macro for specifying the default identity. This helps make the code more readable, especially when only one identity is supported.

BT_DATA(_type, _data, _data_len)

Helper to declare elements of bt_data arrays.

This macro is mainly for creating an array of struct bt_data elements which is then passed to e.g. bt_le_adv_start().

Parameters

• _type – Type of advertising data field
• _data – Pointer to the data field payload
• _data_len – Number of bytes behind the _data pointer
BT_DATA_BYTES(_type, _bytes...)  
Helper to declare elements of bt_data arrays.  
This macro is mainly for creating an array of struct bt_data elements which is then passed to e.g. bt_le_adv_start().

Parameters
- _type – Type of advertising data field  
- _bytes – Variable number of single-byte parameters

BT_LE_ADV_PARAM_INIT(_options, _int_min, _int_max, _peer)  
Initialize advertising parameters.

Parameters
- _options – Advertising Options  
- _int_min – Minimum advertising interval  
- _int_max – Maximum advertising interval  
- _peer – Peer address, set to NULL for undirected advertising or address of peer for directed advertising.

BT_LE_ADV_PARAM(_options, _int_min, _int_max, _peer)  
Helper to declare advertising parameters inline.

Parameters
- _options – Advertising Options  
- _int_min – Minimum advertising interval  
- _int_max – Maximum advertising interval  
- _peer – Peer address, set to NULL for undirected advertising or address of peer for directed advertising.

BT_LE_ADV_CONN_DIR(_peer)  

BT_LE_ADV_CONN  

BT_LE_ADV_CONN_NAME  

BT_LE_ADV_CONN_NAME_AD  

BT_LE_ADV_CONN_DIR_LOW_DUTY(_peer)  

BT_LE_ADV_NCONN  
Non-connectable advertising with private address  

BT_LE_ADV_NCONN_NAME  
Non-connectable advertising with BT_LE_ADV_OPT_USE_NAME  

BT_LE_ADV_NCONN_IDENTITY  
Non-connectable advertising with BT_LE_ADV_OPT_USE_IDENTITY  

BT_LE_EXT_ADV_CONN_NAME  
Connectable extended advertising with BT_LE_ADV_OPT_USE_NAME
**BT_LE_EXT_ADV_SCAN_NAME**  
Scannable extended advertising with *BT_LE_ADV_OPT_USE_NAME*

**BT_LE_EXT_ADV_NCONN**  
Non-connectable extended advertising with private address

**BT_LE_EXT_ADV_NCONN_NAME**  
Non-connectable extended advertising with *BT_LE_ADV_OPT_USE_NAME*

**BT_LE_EXT_ADV_NCONN_IDENTITY**  
Non-connectable extended advertising with *BT_LE_ADV_OPT_USE_IDENTITY*

**BT_LE_EXT_ADV_CODED_NCONN**  
Non-connectable extended advertising on coded PHY with private address

**BT_LE_EXT_ADV_CODED_NCONN_NAME**  
Non-connectable extended advertising on coded PHY with *BT_LE_ADV_OPT_USE_NAME*

**BT_LE_EXT_ADV_CODED_NCONN_IDENTITY**  
Non-connectable extended advertising on coded PHY with *BT_LE_ADV_OPT_USE_IDENTITY*

**BT_LE_EXT_ADV_START_PARAM_INIT(_timeout, _n_evts)**  
Helper to initialize extended advertising start parameters inline

**Parameters**
- `_timeout` – Advertiser timeout
- `_n_evts` – Number of advertising events

**BT_LE_EXT_ADV_START_PARAM(_timeout, _n_evts)**  
Helper to declare extended advertising start parameters inline

**Parameters**
- `_timeout` – Advertiser timeout
- `_n_evts` – Number of advertising events

**BT_LE_EXT_ADV_START_DEFAULT**

**BT_LE_PER_ADV_PARAM_INIT(_int_min, _int_max, _options)**  
Helper to declare periodic advertising parameters inline

**Parameters**
- `_int_min` – Minimum periodic advertising interval
- `_int_max` – Maximum periodic advertising interval
- `_options` – Periodic advertising properties bitfield.

**BT_LE_PER_ADV_PARAM(_int_min, _int_max, _options)**  
Helper to declare periodic advertising parameters inline

**Parameters**
- `_int_min` – Minimum periodic advertising interval
- `_int_max` – Maximum periodic advertising interval
- `_options` – Periodic advertising properties bitfield.
BT_LE_PER_ADV_DEFAULT

BT_LE_SCAN_OPT_FILTER_WHITELIST

BT_LE_SCAN_PARAM_INIT(_type, _options, _interval, _window)
Initialize scan parameters.

Parameters
• _type – Scan Type, BT_LE_SCAN_TYPE_ACTIVE or BT_LE_SCAN_TYPE_PASSIVE.
• _options – Scan options
• _interval – Scan Interval (N * 0.625 ms)
• _window – Scan Window (N * 0.625 ms)

BT_LE_SCAN_PARAM(_type, _options, _interval, _window)
Helper to declare scan parameters inline.

Parameters
• _type – Scan Type, BT_LE_SCAN_TYPE_ACTIVE or BT_LE_SCAN_TYPE_PASSIVE.
• _options – Scan options
• _interval – Scan Interval (N * 0.625 ms)
• _window – Scan Window (N * 0.625 ms)

BT_LE_SCAN_ACTIVE
Helper macro to enable active scanning to discover new devices.

BT_LE_SCAN_PASSIVE
Helper macro to enable passive scanning to discover new devices.

This macro should be used if information required for device identification (e.g., UUID) are known to be placed in Advertising Data.

BT_LE_SCAN_CODED_ACTIVE
Helper macro to enable active scanning to discover new devices. Include scanning on Coded PHY in addition to 1M PHY.

BT_LE_SCAN_CODED_PASSIVE
Helper macro to enable passive scanning to discover new devices. Include scanning on Coded PHY in addition to 1M PHY.

This macro should be used if information required for device identification (e.g., UUID) are known to be placed in Advertising Data.

Typedefs
typedef void (*bt_ready_cb_t)(int err)
Callback for notifying that Bluetooth has been enabled.

Param err zero on success or (negative) error code otherwise.
typedef void bt_le_scan_cb_t(const bt_addr_le_t *addr, int8_t rssi, uint8_t adv_type, struct net_buf_simple *buf)

Callback type for reporting LE scan results.

A function of this type is given to the bt_le_scan_start() function and will be called for any discovered LE device.

**Param addr**  Advertiser LE address and type.

**Param rssi**  Strength of advertiser signal.

**Param adv_type**  Type of advertising response from advertiser.

**Param buf**  Buffer containing advertiser data.

typedef void bt_br_discovery_cb_t(struct bt_br_discovery_result *results, size_t count)

Callback type for reporting BR/EDR discovery (inquiry) results.

A callback of this type is given to the bt_br_discovery_start() function and will be called at the end of the discovery with information about found devices populated in the results array.

**Param results**  Storage used for discovery results

**Param count**  Number of valid discovery results.

### Enums

enum [anonymous]

Advertising options

**Values:**

enumerator BT_LE_ADV_OPT_NONE = 0

Convenience value when no options are specified.

enumerator BT_LE_ADV_OPT_CONNECTABLE = BIT(0)

Advertise as connectable.

Advertise as connectable. If not connectable then the type of advertising is determined by providing scan response data. The advertiser address is determined by the type of advertising and/or enabling privacy CONFIG_BT_PRIVACY.

enumerator BT_LE_ADV_OPT_ONE_TIME = BIT(1)

Advertise one time.

Don’t try to resume connectable advertising after a connection. This option is only meaningful when used together with BT_LE_ADV_OPT_CONNECTABLE. If set the advertising will be stopped when bt_le_adv_stop() is called or when an incoming (peripheral) connection happens. If this option is not set the stack will take care of keeping advertising enabled even as connections occur. If Advertising directed or the advertiser was started with bt_le_ext_adv_start then this behavior is the default behavior and this flag has no effect.

enumerator BT_LE_ADV_OPT_USE_IDENTITY = BIT(2)

Advertise using identity address.

Advertise using the identity address as the advertiser address.

**Note:** The address used for advertising will not be the same as returned by bt_le_oob_get_local, instead bt_id_get should be used to get the LE address.
Warning: This will compromise the privacy of the device, so care must be taken when using this option.

enumerator BT_LE_ADV_OPT_USE_NAME = BIT(3)
Advertise using GAP device name.

- Include the GAP device name automatically when advertising.
- By default the GAP device name is put at the end of the scan response data.
- When advertising using @ref BT_LE_ADV_OPT_EXT_ADV and not @ref BT_LE_ADV_OPT_SCANNABLE then it will be put at the end of the advertising data.
- If the GAP device name does not fit into advertising data it will be converted to a shortened name if possible.
- @ref BT_LE_ADV_OPT_FORCE_NAME_IN_AD can be used to force the device name to appear in the advertising data of an advert with scan response data.

The application can set the device name itself by including the following in the advertising data.

```c
@code
BT_DATA(BT_DATA_NAME_COMPLETE, name, sizeof(name) - 1)
@endcode
```

enumerator BT_LE_ADV_OPT_DIR_MODE_LOW_DUTY = BIT(4)
Low duty cycle directed advertising.
Use low duty directed advertising mode, otherwise high duty mode will be used.

enumerator BT_LE_ADV_OPT_DIR_ADDR_RPA = BIT(5)
Directed advertising to privacy-enabled peer.
Enable use of Resolvable Private Address (RPA) as the target address in directed advertisements. This is required if the remote device is privacy-enabled and supports address resolution of the target address in directed advertisement. It is the responsibility of the application to check that the remote device supports address resolution of directed advertisements by reading its Central Address Resolution characteristic.

enumerator BT_LE_ADV_OPT_FILTER_SCAN_REQ = BIT(6)
Use filter accept list to filter devices that can request scan response data.

enumerator BT_LE_ADV_OPT_FILTER_CONN = BIT(7)
Use filter accept list to filter devices that can connect.

enumerator BT_LE_ADV_OPT_NOTIFY_SCAN_REQ = BIT(8)
Notify the application when a scan response data has been sent to an active scanner.

enumerator BT_LE_ADV_OPT_SCANNABLE = BIT(9)
Support scan response data.
When used together with BT_LE_ADV_OPT_EXT_ADV then this option cannot be used together with the BT_LE_ADV_OPT_CONNECTABLE option. When used together with BT_LE_ADV_OPT_EXT_ADV then scan response data must be set.

enumerator BT_LE_ADV_OPT_EXT_ADV = BIT(10)
Advertise with extended advertising.
This option enables extended advertising in the advertising set. In extended advertising the advertising set will send a small header packet on the three primary advertising channels. This small header points to the advertising data packet that will be sent on one of the 37 secondary advertising channels. The advertiser will send primary advertising on LE 1M PHY, and secondary advertising on LE 2M PHY. Connections will be established on LE 2M PHY.

Without this option the advertiser will send advertising data on the three primary advertising channels.

**Note:** Enabling this option requires extended advertising support in the peer devices scanning for advertisement packets.

**enumerator** BT_LE_ADV_OPT_NO_2M = BIT(11)
Disable use of LE 2M PHY on the secondary advertising channel.

Disabling the use of LE 2M PHY could be necessary if scanners don’t support the LE 2M PHY. The advertiser will send primary advertising on LE 1M PHY, and secondary advertising on LE 1M PHY. Connections will be established on LE 1M PHY.

**Note:** Cannot be set if BT_LE_ADV_OPT_CODED is set.

**Note:** Requires **BT_LE_ADV_OPT_EXT_ADV**.

**enumerator** BT_LE_ADV_OPT_CODED = BIT(12)
Advertise on the LE Coded PHY (Long Range).

The advertiser will send both primary and secondary advertising on the LE Coded PHY. This gives the advertiser increased range with the trade-off of lower data rate and higher power consumption. Connections will be established on LE Coded PHY.

**Note:** Requires **BT_LE_ADV_OPT_EXT_ADV**

**enumerator** BT_LE_ADV_OPT_ANONYMOUS = BIT(13)
Advertise without a device address (identity or RPA).

**Note:** Requires **BT_LE_ADV_OPT_EXT_ADV**

**enumerator** BT_LE_ADV_OPT_USE_TX POWER = BIT(14)
Advertise with transmit power.

**Note:** Requires **BT_LE_ADV_OPT_EXT_ADV**

**enumerator** BT_LE_ADV_OPT_DISABLE_CHAN_37 = BIT(15)
Disable advertising on channel index 37.

**enumerator** BT_LE_ADV_OPT_DISABLE_CHAN_38 = BIT(16)
Disable advertising on channel index 38.
enumerator BT_LE_ADV_OPT_DISABLE_CHAN_39 = BIT(17)
    Disable advertising on channel index 39.

enumerator BT_LE_ADV_OPT_FORCE_NAME_IN_AD = BIT(18)
    Put GAP device name into advert data.
    Will place the GAP device name into the advertising data rather than the scan response data.

**Note:** Requires `BT_LE_ADV_OPT_USE_NAME`

---

**enum [anonymous]**

Periodic Advertising options

**Values:**

enumerator BT_LE_PER_ADV_OPT_NONE = 0
    Convenience value when no options are specified.

enumerator BT_LE_PER_ADV_OPT_USE_TX_POWER = BIT(1)
    Advertise with transmit power.

**Note:** Requires `BT_LE_ADV_OPT_EXT_ADV`

---

**enum [anonymous]**

Periodic advertising sync options

**Values:**

enumerator BT_LE_PER_ADV_SYNC_OPT_NONE = 0
    Convenience value when no options are specified.

enumerator BT_LE_PER_ADV_SYNC_OPT_USE_PER_ADV_LIST = BIT(0)
    Use the periodic advertising list to sync with advertiser.
    When this option is set, the address and SID of the parameters are ignored.

enumerator BT_LE_PER_ADV_SYNC_OPT_REPORTING.Initially.Disabled = BIT(1)
    Disables periodic advertising reports.
    No advertisement reports will be handled until enabled.

enumerator BT_LE_PER_ADV_SYNC_OPT_FILTER.Duplicate = BIT(2)
    Filter duplicate Periodic Advertising reports

enumerator BT_LE_PER_ADV_SYNC_OPT_DONT_SYNC_AOA = BIT(3)
    Sync with Angle of Arrival (AoA) constant tone extension

enumerator BT_LE_PER_ADV_SYNC_OPT.DONT_SYNC_AOD.1US = BIT(4)
    Sync with Angle of Departure (AoD) 1 us constant tone extension

enumerator BT_LE_PER_ADV_SYNC_OPT.DONT_SYNC_AOD.2US = BIT(5)
    Sync with Angle of Departure (AoD) 2 us constant tone extension
enumerator BT_LE_PER_ADV_SYNC_OPT_SYNC ONLY_CONST_TONE_EXT = BIT (6)
Do not sync to packets without a constant tone extension

enum [anonymous]
Periodic Advertising Sync Transfer options
Values:

enumerator BT_LE_PER_ADV_SYNC_TRANSFER_OPT_NONE = 0
Convenience value when no options are specified.

enumerator BT_LE_PER_ADV_SYNC_TRANSFER_OPT_SYNC_NO_AOA = BIT (0)
No Angle of Arrival (AoA)
Do not sync with Angle of Arrival (AoA) constant tone extension

enumerator BT_LE_PER_ADV_SYNC_TRANSFER_OPT_SYNC_NO_AOD_1US = BIT (1)
No Angle of Departure (AoD) 1 us.
Do not sync with Angle of Departure (AoD) 1 us constant tone extension

enumerator BT_LE_PER_ADV_SYNC_TRANSFER_OPT_SYNC_NO_AOD_2US = BIT (2)
No Angle of Departure (AoD) 2.
Do not sync with Angle of Departure (AoD) 2 us constant tone extension

enumerator BT_LE_PER_ADV_SYNC_TRANSFER_OPT_SYNC_ONLY_CTE = BIT (3)
Only sync to packets with constant tone extension

enum [anonymous]
Values:

enumerator BT_LE_SCAN_OPT_NONE = 0
Convenience value when no options are specified.

enumerator BT_LE_SCAN_OPT_FILTER_DUPLICATE = BIT (0)
Filter duplicates.

enumerator BT_LE_SCAN_OPT_FILTER_ACCEPT_LIST = BIT (1)
Filter using filter accept list.

enumerator BT_LE_SCAN_OPT_CODED = BIT (2)
Enable scan on coded PHY (Long Range).

enumerator BT_LE_SCAN_OPT_NO_1M = BIT (3)
Disable scan on 1M phy.

Note: Requires BT_LE_SCAN_OPT_CODED.

enum [anonymous]
Values:

enumerator BT_LE_SCAN_TYPE_PASSIVE = 0x00
Scan without requesting additional information from advertisers.
enumerator BT_LE_SCAN_TYPE_ACTIVE = 0x01
    Scan and request additional information from advertisers.

Functions

int bt_enable(bt_ready_cb_t cb)
    Enable Bluetooth.
    Enable Bluetooth. Must be the called before any calls that require communication with the
    local Bluetooth hardware.
    When CONFIG_BT_SETTINGS is enabled, the application must load the Bluetooth settings after
    this API call successfully completes before Bluetooth APIs can be used. Loading the settings be-
    fore calling this function is insufficient. Bluetooth settings can be loaded with settings_load() or
    settings_load_subtree() with argument “bt”. The latter selectively loads only Bluetooth set-
    tings and is recommended if settings_load() has been called earlier.
    Parameters
        • cb – Callback to notify completion or NULL to perform the enabling syn-
        chronously.
    Returns Zero on success or (negative) error code otherwise.

int bt_set_name(const char *name)
    Set Bluetooth Device Name.
    Set Bluetooth GAP Device Name.
    When advertising with device name in the advertising data the name should be updated by
    calling bt_le_adv_update_data or bt_le_ext_adv_set_data.
    Parameters
        • name – New name
    Returns Zero on success or (negative) error code otherwise.

const char *bt_get_name(void)
    Get Bluetooth Device Name.
    Get Bluetooth GAP Device Name.
    Returns Bluetooth Device Name

uint16_t bt_get_appearance(void)
    Get local Bluetooth appearance.
    Bluetooth Appearance is a description of the external appearance of a device in terms of an
    Appearance Value.
    See also:
    https://specificationrefs.bluetooth.com/assigned-values/Appearance%20Values.pdf
    Returns Appearance Value of local Bluetooth host.

int bt_set_appearance(uint16_t new_appearance)
    Set local Bluetooth appearance.
    Automatically preserves the new appearance across reboots if CONFIG_BT_SETTINGS is en-
    abled.
    This symbol is linkable if CONFIG_BT_DEVICE_APPEARANCE_DYNAMIC is enabled.
Parameters

- **new_appearance** – Appearance Value

Return values

- **0** – Success.
- **other** – Persistent storage failed. Appearance was not updated.

void bt_id_get(bt_addr_le_t *addr, size_t *count)

Get the currently configured identities.

Returns an array of the currently configured identity addresses. To make sure all available identities can be retrieved, the number of elements in the `addr` array should be CONFIG_BT_ID_MAX. The identity identifier that some APIs expect (such as advertising parameters) is simply the index of the identity in the `addr` array.

If `addr` is passed as NULL, then returned `count` contains the count of all available identities that can be retrieved with a subsequent call to this function with non-NULL `addr` parameter.

**Note:** Deleted identities may show up as BT_LE_ADDR_ANY in the returned array.

Parameters

- `addr` – Array where to store the configured identities.
- `count` – Should be initialized to the array size. Once the function returns it will contain the number of returned identities.

int bt_id_create(bt_addr_le_t *addr, uint8_t *irk)

Create a new identity.

Create a new identity using the given address and IRK. This function can be called before calling `bt_enable()`, in which case it can be used to override the controller's public address (in case it has one). However, the new identity will only be stored persistently in flash when this API is used after `bt_enable()`. The reason is that the persistent settings are loaded after `bt_enable()` and would therefore cause potential conflicts with the stack blindly overwriting what's stored in flash. The identity will also not be written to flash in case a pre-defined address is provided, since in such a situation the app clearly has some place it got the address from and will be able to repeat the procedure on every power cycle, i.e. it would be redundant to also store the information in flash.

Generating random static address or random IRK is not supported when calling this function before `bt_enable()`.

If the application wants to have the stack randomly generate identities and store them in flash for later recovery, the way to do it would be to first initialize the stack (using `bt_enable`), then call `settings_load()`, and after that check with `bt_id_get()` how many identities were recovered. If an insufficient amount of identities were recovered the app may then call `bt_id_create()` to create new ones.

Parameters

- `addr` – Address to use for the new identity. If NULL or initialized to BT_ADDR_LE_ANY the stack will generate a new random static address for the identity and copy it to the given parameter upon return from this function (in case the parameter was non-NULL).
- `irk` – Identity Resolving Key (16 bytes) to be used with this identity. If set to all zeroes or NULL, the stack will generate a random IRK for the identity and copy it back to the parameter upon return from this function (in case the parameter was non-NULL). If privacy CONFIG_BT_PRIVACY is not enabled this parameter must be NULL.
Returns Identity identifier (>= 0) in case of success, or a negative error code on failure.

int bt_id_reset(uint8_t id, bt_addr_le_t *addr, uint8_t *irk)

Reset/reclaim an identity for reuse.

The semantics of the \textit{addr} and \textit{irk} parameters of this function are the same as with \texttt{bt_id_create()}. The difference is the first \textit{id} parameter that needs to be an existing identity (if it doesn't exist this function will return an error). When given an existing identity this function will disconnect any connections created using it, remove any pairing keys or other data associated with it, and then create a new identity in the same slot, based on the \textit{addr} and \textit{irk} parameters.

\textbf{Note:} the default identity (BT_ID_DEFAULT) cannot be reset, i.e. this API will return an error if asked to do that.

Parameters

- \textit{id} – Existing identity identifier.
- \textit{addr} – Address to use for the new identity. If NULL or initialized to BT_ADDR_LE_ANY the stack will generate a new static random address for the identity and copy it to the given parameter upon return from this function (in case the parameter was non-NULL).
- \textit{irk} – Identity Resolving Key (16 bytes) to be used with this identity. If set to all zeroes or NULL, the stack will generate a random IRK for the identity and copy it back to the parameter upon return from this function (in case the parameter was non-NULL). If privacy \texttt{CONFIG_BT_PRIVACY} is not enabled this parameter must be NULL.

Returns Identity identifier (>= 0) in case of success, or a negative error code on failure.

int bt_id_delete(uint8_t id)

Delete an identity.

When given a valid identity this function will disconnect any connections created using it, remove any pairing keys or other data associated with it, and then flag is as deleted, so that it can not be used for any operations. To take back into use the slot the identity was occupying the \texttt{bt_id_reset()} API needs to be used.

\textbf{Note:} the default identity (BT_ID_DEFAULT) cannot be deleted, i.e. this API will return an error if asked to do that.

Parameters

- \textit{id} – Existing identity identifier.

Returns 0 in case of success, or a negative error code on failure.

int bt_le_adv_start(const struct bt_le_adv_param *param, const struct bt_data *ad, size_t ad_len, const struct bt_data *sd, size_t sd_len)

Start advertising.

Set advertisement data, scan response data, advertisement parameters and start advertising.

When the advertisement parameter peer address has been set the advertising will be directed to the peer. In this case advertisement data and scan response data parameters are ignored. If the mode is high duty cycle the timeout will be \texttt{BT_GAP_ADV_HIGH_DUTY_CYCLE_MAX_TIMEOUT}.
Parameters

• param – Advertising parameters.
• ad – Data to be used in advertisement packets.
• ad_len – Number of elements in ad
• sd – Data to be used in scan response packets.
• sd_len – Number of elements in sd

Returns Zero on success or (negative) error code otherwise.

Returns -ENOMEM No free connection objects available for connectable advertiser.

Returns -ECONNREFUSED When connectable advertising is requested and there is already maximum number of connections established in the controller. This error code is only guaranteed when using Zephyr controller, for other controllers code returned in this case may be -EIO.

int bt_le_adv_update_data(const struct bt_data *ad, size_t ad_len, const struct bt_data *sd, size_t sd_len)
Update advertising.
Update advertisement and scan response data.

Parameters

• ad – Data to be used in advertisement packets.
• ad_len – Number of elements in ad
• sd – Data to be used in scan response packets.
• sd_len – Number of elements in sd

Returns Zero on success or (negative) error code otherwise.

int bt_le_adv_stop(void)
Stop advertising.
Stops ongoing advertising.

Returns Zero on success or (negative) error code otherwise.

int bt_le_ext_adv_create(const struct bt_le_adv_param *param, const struct bt_le_ext_adv_cb *cb, struct bt_le_ext_adv **adv)
Create advertising set.
Create a new advertising set and set advertising parameters. Advertising parameters can be updated with bt_le_ext_adv_update_param.

Parameters

• cb – [in] Callback struct to notify about advertiser activity. Can be NULL. Must point to valid memory during the lifetime of the advertising set.
• adv – [out] Valid advertising set object on success.

Returns Zero on success or (negative) error code otherwise.

int bt_le_ext_adv_start(struct bt_le_ext_adv *adv, struct bt_le_ext_adv_start_param *param)
Start advertising with the given advertising set.
If the advertiser is limited by either the timeout or number of advertising events the application will be notified by the advertiser sent callback once the limit is reached. If the advertiser is limited by both the timeout and the number of advertising events then the limit that is reached first will stop the advertiser.

Parameters
int bt_le_ext_adv_stop(struct bt_le_ext_adv *adv)
Stop advertising with the given advertising set.

Stop advertising with a specific advertising set. When using this function the advertising sent
callback will not be called.

**Parameters**

- **adv** – Advertising set object.

**Returns** Zero on success or (negative) error code otherwise.

```c
int bt_le_ext_adv_set_data(struct bt_le_ext_adv *adv, const struct bt_data *ad, size_t ad_len,
const struct bt_data *sd, size_t sd_len)
```

Set an advertising set's advertising or scan response data.

Set advertisement data or scan response data. If the advertising set is currently advertising
then the advertising data will be updated in subsequent advertising events.

When both `BT_LE_ADV_OPT_EXT_ADV` and `BT_LE_ADV_OPT_SCANNABLE` are enabled then
advertising data is ignored. When `BT LE_ADV_OPT_SCANNABLE` is not enabled then scan
response data is ignored.

If the advertising set has been configured to send advertising data on the primary ad-
vertising channels then the maximum data length is `BT_GAP_ADV_MAX_ADV_DATA_LEN`
bytes. If the advertising set has been configured for extended advertising, then the
maximum data length is defined by the controller with the maximum possible of
`BT_GAP_ADV_MAX_EXT_ADV_DATA_LEN` bytes.

**Note:** Not all scanners support extended data length advertising data.

---

**Note:** When updating the advertising data while advertising the advertising data and scan
response data length must be smaller or equal to what can be fit in a single advertising packet.
Otherwise the advertiser must be stopped.

---

```c
int bt_le_ext_adv_update_param(struct bt_le_ext_adv *adv, const struct bt_le_adv_param *param)
```

Update advertising parameters.

Update the advertising parameters. The function will return an error if the advertiser set is
currently advertising. Stop the advertising set before calling this function.

**Note:** When changing the option `BT_LE_ADV_OPT_USE_NAME` then `bt_le_ext_adv_set_data`
needs to be called in order to update the advertising data and scan response data.
Parameters

- `adv` – Advertising set object.
- `param` – Advertising parameters.

**Returns** Zero on success or (negative) error code otherwise.

```c
int bt_le_ext_adv_delete(const struct bt_le_ext_adv *adv)
```

Delete advertising set.

Delete advertising set. This will free up the advertising set and make it possible to create a new advertising set.

**Returns** Zero on success or (negative) error code otherwise.

```c
uint8_t bt_le_ext_adv_get_index(const struct bt_le_ext_adv *adv)
```

Get array index of an advertising set.

This function is used to map `bt_adv` to index of an array of advertising sets. The array has `CONFIG_BT_EXT_ADV_MAX_ADV_SET` elements.

**Parameters**

- `adv` – Advertising set.

**Returns** Index of the advertising set object. The range of the returned value is 0..`CONFIG_BT_EXT_ADV_MAX_ADV_SET`

```c
int bt_le_ext_adv_get_info(const struct bt_le_ext_adv *adv, struct bt_le_ext_adv_info *info)
```

Get advertising set info.

**Parameters**

- `adv` – Advertising set object
- `info` – Advertising set info object

**Returns** Zero on success or (negative) error code on failure.

```c
int bt_le_per_adv_set_param(const struct bt_le_ext_adv *adv, const struct bt_le_per_adv_param *param)
```

Set or update the periodic advertising parameters.

The periodic advertising parameters can only be set or updated on an extended advertisement set which is neither scannable, connectable nor anonymous.

**Parameters**

- `adv` – Advertising set object.
- `param` – Advertising parameters.

**Returns** Zero on success or (negative) error code otherwise.

```c
int bt_le_per_adv_set_data(const struct bt_le_ext_adv *adv, const struct bt_data *ad, size_t ad_len)
```

Set or update the periodic advertising data.

The periodic advertisement data can only be set or updated on an extended advertisement set which is neither scannable, connectable nor anonymous.

**Parameters**

- `adv` – Advertising set object.
- `ad` – Advertising data.
- `ad_len` – Advertising data length.

**Returns** Zero on success or (negative) error code otherwise.
int bt_le_per_adv_start(struct bt_le_ext_adv *adv)
Starts periodic advertising.

Enabling the periodic advertising can be done independently of extended advertising, but both
periodic advertising and extended advertising shall be enabled before any periodic advertising
data is sent. The periodic advertising and extended advertising can be enabled in any order.

Once periodic advertising has been enabled, it will continue advertising until
bt_le_per_adv_stop() has been called, or if the advertising set is deleted by
bt_le_ext_adv_delete(). Calling bt_le_ext_adv_stop() will not stop the periodic advertising.

Parameters
  • adv – Advertising set object.

Returns  Zero on success or (negative) error code otherwise.

int bt_le_per_adv_stop(struct bt_le_ext_adv *adv)
Stops periodic advertising.

Disabling the periodic advertising can be done independently of extended advertising. Dis-
abling periodic advertising will not disable extended advertising.

Parameters
  • adv – Advertising set object.

Returns  Zero on success or (negative) error code otherwise.

uint8_t bt_le_per_adv_sync_get_index(struct bt_le_per_adv_sync *per_adv_sync)
Get array index of an periodic advertising sync object.

This function is get the index of an array of periodic advertising sync objects. The array has
CONFIG_BT_PER_ADV_SYNC_MAX elements.

Parameters
  • per_adv_sync – The periodic advertising sync object.

Returns  Index of the periodic advertising sync object. The range of the returned
  value is 0..CONFIG_BT_PER_ADV_SYNC_MAX-1

int bt_le_per_adv_sync_get_info(struct bt_le_per_adv_sync *per_adv_sync, struct
                                  bt_le_per_adv_sync_info *info)
Get periodic adv sync information.

Parameters
  • per_adv_sync – Periodic advertising sync object.
  • info – Periodic advertising sync info object

Returns  Zero on success or (negative) error code on failure.

struct bt_le_per_adv_sync *bt_le_per_adv_sync_lookup_addr(const bt_addr_le_t *adv_addr,
                                                          uint8_t sid)
Look up an existing periodic advertising sync object by advertiser address.

Parameters
  • adv_addr – Advertiser address.
  • sid – The advertising set ID.

Returns  Periodic advertising sync object or NULL if not found.

int bt_le_per_adv_sync_create(const struct bt_le_per_adv_sync_param *param, struct
                             bt_le_per_adv_sync **out_sync)
Create a periodic advertising sync object.
Create a periodic advertising sync object that can try to synchronize to periodic advertising reports from an advertiser. Scan shall either be disabled or extended scan shall be enabled.

**Parameters**

- **param** – [in] Periodic advertising sync parameters.
- **out_sync** – [out] Periodic advertising sync object on.

**Returns** Zero on success or (negative) error code otherwise.

\[
\text{int } \text{bt\_le\_per\_adv\_sync\_delete}(\text{struct bt\_le\_per\_adv\_sync } \ast \text{per\_adv\_sync})
\]

Delete periodic advertising sync.

Delete the periodic advertising sync object. Can be called regardless of the state of the sync. If the syncing is currently syncing, the syncing is cancelled. If the sync has been established, it is terminated. The periodic advertising sync object will be invalidated afterwards.

If the state of the sync object is syncing, then a new periodic advertising sync object may not be created until the controller has finished canceling this object.

**Parameters**

- **per\_adv\_sync** – The periodic advertising sync object.

**Returns** Zero on success or (negative) error code otherwise.

\[
\text{void } \text{bt\_le\_per\_adv\_sync\_cb\_register}(\text{struct bt\_le\_per\_adv\_sync\_cb } \ast \text{cb})
\]

Register periodic advertising sync callbacks.

Adds the callback structure to the list of callback structures for periodic advertising syncs.

This callback will be called for all periodic advertising sync activity, such as synced, terminated and when data is received.

**Parameters**

- **cb** – Callback struct. Must point to memory that remains valid.

\[
\text{int } \text{bt\_le\_per\_adv\_sync\_recv\_enable}(\text{struct bt\_le\_per\_adv\_sync } \ast \text{per\_adv\_sync})
\]

Enables receiving periodic advertising reports for a sync.

If the sync is already receiving the reports, -EALREADY is returned.

**Parameters**

- **per\_adv\_sync** – The periodic advertising sync object.

**Returns** Zero on success or (negative) error code otherwise.

\[
\text{int } \text{bt\_le\_per\_adv\_sync\_recv\_disable}(\text{struct bt\_le\_per\_adv\_sync } \ast \text{per\_adv\_sync})
\]

Disables receiving periodic advertising reports for a sync.

If the sync report receiving is already disabled, -EALREADY is returned.

**Parameters**

- **per\_adv\_sync** – The periodic advertising sync object.

**Returns** Zero on success or (negative) error code otherwise.

\[
\text{int } \text{bt\_le\_per\_adv\_sync\_transfer}(\text{const struct bt\_le\_per\_adv\_sync } \ast \text{per\_adv\_sync}, \text{const struct bt\_conn } \ast \text{conn}, \text{uint16\_t } \text{service\_data})
\]

Transfer the periodic advertising sync information to a peer device.

This will allow another device to quickly synchronize to the same periodic advertising train that this device is currently synced to.

**Parameters**

- **per\_adv\_sync** – The periodic advertising sync to transfer.
- **conn** – The peer device that will receive the sync information.
• service_data – Application service data provided to the remote host.

Returns Zero on success or (negative) error code otherwise.

int bt_le_per_adv_set_info_transfer(const struct bt_le_ext_adv *adv, const struct bt_conn *conn, uint16_t service_data)
Transfer the information about a periodic advertising set.
This will allow another device to quickly synchronize to periodic advertising set from this device.

Parameters
• adv – The periodic advertising set to transfer info of.
• conn – The peer device that will receive the information.
• service_data – Application service data provided to the remote host.

Returns Zero on success or (negative) error code otherwise.

int bt_le_per_adv_sync_transfer_subscribe(const struct bt_conn *conn, const struct bt_le_per_adv_sync_transfer_param *param)
Subscribe to periodic advertising sync transfers (PASTs).
Sets the parameters and allow other devices to transfer periodic advertising syncs.

Parameters
• conn – The connection to set the parameters for. If NULL default parameters for all connections will be set. Parameters set for specific connection will always have precedence.
• param – The periodic advertising sync transfer parameters.

Returns Zero on success or (negative) error code otherwise.

int bt_le_per_adv_sync_transfer_unsubscribe(const struct bt_conn *conn)
Unsubscribe from periodic advertising sync transfers (PASTs).
Remove the parameters that allow other devices to transfer periodic advertising syncs.

Parameters
• conn – The connection to remove the parameters for. If NULL default parameters for all connections will be removed. Unsubscribing for a specific device, will still allow other devices to transfer periodic advertising syncs.

Returns Zero on success or (negative) error code otherwise.

int bt_le_per_adv_list_add(const bt_addr_le_t *addr, uint8_t sid)
Add a device to the periodic advertising list.
Add peer device LE address to the periodic advertising list. This will make it possibly to automatically create a periodic advertising sync to this device.

Parameters
• addr – Bluetooth LE identity address.
• sid – The advertising set ID. This value is obtained from the bt_le_scan_recv_info in the scan callback.

Returns Zero on success or (negative) error code otherwise.

int bt_le_per_adv_list_remove(const bt_addr_le_t *addr, uint8_t sid)
Remove a device from the periodic advertising list.
Removes peer device LE address from the periodic advertising list.

Parameters
• addr – Bluetooth LE identity address.
• **sid** – The advertising set ID. This value is obtained from the `bt_le_scan_recv_info` in the scan callback.

**Returns** Zero on success or (negative) error code otherwise.

```c
int bt_le_per_adv_list_clear(void)
```
Clear the periodic advertising list.

**Returns** Zero on success or (negative) error code otherwise.

```c
int bt_le_scan_start(const struct bt_le_scan_param *param, bt_le_scan_cb_t cb)
```
Start (LE) scanning.

Start LE scanning with given parameters and provide results through the specified callback.

**Note:** The LE scanner by default does not use the Identity Address of the local device when `CONFIG_BT_PRIVACY` is disabled. This is to prevent the active scanner from disclosing the identity information when requesting additional information from advertisers. In order to enable directed advertiser reports then `CONFIG_BT_SCAN_WITH_IDENTITY` must be enabled.

**Parameters**
- `param` – Scan parameters.
- `cb` – Callback to notify scan results. May be NULL if callback registration through `bt_le_scan_cb_register` is preferred.

**Returns** Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
int bt_le_scan_stop(void)
```
Stop (LE) scanning.

**Returns** Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
void bt_le_scan_cb_register(struct bt_le_scan_cb *cb)
```
Register scanner packet callbacks.

Add the callback structure to the list of callback structures that monitors scanner activity. This callback will be called for all scanner activity, regardless of what API was used to start the scanner.

**Parameters**
- `cb` – Callback struct. Must point to memory that remains valid.

```c
void bt_le_scan_cb_unregister(struct bt_le_scan_cb *cb)
```
Unregister scanner packet callbacks.

Remove the callback structure from the list of scanner callbacks.

**Parameters**
- `cb` – Callback struct. Must point to memory that remains valid.

```c
int bt_le_filter_accept_list_add(const bt_addr_le_t *addr)
```
Add device (LE) to filter accept list.

Add peer device LE address to the filter accept list.
Note: The filter accept list cannot be modified when an LE role is using the filter accept list, i.e. advertiser or scanner using a filter accept list or automatic connecting to devices using filter accept list.

Parameters

• addr – Bluetooth LE identity address.

Returns Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
static inline int bt_le_whitelist_add(const bt_addr_le_t *addr)

int bt_le_filter_accept_list_remove(const bt_addr_le_t *addr)
Remove device (LE) from filter accept list.
Remove peer device LE address from the filter accept list.
```

Note: The filter accept list cannot be modified when an LE role is using the filter accept list, i.e. advertiser or scanner using a filter accept list or automatic connecting to devices using filter accept list.

Parameters

• addr – Bluetooth LE identity address.

Returns Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
static inline int bt_le_whitelist_rem(const bt_addr_le_t *addr)

int bt_le_filter_accept_list_clear(void)
Clear filter accept list.
Clear all devices from the filter accept list.
```

Note: The filter accept list cannot be modified when an LE role is using the filter accept list, i.e. advertiser or scanner using a filter accept list or automatic connecting to devices using filter accept list.

Returns Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
static inline int bt_le_whitelist_clear(void)

int bt_le_set_chan_map(uint8_t chan_map[5])
Set (LE) channel map.
```

Parameters

• chan_map – Channel map.

Returns Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.
void bt_data_parse(struct net_buf_simple *ad, bool (*func)(struct bt_data *data, void *user_data), void *user_data)
Helper for parsing advertising (or EIR or OOB) data.

A helper for parsing the basic data types used for Extended Inquiry Response (EIR), Advertising Data (AD), and OOB data blocks. The most common scenario is to call this helper on the advertising data received in the callback that was given to bt_le_scan_start().

**Parameters**
- ad – Advertising data as given to the bt_le_scan_cb_t callback.
- func – Callback function which will be called for each element that’s found in the data. The callback should return true to continue parsing, or false to stop parsing.
- user_data – User data to be passed to the callback.

int bt_le_oob_get_local(uint8_t id, struct bt_le_oob *oob)
Get local LE Out of Band (OOB) information.

This function allows to get local information that are useful for Out of Band pairing or connection creation.

If privacy CONFIG_BT_PRIVACY is enabled this will result in generating new Resolvable Private Address (RPA) that is valid for CONFIG_BT_RPA_TIMEOUT seconds. This address will be used for advertising started by bt_le_adv_start, active scanning and connection creation.

**Note:** If privacy is enabled the RPA cannot be refreshed in the following cases:
- Creating a connection in progress, wait for the connected callback. In addition when extended advertising CONFIG_BT_EXT_ADV is not enabled or not supported by the controller:
- Advertiser is enabled using a Random Static Identity Address for a different local identity.
- The local identity conflicts with the local identity used by other roles.

**Parameters**
- id – [in] Local identity, in most cases BT_ID_DEFAULT.
- oob – [out] LE OOB information

**Returns** Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

int bt_le_ext_adv_oob_get_local(struct bt_le_ext_adv *adv, struct bt_le_oob *oob)
Get local LE Out of Band (OOB) information.

This function allows to get local information that are useful for Out of Band pairing or connection creation.

If privacy CONFIG_BT_PRIVACY is enabled this will result in generating new Resolvable Private Address (RPA) that is valid for CONFIG_BT_RPA_TIMEOUT seconds. This address will be used by the advertising set.

**Note:** When generating OOB information for multiple advertising set all OOB information needs to be generated at the same time.

**Note:** If privacy is enabled the RPA cannot be refreshed in the following cases:
- Creating a connection in progress, wait for the connected callback.
Parameters

- **adv** – [in] The advertising set object
- **oob** – [out] LE OOB information

Returns
Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
int bt_br_discovery_start(const struct bt_br_discovery_param *param, struct bt_br_discovery_result *results, size_t count, bt_br_discovery_cb_t cb)
```
Start BR/EDR discovery.
Start BR/EDR discovery (inquiry) and provide results through the specified callback. When `bt_br_discovery_cb_t` is called it indicates that discovery has completed. If more inquiry results were received during session than fits in provided result storage, only ones with highest RSSI will be reported.

Parameters

- **param** – Discovery parameters.
- **results** – Storage for discovery results.
- **count** – Number of results in storage. Valid range: 1-255.
- **cb** – Callback to notify discovery results.

Returns
Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
int bt_br_discovery_stop(void)
```
Stop BR/EDR discovery.
Stop ongoing BR/EDR discovery. If discovery was stopped by this call results won't be reported.

Returns
Zero on success or error code otherwise, positive in case of protocol error or negative (POSIX) in case of stack internal error.

```c
int bt_br_oob_get_local(struct bt_br_oob *oob)
```
Get BR/EDR local Out Of Band information.
This function allows to get local controller information that are useful for Out Of Band pairing or connection creation process.

Parameters

- **oob** – Out Of Band information

```c
int bt_br_set_discoverable(bool enable)
```
Enable/disable set controller in discoverable state.
Allows make local controller to listen on INQUIRY SCAN channel and responds to devices making general inquiry. To enable this state it's mandatory to first be in connectable state.

Parameters

- **enable** – Value allowing/disallowing controller to become discoverable.

Returns
Negative if fail set to requested state or requested state has been already set. Zero if done successfully.

```c
int bt_br_set_connectable(bool enable)
```
Enable/disable set controller in connectable state.
Allows make local controller to be connectable. It means the controller start listen to devices requests on PAGE SCAN channel. If disabled also resets discoverability if was set.

Parameters
• enable – Value allowing/disallowing controller to be connectable.

**Returns** Negative if fail set to requested state or requested state has been already set. Zero if done successfully.

```c
int bt_unpair(uint8_t id, const bt_addr_le_t *addr)
```

Clear pairing information.

**Parameters**

- **id** – Local identity (mostly just BT_ID_DEFAULT).
- **addr** – Remote address, NULL or BT_ADDR_LE_ANY to clear all remote devices.

**Returns** 0 on success or negative error value on failure.

```c
void bt_foreach_bond(uint8_t id, void (*func)(const struct bt_bond_info *info, void *user_data), void *user_data)
```

Iterate through all existing bonds.

**Parameters**

- **id** – Local identity (mostly just BT_ID_DEFAULT).
- **func** – Function to call for each bond.
- **user_data** – Data to pass to the callback function.

```c
int bt_configure_data_path(uint8_t dir, uint8_t id, uint8_t vs_config_len, const uint8_t *vs_config)
```

Configure vendor data path.

Request the Controller to configure the data transport path in a given direction between the Controller and the Host.

**Parameters**

- **dir** – Direction to be configured, BT_HCI_DATAPATH_DIR_HOST_TO_CTLR or BT_HCI_DATAPATH_DIR_CTLR_TO_HOST
- **id** – Vendor specific logical transport channel ID, range [BT_HCI_DATAPATH_ID_VS..BT_HCI_DATAPATH_ID_VS_END]
- **vs_config_len** – Length of additional vendor specific configuration data
- **vs_config** – Pointer to additional vendor specific configuration data

**Returns** 0 in case of success or negative value in case of error.

```c
struct bt_le_ext_adv_sent_info
#include <bluetooth.h>
```

**Public Members**

```c
uint8_t num_sent
```

The number of advertising events completed.

```c
struct bt_le_ext_adv_connected_info
#include <bluetooth.h>
```
Public Members

struct bt_conn *conn
  Connection object of the new connection

struct bt_le_ext_adv_scanned_info
#include <bluetooth.h>

Public Members

bt_addr_le_t *addr
  Active scanner LE address and type

Public Members

void (*sent)(struct bt_le_ext_adv *adv, struct bt_le_ext_adv_sent_info *info)
The advertising set has finished sending adv data.
  This callback notifies the application that the advertising set has finished sending advertising data. The advertising set can either have been stopped by a timeout or because the specified number of advertising events has been reached.
  Param adv The advertising set object.
  Param info Information about the sent event.

void (*connected)(struct bt_le_ext_adv *adv, struct bt_le_ext_adv_connected_info *info)
The advertising set has accepted a new connection.
  This callback notifies the application that the advertising set has accepted a new connection.
  Param adv The advertising set object.
  Param info Information about the connected event.

void (*scanned)(struct bt_le_ext_adv *adv, struct bt_le_ext_adv_scanned_info *info)
The advertising set has sent scan response data.
  This callback notifies the application that the advertising set has received a Scan Request packet, and has sent a Scan Response packet.
  Param adv The advertising set object.
  Param addr Information about the scanned event.

struct bt_data
#include <bluetooth.h> Bluetooth data.
  Description of different data types that can be encoded into advertising data. Used to form arrays that are passed to the bt_le_adv_start() function.

struct bt_le_adv_param
#include <bluetooth.h> LE Advertising Parameters.
Public Members

uint8_t id
Local identity.

Note: When extended advertising CONFIG_BT_EXT_ADV is not enabled or not supported by the controller it is not possible to scan and advertise simultaneously using two different random addresses.

uint8_t sid
Advertising Set Identifier, valid range 0x00 - 0x0f.

Note: Requires BT_LE_ADV_OPT_EXT_ADV

uint8_t secondary_max_skip
Secondary channel maximum skip count.
Maximum advertising events the advertiser can skip before it must send advertising data on the secondary advertising channel.

Note: Requires BT_LE_ADV_OPT_EXT_ADV

uint32_t options
Bit-field of advertising options

uint32_t interval_min
Minimum Advertising Interval (N * 0.625 milliseconds) Minimum Advertising Interval shall be less than or equal to the Maximum Advertising Interval. The Minimum Advertising Interval and Maximum Advertising Interval should not be the same value (as stated in Bluetooth Core Spec 5.2, section 7.8.5) Range: 0x0020 to 0x4000

uint32_t interval_max
Maximum Advertising Interval (N * 0.625 milliseconds) Minimum Advertising Interval shall be less than or equal to the Maximum Advertising Interval. The Minimum Advertising Interval and Maximum Advertising Interval should not be the same value (as stated in Bluetooth Core Spec 5.2, section 7.8.5) Range: 0x0020 to 0x4000

const bt_addr_le_t *peer
Directed advertising to peer.
When this parameter is set the advertiser will send directed advertising to the remote device.
The advertising type will either be high duty cycle, or low duty cycle if the BT_LE_ADV_OPT_DIR_MODE_LOW_DUTY option is enabled. When using BT_LE_ADV_OPT_EXT_ADV then only low duty cycle is allowed.
In case of connectable high duty cycle if the connection could not be established within the timeout the connected() callback will be called with the status set to BT_HCI_ERR_ADV_TIMEOUT.

struct bt_le_per_adv_param
#include <bluetooth.h>

Public Members

```c
uint16_t interval_min
Minimum Periodic Advertising Interval (N * 1.25 ms)
Shall be greater or equal to BT_GAP_PER_ADV_MIN_INTERVAL and less or equal to interval_max.
```

```c
uint16_t interval_max
Maximum Periodic Advertising Interval (N * 1.25 ms)
Shall be less or equal to BT_GAP_PER_ADV_MAX_INTERVAL and greater or equal to interval_min.
```

```c
uint32_t options
Bit-field of periodic advertising options
```

```c
#include <bluetooth.h>
```

Public Members

```c
uint16_t timeout
Advertiser timeout (N * 10 ms).
Application will be notified by the advertiser sent callback. Set to zero for no timeout.
When using high duty cycle directed connectable advertising then this parameters must be set to a non-zero value less than or equal to the maximum of BT_GAP_ADV_HIGH_DUTY_CYCLE_MAX_TIMEOUT.
If privacy CONFIG_BT_PRIVACY is enabled then the timeout must be less than CONFIG_BT_RPA_TIMEOUT.
```

```c
uint8_t num_events
Number of advertising events.
Application will be notified by the advertiser sent callback. Set to zero for no limit.
```

```c
#include <bluetooth.h> Advertising set info structure.
```

Public Members

```c
int8_t tx_power
Currently selected Transmit Power (dBm).
```

```c
#include <bluetooth.h>
```

Public Members

```c
const bt_addr_le_t *addr
Advertiser LE address and type.
```
```c
#include <bluetooth.h>

uint8_t sid
    Advertiser SID

uint16_t interval
    Periodic advertising interval (N * 1.25 ms)

uint8_t phy
    Advertiser PHY

bool recv_enabled
    True if receiving periodic advertisements, false otherwise.

uint16_t service_data
    Service Data provided by the peer when sync is transferred.
    Will always be 0 when the sync is locally created.

struct bt_conn *conn
    Peer that transferred the periodic advertising sync.
    Will always be 0 when the sync is locally created.
```

```c
#include <bluetooth.h>

struct bt_le_per_adv_sync_term_info

Public Members

const bt_addr_le_t *addr
    Advertiser LE address and type.

uint8_t sid
    Advertiser SID

uint8_t reason
    Cause of periodic advertising termination

struct bt_le_per_adv_sync_recv_info
    #include <bluetooth.h>

Public Members

const bt_addr_le_t *addr
    Advertiser LE address and type.

uint8_t sid
    Advertiser SID

int8_t tx_power
    The TX power of the advertisement.

int8_t rssi
    The RSSI of the advertisement excluding any CTE.
```
uint8_t cte_type
    The Constant Tone Extension (CTE) of the advertisement (bt_df_c te_type)

struct bt_le_per_adv_sync_state_info
#include <bluetooth.h>

Public Members

bool recv_enabled
    True if receiving periodic advertisements, false otherwise.

struct bt_le_per_adv_sync_cb
#include <bluetooth.h>

Public Members

void (*synced)(struct bt_le_per_adv_sync *sync, struct bt_le_per_adv_sync_synced_info *info)
    The periodic advertising has been successfully synced.
    This callback notifies the application that the periodic advertising set has been successfully
    synced, and will now start to receive periodic advertising reports.
    Param sync The periodic advertising sync object.
    Param info Information about the sync event.

void (*term)(struct bt_le_per_adv_sync *sync, const struct bt_le_per_adv_sync_term_info *info)
    The periodic advertising sync has been terminated.
    This callback notifies the application that the periodic advertising sync has been terminated,
    either by local request, remote request or because due to missing data, e.g. by
    being out of range or sync.
    Param sync The periodic advertising sync object.

void (*recv)(struct bt_le_per_adv_sync *sync, const struct bt_le_per_adv_sync_recv_info *info, struct net_buf_simple *buf)
    Periodic advertising data received.
    This callback notifies the application of an periodic advertising report.
    Param sync The advertising set object.
    Param info Information about the periodic advertising event.
    Param buf Buffer containing the periodic advertising data.

void (*state_changed)(struct bt_le_per_adv_sync *sync, const struct bt_le_per_adv_sync_state_info *info)
    The periodic advertising sync state has changed.
    This callback notifies the application about changes to the sync state. Initialize sync and
    termination is handled by their individual callbacks, and won't be notified here.
    Param sync The periodic advertising sync object.
    Param info Information about the state change.

void (*biginfo)(struct bt_le_per_adv_sync *sync, const struct bt_iso_biginfo *biginfo)
    BIGInfo advertising report received.
This callback notifies the application of a BIGInfo advertising report. This is received if the advertiser is broadcasting isochronous streams in a BIG. See iso.h for more information.

**Param sync** The advertising set object.

**Param biginfo** The BIGInfo report.

```c
void (*cte_report_cb)(struct bt_le_per_adv_sync *sync, struct bt_df_per_adv_sync_iq_samples_report *info)
```

Callback for IQ samples report collected when sampling CTE received with periodic advertising PDU.

**Param sync** The periodic advertising sync object.

**Param info** Information about the sync event.

```c
struct bt_le_per_adv_sync_param
#include <bluetooth.h>
```

**Public Members**

- **bt_addr_le_t addr**
  - Periodic Advertiser Address.
  - Only valid if not using the periodic advertising list (BT_LE_PER_ADV_SYNC_OPT_USE_PER_ADV_LIST)

- **uint8_t sid**
  - Advertiser SID.
  - Only valid if not using the periodic advertising list (BT_LE_PER_ADV_SYNC_OPT_USE_PER_ADV_LIST)

- **uint32_t options**
  - Bit-field of periodic advertising sync options.

- **uint16_t skip**
  - Maximum event skip.
  - Maximum number of periodic advertising events that can be skipped after a successful receive. Range: 0x0000 to 0x01F3

- **uint16_t timeout**
  - Synchronization timeout (N * 10 ms)
  - Synchronization timeout for the periodic advertising sync. Range 0x000A to 0x4000 (100 ms to 163840 ms)

```c
struct bt_le_per_adv_sync_info
#include <bluetooth.h> Advertising set info structure.
```

**Public Members**

- **bt_addr_le_t addr**
  - Periodic Advertiser Address

- **uint8_t sid**
  - Advertiser SID
## Public Members

### uint16_t skip
Maximum event skip.

The number of periodic advertising packets that can be skipped after a successful receive.

### uint16_t timeout
Synchronization timeout (N * 10 ms)

Synchronization timeout for the periodic advertising sync. Range 0x000A to 0x4000 (100 ms to 163840 ms)

### uint32_t options
Periodic Advertising Sync Transfer options

## Public Members

### uint8_t type
Scan type (BT_LE_SCAN_TYPE_ACTIVE or BT_LE_SCAN_TYPE_PASSIVE)

### uint32_t options
Bit-field of scanning options.

### uint16_t interval
Scan interval (N * 0.625 ms)

### uint16_t window
Scan window (N * 0.625 ms)

### uint16_t timeout
Scan timeout (N * 10 ms)

Application will be notified by the scan timeout callback. Set zero to disable timeout.

### uint16_t interval_coded
Scan interval LE Coded PHY (N * 0.625 MS)

Set zero to use same as LE 1M PHY scan interval.

### uint16_t window_coded
Scan window LE Coded PHY (N * 0.625 MS)
Set zero to use same as LE 1M PHY scan window.

```c
struct bt_le_scan_recv_info
    #include <bluetooth.h> LE advertisement packet information
```

### Public Members

- `const bt_addr_le_t *addr`
  - Advertiser LE address and type.
  - If advertiser is anonymous then this address will be `BT_ADDR_LE_ANY`.

- `uint8_t sid`  
  - Advertising Set Identifier.

- `int8_t rssi`  
  - Strength of advertiser signal.

- `int8_t tx_power`  
  - Transmit power of the advertiser.

- `uint8_t adv_type`  
  - Advertising packet type.

- `uint16_t adv_props`  
  - Advertising packet properties.

- `uint16_t interval`  
  - Periodic advertising interval.
  - If 0 there is no periodic advertising.

- `uint8_t primary_phy`  
  - Primary advertising channel PHY.

- `uint8_t secondary_phy`  
  - Secondary advertising channel PHY.

```c
struct bt_le_scan_cb
    #include <bluetooth.h> Listener context for (LE) scanning.
```

### Public Members

- `void (*recv)(const struct bt_le_scan_recv_info *info, struct net_buf_simple *buf)`  
  - Advertisement packet received callback.
  - **Param info** Advertiser packet information.
  - **Param buf** Buffer containing advertiser data.

- `void (*timeout)(void)`  
  - The scanner has stopped scanning after scan timeout.

```c
struct bt_le_oob_sc_data
    #include <bluetooth.h> LE Secure Connections pairing Out of Band data.
```
Public Members

```
uint8_t   r[16]
  Random Number.
```

```
uint8_t   c[16]
  Confirm Value.
```

```c
struct bt_le_oob
  #include <bluetooth.h> LE Out of Band information.
```

Public Members

```
bt_addr_le_t  addr
  LE address. If privacy is enabled this is a Resolvable Private Address.
```

```c
struct bt_le_oob_sc_data  le_sc_data
  LE Secure Connections pairing Out of Band data.
```

```c
struct bt_br_discovery_result
  #include <bluetooth.h> BR/EDR discovery result structure.
```

Public Members

```
bt_addr_t  addr
  Remote device address
```

```
int8_t rssi
  RSSI from inquiry
```

```
uint8_t cod[3]
  Class of Device
```

```
uint8_t eir[240]
  Extended Inquiry Response
```

```c
struct bt_br_discovery_param
  #include <bluetooth.h> BR/EDR discovery parameters
```

Public Members

```
uint8_t length
  Maximum length of the discovery in units of 1.28 seconds. Valid range is 0x01 - 0x30.
```

```
bool limited
  True if limited discovery procedure is to be used.
```

```c
struct bt_br_oob
  #include <bluetooth.h>
```
Public Members

bt_addr_t addr
   BR/EDR address.

struct bt_bond_info
   #include <bluetooth.h> Information about a bond with a remote device.

Public Members

bt_addr_le_t addr
   Address of the remote device.

group bt_addr
   Bluetooth device address definitions and utilities.

Defines

BT_ADDR_LE_PUBLIC

BT_ADDR_LE_RANDOM

BT_ADDR_LE_PUBLIC_ID

BT_ADDR_LE_RANDOM_ID

BT_ADDR_LE_UNRESOLVED

BT_ADDR_LE_ANONYMOUS

BT_ADDR_SIZE
   Length in bytes of a standard Bluetooth address

BT_ADDR_LE_SIZE
   Length in bytes of an LE Bluetooth address. Not packed, so no sizeof()

BT_ADDR_ANY
   Bluetooth device “any” address, not a valid address

BT_ADDR_NONE
   Bluetooth device “none” address, not a valid address

BT_ADDR_LE_ANY
   Bluetooth LE device “any” address, not a valid address
BT_ADDR_LE_NONE
Bluetooth LE device “none” address, not a valid address.

BT_ADDR_IS_RPA(a)
Check if a Bluetooth LE random address is resolvable private address.

BT_ADDR_IS_NRPA(a)
Check if a Bluetooth LE random address is a non-resolvable private address.

BT_ADDR_IS_STATIC(a)
Check if a Bluetooth LE random address is a static address.

BT_ADDR_SET_RPA(a)
Set a Bluetooth LE random address as a resolvable private address.

BT_ADDR_SET_NRPA(a)
Set a Bluetooth LE random address as a non-resolvable private address.

BT_ADDR_SET_STATIC(a)
Set a Bluetooth LE random address as a static address.

BT_ADDR_STR_LEN
Recommended length of user string buffer for Bluetooth address.

The recommended length guarantee the output of address conversion will not lose valuable information about address being processed.

BT_ADDR_LE_STR_LEN
Recommended length of user string buffer for Bluetooth LE address.

The recommended length guarantee the output of address conversion will not lose valuable information about address being processed.

Functions

static inline int bt_addr_cmp(const bt_addr_t *a, const bt_addr_t *b)
Compare Bluetooth device addresses.

Parameters

• a – First Bluetooth device address to compare
• b – Second Bluetooth device address to compare

Returns negative value if a < b, 0 if a == b, else positive

static inline int bt_addr_le_cmp(const bt_addr_le_t *a, const bt_addr_le_t *b)
Compare Bluetooth LE device addresses.

Parameters

• a – First Bluetooth LE device address to compare
• b – Second Bluetooth LE device address to compare

Returns negative value if a < b, 0 if a == b, else positive

static inline void bt_addr_copy(bt_addr_t *dst, const bt_addr_t *src)
Copy Bluetooth device address.

Parameters

• dst – Bluetooth device address destination buffer.
• src – Bluetooth device address source buffer.
static inline void bt_addr_le_copy(bt_addr_le_t *dst, const bt_addr_le_t *src)
    Copy Bluetooth LE device address.

Parameters
• dst – Bluetooth LE device address destination buffer.
• src – Bluetooth LE device address source buffer.

int bt_addr_le_create_nrpa(bt_addr_le_t *addr)
    Create a Bluetooth LE random non-resolvable private address.

int bt_addr_le_create_static(bt_addr_le_t *addr)
    Create a Bluetooth LE random static address.

static inline bool bt_addr_le_is_rpa(const bt_addr_le_t *addr)
    Check if a Bluetooth LE address is a random private resolvable address.

Parameters
• addr – Bluetooth LE device address.

Returns true if address is a random private resolvable address.

static inline bool bt_addr_le_is_identity(const bt_addr_le_t *addr)
    Check if a Bluetooth LE address is valid identity address.

Valid Bluetooth LE identity addresses are either public address or random static address.

Parameters
• addr – Bluetooth LE device address.

Returns true if address is a valid identity address.

static inline int bt_addr_to_str(const bt_addr_t *addr, char *str, size_t len)
    Converts binary Bluetooth address to string.

Parameters
• addr – Address of buffer containing binary Bluetooth address.
• str – Address of user buffer with enough room to store formatted string containing binary address.
• len – Length of data to be copied to user string buffer. Refer to BT_ADDR_STR_LEN about recommended value.

Returns Number of successfully formatted bytes from binary address.

static inline int bt_addr_le_to_str(const bt_addr_le_t *addr, char *str, size_t len)
    Converts binary LE Bluetooth address to string.

Parameters
• addr – Address of buffer containing binary LE Bluetooth address.
• str – Address of user buffer with enough room to store formatted string containing binary LE address.
• len – Length of data to be copied to user string buffer. Refer to BT_ADDR_LE_STR_LEN about recommended value.

Returns Number of successfully formatted bytes from binary address.

int bt_addr_from_str(const char *str, bt_addr_t *addr)
    Convert Bluetooth address from string to binary.

Parameters
• str – [in] The string representation of a Bluetooth address.
• addr – [out] Address of buffer to store the Bluetooth address.
Returns  Zero on success or (negative) error code otherwise.

int bt_addr_le_from_str(const char *str, const char *type, bt_addr_le_t *addr)
Convert LE Bluetooth address from string to binary.

Parameters

- type – [in] The string representation of the LE Bluetooth address type.
- addr – [out] Address of buffer to store the LE Bluetooth address

Returns  Zero on success or (negative) error code otherwise.

struct bt_addr_t

  Convert periodic advertising interval (N * 1.25 ms) to milliseconds.

  5 / 4 represents 1.25 ms unit.

BT_LE_SUPP_FEAT_40_ENCODE(w64)

  Encode 40 least significant bits of 64-bit LE Supported Features into array values in little-
  endian format.

  Helper macro to encode 40 least significant bits of 64-bit LE Supported Features value into
  advertising data. The number of bits that are encoded is a number of LE Supported Features
  defined by BT 5.3 Core specification.

  Example of how to encode the 0x000000DFF00DF00D into advertising data.

  \texttt{BT\_DATA\_BYTES\textasciitilde{}BT\_DATA\_LE\_SUPPORTED\_FEATURES, BT\_LE\_SUPP\_FEAT\_40_
  \textasciitilde{}\_ENCODE(0x000000DFF00DF00D))}

  \textbf{Parameters}

  \begin{itemize}
    \item \texttt{w64} – LE Supported Features value (64-bits)
  \end{itemize}

  \textbf{Returns} The comma separated values for LE Supported Features value that may be
  used directly as an argument for \texttt{BT\_DATA\_BYTES}.
BT_LE_SUPP_FEAT_32_ENCODE(w64)
Encode 4 least significant bytes of 64-bit LE Supported Features into 4 bytes long array of values in little-endian format.

Helper macro to encode 64-bit LE Supported Features value into advertising data. The macro encodes 4 least significant bytes into advertising data. Other 4 bytes are not encoded.

Example of how to encode the 0x000000DFF00DF00D into advertising data.

\[
\text{BT_DATA_BYTES(BT_DATA_LE_SUPPORTED_FEATURES, BT_LE_SUPP_FEAT_32_ENCODE(0x000000DFF00DF00D))}
\]

**Parameters**
- w64 – LE Supported Features value (64-bits)

**Returns** The comma separated values for LE Supported Features value that may be used directly as an argument for `BT_DATA_BYTES`.

BT_LE_SUPP_FEAT_24_ENCODE(w64)
Encode 3 least significant bytes of 64-bit LE Supported Features into 3 bytes long array of values in little-endian format.

Helper macro to encode 64-bit LE Supported Features value into advertising data. The macro encodes 3 least significant bytes into advertising data. Other 5 bytes are not encoded.

Example of how to encode the 0x000000DFF00DF00D into advertising data.

\[
\text{BT_DATA_BYTES(BT_DATA_LE_SUPPORTED_FEATURES, BT_LE_SUPP_FEAT_24_ENCODE(0x000000DFF00DF00D))}
\]

**Parameters**
- w64 – LE Supported Features value (64-bits)

**Returns** The comma separated values for LE Supported Features value that may be used directly as an argument for `BT_DATA_BYTES`.

BT_LE_SUPP_FEAT_16_ENCODE(w64)
Encode 2 least significant bytes of 64-bit LE Supported Features into 2 bytes long array of values in little-endian format.

Helper macro to encode 64-bit LE Supported Features value into advertising data. The macro encodes 2 least significant bytes into advertising data. Other 6 bytes are not encoded.

Example of how to encode the 0x000000DFF00DF00D into advertising data.

\[
\text{BT_DATA_BYTES(BT_DATA_LE_SUPPORTED_FEATURES, BT_LE_SUPP_FEAT_16_ENCODE(0x000000DFF00DF00D))}
\]

**Parameters**
- w64 – LE Supported Features value (64-bits)

**Returns** The comma separated values for LE Supported Features value that may be used directly as an argument for `BT_DATA_BYTES`. 

7.4. Bluetooth
Encodes the least significant byte of 64-bit LE Supported Features into single byte long array.

Helper macro to encode 64-bit LE Supported Features value into advertising data. The macro encodes the least significant byte into advertising data. Other 7 bytes are not encoded.

Example of how to encode the 0x000000DFF00DF00D into advertising data.

```c
BT_DATA_BYTES(BT_DATA_LE_SUPPORTED_FEATURES, BT_LE_SUPP_FEAT_8_ENCODE(0x000000DFF00DF00D))
```

**Parameters**

- `w64` – LE Supported Features value (64-bits)

**Returns** The value of least significant byte of LE Supported Features value that may be used directly as an argument for `BT_DATA_BYTES`.

Validates whether LE Supported Features value does not use bits that are reserved for future use.

Helper macro to check if `w64` has zeros as bits 40-63. The macro is compliant with BT 5.3 Core Specification where bits 0-40 has assigned values. In case of invalid value, build time error is reported.

**Enums**

```c
enum [anonymous]
    LE PHY types
    
    Values:
    
    enumerator BT_GAP_LE_PHY_NONE = 0
            Convenience macro for when no PHY is set.

    enumerator BT_GAP_LE_PHY_1M = BIT(0)
            LE 1M PHY

    enumerator BT_GAP_LE_PHY_2M = BIT(1)
            LE 2M PHY

    enumerator BT_GAP_LE_PHY_CODED = BIT(2)
            LE Coded PHY
```

```c
enum [anonymous]
    Advertising PDU types
    
    Values:
    
    enumerator BT_GAP_ADV_TYPE_ADV_IND = 0x00
            Scannable and connectable advertising.

    enumerator BT_GAP_ADV_TYPE_ADV_DIRECT_IND = 0x01
            Directed connectable advertising.
```
enumerator BT_GAP_ADV_TYPE_ADV_SCAN_IND = 0x02
Non-connectable and scannable advertising.

enumerator BT_GAP_ADV_TYPE_ADV_NONCONN_IND = 0x03
Non-connectable and non-scannable advertising.

enumerator BT_GAP_ADV_TYPE_SCAN_RSP = 0x04
Additional advertising data requested by an active scanner.

enumerator BT_GAP_ADV_TYPE_EXT_ADV = 0x05
Extended advertising, see advertising properties.

enum [anonymous]
Advertise PDU properties

Values:

enumerator BT_GAP_ADV_PROP_CONNECTABLE = BIT(0)
Connectable advertising.

enumerator BT_GAP_ADV_PROP_SCANNABLE = BIT(1)
Scannable advertising.

enumerator BT_GAP_ADV_PROP_DIRECTED = BIT(2)
Directed advertising.

enumerator BT_GAP_ADV_PROP_SCAN_RESPONSE = BIT(3)
Additional Advertising data requested by an active scanner.

enumerator BT_GAP_ADV_PROP_EXT_ADV = BIT(4)
Extended advertising.

enum [anonymous]
Constant Tone Extension (CTE) types

Values:

enumerator BT_GAP_CTE_AOA = 0x00
Angle of Arrival

enumerator BT_GAP_CTE_AOD_1US = 0x01
Angle of Departure with 1 us slots

enumerator BT_GAP_CTE_AOD_2US = 0x02
Angle of Departure with 2 us slots

enumerator BT_GAP_CTE_NONE = 0xFF
No extensions

enum [anonymous]
Peripheral sleep clock accuracy (SCA) in ppm (parts per million)

Values:

enumerator BT_GAP_SCA_UNKNOWN = 0
enumerator BT_GAP_SCA_251_500 = 0
enumerator BT_GAP_SCA_151_250 = 1
enumerator BT_GAP_SCA_101_150 = 2
enumerator BT_GAP_SCA_76_100 = 3
enumerator BT_GAP_SCA_51_75 = 4
enumerator BT_GAP_SCA_31_50 = 5
enumerator BT_GAP_SCA_21_30 = 6
enumerator BT_GAP_SCA_0_20 = 7

7.4.6 Generic Attribute Profile (GATT)

GATT layer manages the service database providing APIs for service registration and attribute declaration.

Services can be registered using `bt_gatt_service_register()` API which takes the `bt_gatt_service` struct that provides the list of attributes the service contains. The helper macro `BT_GATT_SERVICE()` can be used to declare a service.

Attributes can be declared using the `bt_gatt_attr` struct or using one of the helper macros:

- `BT_GATT_PRIMARY_SERVICE` Declares a Primary Service.
- `BT_GATT_SECONDARY_SERVICE` Declares a Secondary Service.
- `BT_GATT_INCLUDE_SERVICE` Declares a Include Service.
- `BT_GATT_CHARACTERISTIC` Declares a Characteristic.
- `BT_GATT_DESCRIPTOR` Declares a Descriptor.
- `BT_GATT_ATTRIBUTE` Declares an Attribute.
- `BT_GATT_CCC` Declares a Client Characteristic Configuration.
- `BT_GATT_CEP` Declares a Characteristic Extended Properties.
- `BT_GATT_CUD` Declares a Characteristic User Format.

Each attribute contain a uuid, which describes their type, a read callback, a write callback and a set of permission. Both read and write callbacks can be set to NULL if the attribute permission don’t allow their respective operations.

**Note:** Attribute read and write callbacks are called directly from RX Thread thus it is not recommended to block for long periods of time in them.
Attribute value changes can be notified using `bt_gatt_notify()` API, alternatively there is `bt_gatt_notify_cb()` where it is possible to pass a callback to be called when it is necessary to know the exact instant when the data has been transmitted over the air. Indications are supported by `bt_gatt_indicate()` API.

Client procedures can be enabled with the configuration option: `CONFIG_BT_GATT_CLIENT`

Discover procedures can be initiated with the use of `bt_gatt_discover()` API which takes the `bt_gatt_discover_params` struct which describes the type of discovery. The parameters also serve as a filter when setting the `uuid` field only attributes which matches will be discovered, in contrast setting it to NULL allows all attributes to be discovered.

**Note:** Caching discovered attributes is not supported.

Read procedures are supported by `bt_gatt_read()` API which takes the `bt_gatt_read_params` struct as parameters. In the parameters one or more attributes can be set, though setting multiple handles requires the option: `CONFIG_BT_GATT_READ_MULTIPLE`

Write procedures are supported by `bt_gatt_write()` API and takes `bt_gatt_write_params` struct as parameters. In case the write operation don’t require a response `bt_gatt_write_without_response()` or `bt_gatt_write_without_response_cb()` APIs can be used, with the later working similarly to `bt_gatt_notify_cb()`.

Subscriptions to notification and indication can be initiated with use of `bt_gatt_subscribe()` API which takes `bt_gatt_subscribe_params` as parameters. Multiple subscriptions to the same attribute are supported so there could be multiple `notify` callback being triggered for the same attribute. Subscriptions can be removed with use of `bt_gatt_unsubscribe()` API.

**Note:** When subscriptions are removed `notify` callback is called with the data set to NULL.

### API Reference

#### Group bt_gatt

Generic Attribute Profile (GATT)

**Defines**

- `BT_GATT_ERR(_att_err)`
  
  Construct error return value for attribute read and write callbacks.

  **Parameters**

  - `_att_err` – ATT error code

  **Returns** Appropriate error code for the attribute callbacks.

- `BT_GATT_CHRC_BROADCAST`
  
  Characteristic broadcast property.

  Characteristic Properties Bit field values

  If set, permits broadcasts of the Characteristic Value using Server Characteristic Configuration Descriptor.

- `BT_GATT_CHRC_READ`
  
  Characteristic read property.

  If set, permits reads of the Characteristic Value.
BT_GATT_CHRC_WRITE_WITHOUT_RESP
   Characteristic write without response property.
   If set, permits write of the Characteristic Value without response.

BT_GATT_CHRC_WRITE
   Characteristic write with response property.
   If set, permits write of the Characteristic Value with response.

BT_GATT_CHRC_NOTIFY
   Characteristic notify property.
   If set, permits notifications of a Characteristic Value without acknowledgment.

BT_GATT_CHRC_INDICATE
   Characteristic indicate property.
   If set, permits indications of a Characteristic Value with acknowledgment.

BT_GATT_CHRC_AUTH
   Characteristic Authenticated Signed Writes property.
   If set, permits signed writes to the Characteristic Value.

BT_GATT_CHRC_EXT_PROP
   Characteristic Extended Properties property.
   If set, additional characteristic properties are defined in the Characteristic Extended Properties Descriptor.

BT_GATT_CEP_RELIABLE_WRITE
   Characteristic Extended Properties Bit field values

BT_GATT_CEP_WRITABLE_AUX

BT_GATT_CCC_NOTIFY
   Client Characteristic Configuration Notification.
   Client Characteristic Configuration Values
   If set, changes to Characteristic Value shall be notified.

BT_GATT_CCC_INDICATE
   Client Characteristic Configuration Indication.
   If set, changes to Characteristic Value shall be indicated.

BT_GATT_SCC_BROADCAST
   Server Characteristic Configuration Broadcast.
   Server Characteristic Configuration Values
   If set, the characteristic value shall be broadcast in the advertising data when the server is advertising.
Enums

enum [anonymous]
  GATT attribute permission bit field values

Values:

enumerator BT_GATT_PERM_NONE = 0
  No operations supported, e.g. for notify-only

enumerator BT_GATT_PERM_READ = BIT(0)
  Attribute read permission.

enumerator BT_GATT_PERM_WRITE = BIT(1)
  Attribute write permission.

enumerator BT_GATT_PERM_READ_ENCRYPT = BIT(2)
  Attribute read permission with encryption.

  If set, requires encryption for read access.

enumerator BT_GATT_PERM_WRITE_ENCRYPT = BIT(3)
  Attribute write permission with encryption.

  If set, requires encryption for write access.

enumerator BT_GATT_PERM_READ_AUTHEN = BIT(4)
  Attribute read permission with authentication.

  If set, requires encryption using authenticated link-key for read access.

enumerator BT_GATT_PERM_WRITE_AUTHEN = BIT(5)
  Attribute write permission with authentication.

  If set, requires encryption using authenticated link-key for write access.

enumerator BT_GATT_PERM_PREPARE_WRITE = BIT(6)
  Attribute prepare write permission.

  If set, allows prepare writes with use of BT_GATT_WRITE_FLAG_PREPARE passed to write callback.

enum [anonymous]
  GATT attribute write flags

Values:
enumerator BT_GATT_WRITE_FLAG_PREPARE = BIT(0)
Attribute prepare write flag.

If set, write callback should only check if the device is authorized but no data shall be written.

enumerator BT_GATT_WRITE_FLAG_CMD = BIT(1)
Attribute write command flag.

If set, indicates that write operation is a command (Write without response) which doesn't generate any response.

enumerator BT_GATT_WRITE_FLAG_EXECUTE = BIT(2)
Attribute write execute flag.

If set, indicates that write operation is a execute, which indicates the end of a long write, and will come after 1 or more @ref BT_GATT_WRITE_FLAG_PREPARE.

struct bt_gatt_attr
#include <gatt.h> GATT Attribute structure.

Public Members

const struct bt_uuid *uuid
Attribute UUID

ssize_t (*read)(struct bt_conn *conn, const struct bt_gatt_attr *attr, void *buf, uint16_t len, uint16_t offset)
Attribute read callback.
The callback can also be used locally to read the contents of the attribute in which case no connection will be set.

Param conn The connection that is requesting to read
Param attr The attribute that's being read
Param buf Buffer to place the read result in
Param len Length of data to read
Param offset Offset to start reading from
Return Number of bytes read, or in case of an error BT_GATT_ERR() with a specific ATT error code.

ssize_t (*write)(struct bt_conn *conn, const struct bt_gatt_attr *attr, const void *buf, uint16_t len, uint16_t offset, uint8_t flags)
Attribute write callback.

Param conn The connection that is requesting to write
Param attr The attribute that's being written
Param buf Buffer with the data to write
Param len Number of bytes in the buffer
Param offset Offset to start writing from
Param flags Flags (BT_GATT_WRITE_*)
**Return** Number of bytes written, or in case of an error `BT_GATT_ERR()` with a specific ATT error code.

```c
void *user_data
    Attribute user data

uint16_t handle
    Attribute handle

uint8_t perm
    Attribute permissions
```

```c
struct bt_gatt_service_static
    #include <gatt.h> GATT Service structure.

    Public Members

    const struct bt_gatt_attr *attrs
        Service Attributes

    size_t attr_count
        Service Attribute count
```

```c
struct bt_gatt_service
    #include <gatt.h> GATT Service structure.

    Public Members

    struct bt_gatt_attr *attrs
        Service Attributes

    size_t attr_count
        Service Attribute count
```

```c
struct bt_gatt_service_val
    #include <gatt.h> Service Attribute Value.

    Public Members

    const struct bt_uuid *uuid
        Service UUID.

    uint16_t end_handle
        Service end handle.
```

```c
struct bt_gatt_include
    #include <gatt.h> Include Attribute Value.
```

7.4. Bluetooth
Public Members

const struct bt_uuid *uuid
   Service UUID.

uint16_t start_handle
   Service start handle.

uint16_t end_handle
   Service end handle.

struct bt_gatt_cb
   #include <gatt.h> GATT callback structure.

Public Members

void (*att_mtu_updated)(struct bt_conn *conn, uint16_t tx, uint16_t rx)
   The maximum ATT MTU on a connection has changed.
   Param conn Connection object.
   Param tx Updated TX ATT MTU.
   Param rx Updated RX ATT MTU.

struct bt_gatt_chrc
   #include <gatt.h> Characteristic Attribute Value.

Public Members

const struct bt_uuid *uuid
   Characteristic UUID.

uint16_t value_handle
   Characteristic Value handle.

uint8_t properties
   Characteristic properties.

struct bt_gatt_cep
   #include <gatt.h> Characteristic Extended Properties Attribute Value.

Public Members

uint16_t properties
   Characteristic Extended properties

struct bt_gatt_ccc
   #include <gatt.h> Client Characteristic Configuration Attribute Value
Public Members

```c
uint16_t flags
   Client Characteristic Configuration flags
```

```c
struct bt_gatt_scc
#include <gatt.h> Server Characteristic Configuration Attribute Value
```

Public Members

```c
uint16_t flags
   Server Characteristic Configuration flags
```

```c
struct bt_gatt_cpf
#include <gatt.h> GATT Characteristic Presentation Format Attribute Value.
```

Public Members

```c
uint8_t format
   Format of the value of the characteristic

int8_t exponent
   Exponent field to determine how the value of this characteristic is further formatted

uint16_t unit
   Unit of the characteristic

uint8_t name_space
   Name space of the description

uint16_t description
   Description of the characteristic as defined in a higher layer profile
```

GATT Server

```c
group bt_gatt_server
```

Defines

```c
BT_GATT_SERVICE_DEFINE(_name, ...)
   Statically define and register a service.
   Helper macro to statically define and register a service.
```

```c
Parameters
   • _name – Service name.
```

```c
BT_GATT_SERVICE_INSTANCE_DEFINE(_name, _instances, _instance_num, _attrs_def)
   Statically define service structure array.
   Helper macro to statically define service structure array. Each element of the array is linked to the service attribute array which is also defined in this scope using _attrs_def macro.
```

```c
Parameters
```

7.4. Bluetooth
* _name – Name of service structure array.
* _instances – Array of instances to pass as user context to the attribute call-
  backs.
* _instance_num – Number of elements in instance array.
* _attrs_def – Macro provided by the user that defines attribute array for the
  service. This macro should accept single parameter which is the instance con-
  text.

BT_GATT_SERVICE(_attrs)
Service Structure Declaration Macro.
Helper macro to declare a service structure.

Parameters
* _attrs – Service attributes.

BT_GATT_PRIMARY_SERVICE(_service)
Primary Service Declaration Macro.
Helper macro to declare a primary service attribute.

Parameters
* _service – Service attribute value.

BT_GATT_SECONDARY_SERVICE(_service)
Secondary Service Declaration Macro.
Helper macro to declare a secondary service attribute.

Parameters
* _service – Service attribute value.

BT_GATT_INCLUDE_SERVICE(_service_incl)
Include Service Declaration Macro.
Helper macro to declare database internal include service attribute.

Parameters
* _service_incl – the first service attribute of service to include

BT_GATT_CHRC_INIT(_uuid, _handle, _props)

BT_GATT_CHARACTERISTIC(_uuid, _props, _perm, _read, _write, _user_data)
Characteristic and Value Declaration Macro.
Helper macro to declare a characteristic attribute along with its attribute value.

Parameters
* _uuid – Characteristic attribute uuid.
* _props – Characteristic attribute properties.
* _perm – Characteristic Attribute access permissions.
* _read – Characteristic Attribute read callback.
* _write – Characteristic Attribute write callback.
* _user_data – Characteristic Attribute user data.

BT_GATT_CCC_MAX
BT_GATT_CCC_INITIALIZER(_changed, _write, _match)
Initialize Client Characteristic Configuration Declaration Macro.
Helper macro to initialize a Managed CCC attribute value.

Parameters
• _changed – Configuration changed callback.
• _write – Configuration write callback.
• _match – Configuration match callback.

BT_GATT_CCC_MANAGED(_ccc, _perm)
Managed Client Characteristic Configuration Declaration Macro.
Helper macro to declare a Managed CCC attribute.

Parameters
• _ccc – CCC attribute user data, shall point to a _bt_gatt_ccc.
• _perm – CCC access permissions.

BT_GATT_CCC(_changed, _perm)
Client Characteristic Configuration Declaration Macro.
Helper macro to declare a CCC attribute.

Parameters
• _changed – Configuration changed callback.
• _perm – CCC access permissions.

BT_GATT_CEP(_value)
Characteristic Extended Properties Declaration Macro.
Helper macro to declare a CEP attribute.

Parameters
• _value – Pointer to a struct bt_gatt_cep.

BT_GATT_CUD(_value, _perm)
Characteristic User Format Descriptor Declaration Macro.
Helper macro to declare a CUD attribute.

Parameters
• _value – User description NULL-terminated C string.
• _perm – Descriptor attribute access permissions.

BT_GATT_CPF(_value)
Characteristic Presentation Format Descriptor Declaration Macro.
Helper macro to declare a CPF attribute.

Parameters
• _value – Pointer to a struct bt_gatt_cpf.

BT_GATT_DESCRIPTOR(_uuid, _perm, _read, _write, _user_data)
Descriptor Declaration Macro.
Helper macro to declare a descriptor attribute.

Parameters
• _uuid – Descriptor attribute uuid.
• _perm – Descriptor attribute access permissions.
• _read – Descriptor attribute read callback.
• _write – Descriptor attribute write callback.
• _user_data – Descriptor attribute user data.

BT_GATT_ATTRIBUTE(_uuid, _perm, _read, _write, _user_data)
Attribute Declaration Macro.

Helper macro to declare an attribute.

Parameters
• _uuid – Attribute uuid.
• _perm – Attribute access permissions.
• _read – Attribute read callback.
• _write – Attribute write callback.
• _user_data – Attribute user data.

Typedefs

typedef uint8_t (*bt_gatt_attr_func_t)(const struct bt_gatt_attr *attr, uint16_t handle, void *user_data)
Attribute iterator callback.

    Param attr   Attribute found.
    Param handle Attribute handle found.
    Param user_data Data given.
    Return BT_GATT_ITER_CONTINUE if should continue to the next attribute.
    Return BT_GATT_ITER_STOP to stop.

typedef void (*bt_gatt_complete_func_t)(struct bt_conn *conn, void *user_data)
Notification complete result callback.

    Param conn Connection object.
    Param user_data Data passed in by the user.

typedef void (*bt_gatt_indicate_func_t)(struct bt_conn *conn, struct bt_gatt_indicate_params *params, uint8_t err)
Indication complete result callback.

    Param conn Connection object.
    Param params Indication params object.
    Param err ATT error code

typedef void (*bt_gatt_indicate_params_destroy_t)(struct bt_gatt_indicate_params *params)

Enums

typedef enum [anonymous]
    Values:
enumerator BT_GATT_ITER_STOP = 0

enumerator BT_GATT_ITER_CONTINUE

Functions

void bt_gatt_cb_register(struct bt_gatt_cb *cb)
Register GATT callbacks.

Register callbacks to monitor the state of GATT.

Parameters
• cb – Callback struct.

int bt_gatt_service_register(struct bt_gatt_service *svc)
Register GATT service.

Register GATT service. Applications can make use of macros such as
BT_GATT_PRIMARY_SERVICE, BT_GATT_CHARACTERISTIC, BT_GATT_DESCRIPTOR, etc.

When using CONFIG_BT_SETTINGS then all services that should have bond configuration
loaded, i.e. CCC values, must be registered before calling settings_load.

When using CONFIG_BT_GATT_CACHING and CONFIG_BT_SETTINGS then all services that should
be included in the GATT Database Hash calculation should be added before calling settings_load. All services registered after settings_load will trigger a new database hash cal-
culation and a new hash stored.

Parameters
• svc – Service containing the available attributes

Returns 0 in case of success or negative value in case of error.

int bt_gatt_service_unregister(struct bt_gatt_service *svc)
Unregister GATT service.

Parameters
• svc – Service to be unregistered.

Returns 0 in case of success or negative value in case of error.

bool bt_gatt_service_is_registered(const struct bt_gatt_service *svc)
Check if GATT service is registered.

Parameters
• svc – Service to be checked.

Returns true if registered or false if not register.

void bt_gatt_foreach_attr_type(uint16_t start_handle, uint16_t end_handle, const struct
tb_uuid *uuid, const void *attr_data, uint16_t num_matches,
bt_gatt_attr_func_t func, void *user_data)
Attribute iterator by type.
Iterate attributes in the given range matching given UUID and/or data.

Parameters
• start_handle – Start handle.
• end_handle – End handle.
• uuid – UUID to match, passing NULL skips UUID matching.
• attr_data – Attribute data to match, passing NULL skips data matching.
• num_matches – Number matches, passing 0 makes it unlimited.
• func – Callback function.
• user_data – Data to pass to the callback.

static inline void bt_gatt_foreach_attr(uint16_t start_handle, uint16_t end_handle, bt_gatt_attr_func_t func, void *user_data)

Attribute iterator.

Iterate attributes in the given range.

Parameters
• start_handle – Start handle.
• end_handle – End handle.
• func – Callback function.
• user_data – Data to pass to the callback.

struct bt_gatt_attr *bt_gatt_attr_next(const struct bt_gatt_attr *attr)

Iterate to the next attribute.

Iterate to the next attribute following a given attribute.

Parameters
• attr – Current Attribute.

Returns The next attribute or NULL if it cannot be found.

struct bt_gatt_attr *bt_gatt_find_by_uuid(const struct bt_gatt_attr *attr, uint16_t attr_count, const struct bt_uuid *uuid)

Find Attribute by UUID.

Find the attribute with the matching UUID. To limit the search to a service set the attr to the service attributes and the attr_count to the service attribute count.

Parameters
• attr – Pointer to an attribute that serves as the starting point for the search of a match for the UUID. Passing NULL will search the entire range.
• attr_count – The number of attributes from the starting point to search for a match for the UUID. Set to 0 to search until the end.
• uuid – UUID to match.

uint16_t bt_gatt_attr_get_handle(const struct bt_gatt_attr *attr)

Get Attribute handle.

Parameters
• attr – Attribute object.

Returns Handle of the corresponding attribute or zero if the attribute could not be found.

uint16_t bt_gatt_attr_value_handle(const struct bt_gatt_attr *attr)

Get the handle of the characteristic value descriptor.

Note: The user_data of the attribute must of type bt_gatt_chrc.
• **attr** – A Characteristic Attribute.

**Returns** the handle of the corresponding Characteristic Value. The value will be zero (the invalid handle) if **attr** was not a characteristic attribute.

```c
ssize_t bt_gatt_attr_read(struct bt_conn *conn, const struct bt_gatt_attr *attr, void *buf, uint16_t buf_len, uint16_t offset, const void *value, uint16_t value_len)
```

Generic Read Attribute value helper.

Read attribute value from local database storing the result into buffer.

**Parameters**
- **conn** – Connection object.
- **attr** – Attribute to read.
- **buf** – Buffer to store the value.
- **buf_len** – Buffer length.
- **offset** – Start offset.
- **value** – Attribute value.
- **value_len** – Length of the attribute value.

**Returns** number of bytes read in case of success or negative values in case of error.

```c
ssize_t bt_gatt_attr_read_service(struct bt_conn *conn, const struct bt_gatt_attr *attr, void *buf, uint16_t len, uint16_t offset)
```

Read Service Attribute helper.

Read service attribute value from local database storing the result into buffer after encoding it.

**Note:** Only use this with attributes which user_data is a **bt_uuid**.

**Parameters**
- **conn** – Connection object.
- **attr** – Attribute to read.
- **buf** – Buffer to store the value read.
- **len** – Buffer length.
- **offset** – Start offset.

**Returns** number of bytes read in case of success or negative values in case of error.

```c
ssize_t bt_gatt_attr_read_included(struct bt_conn *conn, const struct bt_gatt_attr *attr, void *buf, uint16_t len, uint16_t offset)
```

Read Include Attribute helper.

Read include service attribute value from local database storing the result into buffer after encoding it.

**Note:** Only use this with attributes which user_data is a **bt_gatt_include**.

**Parameters**
- **conn** – Connection object.
• attr – Attribute to read.
• buf – Buffer to store the value read.
• len – Buffer length.
• offset – Start offset.

Returns number of bytes read in case of success or negative values in case of error.

ssize_t bt_gatt_attr_read_chrc(struct bt_conn *conn, const struct bt_gatt_attr *attr, void *buf, uint16_t len, uint16_t offset)
Read Characteristic Attribute helper.
Read characteristic attribute value from local database storing the result into buffer after encoding it.

Note: Only use this with attributes which user_data is a bt_gatt_chrc.

Parameters
• conn – Connection object.
• attr – Attribute to read.
• buf – Buffer to store the value read.
• len – Buffer length.
• offset – Start offset.

Returns number of bytes read in case of success or negative values in case of error.

ssize_t bt_gatt_attr_read_ccc(struct bt_conn *conn, const struct bt_gatt_attr *attr, void *buf, uint16_t len, uint16_t offset)
Read Client Characteristic Configuration Attribute helper.
Read CCC attribute value from local database storing the result into buffer after encoding it.

Note: Only use this with attributes which user_data is a bt_gatt_ccc.

Parameters
• conn – Connection object.
• attr – Attribute to read.
• buf – Buffer to store the value read.
• len – Buffer length.
• offset – Start offset.

Returns number of bytes read in case of success or negative values in case of error.

ssize_t bt_gatt_attr_write_ccc(struct bt_conn *conn, const struct bt_gatt_attr *attr, const void *buf, uint16_t len, uint16_t offset, uint8_t flags)
Write Client Characteristic Configuration Attribute helper.
Write value in the buffer into CCC attribute.

Note: Only use this with attributes which user_data is a bt_gatt_ccc.
Parameters

- conn – Connection object.
- attr – Attribute to read.
- buf – Buffer to store the value read.
- len – Buffer length.
- offset – Start offset.
- flags – Write flags.

Returns number of bytes written in case of success or negative values in case of error.

```c
ssize_t bt_gatt_attr_read_cep(struct bt_conn *conn, const struct bt_gatt_attr *attr, void *buf,
                            uint16_t len, uint16_t offset)
```

Read Characteristic Extended Properties Attribute helper.

Read CEP attribute value from local database storing the result into buffer after encoding it.

**Note:** Only use this with attributes which user_data is a `bt_gatt_cep`.

Parameters

- conn – Connection object
- attr – Attribute to read
- buf – Buffer to store the value read
- len – Buffer length
- offset – Start offset

Returns number of bytes read in case of success or negative values in case of error.

```c
ssize_t bt_gatt_attr_read_cud(struct bt_conn *conn, const struct bt_gatt_attr *attr, void *buf,
                               uint16_t len, uint16_t offset)
```

Read Characteristic User Description Descriptor Attribute helper.

Read CUD attribute value from local database storing the result into buffer after encoding it.

**Note:** Only use this with attributes which user_data is a NULL-terminated C string.

Parameters

- conn – Connection object
- attr – Attribute to read
- buf – Buffer to store the value read
- len – Buffer length
- offset – Start offset

Returns number of bytes read in case of success or negative values in case of error.

```c
ssize_t bt_gatt_attr_read_cpf(struct bt_conn *conn, const struct bt_gatt_attr *attr, void *buf,
                               uint16_t len, uint16_t offset)
```

Read Characteristic Presentation format Descriptor Attribute helper.

Read CPF attribute value from local database storing the result into buffer after encoding it.
**Note:** Only use this with attributes which user_data is a bt_gatt_pf.

**Parameters**
- `conn` – Connection object
- `attr` – Attribute to read
- `buf` – Buffer to store the value read
- `len` – Buffer length
- `offset` – Start offset

**Returns** number of bytes read in case of success or negative values in case of error.

```c
int bt_gatt_notify_cb(struct bt_conn *conn, struct bt_gatt_notify_params *params)
```

Notify attribute value change.

This function works in the same way as `bt_gatt_notify`. With the addition that after sending the notification the callback function will be called.

The callback is run from System Workqueue context. When called from the System Workqueue context this API will not wait for resources for the callback but instead return an error. The number of pending callbacks can be increased with the `CONFIG_BT_CONN_TX_MAX` option.

Alternatively it is possible to notify by UUID by setting it on the parameters, when using this method the attribute if provided is used as the start range when looking up for possible matches.

**Parameters**
- `conn` – Connection object.
- `params` – Notification parameters.

**Returns** 0 in case of success or negative value in case of error.

```c
int bt_gatt_notify_multiple(struct bt_conn *conn, uint16_t num_params, struct bt_gatt_notify_params *params)
```

Notify multiple attribute value change.

This function works in the same way as `bt_gatt_notify_cb`.

**Parameters**
- `conn` – Connection object.
- `num_params` – Number of notification parameters.
- `params` – Array of notification parameters.

**Returns** 0 in case of success or negative value in case of error.

```c
static inline int bt_gatt_notify(struct bt_conn *conn, const struct bt_gatt_attr *attr, const void *data, uint16_t len)
```

Notify attribute value change.

Send notification of attribute value change, if connection is NULL notify all peer that have notification enabled via CCC otherwise do a direct notification only the given connection.

The attribute object on the parameters can be the so called Characteristic Declaration, which is usually declared with `BT_GATT_CHARACTERISTIC` followed by `BT_GATT_CCC`, or the Characteristic Value Declaration which is automatically created after the Characteristic Declaration when using `BT_GATT_CHARACTERISTIC`.

**Parameters**
- `conn` – Connection object.
• `attr` – Characteristic or Characteristic Value attribute.
• `data` – Pointer to Attribute data.
• `len` – Attribute value length.

**Returns** 0 in case of success or negative value in case of error.

```c
static inline int bt_gatt_notify_uuid(struct bt_conn *conn, const struct bt_uuid *uuid, const struct bt_gatt_attr *attr, const void *data, uint16_t len)
```

Notify attribute value change by UUID.

Send notification of attribute value change, if connection is NULL notify all peer that have notification enabled via CCC otherwise do a direct notification only on the given connection.

The attribute object is the starting point for the search of the UUID.

**Parameters**

• `conn` – Connection object.
• `uuid` – The UUID. If the server contains multiple services with the same UUID, then the first occurrence, starting from the `attr` given, is used.
• `attr` – Pointer to an attribute that serves as the starting point for the search of a match for the UUID.
• `data` – Pointer to Attribute data.
• `len` – Attribute value length.

**Returns** 0 in case of success or negative value in case of error.

```c
int bt_gatt_indicate(struct bt_conn *conn, struct bt_gatt_indicate_params *params)
```

Indicate attribute value change.

Send an indication of attribute value change. if connection is NULL indicate all peer that have notification enabled via CCC otherwise do a direct indication only the given connection.

The attribute object on the parameters can be the so called Characteristic Declaration, which is usually declared with `BT_GATT_CHARACTERISTIC` followed by `BT_GATT_CCC`, or the Characteristic Value Declaration which is automatically created after the Characteristic Declaration when using `BT_GATT_CHARACTERISTIC`.

Alternatively it is possible to indicate by UUID by setting it on the parameters, when using this method the attribute if provided is used as the start range when looking up for possible matches.

**Note:** This procedure is asynchronous therefore the parameters need to remains valid while it is active. The procedure is active until the destroy callback is run.

**Parameters**

• `conn` – Connection object.
• `params` – Indicate parameters.

**Returns** 0 in case of success or negative value in case of error.

```c
bool bt_gatt_is_subscribed(struct bt_conn *conn, const struct bt_gatt_attr *attr, uint16_t ccc_value)
```

Check if connection have subscribed to attribute.

Check if connection has subscribed to attribute value change.

The attribute object can be the so called Characteristic Declaration, which is usually declared with `BT_GATT_CHARACTERISTIC` followed by `BT_GATT_CCC`, or the Characteristic Value Declaration which is automatically created after the Characteristic Declaration when using
BT_GATT_CHARACTERISTIC, or the Client Characteristic Configuration Descriptor (CCCD) which is created by BT_GATT_CCC.

**Parameters**
- `conn` – Connection object.
- `attr` – Attribute object.
- `ccc_value` – The subscription type, either notifications or indications.

**Returns** true if the attribute object has been subscribed.

```c
uint16_t bt_gatt_get_mtu(struct bt_conn *conn)
```

Get ATT MTU for a connection.

Get negotiated ATT connection MTU, note that this does not equal the largest amount of attribute data that can be transferred within a single packet.

**Parameters**
- `conn` – Connection object.

**Returns** MTU in bytes

```c
struct bt_gatt_ccc_cfg
#include <gatt.h> GATT CCC configuration entry.
```

**Public Members**

```c
uint8_t id
Local identity, BT_ID_DEFAULT in most cases.
```

```c
bt_addr_le_t peer
Remote peer address.
```

```c
uint16_t value
Configuration value.
```

```c
struct bt_gatt_notify_params
#include <gatt.h>
```

**Public Members**

```c
const struct bt_uuid *uuid
Notification Attribute UUID type.
```

Optional, use to search for an attribute with matching UUID when the attribute object pointer is not known.

```c
const struct bt_gatt_attr *attr
Notification Attribute object.
```

Optional if uuid is provided, in this case it will be used as start range to search for the attribute with the given UUID.

```c
const void *data
Notification Value data
```

```c
uint16_t len
    Notification Value length

bt_gatt_complete_func_t func
    Notification Value callback

void *user_data
    Notification Value callback user data

struct bt_gatt_indicate_params
    #include <gatt.h> GATT Indicate Value parameters.

Public Members

const struct bt_uuid *uuid
    Indicate Attribute UUID type.
    Optional, use to search for an attribute with matching UUID when the attribute object
    pointer is not known.

const struct bt_gatt_attr *attr
    Indicate Attribute object.
    Optional if uuid is provided, in this case it will be used as start range to search for the
    attribute with the given UUID.

bt_gatt_indicate_func_t func
    Indicate Value callback

bt_gatt_indicate_params_destroy_t destroy
    Indicate operation complete callback

const void *data
    Indicate Value data

uint16_t len
    Indicate Value length
```

**GATT Client**

`group bt_gatt_client`

**Typedefs**

```c
typedef uint8_t (*bt_gatt_discover_func_t)(struct bt_conn *conn, const struct bt_gatt_attr
    *attr, struct bt_gatt_discover_params *params)
    Discover attribute callback function.
```

If discovery procedure has completed this callback will be called with attr set to NULL. This
will not happen if procedure was stopped by returning BT_GATT_ITER_STOP.

---

7.4. Bluetooth
The attribute object as well as its UUID and value objects are temporary and must be copied to in order to cache its information. Only the following fields of the attribute contains valid information:

- **uuid** UUID representing the type of attribute.
- **handle** Handle in the remote database.
- **user_data** The value of the attribute. Will be NULL when discovering descriptors.

To be able to read the value of the discovered attribute the user_data must be cast to an appropriate type.

- **bt_gatt_service_val** when UUID is `BT_UUID_GATT_PRIMARY` or `BT_UUID_GATT_SECONDARY`.
- **bt_gatt_include** when UUID is `BT_UUID_GATT_INCLUDE`.
- **bt_gatt_chrc** when UUID is `BT_UUID_GATT_CHRC`.

**Param conn** Connection object.

**Param attr** Attribute found, or NULL if not found.

**Param params** Discovery parameters given.

**Return** `BT_GATT_ITER_CONTINUE` to continue discovery procedure.

**Return** `BT_GATT_ITER_STOP` to stop discovery procedure.

typedef uint8_t (*bt_gatt_read_func_t)(struct bt_conn *conn, uint8_t err, struct bt_gatt_read_params *params, const void *data, uint16_t length)

Read callback function.

- **Param conn** Connection object.
- **Param err** ATT error code.
- **Param params** Read parameters used.
- **Param data** Attribute value data. NULL means read has completed.
- **Param length** Attribute value length.

**Return** `BT_GATT_ITER_CONTINUE` if should continue to the next attribute.

**Return** `BT_GATT_ITER_STOP` to stop.

typedef void (*bt_gatt_write_func_t)(struct bt_conn *conn, uint8_t err, struct bt_gatt_write_params *params)

Write callback function.

- **Param conn** Connection object.
- **Param err** ATT error code.
- **Param params** Write parameters used.

typedef uint8_t (*bt_gatt_notify_func_t)(struct bt_conn *conn, struct bt_gatt_subscribe_params *params, const void *data, uint16_t length)

Notification callback function.

In the case of an empty notification, the data pointer will be non-NULL while the length will be 0, which is due to the special case where a data NULL pointer means unsubscribed.

- **Param conn** Connection object. May be NULL, indicating that the peer is being un-paired.
- **Param params** Subscription parameters.
**Param data** Attribute value data. If NULL then subscription was removed.

**Param length** Attribute value length.

**Return** BT_GATT_ITER_CONTINUE to continue receiving value notifications. BT_GATT_ITER_STOP to unsubscribe from value notifications.

## Enums

```c
enum [anonymous]
GATT Discover types

Values:

enumerator BT_GATT_DISCOVER_PRIMARY
    Discover Primary Services.

enumerator BT_GATT_DISCOVER_SECONDARY
    Discover Secondary Services.

enumerator BT_GATT_DISCOVER_INCLUDE
    Discover Included Services.

enumerator BT_GATT_DISCOVER_CHARACTERISTIC
    Discover Characteristic Values.
```

Discover Characteristic Value and its properties.

```c
enumerator BT_GATT_DISCOVER_DESCRIPTOR
    Discover Descriptors.
```

Discover Attributes which are not services or characteristics.

@note The use of this type of discover is not recommended for discovering in ranges across multiple services/characteristics as it may incur in extra round trips.

```c
enumerator BT_GATT_DISCOVER_ATTRIBUTE
    Discover Attributes.
```

Discover Attributes of any type.

@note The use of this type of discover is not recommended for discovering in ranges across multiple services/characteristics as it may incur in more round trips.

```c
enumerator BT_GATT_DISCOVER_STD_CHAR_DESC
    Discover standard characteristic descriptor values.
```
Discover standard characteristic descriptor values and their properties.

Supported descriptors:
- Characteristic Extended Properties
- Client Characteristic Configuration
- Server Characteristic Configuration
- Characteristic Presentation Format

```c
enum [anonymous] Subscription flags

Values:

enumerator BT_GATT_SUBSCRIBE_FLAG_VOLATILE
Persistence flag.

If set, indicates that the subscription is not saved on the GATT server side. Therefore, upon disconnection, the subscription will be automatically removed from the client’s subscriptions list and when the client reconnects, it will have to issue a new subscription.

enumerator BT_GATT_SUBSCRIBE_FLAG_NO_RESUB
No resubscribe flag.

By default when BT_GATT_SUBSCRIBE_FLAG_VOLATILE is unset, the subscription will be automatically renewed when the client reconnects, as a workaround for GATT servers that do not persist subscriptions.

This flag will disable the automatic resubscription. It is useful if the application layer knows that the GATT server remembers subscriptions from previous connections and wants to avoid renewing the subscriptions.

enumerator BT_GATT_SUBSCRIBE_FLAG_WRITE_PENDING
Write pending flag.

If set, indicates write operation is pending waiting remote end to respond.

enumerator BT_GATT_SUBSCRIBE_NUM_FLAGS
```

Functions

```c
int bt_gatt_exchange_mtu(struct bt_conn *conn, struct bt_gatt_exchange_params *params)
Exchange MTU.
```
This client procedure can be used to set the MTU to the maximum possible size the buffers can hold.

The Response comes in callback `params->func`. The callback is run from the BT RX thread. `params` must remain valid until start of callback.

This function will block while the ATT request queue is full, except when called from the BT RX thread, as this would cause a deadlock.

**Note:** Shall only be used once per connection.

**Parameters**
- `conn` – Connection object.
- `params` – Exchange MTU parameters.

**Return values**
- `0` – Successfully queued request. Will call `params->func` on resolution.
- `-ENOMEM` – ATT request queue is full and blocking would cause deadlock. Allow a pending request to resolve before retrying, or call this function outside the BT RX thread to get blocking behavior. Queue size is controlled by `CONFIG_BT_L2CAP_TX_BUF_COUNT`.

```c
int bt_gatt_discover(struct bt_conn *conn, struct bt_gatt_discover_params *params)
```

GATT Discover function.

This procedure is used by a client to discover attributes on a server.

Primary Service Discovery: Procedure allows to discover specific Primary Service based on UUID. Include Service Discovery: Procedure allows to discover all Include Services within specified range. Characteristic Discovery: Procedure allows to discover all characteristics within specified handle range as well as discover characteristics with specified UUID. Descriptors Discovery: Procedure allows to discover all characteristic descriptors within specified range.

For each attribute found the callback is called which can then decide whether to continue discovering or stop.

The Response comes in callback `params->func`. The callback is run from the BT RX thread. `params` must remain valid until start of callback where `iter.attr` is `NULL` or callback will return `BT_GATT_ITER_STOP`.

This function will block while the ATT request queue is full, except when called from the BT RX thread, as this would cause a deadlock.

**Parameters**
- `conn` – Connection object.
- `params` – Discover parameters.

**Return values**
- `0` – Successfully queued request. Will call `params->func` on resolution.
- `-ENOMEM` – ATT request queue is full and blocking would cause deadlock. Allow a pending request to resolve before retrying, or call this function outside the BT RX thread to get blocking behavior. Queue size is controlled by `CONFIG_BT_L2CAP_TX_BUF_COUNT`.

7.4. Bluetooth
int bt_gatt_read(struct bt_conn *conn, struct bt_gatt_read_params *params)

Read Attribute Value by handle.

This procedure read the attribute value and return it to the callback.

When reading attributes by UUID the callback can be called multiple times depending on
how many instances of given the UUID exists with the start_handle being updated for each
instance.

If an instance does contain a long value which cannot be read entirely the caller will need to
read the remaining data separately using the handle and offset.

The Response comes in callback params->func. The callback is run from the BT RX thread.
params must remain valid until start of callback.

This function will block while the ATT request queue is full, except when called from the BT
RX thread, as this would cause a deadlock.

Parameters

• conn – Connection object.
• params – Read parameters.

Return values

• 0 – Successfully queued request. Will call params->func on resolution.
• -ENOMEM – ATT request queue is full and blocking would cause deadlock. Al-

dow a pending request to resolve before retrying, or call this function out-
side the BT RX thread to get blocking behavior. Queue size is controlled by
CONFIG_BT_L2CAP_TX_BUF_COUNT.

int bt_gatt_write(struct bt_conn *conn, struct bt_gatt_write_params *params)

Write Attribute Value by handle.

The Response comes in callback params->func. The callback is run from the BT RX thread.
params must remain valid until start of callback.

This function will block while the ATT request queue is full, except when called from Bluetooth
event context. When called from Bluetooth context, this function will instead instead return
-ENOMEM if it would block to avoid a deadlock.

Parameters

• conn – Connection object.
• params – Write parameters.

Return values

• 0 – Successfully queued request. Will call params->func on resolution.
• -ENOMEM – ATT request queue is full and blocking would cause deadlock. Al-

dow a pending request to resolve before retrying, or call this function outside
Bluetooth event context to get blocking behavior. Queue size is controlled by
CONFIG_BT_L2CAP_TX_BUF_COUNT.

int bt_gatt_write_without_response_cb(struct bt_conn *conn, uint16_t handle, const void *
data, uint16_t length, bool sign,
       bt_gatt_complete_func_t func, void *user_data)

Write Attribute Value by handle without response with callback.

This function works in the same way as bt_gatt_write_without_response. With the addition
that after sending the write the callback function will be called.

The callback is run from System Workqueue context. When called from the System Workqueue
context this API will not wait for resources for the callback but instead return an error. The
number of pending callbacks can be increased with the CONFIG_BT_CONN_TX_MAX option.
This function will block while the ATT request queue is full, except when called from the BT RX thread, as this would cause a deadlock.

**Note:** By using a callback it also disable the internal flow control which would prevent sending multiple commands without waiting for their transmissions to complete, so if that is required the caller shall not submit more data until the callback is called.

### Parameters

- `conn` – Connection object.
- `handle` – Attribute handle.
- `data` – Data to be written.
- `length` – Data length.
- `sign` – Whether to sign data
- `func` – Transmission complete callback.
- `user_data` – User data to be passed back to callback.

### Return values

- `0` – Successfully queued request.
- `-ENOMEM` – ATT request queue is full and blocking would cause deadlock. Allow a pending request to resolve before retrying, or call this function outside the BT RX thread to get blocking behavior. Queue size is controlled by `CONFIG_BT_L2CAP_TX_BUF_COUNT`.

```c
static inline int bt_gatt_write_without_response(struct bt_conn *conn, uint16_t handle, const void *data, uint16_t length, bool sign)
```

Write Attribute Value by handle without response.

This procedure write the attribute value without requiring an acknowledgment that the write was successfully performed.

This function will block while the ATT request queue is full, except when called from the BT RX thread, as this would cause a deadlock.

### Parameters

- `conn` – Connection object.
- `handle` – Attribute handle.
- `data` – Data to be written.
- `length` – Data length.
- `sign` – Whether to sign data

### Return values

- `0` – Successfully queued request.
- `-ENOMEM` – ATT request queue is full and blocking would cause deadlock. Allow a pending request to resolve before retrying, or call this function outside the BT RX thread to get blocking behavior. Queue size is controlled by `CONFIG_BT_L2CAP_TX_BUF_COUNT`.

```c
int bt_gatt_subscribe(struct bt_conn *conn, struct bt_gatt_subscribe_params *params)
```

Subscribe Attribute Value Notification.

7.4. Bluetooth

265
This procedure subscribe to value notification using the Client Characteristic Configuration handle. If notification received subscribe value callback is called to return notified value. One may then decide whether to unsubscribe directly from this callback. Notification callback with NULL data will not be called if subscription was removed by this method.

The Response comes in callback params->func. The callback is run from the BT RX thread. params must remain valid until start of callback. The Notification callback params->notify is also called from the BT RX thread.

This function will block while the ATT request queue is full, except when called from the BT RX thread, as this would cause a deadlock.

**Note:** Notifications are asynchronous therefore the parameters need to remain valid while subscribed.

### Parameters
- **conn** – Connection object.
- **params** – Subscribe parameters.

### Return values
- 0 – Successfully queued request. Will call params->write on resolution.
- -ENOMEM – ATT request queue is full and blocking would cause deadlock. Allow a pending request to resolve before retrying, or call this function outside the BT RX thread to get blocking behavior. Queue size is controlled by CONFIG_BT_L2CAP_TX_BUF_COUNT.

```c
int bt_gatt_resubscribe(uint8_t id, const bt_addr_le_t *peer, struct bt_gatt_subscribe_params *params)
```

Resubscribe Attribute Value Notification subscription.

Resubscribe to Attribute Value Notification when already subscribed from a previous connection. The GATT server will remember subscription from previous connections when bonded, so resubscribing can be done without performing a new subscribe procedure after a power cycle.

**Note:** Notifications are asynchronous therefore the parameters need to remain valid while subscribed.

### Parameters
- **id** – Local identity (in most cases BT_ID_DEFAULT).
- **peer** – Remote address.
- **params** – Subscribe parameters.

### Returns
0 in case of success or negative value in case of error.

```c
int bt_gatt_unsubscribe(struct bt_conn *conn, struct bt_gatt_subscribe_params *params)
```

Unsubscribe Attribute Value Notification.

This procedure unsubscribe to value notification using the Client Characteristic Configuration handle. Notification callback with NULL data will be called if subscription was removed by this call, until then the parameters cannot be reused.

The Response comes in callback params->func. The callback is run from the BT RX thread.
This function will block while the ATT request queue is full, except when called from the BT RX thread, as this would cause a deadlock.

**Parameters**

- `conn` – Connection object.
- `params` – Subscribe parameters.

**Return values**

- 0 – Successfully queued request. Will call `params->write` on resolution.
- -ENOMEM – ATT request queue is full and blocking would cause deadlock. Allow a pending request to resolve before retrying, or call this function outside the BT RX thread to get blocking behavior. Queue size is controlled by `CONFIG_BT_L2CAP_TX_BUF_COUNT`.

```c
void bt_gatt_cancel(struct bt_conn *conn, void *params)
```

Try to cancel the first pending request identified by `params`.

This function does not release `params` for reuse. The usual callbacks for the request still apply. A successful cancel simulates a BT_ATT_ERR_UNLIKELY response from the server.

This function can cancel the following request functions:

- `bt_gatt_exchange_mtu`
- `bt_gatt_discover`
- `bt_gatt_read`
- `bt_gatt_write`
- `bt_gatt_subscribe`
- `bt_gatt_unsubscribe`

**Parameters**

- `conn` – The connection the request was issued on.
- `params` – The address `params` used in the request function call.

```c
struct bt_gatt_exchange_params
#include <gatt.h> GATT Exchange MTU parameters.
```

**Public Members**

```c
void (*func)(struct bt_conn *conn, uint8_t err, struct bt_gatt_exchange_params *params)
```

Response callback

```c
struct bt_gatt_discover_params
#include <gatt.h> GATT Discover Attributes parameters.
```

**Public Members**

```c
const struct bt_uuid *uuid
```

Discover UUID type

```c
bt_gatt_discover_func_t func
```

Discover attribute callback

```c
uint16_t attr_handle
    Include service attribute declaration handle

uint16_t start_handle
    Included service start handle
    Discover start handle

uint16_t end_handle
    Included service end handle
    Discover end handle

uint8_t type
    Discover type

struct bt_gatt_read_params
    #include <gatt.h> GATT Read parameters.

    Public Members

    bt_gatt_read_func_t func
        Read attribute callback.

    size_t handle_count
        If equals to 1 single.handle and single.offset are used. If greater than 1 multiple.handles
        are used. If equals to 0 by_uuid is used for Read Using Characteristic UUID.

    uint16_t handle
        Attribute handle.

    uint16_t offset
        Attribute data offset.

    uint16_t *handles
        Attribute handles to read with Read Multiple Characteristic Values.

    bool variable
        If true use Read Multiple Variable Length Characteristic Values procedure. The values of
        the set of attributes may be of variable or unknown length. If false use Read Multiple
        Characteristic Values procedure. The values of the set of attributes must be of a known
        fixed length, with the exception of the last value that can have a variable length.

    uint16_t start_handle
        First requested handle number.

    uint16_t end_handle
        Last requested handle number.

    const struct bt_uuid *uuid
        2 or 16 octet UUID.
```

enumerator BT_HCI_DRIVER_BUS_I2C = 8

enumerator BT_HCI_DRIVER_BUS_IPM = 9
Functions

static inline uint8_t bt_hci_evt_get_flags(uint8_t evt)
Get HCI event flags.

Helper for the HCI driver to get HCI event flags that describes rules that must be followed.

When CONFIG_BT_RECV_IS_RX_THREAD is enabled the flags BT_HCI_EVT_FLAG_RECV and BT_HCI_EVT_FLAG_RECV_PRIO indicates if the event should be given to bt_recv or bt_recv_prio.

**Parameters**
- evt – HCI event code.

**Returns** HCI event flags for the specified event.

int bt_recv(struct net_buf *buf)
Receive data from the controller/HCI driver.

This is the main function through which the HCI driver provides the host with data from the controller. The buffer needs to have its type set with the help of bt_buf_set_type() before calling this API.

When CONFIG_BT_RECV_IS_RX_THREAD is defined then this API should not be used for so-called high priority HCI events, which should instead be delivered to the host stack through bt_recv_prio().

**Parameters**
- buf – Network buffer containing data from the controller.

**Returns** 0 on success or negative error number on failure.

int bt_recv_prio(struct net_buf *buf)
Receive high priority data from the controller/HCI driver.

This is the same as bt_recv(), except that it should be used for so-called high priority HCI events. There's a separate bt_hci_evt_get_flags() helper that can be used to identify which events have the BT_HCI_EVT_FLAG_RECV_PRIO flag set.

As with bt_recv(), the buffer needs to have its type set with the help of bt_buf_set_type() before calling this API. The only exception is so called high priority HCI events which should be delivered to the host stack through bt_recv_prio() instead.

**Parameters**
- buf – Network buffer containing data from the controller.

**Returns** 0 on success or negative error number on failure.

uint8_t bt_read_static_addr(struct bt_hci_vs_static_addr addr[], uint8_t size)
Read static addresses from the controller.

**Parameters**
- addr – Random static address and Identity Root (IR) array.
- size – Size of array.

**Returns** Number of addresses read.

int bt_hci_driver_register(const struct bt_hci_driver *drv)
Register a new HCI driver to the Bluetooth stack.

This needs to be called before any application code runs. The bt_enable() API will fail if there is no driver registered.

**Parameters**
- drv – A bt_hci_driver struct representing the driver.
Returns 0 on success or negative error number on failure.

```c
int bt_hci_transport_setup(const struct device *dev)
```

Setup the HCI transport, which usually means to reset the Bluetooth IC.

**Note:** A weak version of this function is included in the H4 driver, so defining it is optional per board.

### Parameters
- `dev` – The device structure for the bus connecting to the IC

### Returns
0 on success, negative error value on failure

```c
struct net_buf *bt_hci_evt_create(uint8_t evt, uint8_t len)
```

Allocate an HCI event buffer.

This function allocates a new buffer for an HCI event. It is given the event code and the total length of the parameters. Upon successful return the buffer is ready to have the parameters encoded into it.

### Parameters
- `len` – Length of event parameters.

### Returns
Newly allocated buffer.

```c
struct net_buf *bt_hci_cmd_complete_create(uint16_t op, uint8_t plen)
```

Allocate an HCI Command Complete event buffer.

This function allocates a new buffer for HCI Command Complete event. It is given the OpCode (encoded e.g. using the BT_OP macro) and the total length of the parameters. Upon successful return the buffer is ready to have the parameters encoded into it.

### Parameters
- `plen` – Length of command parameters.

### Returns
Newly allocated buffer.

```c
struct net_buf *bt_hci_cmd_status_create(uint16_t op, uint8_t status)
```

Allocate an HCI Command Status event buffer.

This function allocates a new buffer for HCI Command Status event. It is given the OpCode (encoded e.g. using the BT_OP macro) and the status code. Upon successful return the buffer is ready to have the parameters encoded into it.

### Parameters
- `status` – Status code.

### Returns
Newly allocated buffer.

```c
struct bt_hci_driver
#include <hci_driver.h> Abstraction which represents the HCI transport to the controller.
```

This struct is used to represent the HCI transport to the Bluetooth controller.
Public Members

const char *name
   Name of the driver

enum bt HCI_driver_bus bus
   Bus of the transport (BT HCI DRIVER BUS *)

uint32_t quirks
   Specific controller quirks. These are set by the HCI driver and acted upon by the host. They can either be statically set at buildtime, or set at runtime before the HCI driver’s open() callback returns.

int (*open)(void)
   Open the HCI transport.
   Opens the HCI transport for operation. This function must not return until the transport is ready for operation, meaning it is safe to start calling the send() handler.
   If the driver uses its own RX thread, i.e. CONFIG_BT_RECV IS RX THREAD is set, then this function is expected to start that thread.
   Return 0 on success or negative error number on failure.

int (*send)(struct net_buf *buf)
   Send HCI buffer to controller.
   Send an HCI command or ACL data to the controller. The exact type of the data can be checked with the help of bt_buf_get_type().
   Note: This function must only be called from a cooperative thread.
   Param buf Buffer containing data to be sent to the controller.
   Return 0 on success or negative error number on failure.

int (*setup)(void)
   HCI vendor-specific setup.
   Executes vendor-specific commands sequence to initialize BT Controller before BT Host executes Reset sequence.
   Note: CONFIG_BT_HCI_SETUP must be selected for this field to be available.
   Return 0 on success or negative error number on failure.

### 7.4.8 HCI RAW channel

**Overview**

HCI RAW channel API is intended to expose HCI interface to the remote entity. The local Bluetooth controller gets owned by the remote entity and host Bluetooth stack is not used. RAW API provides direct access to packets which are sent and received by the Bluetooth HCI driver.
API Reference

*group* hciraw

HCI RAW channel.

**Defines**

`BT_HCI_ERR_EXT_HANDLED`

`BT_HCI_RAW_CMD_EXT(_op, _min_len, _func)`

Helper macro to define a command extension

**Parameters**

- `_op` – Opcode of the command.
- `_min_len` – Minimal length of the command.
- `_func` – Handler function to be called.

**Enums**

`enum [anonymous]`

**Values:**

- `enumerator BT_HCI_RAW_MODE_PASSTHROUGH = 0x00`
  - Passthrough mode
  - While in this mode the buffers are passed as is between the stack and the driver.

- `enumerator BT_HCI_RAW_MODE_H4 = 0x01`
  - H:4 mode
  - While in this mode H:4 headers will added into the buffers according to the buffer type when coming from the stack and will be removed and used to set the buffer type.

**Functions**

`int bt_send(struct net_buf *buf)`

Send packet to the Bluetooth controller.

Send packet to the Bluetooth controller. Caller needs to implement netbuf pool.

**Parameters**

- `buf` – netbuf packet to be send

**Returns** Zero on success or (negative) error code otherwise.

`int bt_hci_raw_set_mode(uint8_t mode)`

Set Bluetooth RAW channel mode.

Set access mode of Bluetooth RAW channel.

**Parameters**
• mode – Access mode.

**Returns** Zero on success or (negative) error code otherwise.

```c
uint8_t bt_hci_raw_get_mode(void)
```

Get Bluetooth RAW channel mode.

Get access mode of Bluetooth RAW channel.

**Returns** Access mode.

```c
void bt_hci_raw_cmd_ext_register(struct bt_hci_raw_cmd_ext *cmds, size_t size)
```

Register Bluetooth RAW channel command extension table.

Register Bluetooth RAW channel command extension table, opcodes in this table are intercepted to sent to the handler function.

**Parameters**

• cmds – Pointer to the command extension table.

• size – Size of the command extension table.

```c
int bt_enable_raw(struct k_fifo *rx_queue)
```

Enable Bluetooth RAW channel:

Enable Bluetooth RAW HCI channel.

**Parameters**

• rx_queue – netbuf queue where HCI packets received from the Bluetooth controller are to be queued. The queue is defined in the caller while the available buffers pools are handled in the stack.

**Returns** Zero on success or (negative) error code otherwise.

```c
struct bt_hci_raw_cmd_ext
```

`#include <hci_raw.h>`

**Public Members**

```c
uint16_t op
```

Opcode of the command

```c
size_t min_len
```

Minimal length of the command

```c
uint8_t (*func)(struct net_buf *buf)
```

Handler function.

Handler function to be called when a command is intercepted.

**Param buf** Buffer containing the command.

**Return** HCI Status code or BT_HCI_ERR_EXT_HANDLED if command has been handled already and a response has been sent as oppose to BT_HCI_ERR_SUCCESS which just indicates that the command can be sent to the controller to be processed.

### 7.4.9 Hands Free Profile (HFP)
API Reference

__group bt_hfp__

Hands Free Profile (HFP)

Defines

`HFP_HF_CMD_OK`

`HFP_HF_CMD_ERROR`

`HFP_HF_CMD_CME_ERROR`

`HFP_HF_CMD_UNKNOWN_ERROR`

Enums

__enum bt_hfp_hf_at_cmd__

*Values:*

enumerator `BT_HFP_HF_ATA`

enumerator `BT_HFP_HF_AT_CHUP`

Functions

`int bt_hfp_hf_register(struct bt_hfp_hf_cb *cb)`

Register HFP HF profile.

Register Handsfree profile callbacks to monitor the state and get the required HFP details to display.

**Parameters**

- `cb` – callback structure.

**Returns** 0 in case of success or negative value in case of error.

`int bt_hfp_hf_send_cmd(struct bt_conn *conn, enum bt_hfp_hf_at_cmd cmd)`

Handsfree client Send AT.

Send specific AT commands to handsfree client profile.

**Parameters**

- `conn` – Connection object.
- `cmd` – AT command to be sent.

**Returns** 0 in case of success or negative value in case of error.
struct bt_hfp_hf_cmd_complete
#include <hfp_hf.h> HFP HF Command completion field.

struct bt_hfp_hf_cb
#include <hfp_hf.h> HFP profile application callback.

**Public Members**

void (*connected)(struct bt_conn *conn)
HF connected callback to application
    If this callback is provided it will be called whenever the connection completes.
        **Param conn** Connection object.

void (*disconnected)(struct bt_conn *conn)
HF disconnected callback to application
    If this callback is provided it will be called whenever the connection gets disconnected,
        including when a connection gets rejected or cancelled or any error in SLC establisment.
        **Param conn** Connection object.

void (*service)(struct bt_conn *conn, uint32_t value)
HF indicator Callback
    This callback provides service indicator value to the application
        **Param conn** Connection object.
        **Param value** service indicator value received from the AG.

void (*call)(struct bt_conn *conn, uint32_t value)
HF indicator Callback
    This callback provides call indicator value to the application
        **Param conn** Connection object.
        **Param value** call indicator value received from the AG.

void (*call_setup)(struct bt_conn *conn, uint32_t value)
HF indicator Callback
    This callback provides call setup indicator value to the application
        **Param conn** Connection object.
        **Param value** call setup indicator value received from the AG.

void (*call_held)(struct bt_conn *conn, uint32_t value)
HF indicator Callback
    This callback provides call held indicator value to the application
        **Param conn** Connection object.
        **Param value** call held indicator value received from the AG.

void (*signal)(struct bt_conn *conn, uint32_t value)
HF indicator Callback
    This callback provides signal indicator value to the application
        **Param conn** Connection object.
        **Param value** signal indicator value received from the AG.

void (*roam)(struct bt_conn *conn, uint32_t value)
HF indicator Callback
This callback provides roaming indicator value to the application

Param conn  Connection object.
Param value  roaming indicator value received from the AG.

void (*battery)(struct bt_conn *conn, uint32_t value)
HF indicator Callback

This callback battery service indicator value to the application

Param conn  Connection object.
Param value  battery indicator value received from the AG.

void (*ring_indication)(struct bt_conn *conn)
HF incoming call Ring indication callback to application

If this callback is provided it will be called whenever there is an incoming call.

Param conn  Connection object.

void (*cmd_complete_cb)(struct bt_conn *conn, struct bt_hfp_hf_cmd_complete *cmd)
HF notify command completed callback to application

The command sent from the application is notified about its status

Param conn  Connection object.
Param cmd   structure contains status of the command including cme.

7.4.10 Logical Link Control and Adaptation Protocol (L2CAP)

L2CAP layer enables connection-oriented channels which can be enable with the configuration option: CONFIG_BT_L2CAP_DYNAMIC_CHANNEL. This channels support segmentation and reassembly transparently, they also support credit based flow control making it suitable for data streams.

Channels instances are represented by the bt_l2cap_chan struct which contains the callbacks in the bt_l2cap_chan_ops struct to inform when the channel has been connected, disconnected or when the encryption has changed. In addition to that it also contains the recv callback which is called whenever an incoming data has been received. Data received this way can be marked as processed by returning 0 or using bt_l2cap_chan_recv_complete() API if processing is asynchronous.

Note: The recv callback is called directly from RX Thread thus it is not recommended to block for long periods of time.

For sending data the bt_l2cap_chan_send() API can be used noting that it may block if no credits are available, and resuming as soon as more credits are available.

Servers can be registered using bt_l2cap_server_register() API passing the bt_l2cap_server struct which informs what psm it should listen to, the required security level sec_level, and the callback accept which is called to authorize incoming connection requests and allocate channel instances.

Client channels can be initiated with use of bt_l2cap_chan_connect() API and can be disconnected with the bt_l2cap_chan_disconnect() API. Note that the later can also disconnect channel instances created by servers.

API Reference

group bt_l2cap
L2CAP.
Defines

`BT_L2CAP_HDR_SIZE`  
L2CAP PDU header size, used for buffer size calculations

`BT_L2CAP_TX_MTU`  
Maximum Transmission Unit (MTU) for an outgoing L2CAP PDU.

`BT_L2CAP_RX_MTU`  
Maximum Transmission Unit (MTU) for an incoming L2CAP PDU.

`BT_L2CAP_BUF_SIZE(mtu)`  
Helper to calculate needed buffer size for L2CAP PDUs. Useful for creating buffer pools.

**Parameters**
- `mtu` – Needed L2CAP PDU MTU.

**Returns**  
Needed buffer size to match the requested L2CAP PDU MTU.

`BT_L2CAP_SDU_HDR_SIZE`  
L2CAP SDU header size, used for buffer size calculations

`BT_L2CAP_SDU_TX_MTU`  
Maximum Transmission Unit for an unsegmented outgoing L2CAP SDU.

The Maximum Transmission Unit for an outgoing L2CAP SDU when sent without segmentation, i.e a single L2CAP SDU will fit inside a single L2CAP PDU.

The MTU for outgoing L2CAP SDUs with segmentation is defined by the size of the application buffer pool.

`BT_L2CAP_SDU_RX_MTU`  
Maximum Transmission Unit for an unsegmented incoming L2CAP SDU.

The Maximum Transmission Unit for an incoming L2CAP SDU when sent without segmentation, i.e a single L2CAP SDU will fit inside a single L2CAP PDU.

The MTU for incoming L2CAP SDUs with segmentation is defined by the size of the application buffer pool. The application will have to define an alloc_buf callback for the channel in order to support receiving segmented L2CAP SDUs.

`BT_L2CAP_SDU_BUF_SIZE(mtu)`  
Helper to calculate needed buffer size for L2CAP SDUs. Useful for creating buffer pools.

**Parameters**
- `mtu` – Required BT_L2CAP_*_SDU.

**Returns**  
Needed buffer size to match the requested L2CAP SDU MTU.

`BT_L2CAP_LE_CHAN(_ch)`  
Helper macro getting container object of type `bt_l2cap_le_chan` address having the same container chan member address as object in question.

**Parameters**
- `_ch` – Address of object of `bt_l2cap_chan` type

**Returns**  
Address of in memory `bt_l2cap_le_chan` object type containing the address of in question object.

`BT_L2CAP_CHAN_SEND_RESERVE`  
Headroom needed for outgoing L2CAP PDUs.
BT_L2CAP_SDU_CHAN_SEND_RESERVE
Headroom needed for outgoing L2CAP SDUs.

**Typedefs**

typedef void (*bt_l2cap_chan_destroy_t)(struct bt_l2cap_chan *chan)
Channel destroy callback.

**Param chan** Channel object.

typedef enum bt_l2cap_chan_state bt_l2cap_chan_state_t
Life-span states of L2CAP CoC channel.

Used only by internal APIs dealing with setting channel to proper state depending on operational context.

typedef enum bt_l2cap_chan_status bt_l2cap_chan_status_t
Status of L2CAP channel.

**Enums**

enum bt_l2cap_chan_state
Life-span states of L2CAP CoC channel.

Used only by internal APIs dealing with setting channel to proper state depending on operational context.

**Values:**

- enumerator BT_L2CAP_DISCONNECTED
  Channel disconnected

- enumerator BT_L2CAP_CONNECTING
  Channel in connecting state

- enumerator BT_L2CAP_CONFIG
  Channel in config state, BR/EDR specific

- enumerator BT_L2CAP_CONNECTED
  Channel ready for upper layer traffic on it

- enumerator BT_L2CAP_DISCONNECTING
  Channel in disconnecting state

- enumerator BT_L2CAP_STATUS_OUT
  Channel output status

- enumerator BT_L2CAP_STATUS_SHUTDOWN
  Channel shutdown status.
Once this status is notified it means the channel will no longer be able to transmit or receive data.

enumerator BT_L2CAP_STATUS_ENCRYPT_PENDING
Channel encryption pending status.

enumerator BT_L2CAP_NUM_STATUS

Functions

int bt_l2cap_server_register(struct bt_l2cap_server *server)
Register L2CAP server.

Register L2CAP server for a PSM, each new connection is authorized using the accept() callback which in case of success shall allocate the channel structure to be used by the new connection.

For fixed, SIG-assigned PSMs (in the range 0x0001-0x007f) the PSM should be assigned to server->psm before calling this API. For dynamic PSMs (in the range 0x0080-0x00ff) server->psm may be pre-set to a given value (this is however not recommended) or be left as 0, in which case upon return a newly allocated value will have been assigned to it. For dynamically allocated values the expectation is that it’s exposed through a GATT service, and that’s how L2CAP clients discover how to connect to the server.

Parameters
• server – Server structure.

Returns 0 in case of success or negative value in case of error.

int bt_l2cap_br_server_register(struct bt_l2cap_server *server)
Register L2CAP server on BR/EDR oriented connection.

Register L2CAP server for a PSM, each new connection is authorized using the accept() callback which in case of success shall allocate the channel structure to be used by the new connection.

Parameters
• server – Server structure.

Returns 0 in case of success or negative value in case of error.

int bt_l2cap_ecred_chan_connect(struct bt_conn *conn, struct bt_l2cap_chan **chans, uint16_t psm)
Connect Enhanced Credit Based L2CAP channels.

Connect up to 5 L2CAP channels by PSM, once the connection is completed each channel connected() callback will be called. If the connection is rejected disconnected() callback is called instead.

Parameters
• conn – Connection object.
• chans – Array of channel objects.
• psm – Channel PSM to connect to.

Returns 0 in case of success or negative value in case of error.
int bt_l2cap_ecred_chan_reconfigure(struct bt_l2cap_chan **chans, uint16_t mtu)
Reconfigure Enhanced Credit Based L2CAP channels.
Reconfigure up to 5 L2CAP channels. Channels must be from the same bt_conn. Once reconfiguration is completed each channel reconfigured() callback will be called. MTU cannot be decreased on any of provided channels.

Parameters
• chans – Array of channel objects. Null-terminated. Elements after the first 5 are silently ignored.
• mtu – Channel MTU to reconfigure to.

Returns 0 in case of success or negative value in case of error.

int bt_l2cap_chan_connect(struct bt_conn *conn, struct bt_l2cap_chan *chan, uint16_t psm)
Connect L2CAP channel.
Connect L2CAP channel by PSM, once the connection is completed channel connected() callback will be called. If the connection is rejected disconnected() callback is called instead. Channel object passed (over an address of it) as second parameter shouldn’t be instantiated in application as standalone. Instead of, application should create transport dedicated L2CAP objects, i.e. type of bt_l2cap_le_chan for LE and/or type of bt_l2cap_br_chan for BR/EDR. Then pass to this API the location (address) of bt_l2cap_chan type object which is a member of both transport dedicated objects.

Parameters
• conn – Connection object.
• chan – Channel object.
• psm – Channel PSM to connect to.

Returns 0 in case of success or negative value in case of error.

int bt_l2cap_chan_disconnect(struct bt_l2cap_chan *chan)
Disconnect L2CAP channel.
Disconnect L2CAP channel, if the connection is pending it will be canceled and as a result the channel disconnected() callback is called. Regarding to input parameter, to get details see reference description to bt_l2cap_chan_connect() API above.

Parameters
• chan – Channel object.

Returns 0 in case of success or negative value in case of error.

int bt_l2cap_chan_send(struct bt_l2cap_chan *chan, struct net_buf *buf)
Send data to L2CAP channel.
Send data from buffer to the channel. If credits are not available, buf will be queued and sent as and when credits are received from peer. Regarding to first input parameter, to get details see reference description to bt_l2cap_chan_connect() API above.

When sending L2CAP data over an BR/EDR connection the application is sending L2CAP PDUs. The application is required to have reserved BT_L2CAP_CHAN_SEND_RESERVE bytes in the buffer before sending. The application should use the BT_L2CAP_BUF_SIZE() helper to correctly size the buffers for the for the outgoing buffer pool.

When sending L2CAP data over an LE connection the application is sending L2CAP SDUs. The application can optionally reserve BT_L2CAP_SDU_CHAN_SEND_RESERVE bytes in the buffer before sending. By reserving bytes in the buffer the stack can use this buffer as a segment directly, otherwise it will have to allocate a new segment for the first segment. If the application is reserving the bytes it should use the BT_L2CAP_BUF_SIZE() helper to correctly size the buffers for the for the outgoing buffer pool. When segmenting an L2CAP SDU into
L2CAP PDUs the stack will first attempt to allocate buffers from the original buffer pool of the L2CAP SDU before using the stacks own buffer pool.

**Note:** Buffer ownership is transferred to the stack in case of success, in case of an error the caller retains the ownership of the buffer.

**Returns** Bytes sent in case of success or negative value in case of error.

```c
int bt_l2cap_chan_recv_complete(struct bt_l2cap_chan *chan, struct net_buf *buf)
```

Complete receiving L2CAP channel data.

Complete the reception of incoming data. This shall only be called if the channel recv callback has returned -EINPROGRESS to process some incoming data. The buffer shall contain the original user_data as that is used for storing the credits/segments used by the packet.

**Parameters**
- `chan` – Channel object.
- `buf` – Buffer containing the data.

**Returns** 0 in case of success or negative value in case of error.

```c
struct bt_l2cap_chan
#include <l2cap.h> L2CAP Channel structure.
```

**Public Members**

- `struct bt_conn *conn` Channel connection reference
- `const struct bt_l2cap_chan_ops *ops` Channel operations reference

```c
struct bt_l2cap_le_endpoint
#include <l2cap.h> LE L2CAP Endpoint structure.
```

**Public Members**

- `uint16_t cid` Endpoint Channel Identifier (CID)
- `uint16_t mtu` Endpoint Maximum Transmission Unit
- `uint16_t mps` Endpoint Maximum PDU payload Size
- `uint16_t init_credits` Endpoint initial credits
- `atomic_t credits` Endpoint credits
struct bt_l2cap_le_chan
#include <l2cap.h> LE L2CAP Channel structure.

Public Members

struct bt_l2cap_chan chan
Common L2CAP channel reference object

struct bt_l2cap_le_endpoint rx
Channel Receiving Endpoint.
If the application has set an alloc_buf channel callback for the channel to support re-
ceiving segmented L2CAP SDUs the application should initialize the MTU of the Re-
ceiving Endpoint. Otherwise the MTU of the receiving endpoint will be initialized to
BT_L2CAP_SDU_RX_MTU by the stack.

uint16_t pending_rx_mtu
Pending RX MTU on ECFC reconfigure, used internally by stack

struct bt_l2cap_le_endpoint tx
Channel Transmission Endpoint

struct k_fifo tx_queue
Channel Transmission queue

struct net_buf *tx_buf
Channel Pending Transmission buffer

struct k_work tx_work
Channel Transmission work

struct bt_l2cap_br_endpoint
#include <l2cap.h> BREDR L2CAP Endpoint structure.

Public Members

uint16_t cid
Endpoint Channel Identifier (CID)

uint16_t mtu
Endpoint Maximum Transmission Unit

struct bt_l2cap_br_chan
#include <l2cap.h> BREDR L2CAP Channel structure.

Public Members

struct bt_l2cap_chan chan
Common L2CAP channel reference object
struct bt_l2cap_br_endpoint rx
    Channel Receiving Endpoint

struct bt_l2cap_br_endpoint tx
    Channel Transmission Endpoint

struct bt_l2cap_chan_ops

#include <l2cap.h>  L2CAP Channel operations structure.

Public Members

void (*connected)(struct bt_l2cap_chan *chan)
    Channel connected callback.
    If this callback is provided it will be called whenever the connection completes.
    Param chan The channel that has been connected

void (*disconnected)(struct bt_l2cap_chan *chan)
    Channel disconnected callback.
    If this callback is provided it will be called whenever the channel is disconnected, includ-
    ing when a connection gets rejected.
    Param chan The channel that has been Disconnected

void (*encrypt_change)(struct bt_l2cap_chan *chan, uint8_t hci_status)
    Channel encrypt_change callback.
    If this callback is provided it will be called whenever the security level changed (indirectly
    link encryption done) or authentication procedure fails. In both cases security initiator
    and responder got the final status (HCI status) passed by related to encryption and au-
    thentication events from local host's controller.
    Param chan The channel which has made encryption status changed.
    Param status HCI status of performed security procedure caused by channel
    security requirements. The value is populated by HCI layer and set to 0
    when success and to non-zero (reference to HCI Error Codes) when secu-
    rity/authentication failed.

struct net_buf *(*alloc_buf)(struct bt_l2cap_chan *chan)
    Channel alloc_buf callback.
    If this callback is provided the channel will use it to allocate buffers to store incoming
    data. Channels that requires segmentation must set this callback. If the application has
    not set a callback the L2CAP SDU MTU will be truncated to BT_L2CAP_SDU_RX_M Tu.
    Param chan The channel requesting a buffer.
    Return Allocated buffer.

int (*recv)(struct bt_l2cap_chan *chan, struct net_buf *buf)
    Channel recv callback.
    Param chan The channel receiving data.
    Param buf Buffer containing incoming data.
    Return 0 in case of success or negative value in case of error.
    Return -EINPROGRESS in case where user has to confirm once the data has
    been processed by calling bt_l2cap_chan_recv_complete passing back the buffer
    received with its original user_data which contains the number of seg-
    ments/credits used by the packet.
void (*sent)(struct bt_l2cap_chan *chan)
Channel sent callback.
If this callback is provided it will be called whenever a SDU has been completely sent.
   Param chan The channel which has sent data.

void (*status)(struct bt_l2cap_chan *chan, atomic_t *status)
Channel status callback.
If this callback is provided it will be called whenever the channel status changes.
   Param chan The channel which status changed
   Param status The channel status

void (*reconfigured)(struct bt_l2cap_chan *chan)
Channel reconfigured callback.
If this callback is provided it will be called whenever peer or local device requested reconfiguration. Application may check updated MTU and MPS values by inspecting chan->le endpoints.
   Param chan The channel which was reconfigured

struct bt_l2cap_server
#include <l2cap.h> L2CAP Server structure.

Public Members

uint16_t psm
Server PSM.
Possible values: 0 A dynamic value will be auto-allocated when bt_l2cap_server_register() is called.
0x0001-0x007f Standard, Bluetooth SIG-assigned fixed values.
0x0080-0x00ff Dynamically allocated. May be pre-set by the application before server registration (not recommended however), or auto-allocated by the stack if the app gave 0 as the value.

bt_security_t sec_level
Required minimum security level

int (*accept)(struct bt_conn *conn, struct bt_l2cap_chan **chan)
Server accept callback.
This callback is called whenever a new incoming connection requires authorization.
   Param conn The connection that is requesting authorization
   Param chan Pointer to received the allocated channel
   Return 0 in case of success or negative value in case of error.
   Return -ENOMEM if no available space for new channel.
   Return -EACCES if application did not authorize the connection.
   Return -EPERM if encryption key size is too short.

7.4.11  Bluetooth Mesh Profile

The Bluetooth mesh profile adds secure wireless multi-hop communication for Bluetooth Low Energy. This module implements the Bluetooth Mesh Profile Specification v1.0.1.
Read more about Bluetooth mesh on the Bluetooth SIG Website.
Core

The core provides functionality for managing the general Bluetooth mesh state.

**Low Power Node**  The Low Power Node (LPN) role allows battery powered devices to participate in a mesh network as a leaf node. An LPN interacts with the mesh network through a Friend node, which is responsible for relaying any messages directed to the LPN. The LPN saves power by keeping its radio turned off, and only wakes up to either send messages or poll the Friend node for any incoming messages.

The radio control and polling is managed automatically by the mesh stack, but the LPN API allows the application to trigger the polling at any time through `bt_mesh_lpn_poll()`. The LPN operation parameters, including poll interval, poll event timing and Friend requirements is controlled through the `CONFIG_BT_MESH_LOW_POWER` option and related configuration options.

**Replay Protection List**  The Replay Protection List (RPL) is used to hold recently received sequence numbers from elements within the mesh network to perform protection against replay attacks.

To keep a node protected against replay attacks after reboot, it needs to store the entire RPL in the persistent storage before it is powered off. Depending on the amount of traffic in a mesh network, storing recently seen sequence numbers can make flash wear out sooner or later. To mitigate this, `CONFIG_BT_MESH_RPL_STORE_TIMEOUT` can be used. This option postpones storing of RPL entries in the persistent storage.

This option, however, doesn’t completely solve the issue as the node may get powered off before the timer to store the RPL is fired. To ensure that messages can not be replayed, the node can initiate storage of the pending RPL entry (or entries) at any time (or sufficiently before power loss) by calling `bt_mesh_rpl_pending_store`. This is up to the node to decide, which RPL entries are to be stored in this case.

Setting `CONFIG_BT_MESH_RPL_STORE_TIMEOUT` to -1 allows to completely switch off the timer, which can help to significantly reduce flash wear out. This moves the responsibility of storing RPL to the user application and requires that sufficient power backup is available from the time this API is called until all RPL entries are written to the flash.

Finding the right balance between `CONFIG_BT_MESH_RPL_STORE_TIMEOUT` and calling `bt_mesh_rpl_pending_store` may reduce a risk of security vulnerability and flash wear out.

API reference

group bt_mesh
   Bluetooth mesh.

Defines

`BT_MESH_NET_PRIMARY`

`BT_MESH_FEAT_RELAY`
   Relay feature

`BT_MESH_FEAT_PROXY`
   GATT Proxy feature

`BT_MESH_FEAT_FRIEND`
   Friend feature
**BT_MESH_FEAT_LOW_POWER**
Low Power Node feature

**BT_MESH_FEAT_SUPPORTED**

**BT_MESH_LPN_CB_DEFINE(_name)**
Register a callback structure for Friendship events.

**Parameters**

- _name – Name of callback structure.

**BT_MESH_FRIEND_CB_DEFINE(_name)**
Register a callback structure for Friendship events.

Registers a callback structure that will be called whenever Friendship gets established or terminated.

**Parameters**

- _name – Name of callback structure.

**Functions**

```c
int bt_mesh_init(const struct bt_mesh_prov *prov, const struct bt_mesh_comp *comp)
```
Initialize Mesh support.

After calling this API, the node will not automatically advertise as unprovisioned, rather the `bt_mesh_prov_enable()` API needs to be called to enable unprovisioned advertising on one or more provisioning bearers.

**Parameters**

- prov – Node provisioning information.
- comp – Node Composition.

**Returns** Zero on success, or (negative) error code otherwise.

```c
void bt_mesh_reset(void)
```
Reset the state of the local Mesh node.

Resets the state of the node, which means that it needs to be reprovisioned to become an active node in a Mesh network again.

After calling this API, the node will not automatically advertise as unprovisioned, rather the `bt_mesh_prov_enable()` API needs to be called to enable unprovisioned advertising on one or more provisioning bearers.

```c
int bt_mesh_suspend(void)
```
Suspend the Mesh network temporarily.

This API can be used for power saving purposes, but the user should be aware that leaving the local node suspended for a long period of time may cause it to become permanently disconnected from the Mesh network. If at all possible, the Friendship feature should be used instead, to make the node into a Low Power Node.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_resume(void)
```
Resume a suspended Mesh network.

This API resumes the local node, after it has been suspended using the `bt_mesh_suspend()` API.

**Returns** 0 on success, or (negative) error code on failure.
void bt_mesh_iv_update_test(bool enable)
    Toggle the IV Update test mode.
    This API is only available if the IV Update test mode has been enabled in Kconfig. It is needed
    for passing most of the IV Update qualification test cases.

    Parameters
    • enable – true to enable IV Update test mode, false to disable it.

bool bt_mesh_iv_update(void)
    Toggle the IV Update state.
    This API is only available if the IV Update test mode has been enabled in Kconfig. It is needed
    for passing most of the IV Update qualification test cases.

    Returns true if IV Update In Progress state was entered, false otherwise.

int bt_mesh_lpn_set(bool enable)
    Toggle the Low Power feature of the local device.
    Enables or disables the Low Power feature of the local device. This is exposed as a run-time
    feature, since the device might want to change this e.g. based on being plugged into a stable
    power source or running from a battery power source.

    Parameters
    • enable – true to enable LPN functionality, false to disable it.

    Returns Zero on success or (negative) error code otherwise.

int bt_mesh_lpn_poll(void)
    Send out a Friend Poll message.
    Send a Friend Poll message to the Friend of this node. If there is no established Friendship
    the function will return an error.

    Returns Zero on success or (negative) error code otherwise.

int bt_mesh_friend_terminate(uint16_t lpn_addr)
    Terminate Friendship.
    Terminated Friendship for given LPN.

    Parameters
    • lpn_addr – Low Power Node address.

    Returns Zero on success or (negative) error code otherwise.

void bt_mesh_rpl_pending_store(uint16_t addr)
    Store pending RPL entry(ies) in the persistent storage.
    This API allows the user to store pending RPL entry(ies) in the persistent storage without
    waiting for the timeout.

    Note: When flash is used as the persistent storage, calling this API too frequently may wear
    it out.

    Parameters
    • addr – Address of the node which RPL entry needs to be stored or
      BT_MESH_ADDR_ALL_NODES to store all pending RPL entries.

struct bt_mesh_lpn_cb
    #include <main.h> Low Power Node callback functions.
The `bt_mesh_friend` module provides a set of functions for managing friendships between nodes in the mesh network. These functions are used to establish, terminate, and poll friendships.

### Public Members

```c
void (*established)(uint16_t net_idx, uint16_t friend_addr, uint8_t queue_size, uint8_t recv_window)

Friendship established.

This callback notifies the application that friendship has been successfully established.

- **Param net_idx** NetKeyIndex used during friendship establishment.
- **Param friend_addr** Friend address.
- **Param queue_size** Friend queue size.
- **Param recv_window** Low Power Node's listens duration for Friend response.

```c
void (*terminated)(uint16_t net_idx, uint16_t friend_addr)

Friendship terminated.

This callback notifies the application that friendship has been terminated.

- **Param net_idx** NetKeyIndex used during friendship establishment.
- **Param friend_addr** Friend address.

```c
void (*polled)(uint16_t net_idx, uint16_t friend_addr, bool retry)

Local Poll Request.

This callback notifies the application that the local node has polled the friend node.

This callback will be called before `bt_mesh_lpn_cb::established` when attempting to establish a friendship.

- **Param net_idx** NetKeyIndex used during friendship establishment.
- **Param friend_addr** Friend address.
- **Param retry** Retry or first poll request for each transaction.

```c
struct bt_mesh_friend_cb

#include <main.h>

Friend Node callback functions.

### Public Members

```c
void (*established)(uint16_t net_idx, uint16_t lpn_addr, uint8_t recv_delay, uint32_t polltimeout)

Friendship established.

This callback notifies the application that friendship has been successfully established.

- **Param net_idx** NetKeyIndex used during friendship establishment.
- **Param lpn_addr** Low Power Node address.
- **Param recv_delay** Receive Delay in units of 1 millisecond.
- **Param polltimeout** PollTimeout in units of 1 millisecond.

```c
void (*terminated)(uint16_t net_idx, uint16_t lpn_addr)

Friendship terminated.

This callback notifies the application that friendship has been terminated.

- **Param net_idx** NetKeyIndex used during friendship establishment.
- **Param lpn_addr** Low Power Node address.

```c
void (*polled)(uint16_t net_idx, uint16_t lpn_addr)

Friend Poll Request.

This callback notifies the application that the low power node has polled the friend node.

This callback will be called before `bt_mesh_friend_cb::established` when attempting to establish a friendship.
Param net_idx  NetKeyIndex used during friendship establishment.
Param lpn_addr  LPN address.

Access layer

The access layer is the application’s interface to the Bluetooth mesh network. The access layer provides mechanisms for compartmentalizing the node behavior into elements and models, which are implemented by the application.

Mesh models  The functionality of a mesh node is represented by models. A model implements a single behavior the node supports, like being a light, a sensor or a thermostat. The mesh models are grouped into elements. Each element is assigned its own unicast address, and may only contain one of each type of model. Conventionally, each element represents a single aspect of the mesh node behavior. For instance, a node that contains a sensor, two lights and a power outlet would spread this functionality across four elements, with each element instantiating all the models required for a single aspect of the supported behavior.

The node’s element and model structure is specified in the node composition data, which is passed to bt_mesh_init() during initialization. The Bluetooth SIG have defined a set of foundation models (see Foundation models) and a set of models for implementing common behavior in the Bluetooth Mesh Model Specification. All models not specified by the Bluetooth SIG are vendor models, and must be tied to a Company ID.

Mesh models have several parameters that can be configured either through initialization of the mesh stack or with the Configuration Server:

Opcode list  The opcode list contains all message opcodes the model can receive, as well as the minimum acceptable payload length and the callback to pass them to. Models can support any number of opcodes, but each opcode can only be listed by one model in each element.

The full opcode list must be passed to the model structure in the composition data, and cannot be changed at runtime. The end of the opcode list is determined by the special BT_MESH_MODEL_OP_END entry. This entry must always be present in the opcode list, unless the list is empty. In that case, BT_MESH_MODEL_NO_OPS should be used in place of a proper opcode list definition.

AppKey list  The AppKey list contains all the application keys the model can receive messages on. Only messages encrypted with application keys in the AppKey list will be passed to the model.

The maximum number of supported application keys each model can hold is configured with the CONFIG_BT_MESH_MODEL_KEY_COUNT configuration option. The contents of the AppKey list is managed by the Configuration Server.

Subscription list  A model will process all messages addressed to the unicast address of their element (given that the utilized application key is present in the AppKey list). Additionally, the model will process packets addressed to any group or virtual address in its subscription list. This allows nodes to address multiple nodes throughout the mesh network with a single message.

The maximum number of supported addresses in the Subscription list each model can hold is configured with the CONFIG_BT_MESH_MODEL_GROUP_COUNT configuration option. The contents of the subscription list is managed by the Configuration Server.

Model publication  The models may send messages in two ways:

- By specifying a set of message parameters in a bt_mesh_msg_ctx, and calling bt_mesh_model_send().
- By setting up a bt_mesh_model_pub structure and calling bt_mesh_model_publish().
When publishing messages with `bt_mesh_model_publish()`, the model will use the publication parameters configured by the Configuration Server. This is the recommended way to send unprompted model messages, as it passes the responsibility of selecting message parameters to the network administrator, which likely knows more about the mesh network than the individual nodes will.

To support publishing with the publication parameters, the model must allocate a packet buffer for publishing, and pass it to `bt_mesh_model_pub.msg`. The Config Server may also set up period publication for the publication message. To support this, the model must populate the `bt_mesh_model_pub.update` callback. The `bt_mesh_model_pub.update` callback will be called right before the message is published, allowing the model to change the payload to reflect its current state.

By setting `bt_mesh_model_pub.retr_update` to 1, the model can configure the `bt_mesh_model_pub.update` callback to be triggered on every retransmission. This can, for example, be used by models that make use of a Delay parameter, which can be adjusted for every retransmission. The `bt_mesh_model_pub_is_retransmission()` function can be used to differentiate a first publication and a retransmission. The `BT_MESH_PUB_MSG_TOTAL` and `BT_MESH_PUB_MSG_NUM` macros can be used to return total number of transmissions and the retransmission number within one publication interval.

**Extended models** The Bluetooth mesh specification allows the mesh models to extend each other. When a model extends another, it inherits that model’s functionality, and extension can be used to construct complex models out of simple ones, leveraging the existing model functionality to avoid defining new opcodes. Models may extend any number of models, from any element. When one model extends another in the same element, the two models will share subscription lists. The mesh stack implements this by merging the subscription lists of the two models into one, combining the number of subscriptions the models can have in total. Models may extend models that extend others, creating an “extension tree”. All models in an extension tree share a single subscription list per element it spans.

Model extensions are done by calling `bt_mesh_model_extend()` during initialization. A model can only be extended by one other model, and extensions cannot be circular. Note that binding of node states and other relationships between the models must be defined by the model implementations.

The model extension concept adds some overhead in the access layer packet processing, and must be explicitly enabled with `CONFIG_BT_MESH_MODEL_EXTENSIONS` to have any effect.

**Model data storage** Mesh models may have data associated with each model instance that needs to be stored persistently. The access API provides a mechanism for storing this data, leveraging the internal model instance encoding scheme. Models can store one user defined data entry per instance by calling `bt_mesh_model_data_store()`. To be able to read out the data the next time the device reboots, the model’s `bt_mesh_model_cb.settings_set` callback must be populated. This callback gets called when model specific data is found in the persistent storage. The model can retrieve the data by calling the `read_cb` passed as a parameter to the callback. See the `Settings` module documentation for details.

**API reference**

`group bt_mesh_access`

Access layer.

**Defines**

BT_MESH_APP_SEG_SDU_MAX
   Maximum size of an access message segment (in octets).

BT_MESH_APP_UNSEG_SDU_MAX
   Maximum payload size of an unsegmented access message (in octets).

BT_MESH_RX_SEG_MAX
   Maximum number of segments supported for incoming messages.

BT_MESH_TX_SEG_MAX
   Maximum number of segments supported for outgoing messages.

BT_MESH_TX_SDU_MAX
   Maximum possible payload size of an outgoing access message (in octets).
**BT_MESH_RX_SDU_MAX**
Maximum possible payload size of an incoming access message (in octets).

**BT_MESH_ELEM(loc, mods, vnd_mods)**
Helper to define a mesh element within an array.

In case the element has no SIG or Vendor models the helper macro BT_MESH_MODEL_NONE can be given instead.

**Parameters**

- `loc` – Location Descriptor.
- `mods` – Array of models.
- `vnd_mods` – Array of vendor models.

**BT_MESH_MODEL_ID_CFG_SRV**

**BT_MESH_MODEL_ID_CFG_CLI**

BT_MESH_LEN_EXACT(len)
    Macro for encoding exact message length for fixed-length messages.

BT_MESH_LEN_MIN(len)
    Macro for encoding minimum message length for variable-length messages.

BT_MESH_MODEL_OP_END
    End of the opcode list. Must always be present.

BT_MESH_MODEL_NO_OPS
    Helper to define an empty opcode list.

BT_MESH_MODEL_NONE
    Helper to define an empty model array

BT_MESH_MODEL_CB(_id, _op, _pub, _user_data, _cb)
    Composition data SIG model entry with callback functions.

    Parameters
    • _id – Model ID.
    • _op – Array of model opcode handlers.
    • _pub – Model publish parameters.
    • _user_data – User data for the model.
    • _cb – Callback structure, or NULL to keep no callbacks.

BT_MESH_MODEL_VND_CB(_company, _id, _op, _pub, _user_data, _cb)
    Composition data vendor model entry with callback functions.

    Parameters
    • _company – Company ID.
- _id – Model ID.
- _op – Array of model opcode handlers.
- _pub – Model publish parameters.
- _user_data – User data for the model.
- _cb – Callback structure, or NULL to keep no callbacks.

**BT_MESH_MODEL(_id, _op, _pub, _user_data)**
Composition data SIG model entry.

**Parameters**
- _id – Model ID.
- _op – Array of model opcode handlers.
- _pub – Model publish parameters.
- _user_data – User data for the model.

**BT_MESH_MODEL_VND(_company, _id, _op, _pub, _user_data)**
Composition data vendor model entry.

**Parameters**
- _company – Company ID.
- _id – Model ID.
- _op – Array of model opcode handlers.
- _pub – Model publish parameters.
- _user_data – User data for the model.

**BT_MESH_TRANSMIT(count, int_ms)**
Encode transmission count & interval steps.

**Parameters**
- count – Number of retransmissions (first transmission is excluded).
- int_ms – Interval steps in milliseconds. Must be greater than 0, less than or equal to 320, and a multiple of 10.

**Returns** Mesh transmit value that can be used e.g. for the default values of the configuration model data.

**BT_MESH_TRANSMIT_COUNT(transmit)**
Decode transmit count from a transmit value.

**Parameters**
- transmit – Encoded transmit count & interval value.

**Returns** Transmission count (actual transmissions is N + 1).

**BT_MESH_TRANSMIT_INT(transmit)**
Decode transmit interval from a transmit value.

**Parameters**
- transmit – Encoded transmit count & interval value.

**Returns** Transmission interval in milliseconds.

**BT_MESH_PUB_TRANSMIT(count, int_ms)**
Encode Publish Retransmit count & interval steps.

**Parameters**
- count – Number of retransmissions (first transmission is excluded).
• int_ms – Interval steps in milliseconds. Must be greater than 0 and a multiple of 50.

Returns Mesh transmit value that can be used e.g. for the default values of the configuration model data.

BT_MESH_PUB_TRANSMIT_COUNT(transmit)
Decode Publish Retransmit count from a given value.

Parameters
• transmit – Encoded Publish Retransmit count & interval value.

Returns Retransmission count (actual transmissions is N + 1).

BT_MESH_PUB_TRANSMIT_INT(transmit)
Decode Publish Retransmit interval from a given value.

Parameters
• transmit – Encoded Publish Retransmit count & interval value.

Returns Transmission interval in milliseconds.

BT_MESH_PUB_MSG_TOTAL(pub)
Get total number of messages within one publication interval including initial publication.

Parameters
• pub – Model publication context.

Returns total number of messages.

BT_MESH_PUB_MSG_NUM(pub)
Get message number within one publication interval.
Meant to be used inside bt_mesh_model_pub::update.

Parameters
• pub – Model publication context.

Returns message number starting from 1.

BT_MESH_MODEL_PUB_DEFINE(_name, _update, _msg_len)
Define a model publication context.

Parameters
• _name – Variable name given to the context.
• _update – Optional message update callback (may be NULL).
• _msg_len – Length of the publication message.

BT_MESH_TTL_DEFAULT
Special TTL value to request using configured default TTL

BT_MESH_TTL_MAX
Maximum allowed TTL value

Functions

int bt_mesh_model_send(struct bt_mesh_model *model, struct bt_mesh_msg_ctx *ctx, struct net_buf_simple *msg, const struct bt_mesh_send_cb *cb, void *cb_data)
Send an Access Layer message.

Parameters
• model – Mesh (client) Model that the message belongs to.
• ctx – Message context, includes keys, TTL, etc.
• msg – Access Layer payload (the actual message to be sent).
• cb – Optional “message sent” callback.
• cb_data – User data to be passed to the callback.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_model_publish(struct bt_mesh_model *model)
```

Send a model publication message.

Before calling this function, the user needs to ensure that the model publication message
(`bt_mesh_model_pub::msg`) contains a valid message to be sent. Note that this API is only to be
used for non-period publishing. For periodic publishing the app only needs to make sure that
`bt_mesh_model_pub::msg` contains a valid message whenever the `bt_mesh_model_pub::update`
callback is called.

Parameters

• model – Mesh (client) Model that’s publishing the message.

Returns 0 on success, or (negative) error code on failure.

```c
static inline bool bt_mesh_model_pub_is_retransmission(const struct bt_mesh_model *model)
```

Check if a message is being retransmitted.

Meant to be used inside the `bt_mesh_model_pub::update` callback.

Parameters

• model – Mesh Model that supports publication.

Returns true if this is a retransmission, false if this is a first publication.

```c
struct bt_mesh_elem *bt_mesh_model_elem(struct bt_mesh_model *mod)
```

Get the element that a model belongs to.

Parameters

• mod – Mesh model.

Returns Pointer to the element that the given model belongs to.

```c
struct bt_mesh_model *bt_mesh_model_find(const struct bt_mesh_elem *elem, uint16_t id)
```

Find a SIG model.

Parameters

• elem – Element to search for the model in.
• id – Model ID of the model.

Returns A pointer to the Mesh model matching the given parameters, or NULL if no
SIG model with the given ID exists in the given element.

```c
struct bt_mesh_model *bt_mesh_model_find_vnd(const struct bt_mesh_elem *elem, uint16_t company, uint16_t id)
```

Find a vendor model.

Parameters

• elem – Element to search for the model in.
• company – Company ID of the model.
• id – Model ID of the model.

Returns A pointer to the Mesh model matching the given parameters, or NULL if no
vendor model with the given ID exists in the given element.
static inline bool bt_mesh_model_in_primary(const struct bt_mesh_model *mod)
    Get whether the model is in the primary element of the device.

Parameters
• mod – Mesh model.

Returns true if the model is on the primary element, false otherwise.

int bt_mesh_model_data_store(struct bt_mesh_model *mod, bool vnd, const char *name, const
    void *data, size_t data_len)
    Immediately store the model's user data in persistent storage.

Parameters
• mod – Mesh model.
• vnd – This is a vendor model.
• name – Name/key of the settings item. Only SETTINGS_MAX_DIR_DEPTH bytes
    will be used at most.
• data – Model data to store, or NULL to delete any model data.
• data_len – Length of the model data.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_model_extend(struct bt_mesh_model *extending_mod, struct bt_mesh_model
    *base_mod)
    Let a model extend another.

Mesh models may be extended to reuse their functionality, forming a more complex model. A
Mesh model may extend any number of models, in any element. The extensions may also be
nested, i.e. a model that extends another may itself be extended.

A set of models that extend each other form a model extension list.

All models in an extension list share one subscription list per element. The access layer will
utilize the combined subscription list of all models in an extension list and element, giving the
models extended subscription list capacity.

Parameters
• extending_mod – Mesh model that is extending the base model.
• base_mod – The model being extended.

Return values 0 – Successfully extended the base_mod model.

bool bt_mesh_model_is_extended(struct bt_mesh_model *model)
    Check if model is extended by another model.

Parameters
• model – The model to check.

Return values true – If model is extended by another model, otherwise false.

struct bt_mesh_elem
    #include <access.h> Abstraction that describes a Mesh Element

Public Members

uint16_t addr
    Unicast Address. Set at runtime during provisioning.
const uint16_t loc
Location Descriptor (GATT Bluetooth Namespace Descriptors)

const uint8_t model_count
The number of SIG models in this element

const uint8_t vnd_model_count
The number of vendor models in this element

struct bt_mesh_model *const models
The list of SIG models in this element

struct bt_mesh_model *const vnd_models
The list of vendor models in this element

struct bt_mesh_model_op
#include <access.h> Model opcode handler.

Public Members

const uint32_t opcode
OpCode encoded using the BT_MESH_MODEL_OP_* macros

const ssize_t len
Message length. If the message has variable length then this value indicates minimum
message length and should be positive. Handler function should verify precise length
based on the contents of the message. If the message has fixed length then this value
should be negative. Use BT_MESH_LEN_* macros when defining this value.

int (*const func)(struct bt_mesh_model *model, struct bt_mesh_msg_ctx *ctx, struct
net_buf_simple *buf)
Handler function for this opcode.
    Param model Model instance receiving the message.
    Param ctx Message context for the message.
    Param buf Message buffer containing the message payload, not including the
      opcode.
    Return Zero on success or (negative) error code otherwise.

struct bt_mesh_model_pub
#include <access.h> Model publication context.
The context should primarily be created using the BT_MESH_MODEL_PUB_DEFINE macro.

Public Members

struct bt_mesh_model *mod
The model the context belongs to. Initialized by the stack.

uint16_t addr
Publish Address.

uint16_t key
Publish AppKey Index.
uint16_t cred
    Friendship Credentials Flag.

uint16_t send_rel
    Force reliable sending (segment acks)

uint16_t fast_period
    Use FastPeriodDivisor

uint16_t retr_update
    Call update callback on every retransmission.

uint8_t ttl
    Publish Time to Live.

uint8_t retransmit
    Retransmit Count & Interval Steps.

uint8_t period
    Publish Period.

uint8_t period_div
    Divisor for the Period.

uint8_t count
    Transmissions left.

uint32_t period_start
    Start of the current period.

struct net_buf_simple *msg
    Publication buffer, containing the publication message.
    This will get correctly created when the publication context has been defined using the
    BT_MESH_MODEL_PUB_DEFINE macro.

    BT_MESH_MODEL_PUB_DEFINE(name, update, size);

int (*update)(struct bt_mesh_model *mod)
    Callback for updating the publication buffer.
    When set to NULL, the model is assumed not to support periodic publishing. When
    set to non-NULL the callback will be called periodically and is expected to update
    bt_mesh_model_pub::msg with a valid publication message.
    If the callback returns non-zero, the publication is skipped and will resume on the next
    periodic publishing interval.
    When bt_mesh_model_pub::retr_update is set to 1, the callback will be called on every
    retransmission.
    Param mod The Model the Publication Context belongs to.
    Return Zero on success or (negative) error code otherwise.

struct k_work_delayable timer
    Publish Period Timer. Only for stack-internal use.
struct bt_mesh_model_cb
#include <access.h> Model callback functions.

Public Members

int (*const settings_set)(struct bt_mesh_model *model, const char *name, size_t len_rd, settings_read_cb read_cb, void *cb_arg)
Set value handler of user data tied to the model.

See also:
settings_handler::h_set

Param model Model to set the persistent data of.
Param name Name/key of the settings item.
Param len_rd The size of the data found in the backend.
Param read_cb Function provided to read the data from the backend.
Param cb_arg Arguments for the read function provided by the backend.
Return 0 on success, error otherwise.

int (*const start)(struct bt_mesh_model *model)
Callback called when the mesh is started.
This handler gets called after the node has been provisioned, or after all mesh data has been loaded from persistent storage.
When this callback fires, the mesh model may start its behavior, and all Access APIs are ready for use.

Param model Model this callback belongs to.
Return 0 on success, error otherwise.

int (*const init)(struct bt_mesh_model *model)
Model init callback.
Called on every model instance during mesh initialization.
If any of the model init callbacks return an error, the Mesh subsystem initialization will be aborted, and the error will be returned to the caller of bt_mesh_init.

Param model Model to be initialized.
Return 0 on success, error otherwise.

void (*const reset)(struct bt_mesh_model *model)
Model reset callback.
Called when the mesh node is reset. All model data is deleted on reset, and the model should clear its state.

Note: If the model stores any persistent data, this needs to be erased manually.

Param model Model this callback belongs to.

uint16_t vid
    Version ID

size_t elem_count
    The number of elements in this device.

struct bt_mesh_elem *elem
    List of elements.

Foundation models

The Bluetooth mesh specification defines four foundation models that can be used by network administrators to configure and diagnose mesh nodes.

**Configuration Server**  The Configuration Server model is a foundation model defined by the Bluetooth mesh specification. The Configuration Server model controls most parameters of the mesh node. It does not have an API of its own, but relies on a Configuration Client to control it.

..note:: The bt_mesh_cfg_srv structure has been deprecated. The initial values of the Relay, Beacon, Friend, Network transmit and Relay retransmit should be set through Kconfig, and the Heartbeat feature should be controlled through the Heartbeat API.

The Configuration Server model is mandatory on all Bluetooth mesh nodes, and should be instantiated in the first element.

API reference

**group bt_mesh_cfg_srv**

Configuration Server Model.

**Defines**

BT_MESH_MODEL_CFG_SRV
    Generic Configuration Server model composition data entry.

**Configuration Client**  The Configuration Client model is a foundation model defined by the Bluetooth mesh specification. It provides functionality for configuring most parameters of a mesh node, including encryption keys, model configuration and feature enabling.
The Configuration Client model communicates with a Configuration Server model using the device key of the target node. The Configuration Client model may communicate with servers on other nodes or self-configure through the local Configuration Server model.

All configuration functions in the Configuration Client API have net_idx and addr as their first parameters. These should be set to the network index and primary unicast address that the target node was provisioned with.

The Configuration Client model is optional, but should be instantiated on the first element if it is present in the composition data.

API reference

```plaintext
group bt_mesh_cfg_cli
  Configuration Client Model.
```

Defines

```plaintext
BT_MESH_MODEL_CFG_CLI(cli_data)
  Generic Configuration Client model composition data entry.

Parameters
  • cli_data – Pointer to a Configuration Client Model instance.

BT_MESH_PUB_PERIOD_100MS(steps)
  Helper macro to encode model publication period in units of 100ms.

Parameters
  • steps – Number of 100ms steps.

Returns Encoded value that can be assigned to bt_mesh_cfg_mod_pub.period

BT_MESH_PUB_PERIOD_SEC(steps)
  Helper macro to encode model publication period in units of 1 second.

Parameters
  • steps – Number of 1 second steps.

Returns Encoded value that can be assigned to bt_mesh_cfg_mod_pub.period

BT_MESH_PUB_PERIOD_10SEC(steps)
  Helper macro to encode model publication period in units of 10 seconds.

Parameters
  • steps – Number of 10 second steps.

Returns Encoded value that can be assigned to bt_mesh_cfg_mod_pub.period

BT_MESH_PUB_PERIOD_10MIN(steps)
  Helper macro to encode model publication period in units of 10 minutes.

Parameters
  • steps – Number of 10 minute steps.

Returns Encoded value that can be assigned to bt_mesh_cfg_mod_pub.period

Functions

```plaintext
int bt_mesh_cfg_node_reset(uint16_t net_idx, uint16_t addr, bool *status)
  Reset the target node and remove it from the network.
```
Parameters

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `status` – Status response parameter

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_comp_data_get(uint16_t net_idx, uint16_t addr, uint8_t page, uint8_t *rsp,  
                             struct net_buf_simple *comp)
```

Get the target node's composition data.

If the other device does not have the given composition data page, it will return the largest page number it supports that is less than the requested page index. The actual page the device responds with is returned in `rsp`.

This method can be used asynchronously by setting `rsp` and `comp` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `page` – Composition data page, or 0xff to request the first available page.
- `rsp` – Return parameter for the returned page number, or NULL.
- `comp` – Composition data buffer to fill.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_beacon_get(uint16_t net_idx, uint16_t addr, uint8_t *status)
```

Get the target node's network beacon state.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `status` – Status response parameter, returns one of `BT_MESH_BEACON_DISABLED` or `BT_MESH_BEACON_ENABLED` on success.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_krp_get(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, uint8_t *status,  
                        uint8_t *phase)
```

Get the target node's network key refresh phase state.

This method can be used asynchronously by setting `status` and `phase` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `key_net_idx` – Network key index.
- `status` – Status response parameter.
- `phase` – Pointer to the Key Refresh variable to fill.

Returns 0 on success, or (negative) error code on failure.
int bt_mesh_cfg_krp_set(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, uint8_t transition, uint8_t *status, uint8_t *phase)
Set the target node’s network key refresh phase parameters.

This method can be used asynchronously by setting status and phase as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• key_net_idx – Network key index.
• transition – Transition parameter.
• status – Status response parameter.
• phase – Pointer to the new Key Refresh phase. Will return the actual Key Refresh phase after updating.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_beacon_set(uint16_t net_idx, uint16_t addr, uint8_t val, uint8_t *status)
Set the target node’s network beacon state.

This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• val – New network beacon state, should be one of
  BT_MESH_BEACON_DISABLED or BT_MESH_BEACON_ENABLED.
• status – Status response parameter. Returns one of
  BT_MESH_BEACON_DISABLED or BT_MESH_BEACON_ENABLED on success.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_ttl_get(uint16_t net_idx, uint16_t addr, uint8_t *ttl)
Get the target node’s Time To Live value.

This method can be used asynchronously by setting ttl as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• ttl – TTL response buffer.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_ttl_set(uint16_t net_idx, uint16_t addr, uint8_t val, uint8_t *ttl)
Set the target node’s Time To Live value.

This method can be used asynchronously by setting ttl as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• val – New Time To Live value.
• ttl – TTL response buffer.

Returns 0 on success, or (negative) error code on failure.

```
int bt_mesh_cfg_friend_get(uint16_t net_idx, uint16_t addr, uint8_t *status)
```

Get the target node's Friend feature status.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• status – Status response parameter. Returns one of `BT_MESH_FRIEND_DISABLED`, `BT_MESH_FRIEND_ENABLED` or `BT_MESH_FRIEND_NOT_SUPPORTED` on success.

Returns 0 on success, or (negative) error code on failure.

```
int bt_mesh_cfg_friend_set(uint16_t net_idx, uint16_t addr, uint8_t val, uint8_t *status)
```

Set the target node's Friend feature state.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• val – New Friend feature state. Should be one of `BT_MESH_FRIEND_DISABLED` or `BT_MESH_FRIEND_ENABLED`.
• status – Status response parameter. Returns one of `BT_MESH_FRIEND_DISABLED`, `BT_MESH_FRIEND_ENABLED` or `BT_MESH_FRIEND_NOT_SUPPORTED` on success.

Returns 0 on success, or (negative) error code on failure.

```
int bt_mesh_cfg_gatt_proxy_get(uint16_t net_idx, uint16_t addr, uint8_t *status)
```

Get the target node's Proxy feature state.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• status – Status response parameter. Returns one of `BT_MESH_GATT_PROXY_DISABLED`, `BT_MESH_GATT_PROXY_ENABLED` or `BT_MESH_GATT_PROXY_NOT_SUPPORTED` on success.

Returns 0 on success, or (negative) error code on failure.

```
int bt_mesh_cfg_gatt_proxy_set(uint16_t net_idx, uint16_t addr, uint8_t val, uint8_t *status)
```

Set the target node's Proxy feature state.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• val – New Proxy feature state. Must be one of `BT_MESH_GATT_PROXY_DISABLED` or `BT_MESH_GATT_PROXY_ENABLED`.
• status – Status response parameter. Returns one of `BT_MESH_GATT_PROXY_DISABLED`, `BT_MESH_GATT_PROXY_ENABLED` or `BT_MESH_GATT_PROXY_NOT_SUPPORTED` on success.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_net_transmit_get(uint16_t net_idx, uint16_t addr, uint8_t *transmit)
```
Get the target node’s network transmit state.

This method can be used asynchronously by setting `transmit` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• `net_idx` – Network index to encrypt with.
• `addr` – Target node address.
• `transmit` – Network transmit response parameter. Returns the encoded network transmission parameters on success. Decoded with `BT_MESH_TRANSMIT_COUNT` and `BT_MESH_TRANSMIT_INT`.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_net_transmit_set(uint16_t net_idx, uint16_t addr, uint8_t val, uint8_t *transmit)
```
Set the target node’s network transmit parameters.

This method can be used asynchronously by setting `transmit` as NULL. This way the method will not wait for response and will return immediately after sending the command.

See also:

`BT_MESH_TRANSMIT`.

Parameters

• `net_idx` – Network index to encrypt with.
• `addr` – Target node address.
• `val` – New encoded network transmit parameters.
• `transmit` – Network transmit response parameter. Returns the encoded network transmission parameters on success. Decoded with `BT_MESH_TRANSMIT_COUNT` and `BT_MESH_TRANSMIT_INT`.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_relay_get(uint16_t net_idx, uint16_t addr, uint8_t *status, uint8_t *transmit)
```
Get the target node’s Relay feature state.

This method can be used asynchronously by setting `status` and `transmit` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• `net_idx` – Network index to encrypt with.
• `addr` – Target node address.
• `status` – Status response parameter. Returns one of `BT_MESH_RELAY_DISABLED`, `BT_MESH_RELAY_ENABLED` or `BT_MESH_RELAY_NOT_SUPPORTED` on success.
• transmit – Transmit response parameter. Returns the encoded relay transmission parameters on success. Decoded with `BT_MESH_TRANSMIT_COUNT` and `BT_MESH_TRANSMIT_INT`.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_relay_set(uint16_t net_idx, uint16_t addr, uint8_t new_relay, uint8_t new_transmit, uint8_t *status, uint8_t *transmit)
```

Set the target node’s Relay parameters.

This method can be used asynchronously by setting `status` and `transmit` as NULL. This way the method will not wait for response and will return immediately after sending the command.

See also:

`BT_MESH_TRANSMIT`.

Parameters

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `new_relay` – New relay state. Must be one of `BT_MESH_RELAY_DISABLED` or `BT_MESH_RELAY_ENABLED`.
- `new_transmit` – New encoded relay transmit parameters.
- `status` – Status response parameter. Returns one of `BT_MESH_RELAY_DISABLED`, `BT_MESH_RELAY_ENABLED` or `BT_MESH_RELAY_NOT_SUPPORTED` on success.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_net_key_add(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, const uint8_t net_key[16], uint8_t *status)
```

Add a network key to the target node.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `key_net_idx` – Network key index.
- `net_key` – Network key.
- `status` – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_net_key_get(uint16_t net_idx, uint16_t addr, uint16_t *keys, size_t *key_cnt)
```

Get a list of the target node’s network key indexes.

This method can be used asynchronously by setting `keys` or `key_cnt` as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

- `net_idx` – Network index to encrypt with.
addr – Target node address.

keys – Net key index list response parameter. Will be filled with all the returned network key indexes it can fill.

key_cnt – Net key index list length. Should be set to the capacity of the keys list when calling. Will return the number of returned network key indexes upon success.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_net_key_del(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, uint8_t *status)
Delete a network key from the target node.

This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.

• addr – Target node address.

• key_net_idx – Network key index.

• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_app_key_add(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, uint16_t key_app_idx, const uint8_t app_key[16], uint8_t *status)
Add an application key to the target node.

This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.

• addr – Target node address.

• key_net_idx – Network key index the application key belongs to.

• key_app_idx – Application key index.

• app_key – Application key.

• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_app_key_get(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, uint8_t *status, uint16_t *keys, size_t *key_cnt)
Get a list of the target node’s application key indexes for a specific network key.

This method can be used asynchronously by setting status and ( keys or key_cnt ) as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.

• addr – Target node address.

• key_net_idx – Network key index to request the app key indexes of.

• status – Status response parameter.

• keys – App key index list response parameter. Will be filled with all the returned application key indexes it can fill.
• key_cnt – App key index list length. Should be set to the capacity of the keys list when calling. Will return the number of returned application key indexes upon success.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_app_key_del(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, uint16_t key_app_idx, uint8_t *status)
```

Delete an application key from the target node.

This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `key_net_idx` – Network key index the application key belongs to.
- `key_app_idx` – Application key index.
- `status` – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_app_bind(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, uint16_t mod_app_idx, uint16_t mod_id, uint8_t *status)
```

Bind an application to a SIG model on the target node.

This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `elem_addr` – Element address the model is in.
- `mod_app_idx` – Application index to bind.
- `mod_id` – Model ID.
- `status` – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_app_unbind(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, uint16_t mod_app_idx, uint16_t mod_id, uint8_t *status)
```

Unbind an application from a SIG model on the target node.

This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `elem_addr` – Element address the model is in.
- `mod_app_idx` – Application index to unbind.
- `mod_id` – Model ID.
- `status` – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.
int bt_mesh_cfg_mod_app_bind_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, 
    uint16_t mod_app_idx, uint16_t mod_id, uint16_t cid, 
    uint8_t *status)

Bind an application to a vendor model on the target node.

This method can be used asynchronously by setting status as NULL. This way the method 
will not wait for response and will return immediately after sending the command.

Parameters
• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• mod_app_idx – Application index to bind.
• mod_id – Model ID.
• cid – Company ID of the model.
• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_app_unbind_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, 
    uint16_t mod_app_idx, uint16_t mod_id, uint16_t cid, 
    uint8_t *status)

Unbind an application from a vendor model on the target node.

This method can be used asynchronously by setting status as NULL. This way the method 
will not wait for response and will return immediately after sending the command.

Parameters
• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• mod_app_idx – Application index to unbind.
• mod_id – Model ID.
• cid – Company ID of the model.
• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_app_get(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, 
    uint16_t mod_id, uint8_t *status, uint16_t *apps, size_t *app_cnt)

Get a list of all applications bound to a SIG model on the target node.

This method can be used asynchronously by setting status and ( apps or app_cnt ) as NULL. 
This way the method will not wait for response and will return immediately after sending the command.

Parameters
• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• mod_id – Model ID.
• status – Status response parameter.
• apps – App index list response parameter. Will be filled with all the returned application key indexes it can fill.
• app_cnt – App index list length. Should be set to the capacity of the apps list when calling. Will return the number of returned application key indexes upon success.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_app_get_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
                                uint16_t mod_id, uint16_t cid, uint8_t *status, uint16_t *
                                apps, size_t *app_cnt)
```

Get a list of all applications bound to a vendor model on the target node.

This method can be used asynchronously by setting status and (apps or app_cnt) as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**

• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• mod_id – Model ID.
• cid – Company ID of the model.
• status – Status response parameter.
• apps – App index list response parameter. Will be filled with all the returned application key indexes it can fill.
• app_cnt – App index list length. Should be set to the capacity of the apps list when calling. Will return the number of returned application key indexes upon success.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_pub_get(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
                            uint16_t mod_id, struct bt_mesh_cfg_mod_pub *pub, uint8_t *status)
```

Get publish parameters for a SIG model on the target node.

This method can be used asynchronously by setting status and pub as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**

• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• mod_id – Model ID.
• pub – Publication parameter return buffer.
• status – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_pub_get_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
                               uint16_t mod_id, uint16_t cid, struct bt_mesh_cfg_mod_pub
                               *pub, uint8_t *status)
```

Get publish parameters for a vendor model on the target node.

This method can be used asynchronously by setting status and pub as NULL. This way the method will not wait for response and will return immediately after sending the command.
Parameters

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `elem_addr` – Element address the model is in.
- `mod_id` – Model ID.
- `cid` – Company ID of the model.
- `pub` – Publication parameter return buffer.
- `status` – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_pub_set(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, uint16_t mod_id, struct bt_mesh_cfg_mod_pub *pub, uint8_t *status)
```

Set publish parameters for a SIG model on the target node.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

`pub` shall not be NULL.

Parameters

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `elem_addr` – Element address the model is in.
- `mod_id` – Model ID.
- `pub` – Publication parameters.
- `status` – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_pub_set_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, uint16_t mod_id, uint16_t cid, struct bt_mesh_cfg_mod_pub *pub, uint8_t *status)
```

Set publish parameters for a vendor model on the target node.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

`pub` shall not be NULL.

Parameters

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `elem_addr` – Element address the model is in.
- `mod_id` – Model ID.
- `cid` – Company ID of the model.
- `pub` – Publication parameter return buffer.
- `status` – Status response parameter.

Returns 0 on success, or (negative) error code on failure.
int bt_mesh_cfg_mod_sub_add(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, uint16_t sub_addr, uint16_t mod_id, uint8_t *status)
Add a group address to a SIG model’s subscription list.
This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

- **net_idx** – Network index to encrypt with.
- **addr** – Target node address.
- **elem_addr** – Element address the model is in.
- **sub_addr** – Group address to add to the subscription list.
- **mod_id** – Model ID.
- **status** – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_sub_add_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, uint16_t sub_addr, uint16_t mod_id, uint16_t cid, uint8_t *status)
Add a group address to a vendor model’s subscription list.
This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

- **net_idx** – Network index to encrypt with.
- **addr** – Target node address.
- **elem_addr** – Element address the model is in.
- **sub_addr** – Group address to add to the subscription list.
- **mod_id** – Model ID.
- **cid** – Company ID of the model.
- **status** – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_sub_del(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, uint16_t sub_addr, uint16_t mod_id, uint8_t *status)
Delete a group address in a SIG model’s subscription list.
This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

- **net_idx** – Network index to encrypt with.
- **addr** – Target node address.
- **elem_addr** – Element address the model is in.
- **sub_addr** – Group address to add to the subscription list.
- **mod_id** – Model ID.
- **status** – Status response parameter.

Returns 0 on success, or (negative) error code on failure.
int bt_mesh_cfg_mod_sub_del_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
    uint16_t sub_addr, uint16_t mod_id, uint16_t cid, uint8_t *status)

Delete a group address in a vendor model's subscription list.
This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters
- net_idx – Network index to encrypt with.
- addr – Target node address.
- elem_addr – Element address the model is in.
- sub_addr – Group address to add to the subscription list.
- mod_id – Model ID.
- cid – Company ID of the model.
- status – Status response parameter.

Returns
0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_sub_overwrite(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
    uint16_t sub_addr, uint16_t mod_id, uint8_t *status)

Overwrite all addresses in a SIG model's subscription list with a group address.
Deletes all subscriptions in the model's subscription list, and adds a single group address instead.
This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters
- net_idx – Network index to encrypt with.
- addr – Target node address.
- elem_addr – Element address the model is in.
- sub_addr – Group address to add to the subscription list.
- mod_id – Model ID.
- status – Status response parameter.

Returns
0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_sub_overwrite_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
    uint16_t sub_addr, uint16_t mod_id, uint16_t cid, uint8_t *status)

Overwrite all addresses in a vendor model's subscription list with a group address.
Deletes all subscriptions in the model's subscription list, and adds a single group address instead.
This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters
- net_idx – Network index to encrypt with.
- addr – Target node address.
- elem_addr – Element address the model is in.
- sub_addr – Group address to add to the subscription list.
• mod_id – Model ID.
• cid – Company ID of the model.
• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_sub_va_add(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, const uint8_t label[16], uint16_t mod_id, uint16_t *virt_addr, uint8_t *status)

Add a virtual address to a SIG model's subscription list.

This method can be used asynchronously by setting status and virt_addr as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters
• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• label – Virtual address label to add to the subscription list.
• mod_id – Model ID.
• virt_addr – Virtual address response parameter.
• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_sub_va_add_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, const uint8_t label[16], uint16_t mod_id, uint16_t cid, uint16_t *virt_addr, uint8_t *status)

Add a virtual address to a vendor model's subscription list.

This method can be used asynchronously by setting status and virt_addr as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters
• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• label – Virtual address label to add to the subscription list.
• mod_id – Model ID.
• cid – Company ID of the model.
• virt_addr – Virtual address response parameter.
• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_sub_va_del(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, const uint8_t label[16], uint16_t mod_id, uint16_t *virt_addr, uint8_t *status)

Delete a virtual address in a SIG model's subscription list.

This method can be used asynchronously by setting status and virt_addr as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters
• net_idx – Network index to encrypt with.
• **addr** – Target node address.
• **elem_addr** – Element address the model is in.
• **label** – Virtual address parameter to add to the subscription list.
• **mod_id** – Model ID.
• **virt_addr** – Virtual address response parameter.
• **status** – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_sub_va_del_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
const uint8_t label[16], uint16_t mod_id, uint16_t cid,
uint16_t *virt_addr, uint8_t *status)
```

Delete a virtual address in a vendor model's subscription list.

This method can be used asynchronously by setting `status` and `virt_addr` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**

• **net_idx** – Network index to encrypt with.
• **addr** – Target node address.
• **elem_addr** – Element address the model is in.
• **label** – Virtual address label to add to the subscription list.
• **mod_id** – Model ID.
• **cid** – Company ID of the model.
• **virt_addr** – Virtual address response parameter.
• **status** – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_sub_va_overwrite(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
const uint8_t label[16], uint16_t mod_id, uint16_t cid,
uint16_t *virt_addr, uint8_t *status)
```

Overwrite all addresses in a SIG model's subscription list with a virtual address.

Deletes all subscriptions in the model's subscription list, and adds a single group address instead.

This method can be used asynchronously by setting `status` and `virt_addr` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**

• **net_idx** – Network index to encrypt with.
• **addr** – Target node address.
• **elem_addr** – Element address the model is in.
• **label** – Virtual address label to add to the subscription list.
• **mod_id** – Model ID.
• **virt_addr** – Virtual address response parameter.
• **status** – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.
int bt_mesh_cfg_mod_sub_va_overwrite_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, const uint8_t label[16], uint16_t mod_id, uint16_t cid, uint16_t *virt_addr, uint8_t *status)

Overwrite all addresses in a vendor model’s subscription list with a virtual address. Deletes all subscriptions in the model’s subscription list, and adds a single group address instead.

This method can be used asynchronously by setting status and virt_addr as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• label – Virtual address label to add to the subscription list.
• mod_id – Model ID.
• cid – Company ID of the model.
• virt_addr – Virtual address response parameter.
• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_mod_sub_get_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr, uint16_t mod_id, uint16_t *subs, size_t *sub_cnt)

Get the subscription list of a vendor model on the target node.

This method can be used asynchronously by setting status and (subs or sub_cnt) as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters

• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• mod_id – Model ID.
• status – Status response parameter.
• subs – Subscription list response parameter. Will be filled with all the returned subscriptions it can fill.
• sub_cnt – Subscription list element count. Should be set to the capacity of the subs list when calling. Will return the number of returned subscriptions upon success.

Returns 0 on success, or (negative) error code on failure.
• net_idx – Network index to encrypt with.
• addr – Target node address.
• elem_addr – Element address the model is in.
• mod_id – Model ID.
• cid – Company ID of the model.
• status – Status response parameter.
• subs – Subscription list response parameter. Will be filled with all the returned subscriptions it can fill.
• sub_cnt – Subscription list element count. Should be set to the capacity of the subs list when calling. Will return the number of returned subscriptions upon success.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_hb_sub_set(uint16_t net_idx, uint16_t addr, struct bt_mesh_cfg_hb_sub *sub, uint8_t *status)

Set the target node's Heartbeat subscription parameters.

This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

sub shall not be null.

Parameters
• net_idx – Network index to encrypt with.
• addr – Target node address.
• sub – New Heartbeat subscription parameters.
• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_hb_sub_get(uint16_t net_idx, uint16_t addr, struct bt_mesh_cfg_hb_sub *sub, uint8_t *status)

Get the target node's Heartbeat subscription parameters.

This method can be used asynchronously by setting status and sub as NULL. This way the method will not wait for response and will return immediately after sending the command.

Parameters
• net_idx – Network index to encrypt with.
• addr – Target node address.
• sub – Heartbeat subscription parameter return buffer.
• status – Status response parameter.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_cfg_hb_pub_set(uint16_t net_idx, uint16_t addr, const struct bt_mesh_cfg_hb_pub *pub, uint8_t *status)

Set the target node's Heartbeat publication parameters.

This method can be used asynchronously by setting status as NULL. This way the method will not wait for response and will return immediately after sending the command.

pub shall not be NULL;
**Note:** The target node must already have received the specified network key.

**Parameters**
- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `pub` – New Heartbeat publication parameters.
- `status` – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_hb_pub_get(uint16_t net_idx, uint16_t addr, struct bt_mesh_cfg_hb_pub *pub,
                           uint8_t *status)
```
Get the target node’s Heartbeat publication parameters.

This method can be used asynchronously by setting `status` and `pub` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**
- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `pub` – Heartbeat publication parameter return buffer.
- `status` – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_sub_del_all(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
                                uint16_t mod_id, uint8_t *status)
```
Delete all group addresses in a SIG model’s subscription list.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**
- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `elem_addr` – Element address the model is in.
- `mod_id` – Model ID.
- `status` – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_mod_sub_del_all_vnd(uint16_t net_idx, uint16_t addr, uint16_t elem_addr,
                                    uint16_t mod_id, uint16_t cid, uint8_t *status)
```
Delete all group addresses in a vendor model’s subscription list.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**
- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `elem_addr` – Element address the model is in.
- `mod_id` – Model ID.
- cid – Company ID of the model.
- status – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_net_key_update(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, const uint8_t net_key[16], uint8_t *status)
```

Update a network key to the target node.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**
- net_idx – Network index to encrypt with.
- addr – Target node address.
- key_net_idx – Network key index.
- net_key – Network key.
- status – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_app_key_update(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, uint16_t key_app_idx, const uint8_t app_key[16], uint8_t *status)
```

Update an application key to the target node.

This method can be used asynchronously by setting `status` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**
- net_idx – Network index to encrypt with.
- addr – Target node address.
- key_net_idx – Network key index the application key belongs to.
- key_app_idx – Application key index.
- app_key – Application key.
- status – Status response parameter.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_node_identity_set(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, uint8_t new_identity, uint8_t *status, uint8_t *identity)
```

Set the Node Identity parameters.

This method can be used asynchronously by setting `status` and `identity` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**
- net_idx – Network index to encrypt with.
- addr – Target node address.
- new_identity – New identity state. Must be one of `BT_MESH_NODE_IDENTITY_STOPPED` or `BT_MESH_NODE_IDENTITY_RUNNING`
- key_net_idx – Network key index the application key belongs to.
- status – Status response parameter.
- identity – Identity response parameter.
Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_node_identity_get(uint16_t net_idx, uint16_t addr, uint16_t key_net_idx, uint8_t *status, uint8_t *identity)
```

Get the Node Identity parameters.

This method can be used asynchronously by setting `status` and `identity` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `key_net_idx` – Network key index the application key belongs to.
- `status` – Status response parameter.
- `identity` – Identity response parameter. Must be one of `BT_MESH_NODE_IDENTITY_STOPPED` or `BT_MESH_NODE_IDENTITY_RUNNING`.

Returns 0 on success, or (negative) error code on failure.

```c
int bt_mesh_cfg_lpn_timeout_get(uint16_t net_idx, uint16_t addr, uint16_t unicast_addr, int32_t *polltimeout)
```

Get the Low Power Node Polltimeout parameters.

This method can be used asynchronously by setting `polltimeout` as NULL. This way the method will not wait for response and will return immediately after sending the command.

**Parameters**

- `net_idx` – Network index to encrypt with.
- `addr` – Target node address.
- `unicast_addr` – LPN unicast address.
- `polltimeout` – Polltimeout response parameter.

Returns 0 on success, or (negative) error code on failure.

```c
int32_t bt_mesh_cfg_cli_timeout_get(void)
```

Get the current transmission timeout value.

Returns The configured transmission timeout in milliseconds.

```c
void bt_mesh_cfg_cli_timeout_set(int32_t timeout)
```

Set the transmission timeout value.

**Parameters**

- `timeout` – The new transmission timeout.

```c
int bt_mesh_comp_p0_get(struct bt_mesh_comp_p0 *comp, struct net_buf_simple *buf)
```

Create a composition data page 0 representation from a buffer.

The composition data page object will take ownership over the buffer, which should not be manipulated directly after this call.

This function can be used in combination with `bt_mesh_cfg_comp_data_get` to read out composition data page 0 from other devices:

```c
NET_BUF_SIMPLE_DEFINE(buf, BT_MESH_RX_SDU_MAX);
struct bt_mesh_comp_p0 comp;
```
Mesh Configuration Client Model Context

Public Members

- `struct bt_mesh_model *model`
  Composition data model entry pointer.
struct bt_mesh_cfg_mod_pub
    #include <cfg_cli.h> Model publication configuration parameters.

Public Members

uint16_t addr
    Publication destination address.

const uint8_t *uuid
    Virtual address UUID, or NULL if this is not a virtual address.

uint16_t app_idx
    Application index to publish with.

bool cred_flag
    Friendship credential flag.

uint8_t ttl
    Time To Live to publish with.

uint8_t period
    Encoded publish period.
    See also:
    BT_MESH_PUB_PERIOD_100MS, BT_MESH_PUB_PERIOD_SEC,
    BT_MESH_PUB_PERIOD_10SEC, BT_MESH_PUB_PERIOD_10MIN

uint8_t transmit
    Encoded transmit parameters.
    See also:
    BT_MESH_TRANSMIT

struct bt_mesh_cfg_hb_sub
    #include <cfg_cli.h> Heartbeat subscription configuration parameters.

Public Members

uint16_t src
    Source address to receive Heartbeat messages from.

uint16_t dst
    Destination address to receive Heartbeat messages on.

uint8_t period
    Logarithmic subscription period to keep listening for. The decoded subscription period is
    (1 << (period - 1)) seconds, or 0 seconds if period is 0.

uint8_t count
    Logarithmic Heartbeat subscription receive count. The decoded Heartbeat count is
    (1 << (count - 1)) if count is between 1 and 0xfe, 0 if count is 0 and 0xffff if count is 0xff.
    Ignored in Heartbeat subscription set.
uint8_t \texttt{min}
Minimum hops in received messages, ie the shortest registered path from the publishing node to the subscribing node. A Heartbeat received from an immediate neighbor has hop count = 1.
Ignored in Heartbeat subscription set.

uint8_t \texttt{max}
Maximum hops in received messages, ie the longest registered path from the publishing node to the subscribing node. A Heartbeat received from an immediate neighbor has hop count = 1.
Ignored in Heartbeat subscription set.

\textbf{Public Members}

\texttt{uint16_t \texttt{dst}}
Heartbeat destination address.

\texttt{uint8_t \texttt{count}}
Logarithmic Heartbeat count. Decoded as \((1 \ll (\text{count} - 1))\) if \text{count} is between 1 and 0x11, 0 if \text{count} is 0, or “indefinitely” if \text{count} is 0xff.
When used in Heartbeat publication set, this parameter denotes the number of Heartbeat messages to send.
When returned from Heartbeat publication get, this parameter denotes the number of Heartbeat messages remaining to be sent.

\texttt{uint8_t \texttt{period}}
Logarithmic Heartbeat publication transmit interval in seconds. Decoded as \((1 \ll (\text{period} - 1))\) if \text{period} is between 1 and 0x11. If \text{period} is 0, Heartbeat publication is disabled.

\texttt{uint8_t \texttt{ttl}}
Publication message Time To Live value.

\texttt{uint16_t \texttt{feat}}
Bitmap of features that trigger Heartbeat publications. Legal values are \texttt{BT_MESH_FEAT_RELAY}, \texttt{BT_MESH_FEAT_PROXY}, \texttt{BT_MESH_FEAT_FRIEND} and \texttt{BT_MESH_FEAT_LOW_POWER}.

\texttt{uint16_t \texttt{net_idx}}
Network index to publish with.

\textbf{Parsed Composition data page 0}
\#include <cfg_cli.h> Parsed Composition data page 0 representation.
Should be pulled from the return buffer passed to \texttt{bt_mesh_cfg_comp_data_get} using \texttt{bt_mesh_comp_p0_get}.

Health Server  The Health Server model provides attention callbacks and node diagnostics for Health Client models. It is primarily used to report faults in the mesh node and map the mesh nodes to their physical location.

Faults  The Health Server model may report a list of faults that have occurred in the device's lifetime. Typically, the faults are events or conditions that may alter the behavior of the node, like power outages or faulty peripherals. Faults are split into warnings and errors. Warnings indicate conditions that are close to the limits of what the node is designed to withstand, but not necessarily damaging to the device. Errors indicate conditions that are outside of the node's design limits, and may have caused invalid behavior or permanent damage to the device.

Fault values `0x01` to `0x7f` are reserved for the Bluetooth mesh specification, and the full list of specification defined faults are available in Health faults. Fault values `0x80` to `0xff` are vendor specific. The list of faults are always reported with a company ID to help interpreting the vendor specific faults.

Attention state  The attention state is used to make the device call attention to itself through some physical behavior like blinking, playing a sound or vibrating. The attention state may be used during provisioning to let the user know which device they're provisioning, as well as through the Health models at runtime.
The attention state is always assigned a timeout in the range of one to 255 seconds when enabled. The Health Server API provides two callbacks for the application to run their attention calling behavior: `bt_mesh_health_srv_cb.attn_on` is called at the beginning of the attention period, `bt_mesh_health_srv_cb.attn_off` is called at the end.

The remaining time for the attention period may be queried through `bt_mesh_health_srv.attn_timer`.

API reference

**group bt_mesh_health_srv**

Health Server Model.

**Defines**

```c
BT_MESH_HEALTH_PUB_DEFINE(_name, _max_faults)
```

A helper to define a health publication context

**Parameters**

- `_name` – Name given to the publication context variable.
- `_max_faults` – Maximum number of faults the element can have.

```c
BT_MESH_MODEL_HEALTH_SRV(srv, pub)
```

Define a new health server model. Note that this API needs to be repeated for each element that the application wants to have a health server model on. Each instance also needs a unique `bt_mesh_health_srv` and `bt_mesh_model_pub` context.

**Parameters**

- `srv` – Pointer to a unique struct `bt_mesh_health_srv`.
- `pub` – Pointer to a unique struct `bt_mesh_model_pub`.

**Returns** New mesh model instance.

**Functions**

```c
int bt_mesh_fault_update(struct bt_mesh_elem *elem)
```

Notify the stack that the fault array state of the given element has changed.

This prompts the Health server on this element to publish the current fault array if periodic publishing is disabled.

**Parameters**

- `elem` – Element to update the fault state of.

**Returns** 0 on success, or (negative) error code otherwise.

```c
#include <health_srv.h>
```

Callback function for the Health Server model

**Public Members**

```c
int (*fault_get_cur)(struct bt_mesh_model *model, uint8_t *test_id, uint16_t *company_id, uint8_t *faults, uint8_t *fault_count)
```

Callback for fetching current faults.

Fault values may either be defined by the specification, or by a vendor. Vendor specific faults should be interpreted in the context of the accompanying Company ID. Specification
defined faults may be reported for any Company ID, and the same fault may be presented for multiple Company IDs.

All faults shall be associated with at least one Company ID, representing the device vendor or some other vendor whose vendor specific fault values are used.

If there are multiple Company IDs that have active faults, return only the faults associated with one of them at the time. To report faults for multiple Company IDs, interleave which Company ID is reported for each call.

Param `model` Health Server model instance to get faults of.
Param `test_id` Test ID response buffer.
Param `company_id` Company ID response buffer.
Param `faults` Array to fill with current faults.
Param `fault_count` The number of faults the fault array can fit. Should be updated to reflect the number of faults copied into the array.

Return 0 on success, or (negative) error code otherwise.

### Callbacks

```c
int (*fault_get_reg)(struct bt_mesh_model *model, uint16_t company_id, uint8_t *test_id, uint8_t *faults, uint8_t *fault_count)
```

Callback for fetching all registered faults.

Registered faults are all past and current faults since the last call to `fault_clear`. Only faults associated with the given Company ID should be reported.

Fault values may either be defined by the specification, or by a vendor. Vendor specific faults should be interpreted in the context of the accompanying Company ID. Specification defined faults may be reported for any Company ID, and the same fault may be presented for multiple Company IDs.

Param `model` Health Server model instance to get faults of.
Param `company_id` Company ID to get faults for.
Param `test_id` Test ID response buffer.
Param `faults` Array to fill with registered faults.
Param `fault_count` The number of faults the fault array can fit. Should be updated to reflect the number of faults copied into the array.

Return 0 on success, or (negative) error code otherwise.

```c
int (*fault_clear)(struct bt_mesh_model *model, uint16_t company_id)
```

Clear all registered faults associated with the given Company ID.

Param `model` Health Server model instance to clear faults of.
Param `company_id` Company ID to clear faults for.

Return 0 on success, or (negative) error code otherwise.

```c
int (*fault_test)(struct bt_mesh_model *model, uint8_t test_id, uint16_t company_id)
```

Run a self-test.

The Health server may support up to 256 self-tests for each Company ID. The behavior for all test IDs are vendor specific, and should be interpreted based on the accompanying Company ID. Test failures should result in changes to the fault array.

Param `model` Health Server model instance to run test for.
Param `test_id` Test ID to run.
Param `company_id` Company ID to run test for.

Return 0 if the test execution was started successfully, or (negative) error code otherwise. Note that the fault array will not be reported back to the client if the test execution didn't start.

```c
void (*attn_on)(struct bt_mesh_model *model)
```

Start calling attention to the device.

The attention state is used to map an element address to a physical device. When this callback is called, the device should start some physical procedure meant to call attention
to itself, like blinking, buzzing, vibrating or moving. If there are multiple Health server instances on the device, the attention state should also help identify the specific element the server is in.

The attention calling behavior should continue until the `attn_off` callback is called.

**Param model**  Health Server model to start the attention state of.

```c
void (*attn_off)(struct bt_mesh_model *model)
```

Stop the attention state.

Any physical activity started to call attention to the device should be stopped.

**Param model**

```c
struct bt_mesh_health_srv
```

#include `<health_srv.h>`  Mesh Health Server Model Context

### Public Members

Health Client  The Health Client model interacts with a Health Server model to read out diagnostics and control the node’s attention state.

All message passing functions in the Health Client API have `net_idx` and `addr` as their first parameters. These should be set to the network index and primary unicast address that the target node was provisioned with.

The Health Client model is optional, and may be instantiated in any element. However, if a Health Client model is instantiated in an element other than the first, an instance must also be present in the first element.

See Health faults for a list of specification defined fault values.

API reference

\[\text{group bt_mesh_health_cli}\]

\[\text{Health Client Model.}\]

Defines

\[\text{BT_MESH_MODEL_HEALTH_CLI(cli_data)}\]

Generic Health Client model composition data entry.

Parameters
• cli_data – Pointer to a Health Client Model instance.

Functions

int bt_mesh_health_cli_set(struct bt_mesh_model *model)

Set Health client model instance to use for communication.

Parameters

• model – Health Client model instance from the composition data.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_health_fault_get(uint16_t addr, uint16_t app_idx, uint16_t cid, uint8_t *test_id,
uint8_t *faults, size_t *fault_count)

Get the registered fault state for the given Company ID.

This method can be used asynchronously by setting test_id and (faults or fault_count) as NULL. This way the method will not wait for response and will return immediately after sending the command.

To process the response arguments of an async method, register the fault_status callback in bt_mesh_health_cli struct.

See also:
Health faults

Parameters

• addr – Target node element address.
• app_idx – Application index to encrypt with.
• cid – Company ID to get the registered faults of.
• test_id – Test ID response buffer.
• faults – Fault array response buffer.
• fault_count – Fault count response buffer.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_health_fault_clear(uint16_t addr, uint16_t app_idx, uint16_t cid, uint8_t *test_id,
uint8_t *faults, size_t *fault_count)

Clear the registered faults for the given Company ID.

This method can be used asynchronously by setting test_id and (faults or fault_count) as NULL. This way the method will not wait for response and will return immediately after sending the command.

To process the response arguments of an async method, register the fault_status callback in bt_mesh_health_cli struct.

See also:
Health faults

Parameters

• addr – Target node element address.
• app_idx – Application index to encrypt with.
- `cid` – Company ID to clear the registered faults for.
- `test_id` – Test ID response buffer.
- `faults` – Fault array response buffer.
- `fault_count` – Fault count response buffer.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_health_fault_clear_unack(uint16_t addr, uint16_t app_idx, uint16_t cid)
```
Clear the registered faults for the given Company ID (unacked).

**See also:**

*Health faults*

**Parameters**

- `addr` – Target node element address.
- `app_idx` – Application index to encrypt with.
- `cid` – Company ID to clear the registered faults for.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_health_fault_test(uint16_t addr, uint16_t app_idx, uint16_t cid, uint8_t test_id, uint8_t *faults, size_t *fault_count)
```
Invoke a self-test procedure for the given Company ID.

This method can be used asynchronously by setting `faults` or `fault_count` as NULL. This way the method will not wait for response and will return immediately after sending the command.

To process the response arguments of an async method, register the `fault_status` callback in `bt_mesh_health_cli` struct.

**Parameters**

- `addr` – Target node element address.
- `app_idx` – Application index to encrypt with.
- `cid` – Company ID to invoke the test for.
- `test_id` – Test ID response buffer.
- `faults` – Fault array response buffer.
- `fault_count` – Fault count response buffer.

**Returns** 0 on success, or (negative) error code on failure.

```c
int bt_mesh_health_fault_test_unack(uint16_t addr, uint16_t app_idx, uint16_t cid, uint8_t test_id)
```
Invoke a self-test procedure for the given Company ID (unacked).

**Parameters**

- `addr` – Target node element address.
- `app_idx` – Application index to encrypt with.
- `cid` – Company ID to invoke the test for.
- `test_id` – Test ID response buffer.

**Returns** 0 on success, or (negative) error code on failure.
```c
int bt_mesh_health_period_get(uint16_t addr, uint16_t app_idx, uint8_t *divisor)
    Get the target node's Health fast period divisor.

    The health period divisor is used to increase the publish rate when a fault is registered. Normally, the Health server will publish with the period in the configured publish parameters. When a fault is registered, the publish period is divided by (1 << divisor). For example, if the target node's Health server is configured to publish with a period of 16 seconds, and the Health fast period divisor is 5, the Health server will publish with an interval of 500 ms when a fault is registered.

    This method can be used asynchronously by setting divisor as NULL. This way the method will not wait for response and will return immediately after sending the command.

    To process the response arguments of an async method, register the period_status callback in bt_mesh_health_cli struct.

    Parameters
    • addr – Target node element address.
    • app_idx – Application index to encrypt with.
    • divisor – Health period divisor response buffer.

    Returns 0 on success, or (negative) error code on failure.
```

```c
int bt_mesh_health_period_set(uint16_t addr, uint16_t app_idx, uint8_t divisor, uint8_t *updated_divisor)
    Set the target node's Health fast period divisor.

    The health period divisor is used to increase the publish rate when a fault is registered. Normally, the Health server will publish with the period in the configured publish parameters. When a fault is registered, the publish period is divided by (1 << divisor). For example, if the target node's Health server is configured to publish with a period of 16 seconds, and the Health fast period divisor is 5, the Health server will publish with an interval of 500 ms when a fault is registered.

    This method can be used asynchronously by setting updated_divisor as NULL. This way the method will not wait for response and will return immediately after sending the command.

    To process the response arguments of an async method, register the period_status callback in bt_mesh_health_cli struct.

    Parameters
    • addr – Target node element address.
    • app_idx – Application index to encrypt with.
    • divisor – New Health period divisor.
    • updated_divisor – Health period divisor response buffer.

    Returns 0 on success, or (negative) error code on failure.
```

```c
int bt_mesh_health_period_set_unack(uint16_t addr, uint16_t app_idx, uint8_t divisor)
    Set the target node's Health fast period divisor (unacknowledged).

    This is an unacknowledged version of this API.

    Parameters
    • addr – Target node element address.
    • app_idx – Application index to encrypt with.
    • divisor – New Health period divisor.

    Returns 0 on success, or (negative) error code on failure.
```
int bt_mesh_health_attention_get(uint16_t addr, uint16_t app_idx, uint8_t *attention)

Get the current attention timer value.

This method can be used asynchronously by setting attention as NULL. This way the method will not wait for response and will return immediately after sending the command.

To process the response arguments of an async method, register the attention_status callback in bt_mesh_health_cli struct.

Parameters

• addr – Target node element address.
• app_idx – Application index to encrypt with.
• attention – Attention timer response buffer, measured in seconds.

Returns

0 on success, or (negative) error code on failure.

int bt_mesh_health_attention_set(uint16_t addr, uint16_t app_idx, uint8_t attention, uint8_t *updated_attention)

Set the attention timer.

This method can be used asynchronously by setting updated_attention as NULL. This way the method will not wait for response and will return immediately after sending the command.

To process the response arguments of an async method, register the attention_status callback in bt_mesh_health_cli struct.

Parameters

• addr – Target node element address.
• app_idx – Application index to encrypt with.
• attention – New attention timer time, in seconds.
• updated_attention – Attention timer response buffer, measured in seconds.

Returns

0 on success, or (negative) error code on failure.

int bt_mesh_health_attention_set_unack(uint16_t addr, uint16_t app_idx, uint8_t attention)

Set the attention timer (unacknowledged).

Parameters

• addr – Target node element address.
• app_idx – Application index to encrypt with.
• attention – New attention timer time, in seconds.

Returns

0 on success, or (negative) error code on failure.

int32_t bt_mesh_health_cli_timeout_get(void)

Get the current transmission timeout value.

Returns

The configured transmission timeout in milliseconds.

void bt_mesh_health_cli_timeout_set(int32_t timeout)

Set the transmission timeout value.

Parameters

• timeout – The new transmission timeout.
Public Members

```c
struct bt_mesh_model *model
Composition data model entry pointer.
```

```c
void (*period_status)(struct bt_mesh_health_cli *cli, uint16_t addr, uint8_t divisor)
Optional callback for Health Period Status messages.
Handles received Health Period Status messages from a Health server. The divisor param
represents the period divisor value.
  Param cli Health client that received the status message.
  Param addr Address of the sender.
  Param divisor Health Period Divisor value.
```

```c
void (*attention_status)(struct bt_mesh_health_cli *cli, uint16_t addr, uint8_t attention)
Optional callback for Health Attention Status messages.
Handles received Health Attention Status messages from a Health server. The attention
param represents the current attention value.
  Param cli Health client that received the status message.
  Param addr Address of the sender.
  Param attention Current attention value.
```

```c
void (*fault_status)(struct bt_mesh_health_cli *cli, uint16_t addr, uint8_t test_id, uint16_t cid, uint8_t *faults, size_t fault_count)
Optional callback for Health Fault Status messages.
Handles received Health Fault Status messages from a Health server. The fault array
represents all faults that are currently present in the server's element.
  Param cli Health client that received the status message.
  Param addr Address of the sender.
  Param test_id Identifier of a most recently performed test.
  Param cid Company Identifier of the node.
  Param faults Array of faults.
  Param fault_count Number of faults in the fault array.
```

```c
void (*current_status)(struct bt_mesh_health_cli *cli, uint16_t addr, uint8_t test_id, uint16_t cid, uint8_t *faults, size_t fault_count)
Optional callback for Health Current Status messages.
Handles received Health Current Status messages from a Health server. The fault array
represents all faults that are currently present in the server's element.
  Param cli Health client that received the status message.
  Param addr Address of the sender.
  Param test_id Identifier of a most recently performed test.
  Param cid Company Identifier of the node.
  Param faults Array of faults.
  Param fault_count Number of faults in the fault array.
```

See also:

- Param fault_count Number of faults in the fault array.
Message

The Bluetooth mesh message provides a set of structures, macros, and functions used for preparing message buffers, managing message and acknowledged message contexts.

API reference

group bt_mesh_msg
   Message.

Defines

BT_MESH_MIC_SHORT
   Length of a short Mesh MIC.

BT_MESH_MIC_LONG
   Length of a long Mesh MIC.

BT_MESH_MODEL_OP_LEN(_op)
   Helper to determine the length of an opcode.

Parameters
   • _op – Opcode.

BT_MESH_MODEL_BUF_LEN(_op, _payload_len)
   Helper for model message buffer length.
   Returns the length of a Mesh model message buffer, including the opcode length and a short MIC.

Parameters
   • _op – Opcode of the message.
   • _payload_len – Length of the model payload.

BT_MESH_MODEL_BUF_LEN_LONG_MIC(_op, _payload_len)
   Helper for model message buffer length.
   Returns the length of a Mesh model message buffer, including the opcode length and a long MIC.

Parameters
   • _op – Opcode of the message.
   • _payload_len – Length of the model payload.

BT_MESH_MODEL_BUF_DEFINE(_buf, _op, _payload_len)
   Define a Mesh model message buffer using NET_BUF_SIMPLE_DEFINE.

Parameters
   • _buf – Buffer name.
   • _op – Opcode of the message.
   • _payload_len – Length of the model message payload.
Functions

void bt_mesh_model_msg_init(struct net_buf_simple *msg, uint32_t opcode)
Initialize a model message.

Clears the message buffer contents, and encodes the given opcode. The message buffer will be ready for filling in payload data.

Parameters
  • msg – Message buffer.
  • opcode – Opcode to encode.

static inline void bt_mesh_msg_ack_ctx_init(struct bt_mesh_msg_ack_ctx *ack)
Initialize an acknowledged message context.

Initializes semaphore used for synchronization between bt_mesh_msg_ack_ctx_wait and bt_mesh_msg_ack_ctx_rx calls. Call this function before using bt_mesh_msg_ack_ctx.

Parameters
  • ack – Acknowledged message context to initialize.

static inline void bt_mesh_msg_ack_ctx_reset(struct bt_mesh_msg_ack_ctx *ack)
Reset the synchronization semaphore in an acknowledged message context.

This function aborts call to bt_mesh_msg_ack_ctx_wait.

Parameters
  • ack – Acknowledged message context to be reset.

void bt_mesh_msg_ack_ctx_clear(struct bt_mesh_msg_ack_ctx *ack)
Clear parameters of an acknowledged message context.

This function clears the opcode, remote address and user data set by bt_mesh_msg_ack_ctx_prepare.

Parameters
  • ack – Acknowledged message context to be cleared.

int bt_mesh_msg_ack_ctx_prepare(struct bt_mesh_msg_ack_ctx *ack, uint32_t op, uint16_t dst,
 void *user_data)
Prepare an acknowledged message context for the incoming message to wait.

This function sets the opcode, remote address of the incoming message and stores the user data. Use this function before calling bt_mesh_msg_ack_ctx_wait.

Parameters
  • ack – Acknowledged message context to prepare.
  • dst – Destination address of the message.
  • user_data – User data for the acknowledged message context.

Returns 0 on success, or (negative) error code on failure.

static inline bool bt_mesh_msg_ack_ctx_busy(struct bt_mesh_msg_ack_ctx *ack)
Check if the acknowledged message context is initialized with an opcode.

Parameters
  • ack – Acknowledged message context.

Returns true if the acknowledged message context is initialized with an opcode, false otherwise.
int bt_mesh_msg_ack_ctx_wait(struct bt_mesh_msg_ack_ctx *ack, k_timeout_t timeout)
    Wait for a message acknowledge.
This function blocks execution until bt_mesh_msg_ack_ctx_rx is called or by timeout.

Parameters
- ack – Acknowledged message context of the message to wait for.
- timeout – Wait timeout.

Returns 0 on success, or (negative) error code on failure.

static inline void bt_mesh_msg_ack_ctx_rx(struct bt_mesh_msg_ack_ctx *ack)
    Mark a message as acknowledged.
This function unblocks call to bt_mesh_msg_ack_ctx_wait.

Parameters
- ack – Context of a message to be acknowledged.

bool bt_mesh_msg_ack_ctx_match(const struct bt_mesh_msg_ack_ctx *ack, uint32_t op, uint16_t addr, void **user_data)
    Check if an opcode and address of a message matches the expected one.

Parameters
- ack – Acknowledged message context to be checked.
- addr – Source address of the incoming message.
- user_data – If not NULL, returns a user data stored in the acknowledged message context by bt_mesh_msg_ack_ctx_prepare.

Returns true if the incoming message matches the expected one, false otherwise.

struct bt_mesh_msg_ctx
    #include <msg.h> Message sending context.

Public Members

uint16_t net_idx
    NetKey Index of the subnet to send the message on.

uint16_t app_idx
    AppKey Index to encrypt the message with.

uint16_t addr
    Remote address.

uint16_t recv_dst
    Destination address of a received message. Not used for sending.

int8_t recv_rssi
    RSSI of received packet. Not used for sending.

uint8_t recv_ttl
    Received TTL value. Not used for sending.
bool send_re1
   Force sending reliably by using segment acknowledgment

uint8_t send_ttl
   TTL, or BT_MESH_TTL_DEFAULT for default TTL.

struct bt_mesh_msg_ack_ctx
   #include <msg.h> Acknowledged message context for tracking the status of model messages pending a response.

Public Members

struct k_sem sem
   Sync semaphore.

uint32_t op
   Opcode we’re waiting for.

uint16_t dst
   Address of the node that should respond.

void *user_data
   User specific parameter.

Provisioning

Provisioning is the process of adding devices to a mesh network. It requires two devices operating in the following roles:

- The **provisioner** represents the network owner, and is responsible for adding new nodes to the mesh network.
- The **provisionee** is the device that gets added to the network through the Provisioning process. Before the provisioning process starts, the provisionee is an **unprovisioned device**.

The Provisioning module in the Zephyr Bluetooth mesh stack supports both the Advertising and GATT Provisioning bearers for the provisionee role, as well as the Advertising Provisioning bearer for the provisioner role.

The **Provisioning process** All Bluetooth mesh nodes must be provisioned before they can participate in a Bluetooth mesh network. The Provisioning API provides all the functionality necessary for a device to become a provisioned mesh node. Provisioning is a five-step process, involving the following steps:

- Beaconing
- Invitation
- Public key exchange
- Authentication
- Provisioning data transfer
Beaconing To start the provisioning process, the unprovisioned device must first start broadcasting the Unprovisioned Beacon. This makes it visible to nearby provisioners, which can initiate the provisioning. To indicate that the device needs to be provisioned, call `bt_mesh_prov_enable()`. The device starts broadcasting the Unprovisioned Beacon with the device UUID and the OOB information field, as specified in the `prov` parameter passed to `bt_mesh_init()`. Additionally, a Uniform Resource Identifier (URI) may be specified, which can point the provisioner to the location of some Out Of Band information, such as the device's public key or an authentication value database. The URI is advertised in a separate beacon, with a URI hash included in the unprovisioned beacon, to tie the two together.

Uniform Resource Identifier The Uniform Resource Identifier shall follow the format specified in the Bluetooth Core Specification Supplement. The URI must start with a URI scheme, encoded as a single utf-8 data point, or the special `none` scheme, encoded as 0x01. The available schemes are listed on the Bluetooth website.

Examples of encoded URIs:

<table>
<thead>
<tr>
<th>URI</th>
<th>Encoded</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://example.com">http://example.com</a></td>
<td>\x16//example.com</td>
</tr>
<tr>
<td><a href="https://www.zephyrproject.org/">https://www.zephyrproject.org/</a></td>
<td>\x17//www.zephyrproject.org/</td>
</tr>
<tr>
<td>just a string</td>
<td>\x01just a string</td>
</tr>
</tbody>
</table>

Provisioning invitation The provisioner initiates the Provisioning process by sending a Provisioning invitation. The invitations prompts the provisionee to call attention to itself using the Health Server Attention state, if available.

The Unprovisioned device automatically responds to the invite by presenting a list of its capabilities, including the supported Out of Band Authentication methods.

Public key exchange Before the provisioning process can begin, the provisioner and the unprovisioned device exchange public keys, either in-band or Out of Band (OOB).

In-band public key exchange is a part of the provisioning process and always supported by the unprovisioned device and provisioner.

If the application wants to support public key exchange via OOB, it needs to provide public and private keys to the mesh stack. The unprovisioned device will reflect this in its capabilities. The provisioner obtains the public key via any available OOB mechanism (e.g. the device may advertise a packet containing the public key or it can be encoded in a QR code printed on the device packaging). Note that even if the unprovisioned device has specified the public key for the Out of Band exchange, the provisioner may choose to exchange the public key in-band if it can't retrieve the public key via OOB mechanism. In this case, a new key pair will be generated by the mesh stack for each Provisioning process.

To enable support of OOB public key on the unprovisioned device side, `CONFIG_BT_MESH_PROV_OOB_PUBLIC_KEY` needs to be enabled. The application must provide public and private keys before the Provisioning process is started by initializing pointers to `bt_mesh_prov.public_key_be` and `bt_mesh_prov.private_key_be`. The keys needs to be provided in big-endian bytes order.

To provide the device's public key obtained via OOB, call `bt_mesh_prov_remote_pub_key_set()` on the provisioner side.

Authentication After the initial exchange, the provisioner selects an Out of Band (OOB) Authentication method. This allows the user to confirm that the device the provisioner connected to is actually the device they intended, and not a malicious third party.

The Provisioning API supports the following authentication methods for the provisionee:
• **Static OOB:** An authentication value is assigned to the device in production, which the provisioner can query in some application specific way.

• **Input OOB:** The user inputs the authentication value. The available input actions are listed in `bt_mesh_input_action_t`.

• **Output OOB:** Show the user the authentication value. The available output actions are listed in `bt_mesh_output_action_t`.

The application must provide callbacks for the supported authentication methods in `bt_mesh_prov`, as well as enabling the supported actions in `bt_mesh_prov.output_actions` and `bt_mesh_prov.input_actions`.

When an Output OOB action is selected, the authentication value should be presented to the user when the output callback is called, and remain until the `bt_mesh_prov.input_complete` or `bt_mesh_prov.complete` callback is called. If the action is `blink`, `beep` or `vibrate`, the sequence should be repeated after a delay of three seconds or more.

When an Input OOB action is selected, the user should be prompted when the application receives the `bt_mesh_prov.input` callback. The user response should be fed back to the Provisioning API through `bt_mesh_input_string()` or `bt_mesh_input_number()`. If no user response is recorded within 60 seconds, the Provisioning process is aborted.

**Data transfer**  
After the device has been successfully authenticated, the provisioner transfers the Provisioning data:

- Unicast address
- A network key
- IV index
- Network flags
  - Key refresh
  - IV update

Additionally, a device key is generated for the node. All this data is stored by the mesh stack, and the provisioning `bt_mesh_prov.complete` callback gets called.

**Provisioning security**  
Depending on the choice of public key exchange mechanism and authentication method, the provisioning process can be secure or insecure.

On May 24th 2021, ANSSI disclosed a set of vulnerabilities in the Bluetooth mesh provisioning protocol that showcased how the low entropy provided by the Blink, Vibrate, Push, Twist and Input/Output numeric OOB methods could be exploited in impersonation and MITM attacks. In response, the Bluetooth SIG has reclassified these OOB methods as insecure in the Mesh Profile specification erratum 16350, as AuthValue may be brute forced in real time. To ensure secure provisioning, applications should use a static OOB value and OOB public key transfer.

\textbf{Functions}

\begin{verbatim}
int bt_mesh_input_string(const char *str)
  Provide provisioning input OOB string.
  This is intended to be called after the \texttt{bt_mesh_prov} input callback has been called with BT_MESH_ENTER_STRING as the action.

  \textbf{Parameters}
  \begin{itemize}
    \item \texttt{str} – String.
  \end{itemize}

  \textbf{Returns} Zero on success or (negative) error code otherwise.

int bt_mesh_input_number(uint32_t num)
  Provide provisioning input OOB number.
  This is intended to be called after the \texttt{bt_mesh_prov} input callback has been called with BT_MESH_ENTER_NUMBER as the action.

  \textbf{Parameters}
  \begin{itemize}
    \item \texttt{num} – Number.
  \end{itemize}

  \textbf{Returns} Zero on success or (negative) error code otherwise.
\end{verbatim}

7.4. Bluetooth
int bt_mesh_prov_remote_pub_key_set(const uint8_t public_key[64])
Provide Device public key.

Parameters

• public_key – Device public key in big-endian.

Returns Zero on success or (negative) error code otherwise.

int bt_mesh_auth_method_set_input(bt_mesh_input_action_t action, uint8_t size)
Use Input OOB authentication.
Provisioner only.
Instruct the unprovisioned device to use the specified Input OOB authentication action. When using BT_MESH_PUSH, BT_MESH_TWIST or BT_MESH_ENTER_NUMBER, the bt_mesh_prov::output_number callback is called with a random number that has to be entered on the unprovisioned device.

When using BT_MESH_ENTER_STRING, the bt_mesh_prov::output_string callback is called with a random string that has to be entered on the unprovisioned device.

Parameters

• action – Authentication action used by the unprovisioned device.
• size – Authentication size.

Returns Zero on success or (negative) error code otherwise.

int bt_mesh_auth_method_set_output(bt_mesh_output_action_t action, uint8_t size)
Use Output OOB authentication.
Provisioner only.
Instruct the unprovisioned device to use the specified Output OOB authentication action. The bt_mesh_prov::input callback will be called.

When using BT_MESH_BLINK, BT_MESH_BEEP, BT_MESH_VIBRATE or BT_MESH_DISPLAY_NUMBER, and the application has to call bt_mesh_input_number with the random number indicated by the unprovisioned device.

When using BT_MESH_DISPLAY_STRING, the application has to call bt_mesh_input_string with the random string displayed by the unprovisioned device.

Parameters

• action – Authentication action used by the unprovisioned device.
• size – Authentication size.

Returns Zero on success or (negative) error code otherwise.

int bt_mesh_auth_method_set_static(const uint8_t *static_val, uint8_t size)
Use static OOB authentication.
Provisioner only.
Instruct the unprovisioned device to use static OOB authentication, and use the given static authentication value when provisioning.

Parameters

• static_val – Static OOB value.
• size – Static OOB value size.

Returns Zero on success or (negative) error code otherwise.

int bt_mesh_auth_method_set_none(void)
Don’t use OOB authentication.
Provisioner only.
Don’t use any authentication when provisioning new devices. This is the default behavior.

**Warning:** Not using any authentication exposes the mesh network to impersonation attacks, where attackers can pretend to be the unprovisioned device to gain access to the network. Authentication is strongly encouraged.

### Returns
Zero on success or (negative) error code otherwise.

```c
int bt_mesh_prov_enable(bt_mesh_prov_bearer_t bears)
Enable specific provisioning bearers.
Enable one or more provisioning bearers.

**Parameters**

- **bears** – Bit-wise or of provisioning bearers.

**Returns**
Zero on success or (negative) error code otherwise.

```c
int bt_mesh_prov_disable(bt_mesh_prov_bearer_t bears)
Disable specific provisioning bearers.
Disable one or more provisioning bearers.

**Parameters**

- **bears** – Bit-wise or of provisioning bearers.

**Returns**
Zero on success or (negative) error code otherwise.

```c
int bt_mesh_provision(const uint8_t net_key[16], uint16_t net_idx, uint8_t flags, uint32_t iv_index, uint16_t addr, const uint8_t dev_key[16])
Provision the local Mesh Node.
This API should normally not be used directly by the application. The only exception is for testing purposes where manual provisioning is desired without an actual external provisioner.

**Parameters**

- **net_key** – Network Key
- **net_idx** – Network Key Index
- **flags** – Provisioning Flags
- **iv_index** – IV Index
- **addr** – Primary element address
- **dev_key** – Device Key

**Returns**
Zero on success or (negative) error code otherwise.

```c
int bt_mesh_provision_adv(const uint8_t uuid[16], uint16_t net_idx, uint16_t addr, uint8_t attention_duration)
Provision a Mesh Node using PB-ADV.

**Parameters**

- **uuid** – UUID
- **net_idx** – Network Key Index
- **addr** – Address to assign to remote device. If addr is 0, the lowest available address will be chosen.
- **attention_duration** – The attention duration to be send to remote device

**Returns**
Zero on success or (negative) error code otherwise.
int bt_mesh_provision_gatt(const uint8_t uuid[16], uint16_t net_idx, uint16_t addr, uint8_t
attention_duration)

Provision a Mesh Node using PB-GATT.

Parameters

• uuid – UUID
• net_idx – Network Key Index
• addr – Address to assign to remote device. If addr is 0, the lowest available
  address will be chosen.
• attention_duration – The attention duration to be send to remote device

Returns Zero on success or (negative) error code otherwise.

bool bt_mesh_is_provisioned(void)
Check if the local node has been provisioned.

This API can be used to check if the local node has been provisioned or not. It can e.g. be
helpful to determine if there was a stored network in flash, i.e. if the network was restored
after calling settings_load().

Returns True if the node is provisioned. False otherwise.

struct bt_mesh_dev_capabilities
#include <main.h> Device Capabilities.

Public Members

uint8_t elem_count
Number of elements supported by the device

uint16_t algorithms
Supported algorithms and other capabilities

uint8_t pub_key_type
Supported public key types

uint8_t static_oob
Supported static OOB Types

bt_mesh_output_action_t output_actions
Supported Output OOB Actions

bt_mesh_input_action_t input_actions
Supported Input OOB Actions

uint8_t output_size
Maximum size of Output OOB supported

uint8_t input_size
Maximum size in octets of Input OOB supported

struct bt_mesh_prov
#include <main.h> Provisioning properties & capabilities.
Public Members

const uint8_t *uuid
The UUID that's used when advertising as unprovisioned

const char *uri
Optional URI. This will be advertised separately from the unprovisioned beacon, however the unprovisioned beacon will contain a hash of it so the two can be associated by the provisioner.

bt_mesh_prov_oob_info_t oob_info
Out of Band information field.

const uint8_t *public_key_be
Pointer to Public Key in big-endian for OOB public key type support.
Remember to enable CONFIG_BT_MESH_PROV_OOB_PUBLIC_KEY when initializing this parameter.
Must be used together with bt_mesh_prov::private_key_be.

const uint8_t *private_key_be
Pointer to Private Key in big-endian for OOB public key type support.
Remember to enable CONFIG_BT_MESH_PROV_OOB_PUBLIC_KEY when initializing this parameter.
Must be used together with bt_mesh_prov::public_key_be.

const uint8_t *static_val
Static OOB value

uint8_t static_val_len
Static OOB value length

uint8_t output_size
Maximum size of Output OOB supported

uint16_t output_actions
Supported Output OOB Actions

uint8_t input_size
Maximum size of Input OOB supported

uint16_t input_actions
Supported Input OOB Actions

void (*capabilities)(const struct bt_mesh_dev_capabilities *cap)
Provisioning Capabilities.
This callback notifies the application that the provisioning capabilities of the unprovisioned device has been received.
The application can consequently call bt_mesh_auth_method_set_<*> to select suitable provisioning oob authentication method.
When this callback returns, the provisioner will start authentication with the chosen method.

Param cap capabilities supported by device.
int (*output_number)(bt_mesh_output_action_t act, uint32_t num)
Output of a number is requested.
This callback notifies the application that it should output the given number using the
given action.
   Param act  Action for outputting the number.
   Param num  Number to be outputted.
   Return  Zero on success or negative error code otherwise

int (*output_string)(const char *str)
Output of a string is requested.
This callback notifies the application that it should display the given string to the user.
   Param str  String to be displayed.
   Return  Zero on success or negative error code otherwise

int (*input)(bt_mesh_input_action_t act, uint8_t size)
Input is requested.
This callback notifies the application that it should request input from the user using the
given action. The requested input will either be a string or a number, and the applica-
tion needs to consequently call the bt_mesh_input_string() or bt_mesh_input_number()
funtions once the data has been acquired from the user.
   Param act  Action for inputting data.
   Param num  Maximum size of the inputted data.
   Return  Zero on success or negative error code otherwise

void (*input_complete)(void)
The other device finished their OOB input.
This callback notifies the application that it should stop displaying its output OOB value,
as the other party finished their OOB input.

void (*unprovisioned_beacon)(uint8_t uuid[16], bt_mesh_prov_oob_info_t oob_info,
uint32_t *uri_hash)
Unprovisioned beacon has been received.
This callback notifies the application that an unprovisioned beacon has been received.
   Param uuid  UUID
   Param oob_info  OOB Information
   Param uri_hash  Pointer to URI Hash value. NULL if no hash was present in the
                   beacon.

void (*unprovisioned_beacon_gatt)(uint8_t uuid[16], bt_mesh_prov_oob_info_t oob_info)
PB-GATT Unprovisioned Advertising has been received.
This callback notifies the application that an PB-GATT unprovisioned Advertising has been
received.
   Param uuid  UUID
   Param oob_info  OOB Information

void (*link_open)(bt_mesh_prov_bearer_t bearer)
Provisioning link has been opened.
This callback notifies the application that a provisioning link has been opened on the
given provisioning bearer.
   Param bearer  Provisioning bearer.

void (*link_close)(bt_mesh_prov_bearer_t bearer)
Provisioning link has been closed.
This callback notifies the application that a provisioning link has been closed on the given provisioning bearer.

**Param bearer** Provisioning bearer.

```c
void (*complete)(uint16_t net_idx, uint16_t addr)
Provisioning is complete.
```

This callback notifies the application that provisioning has been successfully completed, and that the local node has been assigned the specified NetKeyIndex and primary element address.

**Param net_idx** NetKeyIndex given during provisioning.

**Param addr** Primary element address.

```c
void (*node_added)(uint16_t net_idx, uint8_t* uuid[16], uint16_t addr, uint8_t num_elem)
A new node has been added to the provisioning database.
```

This callback notifies the application that provisioning has been successfully completed, and that a node has been assigned the specified NetKeyIndex and primary element address.

**Param net_idx** NetKeyIndex given during provisioning.

**Param uuid** UUID of the added node

**Param addr** Primary element address.

**Param num_elem** Number of elements that this node has.

```c
void (*reset)(void)
Node has been reset.
```

This callback notifies the application that the local node has been reset and needs to be reprovisioned. The node will not automatically advertise as unprovisioned, rather the `bt_mesh_prov_enable()` API needs to be called to enable unprovisioned advertising on one or more provisioning bearers.

**Proxy**

The Proxy feature allows legacy devices like phones to access the Bluetooth mesh network through GATT. The Proxy feature is only compiled in if the `CONFIG_BT_MESH_GATT_PROXY` option is set. The Proxy feature state is controlled by the `bt_mesh_cfg_srv.gatt.proxy`.

**API reference**

```c
group bt_mesh_proxy
Proxy.
```

**Defines**

```c
BT_MESH_PROXY_CB_DEFINE(_name)
Register a callback structure for Proxy events.
```

Registers a structure with callback functions that gets called on various Proxy events.

**Parameters**

- `_name` – Name of callback structure.
Functions

int bt_mesh_proxy_identity_enable(void)
Enable advertising with Node Identity.
This API requires that GATT Proxy support has been enabled. Once called each subnet will start advertising using Node Identity for the next 60 seconds.

Returns 0 on success, or (negative) error code on failure.

int bt_mesh_proxy_connect(uint16_t net_idx)
Allow Proxy Client to auto connect to a network.
This API allows a proxy client to auto-connect a given network.

Parameters
• net_idx – Network Key Index

 Returns 0 on success, or (negative) error code on failure.

int bt_mesh_proxy_disconnect(uint16_t net_idx)
Disallow Proxy Client to auto connect to a network.
This API disallows a proxy client to connect a given network.

Parameters
• net_idx – Network Key Index

Returns 0 on success, or (negative) error code on failure.

struct bt_mesh_proxy_cb
#include <proxy.h> Callbacks for the Proxy feature.
Should be instantiated with BT_MESH_PROXY_CB_DEFINE.

Public Members

void (*identity_enabled)(uint16_t net_idx)
Started sending Node Identity beacons on the given subnet.

Param net_idx Network index the Node Identity beacons are running on.

void (*identity_disabled)(uint16_t net_idx)
Stopped sending Node Identity beacons on the given subnet.

Param net_idx Network index the Node Identity beacons were running on.

Heartbeat

The Heartbeat feature provides functionality for monitoring Bluetooth mesh nodes and determining the distance between nodes.
The Heartbeat feature is configured through the Configuration Server model.

Heartbeat messages Heartbeat messages are sent as transport control packets through the network, and are only encrypted with a network key. Heartbeat messages contain the original Time To Live (TTL) value used to send the message and a bitfield of the active features on the node. Through this, a receiving node can determine how many relays the message had to go through to arrive at the receiver, and what features the node supports.

Available Heartbeat feature flags:
Heartbeat publication Heartbeat publication is controlled through the Configuration models, and can be triggered in two ways:

Periodic publication The node publishes a new Heartbeat message at regular intervals. The publication can be configured to stop after a certain number of messages, or continue indefinitely.

Triggered publication The node publishes a new Heartbeat message every time a feature changes. The set of features that can trigger the publication is configurable.

The two publication types can be combined.

Heartbeat subscription A node can be configured to subscribe to Heartbeat messages from one node at the time. To receive a Heartbeat message, both the source and destination must match the configured subscription parameters.

Heartbeat subscription is always time limited, and throughout the subscription period, the node keeps track of the number of received Heartbeats as well as the minimum and maximum received hop count.

All Heartbeats received with the configured subscription parameters are passed to the `bt_mesh_hb_cb::recv` event handler.

When the Heartbeat subscription period ends, the `bt_mesh_hb_cb::sub_end` callback gets called.

API reference

```c

#define BT_MESH_HB_CB_DEFINE(_name)
    Register a callback structure for Heartbeat events.
    Registers a callback structure that will be called whenever Heartbeat events occur

    Parameters
    • _name – Name of callback structure.

#define void bt_mesh_hb_pub_get(struct bt_mesh_hb_pub *get)
    Get the current Heartbeat publication parameters.

    Parameters
    • get – Heartbeat publication parameters return buffer.

#define void bt_mesh_hb_sub_get(struct bt_mesh_hb_sub *get)
    Get the current Heartbeat subscription parameters.

    Parameters
    • get – Heartbeat subscription parameters return buffer.
```

7.4. Bluetooth
struct bt_mesh_hb_pub
   #include <heartbeat.h> Heartbeat Publication parameters

Public Members

uint16_t dst
   Destination address.

uint16_t count
   Remaining publish count.

uint8_t ttl
   Time To Live value.

uint16_t feat
   Bitmap of features that trigger a Heartbeat publication if they change. Legal values are BT_MESH_FEAT_RELAY, BT_MESH_FEAT_PROXY, BT_MESH_FEAT_FRIEND and BT_MESH_FEAT_LOW_POWER.

uint16_t net_idx
   Network index used for publishing.

uint32_t period
   Publication period in seconds.

struct bt_mesh_hb_sub
   #include <heartbeat.h> Heartbeat Subscription parameters.

Public Members

uint32_t period
   Subscription period in seconds.

uint32_t remaining
   Remaining subscription time in seconds.

uint16_t src
   Source address to receive Heartbeats from.

uint16_t dst
   Destination address to received Heartbeats on.

uint16_t count
   The number of received Heartbeat messages so far.

uint8_t min_hops
   Minimum hops in received messages, ie the shortest registered path from the publishing node to the subscribing node. A Heartbeat received from an immediate neighbor has hop count = 1.
uint8_t max_hops
Maximum hops in received messages, i.e., the longest registered path from the publishing node to the subscribing node. A Heartbeat received from an immediate neighbor has hop count = 1.

struct bt_mesh_hb_cb
#include <heartbeat.h> Heartbeat callback structure

Public Members

void (*recv)(const struct bt_mesh_hb_sub *sub, uint8_t hops, uint16_t feat)
Receive callback for heartbeats.
Gets called on every received Heartbeat that matches the current Heartbeat subscription parameters.

Param sub Current Heartbeat subscription parameters.

Param hops The number of hops the Heartbeat was received with.

Param feat The feature set of the publishing node. The value is a bitmap of BT_MESH_FEAT_RELAY, BT_MESH_FEAT_PROXY, BT_MESH_FEAT_FRIEND and BT_MESH_FEAT_LOW_POWER.

void (*sub_end)(const struct bt_mesh_hb_sub *sub)
Subscription end callback for heartbeats.
Gets called when the subscription period ends, providing a summary of the received heartbeat messages.

Param sub Current Heartbeat subscription parameters.

Runtime Configuration

The runtime configuration API allows applications to change their runtime configuration directly, without going through the Configuration models.

Bluetooth mesh nodes should generally be configured by a central network configurator device with a Configuration Client model. Each mesh node instantiates a Configuration Server model that the Configuration Client can communicate with to change the node configuration. In some cases, the mesh node can’t rely on the Configuration Client to detect or determine local constraints, such as low battery power or changes in topology. For these scenarios, this API can be used to change the configuration locally.

API reference

group bt_mesh_cfg
Runtime Configuration.

Enums

def bt_mesh_feat_state
    "Bluetooth mesh feature states"

Values:
enumerator BT_MESH_FEATURE_DISABLED
Feature is supported, but disabled.

enumerator BT_MESH_FEATURE_ENABLED
Feature is supported and enabled.

enumerator BT_MESH_FEATURE_NOT_SUPPORTED
Feature is not supported, and cannot be enabled.

Functions

void bt_mesh_beacon_set(bool beacon)
Enable or disable sending of the Secure Network Beacon.

Parameters
• beacon – New Secure Network Beacon state.

bool bt_mesh_beacon_enabled(void)
Get the current Secure Network Beacon state.

Returns Whether the Secure Network Beacon feature is enabled.

int bt_mesh_default_ttl_set(uint8_t default_ttl)
Set the default TTL value.

The default TTL value is used when no explicit TTL value is set. Models will use the default TTL value when bt_mesh_msg_ctx::send_ttl is BT_MESH_TTL_DEFAULT.

Parameters
• default_ttl – The new default TTL value. Valid values are 0x00 and 0x02 to BT_MESH_TTL_MAX.

Return values
• 0 – Successfully set the default TTL value.
• -EINVAL – Invalid TTL value.

uint8_t bt_mesh_default_ttl_get(void)
Get the current default TTL value.

Returns The current default TTL value.

void bt_mesh_net_transmit_set(uint8_t xmit)
Set the Network Transmit parameters.

The Network Transmit parameters determine the parameters local messages are transmitted with.

See also:
BT_MESH_TRANSMIT

Parameters
• xmit – New Network Transmit parameters. Use BT_MESH_TRANSMIT for encoding.

uint8_t bt_mesh_net_transmit_get(void)
Get the current Network Transmit parameters.
The `BT_MESH_TRANSMIT_COUNT` and `BT_MESH_TRANSMIT_INT` macros can be used to decode the Network Transmit parameters.

**Returns** The current Network Transmit parameters.

```c
int bt_mesh_relay_set(enum bt_mesh_feat_state relay, uint8_t xmit)
```

Configure the Relay feature.

Enable or disable the Relay feature, and configure the parameters to transmit relayed messages with.

Support for the Relay feature must be enabled through the `CONFIG_BT_MESH_RELAY` configuration option.

**See also:**

**BT_MESH_TRANSMIT**

**Parameters**

- `relay` – New Relay feature state. Must be one of `BT_MESH_FEATURE_ENABLED` and `BT_MESH_FEATURE_DISABLED`.
- `xmit` – New Relay retransmit parameters. Use `BT_MESH_TRANSMIT` for encoding.

**Return values**

- `0` – Successfully changed the Relay configuration.
- `-ENOTSUP` – The Relay feature is not supported.
- `-EINVAL` – Invalid parameter.
- `-EALREADY` – Already using the given parameters.

```c
enum bt_mesh_feat_state bt_mesh_relay_get(void)
```

Get the current Relay feature state.

**Returns** The Relay feature state.

```c
uint8_t bt_mesh_relay_retransmit_get(void)
```

Get the current Relay Retransmit parameters.

The `BT_MESH_TRANSMIT_COUNT` and `BT_MESH_TRANSMIT_INT` macros can be used to decode the Relay Retransmit parameters.

**Returns** The current Relay Retransmit parameters, or `0` if relay is not supported.

```c
int bt_mesh_gatt_proxy_set(enum bt_mesh_feat_state gatt_proxy)
```

Enable or disable the GATT Proxy feature.

Support for the GATT Proxy feature must be enabled through the `CONFIG_BT_MESH_GATT_PROXY` configuration option.

**Note:** The GATT Proxy feature only controls a Proxy node’s ability to relay messages to the mesh network. A node that supports GATT Proxy will still advertise Connectable Proxy beacons, even if the feature is disabled. The Proxy feature can only be fully disabled through compile time configuration.

**Parameters**

- `gatt_proxy` – New GATT Proxy state. Must be one of `BT_MESH_FEATURE_ENABLED` and `BT_MESH_FEATURE_DISABLED`.

**Return values**
enum bt_mesh_feat_state bt_mesh_gatt_proxy_get(void)
Get the current GATT Proxy state.

Returns The GATT Proxy feature state.

int bt_mesh_friend_set(enum bt_mesh_feat_state friendship)
Enable or disable the Friend feature.

Any active friendships will be terminated immediately if the Friend feature is disabled.
Support for the Friend feature must be enabled through the CONFIG_BT_MESH_FRIEND configuration option.

Parameters
- friendship – New Friend feature state. Must be one of BT_MESH_FEATURE_ENABLED and BT_MESH_FEATURE_DISABLED.

Return values
- 0 – Successfully changed the Friend feature state.
- -ENOTSUP – The Friend feature is not supported.
- -EINVAL – Invalid parameter.
- -EALREADY – Already in the given state.

enum bt_mesh_feat_state bt_mesh_friend_get(void)
Get the current Friend state.

Returns The Friend feature state.

Bluetooth Mesh Shell

The Bluetooth mesh shell subsystem provides a set of Bluetooth mesh shell commands for the Shell module. It allows for testing and exploring the Bluetooth mesh API through an interactive interface, without having to write an application.

The Bluetooth mesh shell interface provides access to most Bluetooth mesh features, including provisioning, configuration, and message sending.

Prerequisites The Bluetooth mesh shell subsystem depends on the application to create the composition data and do the mesh initialization.

Application The Bluetooth mesh shell subsystem is most easily used through the Bluetooth mesh shell application under tests/bluetooth/mesh_shell. See Shell for information on how to connect and interact with the Bluetooth mesh shell application.

Basic usage The Bluetooth mesh shell subsystem adds a single mesh command, which holds a set of sub-commands. Every time the device boots up, make sure to call mesh init before any of the other Bluetooth mesh shell commands can be called:

uart:~$ mesh init
**Provisioning**  The mesh node must be provisioned to become part of the network. This is only necessary the first time the device boots up, as the device will remember its provisioning data between reboots.

The simplest way to provision the device is through self-provisioning. To provision the device with the default network key and address 0x0001, execute:

```
uart:~$ mesh provision 0x0001
```

Since all mesh nodes use the same values for the default network key, this can be done on multiple devices, as long as they're assigned non-overlapping unicast addresses. Alternatively, to provision the device into an existing network, the unprovisioned beacon can be enabled with `mesh pb-adv on` or `mesh pb-gatt on`. The beacons can be picked up by an external provisioner, which can provision the node into its network.

Once the mesh node is part of a network, its transmission parameters can be controlled by the general configuration commands:

- To set the destination address, call `mesh dst <addr>`.
- To set the network key index, call `mesh netidx <NetIdx>`.
- To set the application key index, call `mesh appidx <AppIdx>`.

By default, the transmission parameters are set to send messages to the provisioned address and network key.

**Configuration**  By setting the destination address to the local unicast address (0x0001 in the `mesh provision` command above), we can perform self-configuration through any of the `Configuration Client model` commands.

A good first step is to read out the node's own composition data:

```
uart:~$ mesh get-comp
```

This prints a list of the composition data of the node, including a list of its model IDs.

Next, since the device has no application keys by default, it's a good idea to add one:

```
uart:~$ mesh app-key-add 0 0
```

**Message sending**  With an application key added (see above), the mesh node's transition parameters are all valid, and the Bluetooth mesh shell can send raw mesh messages through the network.

For example, to send a Generic OnOff Set message, call:

```
uart:~$ mesh net-send 82020100
```

**Note:** All multibyte fields model messages are in little endian, except the opcode.

The message will be sent to the current destination address, using the current network and application key indexes. As the destination address points to the local unicast address by default, the device will only send packets to itself. To change the destination address to the All Nodes broadcast address, call:

```
uart:~$ mesh dst 0xffff
```

With the destination address set to 0xffff, any other mesh nodes in the network with the configured network and application keys will receive and process the messages we send.
Note: To change the configuration of the device, the destination address must be set back to the local unicast address before issuing any configuration commands.

Sending raw mesh packets is a good way to test model message handler implementations during development, as it can be done without having to implement the sending model. By default, only the reception of the model messages can be tested this way, as the Bluetooth mesh shell only includes the foundation models. To receive a packet in the mesh node, you have to add a model with a valid opcode handler list to the composition data in `subsys/bluetooth/mesh/shell.c`, and print the incoming message to the shell in the handler callback.

Parameter formats The Bluetooth mesh shell commands are parsed with a variety of formats:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integers</td>
<td>The default format unless something else is specified. Can be either decimal or hexadecimal.</td>
<td>1234, 0xabcd01234</td>
</tr>
<tr>
<td>Hexstrings</td>
<td>For raw byte arrays, like UUIDs, key values and message payloads, the parameters should be formatted as an unbroken string of hexadecimal values without any prefix.</td>
<td>deadbeef01234</td>
</tr>
<tr>
<td>Booleans</td>
<td>Boolean values are denoted in the API documentation as &lt;val: on, off&gt;.</td>
<td>on, off, enabled, disabled, 1, 0</td>
</tr>
</tbody>
</table>

Commands The Bluetooth mesh shell implements a large set of commands. Some of the commands accept parameters, which are mentioned in brackets after the command name. For example, `mesh lpn <value: off, on>`. Mandatory parameters are marked with angle brackets (e.g. `<NetKeyIndex>`), and optional parameters are marked with square brackets (e.g. `[destination address]`).

The Bluetooth mesh shell commands are divided into the following groups:

- General configuration
- Testing
- Provisioning
- Proxy Client
- Configuration Client model
- Health Client model
- Health Server model
- Configuration database

Note: Some commands depend on specific features being enabled in the compile time configuration of the application. Not all features are enabled by default. The list of available Bluetooth mesh shell commands can be shown in the shell by calling `mesh` without any arguments.

General configuration

`mesh init`

Initialize the mesh shell. This command must be run before any other mesh command.
mesh reset <addr>
reset the local mesh node to its initial unprovisioned state or reset a remote node and remove it from the network. * addr: address of the node to reset.

mesh lpn <value: off, on>
Enable or disable Low Power operation. Once enabled, the device will turn off its radio and start polling for friend nodes. The device will not be able to receive messages from the mesh network until the friendship has been established.

- value: Sets whether Low Power operation is enabled.

mesh poll
Perform a poll to the friend node, to receive any pending messages. Only available when LPN is enabled.

mesh ident
Enable the Proxy Node Identity beacon, allowing Proxy devices to connect explicitly to this device. The beacon will run for 60 seconds before the node returns to normal Proxy beacons.

mesh dst [destination address]
Get or set the message destination address. The destination address determines where mesh packets are sent with the shell, but has no effect on modules outside the shell’s control.

- destination address: If present, sets the new 16-bit mesh destination address. If omitted, the current destination address is printed.

mesh netidx [NetIdx]
Get or set the message network index. The network index determines which network key is used to encrypt mesh packets that are sent with the shell, but has no effect on modules outside the shell’s control. The network key must already be added to the device, either through provisioning or by a Configuration Client.

- NetIdx: If present, sets the new network index. If omitted, the current network index is printed.

mesh appidx [AppIdx]
Get or set the message application index. The application index determines which application key is used to encrypt mesh packets that are sent with the shell, but has no effect on modules outside the shell’s control. The application key must already be added to the device by a Configuration Client, and must be bound to the current network index.

- AppIdx: If present, sets the new application index. If omitted, the current application index is printed.

mesh net-send <hex string>
Send a raw mesh message with the current destination address, network and application index. The message opcode must be encoded manually.

- hex string: Raw hexadecimal representation of the message to send.
Testing

mesh iv-update

Force an IV update.

mesh iv-update-test <value: off, on>

Set the IV update test mode. In test mode, the IV update timing requirements are bypassed.

- value: Enable or disable the IV update test mode.

mesh rpl-clear

Clear the replay protection list, forcing the node to forget all received messages.

**Warning:** Clearing the replay protection list breaks the security mechanisms of the mesh node, making it susceptible to message replay attacks. This should never be performed in a real deployment.

Provisioning

mesh pb-gatt <val: off, on>

Start or stop advertising a connectable unprovisioned beacon. The connectable unprovisioned beacon allows the mesh node to be discovered by nearby GATT based provisioners, and provisioned through the GATT bearer.

- val: Enable or disable provisioning with GATT

mesh pb-adv <val: off, on>

Start or stop advertising the unprovisioned beacon. The unprovisioned beacon allows the mesh node to be discovered by nearby advertising-based provisioners, and provisioned through the advertising bearer.

- val: Enable or disable provisioning with advertiser

mesh provision-adv <UUID> <NetKeyIndex> <addr> <AttentionDuration>

Provision a nearby device into the mesh. The mesh node starts scanning for unprovisioned beacons with the given UUID. Once found, the unprovisioned device will be added to the mesh network with the given unicast address, and given the network key indicated by NetKeyIndex.

- UUID: UUID of the unprovisioned device.
- NetKeyIndex: Index of the network key to pass to the device.
- addr: First unicast address to assign to the unprovisioned device. The device will occupy as many addresses as it has elements, and all must be available.
- AttentionDuration: The duration in seconds the unprovisioned device will identify itself for, if supported. See *Attention state* for details.

7.4. Bluetooth
mesh provision-gatt <UUID> <NetKeyIndex> <addr> <AttentionDuration>

Provision a nearby device into the mesh. The mesh node starts scanning for connectable advertising for PB-GATT with the given UUID. Once found, the unprovisioned device will be added to the mesh network with the given unicast address, and given the network key indicated by NetKeyIndex.

- **UUID**: UUID of the unprovisioned device.
- **NetKeyIndex**: Index of the network key to pass to the device.
- **addr**: First unicast address to assign to the unprovisioned device. The device will occupy as many addresses as it has elements, and all must be available.
- **AttentionDuration**: The duration in seconds the unprovisioned device will identify itself for, if supported. See Attention state for details.

mesh uuid <UUID: 1-16 hex values>

Set the mesh node's UUID, used in the unprovisioned beacons.

- **UUID**: New 128-bit UUID value. Any missing bytes will be zero.

mesh input-num <number>

Input a numeric OOB authentication value. Only valid when prompted by the shell during provisioning. The input number must match the number presented by the other participant in the provisioning.

- **number**: Decimal authentication number.

mesh input-str <string>

Input an alphanumeric OOB authentication value. Only valid when prompted by the shell during provisioning. The input string must match the string presented by the other participant in the provisioning.

- **string**: Unquoted alphanumeric authentication string.

mesh static-oob [val: 1-16 hex values]

Set or clear the static OOB authentication value. The static OOB authentication value must be set before provisioning starts to have any effect. The static OOB value must be same on both participants in the provisioning.

- **val**: If present, indicates the new hexadecimal value of the static OOB. If omitted, the static OOB value is cleared.

mesh provision <NetKeyIndex> <addr> [IVIndex]

Provision the mesh node itself. If the Configuration database is enabled, the network key must be created. Otherwise, the default key value is used.

- **NetKeyIndex**: Index of the network key to provision.
- **addr**: First unicast address to assign to the device. The device will occupy as many addresses as it has elements, and all must be available.
- **IVIndex**: Indicates the current network IV index. Defaults to 0 if omitted.
mesh beacon-listen <val: off, on>

Enable or disable printing of incoming unprovisioned beacons. Allows a provisioner device
to detect nearby unprovisioned devices and provision them.

• val: Whether to enable the unprovisioned beacon printing.

Proxy Client  The Proxy Client model is an optional mesh subsystem that can be enabled through the
CONFIG_BT_MESH_PROXY_CLIENT configuration option.

mesh proxy-connect <NetKeyIndex>

Auto-Connect a nearby proxy server into the mesh.

• NetKeyIndex: Index of the network key to connect.

mesh proxy-disconnect <NetKeyIndex>

Disconnect the existing proxy connection.

• NetKeyIndex: Index of the network key to disconnect.

Configuration Client model  The Configuration Client model is an optional mesh subsystem that can
be enabled through the CONFIG_BT_MESH_CFG_CLI configuration option. If included, the Bluetooth mesh
shell module instantiates a Configuration Client model for configuring itself and other nodes in the mesh
network.

The Configuration Client uses the general messages parameters set by mesh dst and mesh netidx to
target specific nodes. When the Bluetooth mesh shell node is provisioned, the Configuration Client
model targets itself by default. When another node has been provisioned by the Bluetooth mesh shell,
the Configuration Client model targets the new node. The Configuration Client always sends messages
using the Device key bound to the destination address, so it will only be able to configure itself and mesh
nodes it provisioned.

mesh timeout [timeout in seconds]

Get and set the Config Client model timeout used during message sending.

• timeout in seconds: If present, set the Config Client model timeout in seconds. If
omitted, the current timeout is printed.

mesh get-comp [page]

Read a composition data page. The full composition data page will be printed. If the target
does not have the given page, it will return the last page before it.

• page: The composition data page to request. Defaults to 0 if omitted.

mesh beacon [val: off, on]

Get or set the network beacon transmission.

• val: If present, enables or disables sending of the network beacon. If omitted, the
current network beacon state is printed.
mesh ttl [ttl: 0x00, 0x02-0x7f]

Get or set the default TTL value.

- **ttl**: If present, sets the new default TTL value. If omitted, the current default TTL value is printed.

mesh friend [val: off, on]

Get or set the Friend feature.

- **val**: If present, enables or disables the Friend feature. If omitted, the current Friend feature state is printed:
  - 0x00: The feature is supported, but disabled.
  - 0x01: The feature is enabled.
  - 0x02: The feature is not supported.

mesh gatt-proxy [val: off, on]

Get or set the GATT Proxy feature.

- **val**: If present, enables or disables the GATT Proxy feature. If omitted, the current GATT Proxy feature state is printed:
  - 0x00: The feature is supported, but disabled.
  - 0x01: The feature is enabled.
  - 0x02: The feature is not supported.

mesh relay [val: off, on] [count: 0-7] [interval: 10-320]

Get or set the Relay feature and its parameters.

- **val**: If present, enables or disables the Relay feature. If omitted, the current Relay feature state is printed:
  - 0x00: The feature is supported, but disabled.
  - 0x01: The feature is enabled.
  - 0x02: The feature is not supported.
- **count**: Sets the new relay retransmit count if **val** is on. Ignored if **val** is off. Defaults to 2 if omitted.
- **interval**: Sets the new relay retransmit interval in milliseconds if **val** is on. Ignored if **val** is off. Defaults to 20 if omitted.

mesh node-id <NetKeyIndex> [Identity]

Get or Set of current Node Identity state of a subnet.

- **NetKeyIndex**: The network key index to Get/Set.
- **Identity**: If present, sets the identity of Node Identity state.

mesh polltimeout-get <LPN Address>

Get current value of the PollTimeout timer of the LPN within a Friend node.

- **addr**: Address of Low Power node.
mesh net-transmit-param [\text{<count: 0-7> <interval: 10-320>}] 

Get or set the network transmit parameters.

- \text{count}: Sets the number of additional network transmits for every sent message.
- \text{interval}: Sets the new network retransmit interval in milliseconds.

mesh net-key-add <NetKeyIndex> [\text{val}] 

Add a network key to the target node. Adds the key to the Configuration Database if enabled.

- \text{NetKeyIndex}: The network key index to add.
- \text{val}: If present, sets the key value as a 128-bit hexadecimal value. Any missing bytes will be zero. Only valid if the key does not already exist in the Configuration Database. If omitted, the default key value is used.

mesh net-key-upd <NetKeyIndex> [\text{val}] 

Update a network key to the target node.

- \text{NetKeyIndex}: The network key index to updated.
- \text{val}: If present, sets the key value as a 128-bit hexadecimal value. Any missing bytes will be zero. If omitted, the default key value is used.

mesh net-key-get 

Get a list of known network key indexes.

mesh net-key-del <NetKeyIndex> 

Delete a network key from the target node.

- \text{NetKeyIndex}: The network key index to delete.

mesh app-key-add <NetKeyIndex> <AppKeyIndex> [\text{val}] 

Add an application key to the target node. Adds the key to the Configuration Database if enabled.

- \text{NetKeyIndex}: The network key index the application key is bound to.
- \text{AppKeyIndex}: The application key index to add.
- \text{val}: If present, sets the key value as a 128-bit hexadecimal value. Any missing bytes will be zero. Only valid if the key does not already exist in the Configuration Database. If omitted, the default key value is used.

mesh app-key-upd <NetKeyIndex> <AppKeyIndex> [\text{val}] 

Update an application key to the target node.

- \text{NetKeyIndex}: The network key index the application key is bound to.
- \text{AppKeyIndex}: The application key index to update.
- \text{val}: If present, sets the key value as a 128-bit hexadecimal value. Any missing bytes will be zero. If omitted, the default key value is used.
**mesh app-key-get <NetKeyIndex>**

Get a list of known application key indexes bound to the given network key index.
- **NetKeyIndex**: Network key indexes to get a list of application key indexes from.

**mesh app-key-del <NetKeyIndex> <AppKeyIndex>**

Delete an application key from the target node.
- **NetKeyIndex**: The network key index the application key is bound to.
- **AppKeyIndex**: The application key index to delete.

**mesh mod-app-bind <addr> <AppIndex> <Model ID> [Company ID]**

Bind an application key to a model. Models can only encrypt and decrypt messages sent with application keys they are bound to.
- **addr**: Address of the element the model is on.
- **AppIndex**: The application key to bind to the model.
- **Model ID**: The model ID of the model to bind the key to.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

**mesh mod-app-unbind <addr> <AppIndex> <Model ID> [Company ID]**

Unbind an application key from a model.
- **addr**: Address of the element the model is on.
- **AppIndex**: The application key to unbind from the model.
- **Model ID**: The model ID of the model to unbind the key from.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

**mesh mod-app-get <elem addr> <Model ID> [Company ID]**

Get a list of application keys bound to a model.
- **elem addr**: Address of the element the model is on.
- **Model ID**: The model ID of the model to get the bound keys of.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

**mesh mod-pub <addr> <mod id> [cid] [<PubAddr> <AppKeyIndex> <cred: off, on> <ttl> <period> <count> <interval>]]**

Get or set the publication parameters of a model. If all publication parameters are included, they become the new publication parameters of the model. If all publication parameters are omitted, print the current publication parameters of the model.
- **addr**: Address of the element the model is on.
- **Model ID**: The model ID of the model to get the bound keys of.
- **cid**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.
Publication parameters:

- PubAddr: The destination address to publish to.
- AppKeyIndex: The application key index to publish with.
- cred: Whether to publish with Friendship credentials when acting as a Low Power Node.
- ttl: TTL value to publish with (0x00 to 0x07f).
- period: Encoded publication period, or 0 to disable periodic publication.
- count: Number of retransmission for each published message (0 to 7).
- interval: The interval between each retransmission, in milliseconds. Must be a multiple of 50.

```
mesh mod-pub-va <addr> <UUID> <AppKeyIndex> <cred: off, on> <ttl> <period> <count> <interval> <mod id> [cid]
```

Set the publication parameters of a model.

- addr: Address of the element the model is on.
- Model ID: The model ID of the model to get the bound keys of.
- cid: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

Publication parameters:

- UUID: The destination virtual address to publish to.
- AppKeyIndex: The application key index to publish with.
- cred: Whether to publish with Friendship credentials when acting as a Low Power Node.
- ttl: TTL value to publish with (0x00 to 0x07f).
- period: Encoded publication period, or 0 to disable periodic publication.
- count: Number of retransmission for each published message (0 to 7).
- interval: The interval between each retransmission, in milliseconds. Must be a multiple of 50.

```
mesh mod-sub-add <elem addr> <sub addr> <Model ID> [Company ID]
```

Subscription the model to a group address. Models only receive messages sent to their unicast address or a group or virtual address they subscribe to. Models may subscribe to multiple group and virtual addresses.

- elem addr: Address of the element the model is on.
- sub addr: 16-bit group address the model should subscribe to (0xc000 to 0xFEFF).
- Model ID: The model ID of the model to add the subscription to.
- Company ID: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

```
mesh mod-sub-del <elem addr> <sub addr> <Model ID> [Company ID]
```

Unsubscribe a model from a group address.

- elem addr: Address of the element the model is on.
- sub addr: 16-bit group address the model should remove from its subscription list (0xc000 to 0xFEFF).
- **Model ID**: The model ID of the model to add the subscription to.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

```bash
mesh mod-sub-add-va <elem addr> <Label UUID> <Model ID> [Company ID]
```

Subscribe the model to a virtual address. Models only receive messages sent to their unicast address or a group or virtual address they subscribe to. Models may subscribe to multiple group and virtual addresses.

- **elem addr**: Address of the element the model is on.
- **Label UUID**: 128-bit label UUID of the virtual address to subscribe to. Any omitted bytes will be zero.
- **Model ID**: The model ID of the model to add the subscription to.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

```bash
mesh mod-sub-del-va <elem addr> <Label UUID> <Model ID> [Company ID]
```

Unsubscribe a model from a virtual address.

- **elem addr**: Address of the element the model is on.
- **Label UUID**: 128-bit label UUID of the virtual address to remove the subscription of. Any omitted bytes will be zero.
- **Model ID**: The model ID of the model to add the subscription to.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

```bash
mesh mod-sub-ow <elem addr> <sub addr> <Model ID> [Company ID]
```

Overwrite all model subscriptions with a single new group address.

- **elem addr**: Address of the element the model is on.
- **sub addr**: 16-bit group address the model should added to the subscription list (0xc000 to 0xFEFF).
- **Model ID**: The model ID of the model to add the subscription to.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

```bash
mesh mod-sub-ow-va <elem addr> <Label UUID> <Model ID> [Company ID]
```

Overwrite all model subscriptions with a single new virtual address. Models only receive messages sent to their unicast address or a group or virtual address they subscribe to. Models may subscribe to multiple group and virtual addresses.

- **elem addr**: Address of the element the model is on.
- **Label UUID**: 128-bit label UUID of the virtual address as the new Address to be added to the subscription list. Any omitted bytes will be zero.
- **Model ID**: The model ID of the model to add the subscription to.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.
mesh mod-sub-del-all <elem addr> <Model ID> [Company ID]

Remove all group and virtual address subscriptions from of a model.

- **elem addr**: Address of the element the model is on.
- **Model ID**: The model ID of the model to Unsubscribe all.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

mesh mod-sub-get <elem addr> <Model ID> [Company ID]

Get a list of addresses the model subscribes to.

- **elem addr**: Address of the element the model is on.
- **Model ID**: The model ID of the model to get the subscription list of.
- **Company ID**: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

mesh krp <NetKeyIdx> [Phase]

Get or set the key refresh phase of a subnet.

- **NetKeyIdx**: The identified network key used to Get/Set the current Key Refresh Phase state.
- **Phase**: New Key Refresh Phase. Valid phases are 0, 1 or 2.

mesh hb-sub [<src> <dst> <period>]

Get or set the Heartbeat subscription parameters. A node only receives Heartbeat messages matching the Heartbeat subscription parameters. Sets the Heartbeat subscription parameters if present, or prints the current Heartbeat subscription parameters if called with no parameters.

- **src**: Unicast source address to receive Heartbeat messages from.
- **dst**: Destination address to receive Heartbeat messages on.
- **period**: Logarithmic representation of the Heartbeat subscription period:
  - 0: Heartbeat subscription will be disabled.
  - 1 to 17: The node will subscribe to Heartbeat messages for \(2^{(period-1)}\) seconds.

mesh hb-pub [<dst> <count> <period> <ttl> <features> <NetKeyIndex>]

Get or set the Heartbeat publication parameters. Sets the Heartbeat publication parameters if present, or prints the current Heartbeat publication parameters if called with no parameters.

- **dst**: Destination address to publish Heartbeat messages to.
- **count**: Logarithmic representation of the number of Heartbeat messages to publish periodically:
  - 0: Heartbeat messages are not published periodically.
  - 1 to 17: The node will periodically publish \(2^{(count-1)}\) Heartbeat messages.
  - 255: Heartbeat messages will be published periodically indefinitely.
- **period**: Logarithmic representation of the Heartbeat publication period:
  - 0: Heartbeat messages are not published periodically.

7.4. Bluetooth
- 1 to 17: The node will publish Heartbeat messages every \(2^{(\text{period} - 1)}\) seconds.

- **ttl**: The TTL value to publish Heartbeat messages with (0x00 to 0x7f).

- **features**: Bitfield of features that should trigger a Heartbeat publication when changed:
  - Bit 0: Relay feature.
  - Bit 1: Proxy feature.
  - Bit 2: Friend feature.
  - Bit 3: Low Power feature.

- **NetKeyIndex**: Index of the network key to publish Heartbeat messages with.

**Health Client model**  
The Health Client model is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_HEALTH_CLI` configuration option. If included, the Bluetooth mesh shell module instantiates a Health Client model for configuring itself and other nodes in the mesh network.

The Health Client uses the general messages parameters set by `mesh dst` and `mesh netidx` to target specific nodes. When the Bluetooth mesh shell node is provisioned, the Health Client model targets itself by default. When another node has been provisioned by the Bluetooth mesh shell, the Health Client model targets the new node. The Health Client always sends messages using the Device key bound to the destination address, so it will only be able to configure itself and mesh nodes it provisioned.

`mesh fault-get <Company ID>`

Get a list of registered faults for a Company ID.

- **Company ID**: Company ID to get faults for.

`mesh fault-clear <Company ID>`

Clear the list of faults for a Company ID.

- **Company ID**: Company ID to clear the faults for.

`mesh fault-clear-unack <Company ID>`

Clear the list of faults for a Company ID without requesting a response.

- **Company ID**: Company ID to clear the faults for.

`mesh fault-test <Company ID> <Test ID>`

Invoke a self-test procedure, and show a list of triggered faults.

- **Company ID**: Company ID to perform self-tests for.
- **Test ID**: Test to perform.

`mesh fault-test-unack <Company ID> <Test ID>`

Invoke a self-test procedure without requesting a response.

- **Company ID**: Company ID to perform self-tests for.
- **Test ID**: Test to perform.
mesh period-get
Get the current Health Server publish period divisor.

mesh period-set <divisor>
Set the current Health Server publish period divisor. When a fault is detected, the Health Server will start publishing is fault status with a reduced interval. The reduced interval is determined by the Health Server publish period divisor: Fault publish period = Publish period / $2^{\text{divisor}}$.
- \text{divisor}: The new Health Server publish period divisor.

mesh period-set-unack <divisor>
Set the current Health Server publish period divisor. When a fault is detected, the Health Server will start publishing is fault status with a reduced interval. The reduced interval is determined by the Health Server publish period divisor: Fault publish period = Publish period / $2^{\text{divisor}}$.
- \text{divisor}: The new Health Server publish period divisor.

mesh attention-get
Get the current Health Server attention state.

mesh attention-set <timer>
Enable the Health Server attention state for some time.
- \text{timer}: Duration of the attention state, in seconds (0 to 255)

mesh attention-set-unack <timer>
Enable the Health Server attention state for some time without requesting a response.
- \text{timer}: Duration of the attention state, in seconds (0 to 255)

Health Server model

mesh add-fault <Fault ID>
Register a new Fault for the Linux Foundation Company ID.
- Fault ID: ID of the fault to register (0x0001 to 0xFFFF)

mesh del-fault [Fault ID]
Remove registered faults for the Linux Foundation Company ID.
- Fault ID: If present, the given fault ID will be deleted. If omitted, all registered faults will be cleared.

Configuration database The Configuration database is an optional mesh subsystem that can be enabled through the CONFIG_BT_MESH_CDB configuration option. The Configuration database is only available on provisioner devices, and allows them to store all information about the mesh network. To avoid conflicts, there should only be one mesh node in the network with the Configuration database enabled. This node is the Configurator, and is responsible for adding new nodes to the network and configuring them.
mesh cdb-create [NetKey]

Create a Configuration database.

- **NetKey**: Optional network key value of the primary network key (NetKeyIndex=0). Defaults to the default key value if omitted.

mesh cdb-clear

Clear all data from the Configuration database.

mesh cdb-show

Show all data in the Configuration database.

mesh cdb-node-add <UUID> <addr> <num-elem> <NetKeyIdx> [DevKey]

Manually add a mesh node to the configuration database. Note that devices provisioned with mesh provision and mesh provision-adv will be added automatically if the Configuration Database is enabled and created.

- **UUID**: 128-bit hexadecimal UUID of the node. Any omitted bytes will be zero.
- **addr**: Unicast address of the node, or 0 to automatically choose the lowest available address.
- **num-elem**: Number of elements on the node.
- **NetKeyIdx**: The network key the node was provisioned with.
- **DevKey**: Optional 128-bit device key value for the device. If omitted, a random value will be generated.

mesh cdb-node-del <addr>

Delete a mesh node from the Configuration database. If possible, the node should be reset with mesh reset before it is deleted from the Configuration database, to avoid unexpected behavior and uncontrolled access to the network.

- **addr**: Address of the node to delete.

mesh cdb-subnet-add <NeyKeyIdx> [<NetKey>]

Add a network key to the Configuration database. The network key can later be passed to mesh nodes in the network. Note that adding a key to the Configuration database does not automatically add it to the local node's list of known network keys.

- **NetKeyIdx**: Key index of the network key to add.
- **NetKey**: Optional 128-bit network key value. Any missing bytes will be zero. If omitted, a random value will be generated.

mesh cdb-subnet-del <NetKeyIdx>

Delete a network key from the Configuration database.

- **NetKeyIdx**: Key index of the network key to delete.
Add an application key to the Configuration database. The application key can later be passed to mesh nodes in the network. Note that adding a key to the Configuration database does not automatically add it to the local node's list of known application keys.

- **NetKeyIdx**: Network key index the application key is bound to.
- **AppKeyIdx**: Key index of the application key to add.
- **AppKey**: Optional 128-bit application key value. Any missing bytes will be zero. If omitted, a random value will be generated.

Delete an application key from the Configuration database.

- **AppKeyIdx**: Key index of the application key to delete.

### 7.4.12 Serial Port Emulation (RFCOMM)

**API Reference**

```plaintext
group bt_rfcomm
RFCOMM.
```

**Typedefs**

```plaintext
typedef enum bt_rfcomm_role bt_rfcomm_role_t
Role of RFCOMM session and dlc. Used only by internal APIs.
```

**Enums**

```plaintext
define enum [anonymous]
Values:

- enumerator BT_RFCOMM_CHAN_HFP_HF = 1
- enumerator BT_RFCOMM_CHAN_HFP_AG
- enumerator BT_RFCOMM_CHAN_HSP_AG
- enumerator BT_RFCOMM_CHAN_HSP_HS
- enumerator BT_RFCOMM_CHAN_SPP
```

**Values:**

```plaintext
enum bt_rfcomm_role
Role of RFCOMM session and dlc. Used only by internal APIs.
Values:
```
enumerator BT_RFCOMM_ROLE_ACCEPTOR

enumerator BT_RFCOMM_ROLE_INITIATOR

Functions

int bt_rfcomm_server_register(struct bt_rfcomm_server *server)
Register RFCOMM server.

Register RFCOMM server for a channel, each new connection is authorized using the accept() callback which in case of success shall allocate the dlc structure to be used by the new connection.

Parameters
• server – Server structure.

Returns 0 in case of success or negative value in case of error.

int bt_rfcomm_dlc_connect(struct bt_conn *conn, struct bt_rfcomm_dlc *dlc, uint8_t channel)
Connect RFCOMM channel.

Connect RFCOMM dlc by channel, once the connection is completed dlc connected() callback will be called. If the connection is rejected disconnected() callback is called instead.

Parameters
• conn – Connection object.
• dlc – Dlc object.
• channel – Server channel to connect to.

Returns 0 in case of success or negative value in case of error.

int bt_rfcomm_dlc_send(struct bt_rfcomm_dlc *dlc, struct net_buf *buf)
Send data to RFCOMM.

Send data from buffer to the dlc. Length should be less than or equal to mtu.

Parameters
• dlc – Dlc object.
• buf – Data buffer.

Returns Bytes sent in case of success or negative value in case of error.

int bt_rfcomm_dlc_disconnect(struct bt_rfcomm_dlc *dlc)
Disconnect RFCOMM dlc.

Disconnect RFCOMM dlc, if the connection is pending it will be canceled and as a result the dlc disconnected() callback is called.

Parameters
• dlc – Dlc object.

Returns 0 in case of success or negative value in case of error.

struct net_buf *bt_rfcomm_create_pdu(struct net_buf_pool *pool)
Allocate the buffer from pool after reserving head room for RFCOMM, L2CAP and ACL headers.

Parameters
• pool – Which pool to take the buffer from.
struct bt_rfcomm_dlc_ops

    #include <rfcomm.h> RFCOMM DLC operations structure.

Public Members

void (*connected)(struct bt_rfcomm_dlc *dlc)
DLC connected callback

    If this callback is provided it will be called whenever the connection completes.
    
    Param dlc The dlc that has been connected

void (*disconnected)(struct bt_rfcomm_dlc *dlc)
DLC disconnected callback

    If this callback is provided it will be called whenever the dlc is disconnected, including
    when a connection gets rejected or cancelled (both incoming and outgoing)
    
    Param dlc The dlc that has been Disconnected

void (*recv)(struct bt_rfcomm_dlc *dlc, struct net_buf *buf)
DLC recv callback

    Param dlc The dlc receiving data.
    Param buf Buffer containing incoming data.

struct bt_rfcomm_dlc
    #include <rfcomm.h> RFCOMM DLC structure.

struct bt_rfcomm_server
    #include <rfcomm.h>

Public Members

uint8_t channel
Server Channel

int (*accept)(struct bt_conn *conn, struct bt_rfcomm_dlc **dlc)
Server accept callback

    This callback is called whenever a new incoming connection requires authorization.
    
    Param conn The connection that is requesting authorization
    Param dlc Pointer to received the allocated dlc
    Return 0 in case of success or negative value in case of error.

BT_SDP_ARRAY_8(...)  
Declare an array of 8-bit elements in an attribute.

BT_SDP_ARRAY_16(...)  
Declare an array of 16-bit elements in an attribute.

BT_SDP_ARRAY_32(...)  
Declare an array of 32-bit elements in an attribute.

BT_SDP_TYPE_SIZE(_type)  
Declare a fixed-size data element header.

**Parameters**

- _type – Data element header containing type and size descriptors.

BT_SDP_TYPE_SIZE_VAR(_type, _size)  
Declare a variable-size data element header.

**Parameters**

- _type – Data element header containing type and size descriptors.
- _size – The actual size of the data.
BT_SDP_DATA_ELEM_LIST(...)  
Declare a list of data elements.

BT_SDP_NEW_SERVICE  
SDP New Service Record Declaration Macro.  
Helper macro to declare a new service record. Default attributes: Record Handle, Record State, Language Base, Root Browse Group

BT_SDP_LIST(_att_id, _type_size, _data_elem_seq)  
Generic SDP List Attribute Declaration Macro.  
Helper macro to declare a list attribute.

Parameters
- _att_id – List Attribute ID.
- _data_elem_seq – Data element sequence for the list.
- _type_size – SDP type and size descriptor.

BT_SDP_SERVICE_ID(_uuid)  
SDP Service ID Attribute Declaration Macro.  
Helper macro to declare a service ID attribute.

Parameters
- _uuid – Service ID 16bit UUID.

BT_SDP_SERVICE_NAME(_name)  
SDP Name Attribute Declaration Macro.  
Helper macro to declare a service name attribute.

Parameters
- _name – Service name as a string (up to 256 chars).

BT_SDP_SUPPORTED_FEATURES(_features)  
SDP Supported Features Attribute Declaration Macro.  
Helper macro to declare supported features of a profile/protocol.

Parameters
- _features – Feature mask as 16bit unsigned integer.

BT_SDP_RECORD(_attrs)  
SDP Service Declaration Macro.  
Helper macro to declare a service.

Parameters
- _attrs – List of attributes for the service record.

Typedefs

typedef uint8_t (*bt_sdp_discover_func_t)(struct bt_conn *conn, struct bt_sdp_client_result *result)  
Callback type reporting to user that there is a resolved result on remote for given UUID and the result record buffer can be used by user for further inspection.

A function of this type is given by the user to the bt_sdp_discover_params object. It'll be called on each valid record discovery completion for given UUID. When UUID resolution gives back no records then NULL is passed to the user. Otherwise user can get valid record(s) and then

7.4. Bluetooth 393
the internal hint 'next record' is set to false saying the UUID resolution is complete or the hint can be set by caller to true meaning that next record is available for given UUID. The returned function value allows the user to control retrieving follow-up resolved records if any. If the user doesn't want to read more resolved records for given UUID since current record data fulfills its requirements then should return BT_SDP_DISCOVER_UUID_STOP. Otherwise returned value means more subcall iterations are allowable.

**Param conn**  Connection object identifying connection to queried remote.

**Param result**  Object pointing to logical unparsed SDP record collected on base of response driven by given UUID.

**Return**  BT_SDP_DISCOVER_UUID_STOP in case of no more need to read next record data and continue discovery for given UUID. By returning BT_SDP_DISCOVER_UUID_CONTINUE user allows this discovery continuation.

### Enums

enum [anonymous]

Helper enum to be used as return value of bt_sdp_discover_func_t. The value informs the caller to perform further pending actions or stop them.

**Values:**

enumerator BT_SDP_DISCOVER_UUID_STOP = 0

enumerator BT_SDP_DISCOVER_UUID_CONTINUE

enum bt_sdp_proto

Protocols to be asked about specific parameters.

**Values:**

enumerator BT_SDP_PROTO_RFCOMM = 0x0003

enumerator BT_SDP_PROTO_L2CAP = 0x0100

### Functions

**int bt_sdp_register_service(struct bt_sdp_record *service)**

Register a Service Record.

Register a Service Record. Applications can make use of macros such as BT_SDP_DECLARE_SERVICE, BT_SDP_LIST, BT_SDP_SERVICE_ID, BT_SDP_SERVICE_NAME, etc. A service declaration must start with BT_SDP_NEW_SERVICE.

**Parameters**

- service  – Service record declared using BT_SDP_DECLARE_SERVICE.

**Returns**  0 in case of success or negative value in case of error.

**int bt_sdp_discover(struct bt_conn *conn, const struct bt_sdp_discover_params *params)**

Allows user to start SDP discovery session.
The function performs SDP service discovery on remote server driven by user delivered discovery parameters. Discovery session is made as soon as no SDP transaction is ongoing between peers and if any then this one is queued to be processed at discovery completion of previous one. On the service discovery completion the callback function will be called to get feedback to user about findings.

**Parameters**

- conn – Object identifying connection to remote.
- params – SDP discovery parameters.

**Returns** 0 in case of success or negative value in case of error.

```c
int bt_sdp_discover_cancel(struct bt_conn *conn, const struct bt_sdp_discover_params *params)
```

Release waiting SDP discovery request.

It can cancel valid waiting SDP client request identified by SDP discovery parameters object.

**Parameters**

- conn – Object identifying connection to remote.
- params – SDP discovery parameters.

**Returns** 0 in case of success or negative value in case of error.

```c
int bt_sdp_get_proto_param(const struct net_buf *buf, enum bt_sdp_proto proto, uint16_t *param)
```

Give to user parameter value related to given stacked protocol UUID.

API extracts specific parameter associated with given protocol UUID available in Protocol Descriptor List attribute.

**Parameters**

- buf – Original buffered raw record data.
- proto – Known protocol to be checked like RFCOMM or L2CAP.
- param – On success populated by found parameter value.

**Returns** 0 on success when specific parameter associated with given protocol value is found, or negative if error occurred during processing.

```c
int bt_sdp_get_addl_proto_param(const struct net_buf *buf, enum bt_sdp_proto proto, uint8_t param_index, uint16_t *param)
```

Get additional parameter value related to given stacked protocol UUID.

API extracts specific parameter associated with given protocol UUID available in Additional Protocol Descriptor List attribute.

**Parameters**

- buf – Original buffered raw record data.
- proto – Known protocol to be checked like RFCOMM or L2CAP.
- param_index – There may be more than one parameter related to the given protocol UUID. This function returns the result that is indexed by this parameter. It's value is from 0, 0 means the first matched result, 1 means the second matched result.
- param – [out] On success populated by found parameter value.

**Returns** 0 on success when a specific parameter associated with a given protocol value is found, or negative if error occurred during processing.
int bt_sdp_get_profile_version(const struct net_buf *buf, uint16_t profile, uint16_t *version)
Get profile version.
Helper API extracting remote profile version number. To get it proper generic profile parameter needs to be selected usually listed in SDP Interoperability Requirements section for given profile specification.

Parameters

- buf – Original buffered raw record data.
- profile – Profile family identifier the profile belongs.
- version – On success populated by found version number.

Returns 0 on success, negative value if error occurred during processing.

int bt_sdp_get_features(const struct net_buf *buf, uint16_t *features)
Get SupportedFeatures attribute value.
Allows if exposed by remote retrieve SupportedFeature attribute.

Parameters

- buf – Buffer holding original raw record data from remote.
- features – On success object to be populated with SupportedFeature mask.

Returns 0 on success if feature found and valid, negative in case any error

struct bt_sdp_data_elem
#include <sdp.h> SDP Generic Data Element Value.

struct bt_sdp_attribute
#include <sdp.h> SDP Attribute Value.

struct bt_sdp_record
#include <sdp.h> SDP Service Record Value.

struct bt_sdp_client_result
#include <sdp.h> Generic SDP Client Query Result data holder.

struct bt_sdp_discover_params
#include <sdp.h> Main user structure used in SDP discovery of remote.

Public Members

const struct bt_uuid *uuid
UUID (service) to be discovered on remote SDP entity

bt_sdp_discover_func_t func
Discover callback to be called on resolved SDP record

struct net_buf_pool *pool
Memory buffer enabled by user for SDP query results

7.4.14 Universal Unique Identifiers (UUIDs)
API Reference

**group** bt_uuid

UUIDs.

**Defines**

`BT_UUID_SIZE_16`

Size in octets of a 16-bit UUID

`BT_UUID_SIZE_32`

Size in octets of a 32-bit UUID

`BT_UUID_SIZE_128`

Size in octets of a 128-bit UUID

`BT_UUID_INIT_16(value)`

Initialize a 16-bit UUID.

**Parameters**

- `value` – 16-bit UUID value in host endianness.

`BT_UUID_INIT_32(value)`

Initialize a 32-bit UUID.

**Parameters**

- `value` – 32-bit UUID value in host endianness.

`BT_UUID_INIT_128(value...)`

Initialize a 128-bit UUID.

**Parameters**

- `value` – 128-bit UUID array values in little-endian format. Can be combined with `BT_UUID_128_ENCODE` to initialize a UUID from the readable form of UUIDs.

`BT_UUID_DECLARE_16(value)`

Helper to declare a 16-bit UUID inline.

**Parameters**

- `value` – 16-bit UUID value in host endianness.

**Returns** Pointer to a generic UUID.

`BT_UUID_DECLARE_32(value)`

Helper to declare a 32-bit UUID inline.

**Parameters**

- `value` – 32-bit UUID value in host endianness.

**Returns** Pointer to a generic UUID.

`BT_UUID_DECLARE_128(value...)`

Helper to declare a 128-bit UUID inline.

**Parameters**

- `value` – 128-bit UUID array values in little-endian format. Can be combined with `BT_UUID_128_ENCODE` to declare a UUID from the readable form of UUIDs.
Returns Pointer to a generic UUID.

`BT_UUID_16(__u)`
Helper macro to access the 16-bit UUID from a generic UUID.

`BT_UUID_32(__u)`
Helper macro to access the 32-bit UUID from a generic UUID.

`BT_UUID_128(__u)`
Helper macro to access the 128-bit UUID from a generic UUID.

`BT_UUID_128_ENCODE(w32, w1, w2, w3, w48)`
Encode 128 bit UUID into array values in little-endian format.
Helper macro to initialize a 128-bit UUID array value from the readable form of UUIDs, or encode 128-bit UUID values into advertising data. Can be combined with `BT_UUID_DECLARE_128` to declare a 128-bit UUID.

Example of how to declare the UUID `6E400001-B5A3-F393-E0A9-E50E24DCCA9E`

```c
BT_UUID_DECLARE_128(
    BT_UUID_128_ENCODE(0x6E400001, 0xB5A3, 0xF393, 0xE0A9, 0xE50E24DCCA9E))
```

Example of how to encode the UUID `6E400001-B5A3-F393-E0A9-E50E24DCCA9E` into advertising data.

```c
BT_DATA_BYTES(BT_DATA_UUID128_ALL,
    BT_UUID_128_ENCODE(0x6E400001, 0xB5A3, 0xF393, 0xE0A9, 0xE50E24DCCA9E))
```

Just replace the hyphen by the comma and add 0x prefixes.

Parameters
- `w32` – First part of the UUID (32 bits)
- `w1` – Second part of the UUID (16 bits)
- `w2` – Third part of the UUID (16 bits)
- `w3` – Fourth part of the UUID (16 bits)
- `w48` – Fifth part of the UUID (48 bits)

Returns The comma separated values for UUID 128 initializer that may be used directly as an argument for `BT_UUID_INIT_128` or `BT_UUID_DECLARE_128`.

`BT_UUID_16_ENCODE(w16)`
Encode 16-bit UUID into array values in little-endian format.
Helper macro to encode 16-bit UUID values into advertising data.

Example of how to encode the UUID `0x180a` into advertising data.

```c
BT_DATA_BYTES(BT_DATA_UUID16_ALL, BT_UUID_16_ENCODE(0x180a))
```

Parameters
- `w16` – UUID value (16-bits)

Returns The comma separated values for UUID 16 value that may be used directly as an argument for `BT_DATA_BYTES`.
BT_UUID_32_ENCODE(w32)
Encode 32-bit UUID into array values in little-endian format.
Helper macro to encode 32-bit UUID values into advertising data.
Example of how to encode the UUID 0x180a01af into advertising data.

```
BT_DATA_BYTES(BT_DATA_UUID32_ALL, BT_UUID_32_ENCODE(0x180a01af))
```

**Parameters**
- w32 – UUID value (32-bits)

**Returns** The comma separated values for UUID 32 value that may be used directly as an argument for `BT_DATA_BYTES`.

BT_UUID_STR_LEN
Recommended length of user string buffer for Bluetooth UUID.

The recommended length guarantee the output of UUID conversion will not lose valuable information about the UUID being processed. If the length of the UUID is known the string can be shorter.

BT_UUID_GAP_VAL
Generic Access UUID value.

BT_UUID_GAP
Generic Access.

BT_UUID_GATT_VAL
Generic attribute UUID value.

BT_UUID_GATT
Generic Attribute.

BT_UUID_IAS_VAL
Immediate Alert Service UUID value.

BT_UUID_IAS
Immediate Alert Service.

BT_UUID_LLS_VAL
Link Loss Service UUID value.

BT_UUID_LLS
Link Loss Service.

BT_UUID_TPS_VAL
Tx Power Service UUID value.

BT_UUID_TPS
Tx Power Service.

BT_UUID_CTS_VAL
Current Time Service UUID value.
BT_UUID_CTS
    Current Time Service.

BT_UUID_HTS_VAL
    Health Thermometer Service UUID value.

BT_UUID_HTS
    Health Thermometer Service.

BT_UUID_DIS_VAL
    Device Information Service UUID value.

BT_UUID_DIS
    Device Information Service.

BT_UUID_HRS_VAL
    Heart Rate Service UUID value.

BT_UUID_HRS
    Heart Rate Service.

BT_UUID_BAS_VAL
    Battery Service UUID value.

BT_UUID_BAS
    Battery Service.

BT_UUID_HIDS_VAL
    HID Service UUID value.

BT_UUID_HIDS
    HID Service.

BT_UUID_RSCS_VAL
    Running Speed and Cadence Service UUID value.

BT_UUID_RSCS
    Running Speed and Cadence Service.

BT_UUID_CSC_VAL
    Cycling Speed and Cadence Service UUID value.

BT_UUID_CSC
    Cycling Speed and Cadence Service.

BT_UUID_ESS_VAL
    Environmental Sensing Service UUID value.

BT_UUID_ESS
    Environmental Sensing Service.

BT_UUID_BMS_VAL
    Bond Management Service UUID value.
**BT_UUID_BMS**
Bond Management Service.

**BT_UUID_IPSS_VAL**
IP Support Service UUID value.

**BT_UUID_IPSS**
IP Support Service.

**BT_UUID_HPS_VAL**
HTTP Proxy Service UUID value.

**BT_UUID_HPS**
HTTP Proxy Service.

**BT_UUID_OTS_VAL**
Object Transfer Service UUID value.

**BT_UUID_OTS**
Object Transfer Service.

**BT_UUID_MESH_PROV_VAL**
Mesh Provisioning Service UUID value.

**BT_UUID_MESH_PROV**
Mesh Provisioning Service.

**BT_UUID_MESH_PROXY_VAL**
Mesh Proxy Service UUID value.

**BT_UUID_MESH_PROXY**
Mesh Proxy Service.

**BT_UUID_AICS_VAL**
Audio Input Control Service value.

**BT_UUID_AICS**
Audio Input Control Service.

**BT_UUID_VCS_VAL**
Volume Control Service value.

**BT_UUID_VCS**
Volume Control Service.

**BT_UUID_VOCS_VAL**
Volume Offset Control Service value.

**BT_UUID_VOCS**
Volume Offset Control Service.

**BT_UUID_CSIS_VAL**
Coordinated Set Identification Service value.

---

7.4. Bluetooth
BT_UUID_CSIS
   Coordinated Set Identification Service.

BT_UUID_MCS_VAL
   Media Control Service value.

BT_UUID_MCS
   Media Control Service.

BT_UUID_GMCS_VAL
   Generic Media Control Service value.

BT_UUID_GMCS
   Generic Media Control Service.

BT_UUID_MICS_VAL
   Microphone Input Control Service value.

BT_UUID_MICS
   Microphone Input Control Service.

BT_UUID_ASCS_VAL
   Audio Stream Control Service value.

BT_UUID_ASCS
   Audio Stream Control Service.

BT_UUID_BASS_VAL
   Broadcast Audio Scan Service value.

BT_UUID_BASS
   Broadcast Audio Scan Service.

BT_UUID_PACS_VAL
   Published Audio Capabilities Service value.

BT_UUID_PACS
   Published Audio Capabilities Service.

BT_UUID_BASIC_AUDIO_VAL
   Basic Audio Announcement Service value.

BT_UUID_BASIC_AUDIO
   Basic Audio Announcement Service.

BT_UUID_BROADCAST_AUDIO_VAL
   Broadcast Audio Announcement Service value.

BT_UUID_BROADCAST_AUDIO
   Broadcast Audio Announcement Service.

BT_UUID_GATT_PRIMARY_VAL
   GATT Primary Service UUID value.
7.4. Bluetooth

BT_UUID_GATT_PRIMARY
   GATT Primary Service.

BT_UUID_GATT_SECONDARY_VAL
   GATT Secondary Service UUID value.

BT_UUID_GATT_SECONDARY
   GATT Secondary Service.

BT_UUID_GATT_INCLUDE_VAL
   GATT Include Service UUID value.

BT_UUID_GATT_INCLUDE
   GATT Include Service.

BT_UUID_GATT_CHRC_VAL
   GATT Characteristic UUID value.

BT_UUID_GATT_CHRC
   GATT Characteristic.

BT_UUID_GATT_CEP_VAL
   GATT Characteristic Extended Properties UUID value.

BT_UUID_GATT_CEP
   GATT Characteristic Extended Properties.

BT_UUID_GATT_CUD_VAL
   GATT Characteristic User Description UUID value.

BT_UUID_GATT_CUD
   GATT Characteristic User Description.

BT_UUID_GATT_CCC_VAL
   GATT Client Characteristic Configuration UUID value.

BT_UUID_GATT_CCC
   GATT Client Characteristic Configuration.

BT_UUID_GATT_SCC_VAL
   GATT Server Characteristic Configuration UUID value.

BT_UUID_GATT_SCC
   GATT Server Characteristic Configuration.

BT_UUID_GATT_CPF_VAL
   GATT Characteristic Presentation Format UUID value.

BT_UUID_GATT_CPF
   GATT Characteristic Presentation Format.

BT_UUID_GATT_CAF_VAL
   GATT Characteristic Aggregated Format UUID value.
BT_UUID_GATT_CAF
GATT Characteristic Aggregated Format.

BT_UUID_VALID_RANGE_VAL
Valid Range Descriptor UUID value.

BT_UUID_VALID_RANGE
Valid Range Descriptor.

BT_UUID_HIDS_EXT_REPORT_VAL
HID External Report Descriptor UUID value.

BT_UUID_HIDS_EXT_REPORT
HID External Report Descriptor.

BT_UUID_HIDS_REPORT_REF_VAL
HID Report Reference Descriptor UUID value.

BT_UUID_HIDS_REPORT_REF
HID Report Reference Descriptor.

BT_UUID_ES_CONFIGURATION_VAL
Environmental Sensing Configuration Descriptor UUID value.

BT_UUID_ES_CONFIGURATION
Environmental Sensing Configuration Descriptor.

BT_UUID_ES_MEASUREMENT_VAL
Environmental Sensing Measurement Descriptor UUID value.

BT_UUID_ES_MEASUREMENT
Environmental Sensing Measurement Descriptor.

BT_UUID_ES_TRIGGER_SETTING_VAL
Environmental Sensing Trigger Setting Descriptor UUID value.

BT_UUID_ES_TRIGGER_SETTING
Environmental Sensing Trigger Setting Descriptor.

BT_UUID_GAP_DEVICE_NAME_VAL
GAP Characteristic Device Name UUID value.

BT_UUID_GAP_DEVICE_NAME
GAP Characteristic Device Name.

BT_UUID_GAP_APPEARANCE_VAL
GAP Characteristic Appearance UUID value.

BT_UUID_GAP_APPEARANCE
GAP Characteristic Appearance.

BT_UUID_GAP_PPCP_VAL
GAP Characteristic Peripheral Preferred Connection Parameters UUID value.
BT_UUID_GAP_PPCP
GAP Characteristic Peripheral Preferred Connection Parameters.

BT_UUID_GATT_SC_VAL
GATT Characteristic Service Changed UUID value.

BT_UUID_GATT_SC
GATT Characteristic Service Changed.

BT_UUID_ALERT_LEVEL_VAL
Alert Level UUID value.

BT_UUID_ALERT_LEVEL
Alert Level.

BT_UUID_TPS_TX_POWER_LEVEL_VAL
TPS Characteristic Tx Power Level UUID value.

BT_UUID_TPS_TX_POWER_LEVEL
TPS Characteristic Tx Power Level.

BT_UUID_BAS_BATTERY_LEVEL_VAL
BAS Characteristic Battery Level UUID value.

BT_UUID_BAS_BATTERY_LEVEL
BAS Characteristic Battery Level.

BT_UUID_HTS_MEASUREMENT_VAL
HTS Characteristic Measurement Value UUID value.

BT_UUID_HTS_MEASUREMENT
HTS Characteristic Measurement Value.

BT_UUID_HIDS_BOOT_KB_IN_REPORT_VAL
HID Characteristic Boot Keyboard Input Report UUID value.

BT_UUID_HIDS_BOOT_KB_IN_REPORT
HID Characteristic Boot Keyboard Input Report.

BT_UUID_DIS_SYSTEM_ID_VAL
DIS Characteristic System ID UUID value.

BT_UUID_DIS_SYSTEM_ID
DIS Characteristic System ID.

BT_UUID_DIS_MODEL_NUMBER_VAL
DIS Characteristic Model Number String UUID value.

BT_UUID_DIS_MODEL_NUMBER
DIS Characteristic Model Number String.

BT_UUID_DIS_SERIAL_NUMBER_VAL
DIS Characteristic Serial Number String UUID value.
BT_UUID_DIS_SERIAL_NUMBER
DIS Characteristic Serial Number String.

BT_UUID_DIS_FIRMWARE_REVISION_VAL
DIS Characteristic Firmware Revision String UUID value.

BT_UUID_DIS_FIRMWARE_REVISION
DIS Characteristic Firmware Revision String.

BT_UUID_DIS_HARDWARE_REVISION_VAL
DIS Characteristic Hardware Revision String UUID value.

BT_UUID_DIS_HARDWARE_REVISION
DIS Characteristic Hardware Revision String.

BT_UUID_DIS_SOFTWARE_REVISION_VAL
DIS Characteristic Software Revision String UUID value.

BT_UUID_DIS_SOFTWARE_REVISION
DIS Characteristic Software Revision String.

BT_UUID_DIS_MANUFACTURER_NAME_VAL
DIS Characteristic Manufacturer Name String UUID Value.

BT_UUID_DIS_MANUFACTURER_NAME
DIS Characteristic Manufacturer Name String.

BT_UUID_DIS_PNP_ID_VAL
DIS Characteristic PnP ID UUID value.

BT_UUID_DIS_PNP_ID
DIS Characteristic PnP ID.

BT_UUID_CTS_CURRENT_TIME_VAL
CTS Characteristic Current Time UUID value.

BT_UUID_CTS_CURRENT_TIME
CTS Characteristic Current Time.

BT_UUID_MAGN_DECLINATION_VAL
Magnetic Declination Characteristic UUID value.

BT_UUID_MAGN_DECLINATION
Magnetic Declination Characteristic.

BT_UUID_HIDS_BOOT_KB_OUT_REPORT_VAL
HID Boot Keyboard Output Report Characteristic UUID value.

BT_UUID_HIDS_BOOT_KB_OUT_REPORT
HID Boot Keyboard Output Report Characteristic.

BT_UUID_HIDS_BOOT_MOUSE_IN_REPORT_VAL
HID Boot Mouse Input Report Characteristic UUID value.
BT_UUID_HIDS_BOOT_MOUSE_IN_REPORT
HID Boot Mouse Input Report Characteristic.

BT_UUID_HRS_MEASUREMENT_VAL
HRS Characteristic Measurement Interval UUID value.

BT_UUID_HRS_MEASUREMENT
HRS Characteristic Measurement Interval.

BT_UUID_HRS_BODY_SENSOR
HRS Characteristic Body Sensor Location.

BT_UUID_HRS_BODY_SENSOR_VAL

BT_UUID_HRS_CONTROL_POINT
HRS Characteristic Control Point.

BT_UUID_HRS_CONTROL_POINT_VAL
HRS Characteristic Control Point UUID value.

BT_UUID_HIDS_INFO_VAL
HID Information Characteristic UUID value.

BT_UUID_HIDS_INFO
HID Information Characteristic.

BT_UUID_HIDS_REPORT_MAP_VAL
HID Report Map Characteristic UUID value.

BT_UUID_HIDS_REPORT_MAP
HID Report Map Characteristic.

BT_UUID_HIDS_CTRL_POINT_VAL
HID Control Point Characteristic UUID value.

BT_UUID_HIDS_CTRL_POINT
HID Control Point Characteristic.

BT_UUID_HIDS_REPORT_VAL
HID Report Characteristic UUID value.

BT_UUID_HIDS_REPORT
HID Report Characteristic.

BT_UUID_HIDS_PROTOCOL_MODE_VAL
HID Protocol Mode Characteristic UUID value.

BT_UUID_HIDS_PROTOCOL_MODE
HID Protocol Mode Characteristic.

BT_UUID_RSC_MEASUREMENT_VAL
RSC Measurement Characteristic UUID value.
Zephyr Project Documentation, Release 3.0.99

BT_UUID_RSC_MEASUREMENT
RSC Measurement Characteristic.

BT_UUID_RSC_FEATURE_VAL
RSC Feature Characteristic UUID value.

BT_UUID_RSC_FEATURE
RSC Feature Characteristic.

BT_UUID_CSC_MEASUREMENT_VAL
CSC Measurement Characteristic UUID value.

BT_UUID_CSC_MEASUREMENT
CSC Measurement Characteristic.

BT_UUID_CSC_FEATURE_VAL
CSC Feature Characteristic UUID value.

BT_UUID_CSC_FEATURE
CSC Feature Characteristic.

BT_UUID_SENSOR_LOCATION_VAL
Sensor Location Characteristic UUID value.

BT_UUID_SENSOR_LOCATION
Sensor Location Characteristic.

BT_UUID_SC_CONTROL_POINT_VAL
SC Control Point Characteristic UUID value.

BT_UUID_SC_CONTROL_POINT
SC Control Point Characteristic.

BT_UUID_ELEVATION_VAL
Elevation Characteristic UUID value.

BT_UUID_ELEVATION
Elevation Characteristic.

BT_UUID_PRESSURE_VAL
Pressure Characteristic UUID value.

BT_UUID_PRESSURE
Pressure Characteristic.

BT_UUID_TEMPERATURE_VAL
Temperature Characteristic UUID value.

BT_UUID_TEMPERATURE
Temperature Characteristic.

BT_UUID_HUMIDITY_VAL
Humidity Characteristic UUID value.
BT_UUID_HUMIDITY
Humidity Characteristic.

BT_UUID_TRUE_WIND_SPEED_VAL
True Wind Speed Characteristic UUID value.

BT_UUID_TRUE_WIND_SPEED
True Wind Speed Characteristic.

BT_UUID_TRUE_WIND_DIR_VAL
True Wind Direction Characteristic UUID value.

BT_UUID_TRUE_WIND_DIR
True Wind Direction Characteristic.

BT_UUID_APPARENT_WIND_SPEED_VAL
Apparent Wind Speed Characteristic UUID value.

BT_UUID_APPARENT_WIND_SPEED
Apparent Wind Speed Characteristic.

BT_UUID_APPARENT_WIND_DIR_VAL
Apparent Wind Direction Characteristic UUID value.

BT_UUID_APPARENT_WIND_DIR
Apparent Wind Direction Characteristic.

BT_UUID_GUST_FACTOR_VAL
Gust Factor Characteristic UUID value.

BT_UUID_GUST_FACTOR
Gust Factor Characteristic.

BT_UUID_POLLEN_CONCENTRATION_VAL
Pollen Concentration Characteristic UUID value.

BT_UUID_POLLEN_CONCENTRATION
Pollen Concentration Characteristic.

BT_UUID_UV_INDEX_VAL
UV Index Characteristic UUID value.

BT_UUID_UV_INDEX
UV Index Characteristic.

BT_UUID_IRRADIANCE_VAL
Irradiance Characteristic UUID value.

BT_UUID_IRRADIANCE
Irradiance Characteristic.

BT_UUID_RAINFALL_VAL
Rainfall Characteristic UUID value.
BT_UUID_RAINFALL
Rainfall Characteristic.

BT_UUID_WIND_CHILL_VAL
Wind Chill Characteristic UUID value.

BT_UUID_WIND_CHILL
Wind Chill Characteristic.

BT_UUID_HEAT_INDEX_VAL
Heat Index Characteristic UUID value.

BT_UUID_HEAT_INDEX
Heat Index Characteristic.

BT_UUID_DEW_POINT_VAL
Dew Point Characteristic UUID value.

BT_UUID_DEW_POINT
Dew Point Characteristic.

BT_UUID_DESC_VALUE_CHANGED_VAL
Descriptor Value Changed Characteristic UUID value.

BT_UUID_DESC_VALUE_CHANGED
Descriptor Value Changed Characteristic.

BT_UUID_MAGN_FLUX_DENSITY_2D_VAL
Magnetic Flux Density - 2D Characteristic UUID value.

BT_UUID_MAGN_FLUX_DENSITY_2D
Magnetic Flux Density - 2D Characteristic.

BT_UUID_MAGN_FLUX_DENSITY_3D_VAL
Magnetic Flux Density - 3D Characteristic UUID value.

BT_UUID_MAGN_FLUX_DENSITY_3D
Magnetic Flux Density - 3D Characteristic.

BT_UUID_BAR_PRESSURE_TREND_VAL
Barometric Pressure Trend Characteristic UUID value.

BT_UUID_BAR_PRESSURE_TREND
Barometric Pressure Trend Characteristic.

BT_UUID_BMS_CONTROL_POINT_VAL
Bond Management Control Point UUID value.

BT_UUID_BMS_CONTROL_POINT
Bond Management Control Point.

BT_UUID_BMS_FEATURE_VAL
Bond Management Feature UUID value.
BT_UUID_BMS_FEATURE
Bond Management Feature.

BT_UUID_CENTRAL_ADDR_RES_VAL
Central Address Resolution Characteristic UUID value.

BT_UUID_CENTRAL_ADDR_RES
Central Address Resolution Characteristic.

BT_UUID_URI_VAL
URI UUID value.

BT_UUID_URI
URI.

BT_UUID_HTTP_HEADERS_VAL
HTTP Headers UUID value.

BT_UUID_HTTP_HEADERS
HTTP Headers.

BT_UUID_HTTP_STATUS_CODE_VAL
HTTP Status Code UUID value.

BT_UUID_HTTP_STATUS_CODE
HTTP Status Code.

BT_UUID_HTTP_ENTITY_BODY_VAL
HTTP Entity Body UUID value.

BT_UUID_HTTP_ENTITY_BODY
HTTP Entity Body.

BT_UUID_HTTP_CONTROL_POINT_VAL
HTTP Control Point UUID value.

BT_UUID_HTTP_CONTROL_POINT
HTTP Control Point.

BT_UUID_HTTPS_SECURITY_VAL
HTTPS Security UUID value.

BT_UUID_HTTPS_SECURITY
HTTPS Security.

BT_UUID_OTS_FEATURE_VAL
OTS Feature Characteristic UUID value.

BT_UUID_OTS_FEATURE
OTS Feature Characteristic.

BT_UUID_OTS_NAME_VAL
OTS Object Name Characteristic UUID value.
<table>
<thead>
<tr>

</tbody>
</table>
**BT_UUID OTS LIST FILTER**
OTS Object List Filter Characteristic.

**BT_UUID OTS CHANGED VAL**
OTS Object Changed Characteristic UUID value.

**BT_UUID OTS CHANGED**
OTS Object Changed Characteristic.

**BT_UUID OTS TYPE UNSPECIFIED VAL**
OTS Unspecified Object Type UUID value.

**BT_UUID OTS TYPE UNSPECIFIED**
OTS Unspecified Object Type.

**BT_UUID OTS DIRECTORY LISTING VAL**
OTS Directory Listing UUID value.

**BT_UUID OTS DIRECTORY LISTING**
OTS Directory Listing.

**BT_UUID MESH PROV DATA IN VAL**
Mesh Provisioning Data In UUID value.

**BT_UUID MESH PROV DATA IN**
Mesh Provisioning Data In.

**BT_UUID MESH PROV DATA OUT VAL**
Mesh Provisioning Data Out UUID value.

**BT_UUID MESH PROV DATA OUT**
Mesh Provisioning Data Out.

**BT_UUID MESH PROXY DATA IN VAL**
Mesh Proxy Data In UUID value.

**BT_UUID MESH PROXY DATA IN**
Mesh Proxy Data In.

**BT_UUID MESH PROXY DATA OUT VAL**
Mesh Proxy Data Out UUID value.

**BT_UUID MESH PROXY DATA OUT**
Mesh Proxy Data Out.

**BT_UUID GATT CLIENT FEATURES VAL**
Client Supported Features UUID value.

**BT_UUID GATT CLIENT FEATURES**
Client Supported Features.

**BT_UUID GATT DB HASH VAL**
Database Hash UUID value.
BT_UUID_GATT_DB_HASH
   Database Hash.

BT_UUID_GATT_SERVER_FEATURES_VAL
   Server Supported Features UUID value.

BT_UUID_GATT_SERVER_FEATURES
   Server Supported Features.

BT_UUID_AICS_STATE_VAL
   Audio Input Control Service State value.

BT_UUID_AICS_STATE
   Audio Input Control Service State.

BT_UUID_AICS_GAIN_SETTINGS_VAL
   Audio Input Control Service Gain Settings Properties value.

BT_UUID_AICS_GAIN_SETTINGS
   Audio Input Control Service Gain Settings Properties.

BT_UUID_AICS_INPUT_TYPE_VAL
   Audio Input Control Service Input Type value.

BT_UUID_AICS_INPUT_TYPE
   Audio Input Control Service Input Type.

BT_UUID_AICS_INPUT_STATUS_VAL
   Audio Input Control Service Input Status value.

BT_UUID_AICS_INPUT_STATUS
   Audio Input Control Service Input Status.

BT_UUID_AICS_CONTROL_VAL
   Audio Input Control Service Control Point value.

BT_UUID_AICS_CONTROL
   Audio Input Control Service Control Point.

BT_UUID_AICS_DESCRIPTION_VAL
   Audio Input Control Service Input Description value.

BT_UUID_AICS_DESCRIPTION
   Audio Input Control Service Input Description.

BT_UUID_VCS_STATE_VAL
   Volume Control Setting value.

BT_UUID_VCS_STATE
   Volume Control Setting.

BT_UUID_VCS_CONTROL_VAL
   Volume Control Control point value.
**BT_UUID_VCS_CONTROL**
Volume Control Control point.

**BT_UUID_VCS_FLAGS_VAL**
Volume Control Flags value.

**BT_UUID_VCS_FLAGS**
Volume Control Flags.

**BT_UUID_VOCS_STATE_VAL**
Volume Offset State value.

**BT_UUID_VOCS_STATE**
Volume Offset State.

**BT_UUID_VOCS_LOCATION_VAL**
Audio Location value.

**BT_UUID_VOCS_LOCATION**
Audio Location.

**BT_UUID_VOCS_CONTROL_VAL**
Volume Offset Control Point value.

**BT_UUID_VOCS_CONTROL**
Volume Offset Control Point.

**BT_UUID_VOCS_DESCRIPTION_VAL**
Volume Offset Audio Output Description value.

**BT_UUID_VOCS_DESCRIPTION**
Volume Offset Audio Output Description.

**BT_UUID_CSIS_SET_SIRK_VAL**
Set Identity Resolving Key value.

**BT_UUID_CSIS_SET_SIRK**
Set Identity Resolving Key.

**BT_UUID_CSIS_SET_SIZE_VAL**
Set size value.

**BT_UUID_CSIS_SET_SIZE**
Set size.

**BT_UUID_CSIS_SET_LOCK_VAL**
Set lock value.

**BT_UUID_CSIS_SET_LOCK**
Set lock.

**BT_UUID_CSIS_RANK_VAL**
Rank value.
BT_UUID_CSIS_RANK
Rank.

BT_UUID_MCS_PLAYER_NAME_VAL
Media player name value.

BT_UUID_MCS_PLAYER_NAME
Media player name.

BT_UUID_MCS_ICON_OBJ_ID_VAL
Media Icon Object ID value.

BT_UUID_MCS_ICON_OBJ_ID
Media Icon Object ID.

BT_UUID_MCS_ICON_URL_VAL
Media Icon URL value.

BT_UUID_MCS_ICON_URL
Media Icon URL.

BT_UUID_MCS_TRACK_CHANGED_VAL
Track Changed value.

BT_UUID_MCS_TRACK_CHANGED
Track Changed.

BT_UUID_MCS_TRACK_TITLE_VAL
Track Title value.

BT_UUID_MCS_TRACK_TITLE
Track Title.

BT_UUID_MCS_TRACK_DURATION_VAL
Track Duration value.

BT_UUID_MCS_TRACK_DURATION
Track Duration.

BT_UUID_MCS_TRACK_POSITION_VAL
Track Position value.

BT_UUID_MCS_TRACK_POSITION
Track Position.

BT_UUID_MCS_PLAYBACK_SPEED_VAL
Playback Speed value.

BT_UUID_MCS_PLAYBACK_SPEED
Playback Speed.

BT_UUID_MCSSEEKING_SPEED_VAL
Seeking Speed value.
BT_UUID_MCS_SEEKING_SPEED
Seeking Speed.

BT_UUID_MCS_TRACK_SEGMENTS_OBJ_ID_VAL
Track Segments Object ID value.

BT_UUID_MCS_TRACK_SEGMENTS_OBJ_ID
Track Segments Object ID.

BT_UUID_MCS_CURRENT_TRACK_OBJ_ID_VAL
Current Track Object ID value.

BT_UUID_MCS_CURRENT_TRACK_OBJ_ID
Current Track Object ID.

BT_UUID_MCS_NEXT_TRACK_OBJ_ID_VAL
Next Track Object ID value.

BT_UUID_MCS_NEXT_TRACK_OBJ_ID
Next Track Object ID.

BT_UUID_MCS_PARENT_GROUP_OBJ_ID_VAL
Parent Group Object ID value.

BT_UUID_MCS_PARENT_GROUP_OBJ_ID
Parent Group Object ID.

BT_UUID_MCS_CURRENT_GROUP_OBJ_ID_VAL
Group Object ID value.

BT_UUID_MCS_CURRENT_GROUP_OBJ_ID
Group Object ID.

BT_UUID_MCS_PLAYING_ORDER_VAL
Playing Order value.

BT_UUID_MCS_PLAYING_ORDER
Playing Order.

BT_UUID_MCS_PLAYING_ORDERS_VAL
Playing Orders supported value.

BT_UUID_MCS_PLAYING_ORDERS
Playing Orders supported.

BT_UUID_MCS_MEDIA_STATE_VAL
Media State value.

BT_UUID_MCS_MEDIA_STATE
Media State.

BT_UUID_MCS_MEDIA_CONTROL_POINT_VAL
Media Control Point value.
BT_UUID_MCS_MEDIA_CONTROL_POINT
Media Control Point.

BT_UUID_MCS_MEDIA_CONTROL_OPCODES_VAL
Media control opcodes supported value.

BT_UUID_MCS_MEDIA_CONTROL_OPCODES
Media control opcodes supported.

BT_UUID_MCS_SEARCH_RESULTS_OBJ_ID_VAL
Search result object ID value.

BT_UUID_MCS_SEARCH_RESULTS_OBJ_ID
Search result object ID.

BT_UUID_MCS_SEARCH_CONTROL_POINT_VAL
Search control point value.

BT_UUID_MCSSEARCH_CONTROL_POINT
Search control point.

BT_UUID_OTS_TYPE_MPL_ICON_VAL
Media Player Icon Object Type value.

BT_UUID_OTS_TYPE_MPL_ICON
Media Player Icon Object Type.

BT_UUID_OTS_TYPE_TRACK_SEGMENT_VAL
Track Segments Object Type value.

BT_UUID_OTS_TYPE_TRACK_SEGMENT
Track Segments Object Type.

BT_UUID_OTS_TYPE_TRACK_VAL
Track Object Type value.

BT_UUID_OTS_TYPE_TRACK
Track Object Type.

BT_UUID_OTS_TYPE_GROUP_VAL
Group Object Type value.

BT_UUID_OTS_TYPE_GROUP
Group Object Type.

BT_UUID_CCID_VAL
Content Control ID value.

BT_UUID_CCID
Content Control ID.

BT_UUID_MICS_MUTE_VAL
Microphone Input Control Service Mute value.
BT_UUID_MICS_MUTE
    Microphone Input Control Service Mute.

BT_UUID_ASCS_ASE_SNK_VAL
    Audio Stream Endpoint Sink Characteristic value.

BT_UUID_ASCS_ASE_SNK

Enums

enum [anonymous]
    Bluetooth UUID types.

Values:

enumerator BT_UUID_TYPE_16
    UUID type 16-bit.

enumerator BT_UUID_TYPE_32
    UUID type 32-bit.

enumerator BT_UUID_TYPE_128
    UUID type 128-bit.

Functions

int bt_uuid_cmp(const struct bt_uuid *u1, const struct bt_uuid *u2)
    Compare Bluetooth UUIDs.

    Compares 2 Bluetooth UUIDs, if the types are different both UUIDs are first converted to 128
    bits format before comparing.

    Parameters
    • u1 – First Bluetooth UUID to compare
    • u2 – Second Bluetooth UUID to compare

    Returns negative value if u1 < u2, 0 if u1 == u2, else positive

bool bt_uuid_create(struct bt_uuid *uuid, const uint8_t *data, uint8_t data_len)
    Create a bt_uuid from a little-endian data buffer.

    Create a bt_uuid from a little-endian data buffer. The data_len parameter is used to determine
    whether the UUID is in 16, 32 or 128 bit format (length 2, 4 or 16). Note: 32 bit format is
    not allowed over the air.

    Parameters
    • uuid – Pointer to the bt_uuid variable
    • data – pointer to UUID stored in little-endian data buffer
    • data_len – length of the UUID in the data buffer

    Returns true if the data was valid and the UUID was successfully created.

void bt_uuid_to_str(const struct bt_uuid *uuid, char *str, size_t len)
    Convert Bluetooth UUID to string.

    Converts Bluetooth UUID to string. UUID can be in any format, 16-bit, 32-bit or 128-bit.

    Parameters
    • uuid – Bluetooth UUID
    • str – pointer where to put converted string
    • len – length of str

struct bt_uuid

#include <uuid.h> This is a ‘tentative’ type and should be used as a pointer only.
struct bt_uuid_16
#include <uuid.h>

Public Members

struct bt_uuid uid
UUID generic type.

uint16_t val
UUID value, 16-bit in host endianness.

struct bt_uuid_32
#include <uuid.h>

Public Members

struct bt_uuid uid
UUID generic type.

uint32_t val
UUID value, 32-bit in host endianness.

struct bt_uuid_128
#include <uuid.h>

Public Members

struct bt_uuid uid
UUID generic type.

uint8_t val[16]
UUID value, 128-bit in little-endian format.

7.4.15 Bluetooth: Basic Audio Profile

This document describes how to run basic audio profile functionality which includes:

- Capabilities and Endpoint discovery
- Audio Stream Endpoint procedures

Commands

Example Central

Connect and establish a stream:

```
uart:~$ bt init
uart:~$ audio init
uart:~$ bt connect <address>
uart:~$ gatt exchange-mtu
uart:~$ audio discover sink
uart:~$ audio config sink 0
uart:~$ audio qos
uart:~$ audio enable
```

Or using connect command:

```
uart:~$ audio connect <address>
uart:~$ audio connect <address> <index> [codec] [preset]
```
uart:~$ bt init
uart:~$ audio init
uart:~$ bt connect <address>
uart:~$ gatt exchange-mtu
uart:~$ audio discover sink
uart:~$ audio connect sink 0

Disconnect and release:

uart:~$ audio disable
uart:~$ audio release

Example Peripheral

Listen:

uart:~$ bt init
uart:~$ audio init
uart:~$ bt advertise on

Server initiated disable and release:

uart:~$ audio disable
uart:~$ audio release

Example Broadcast Source

Create and establish a broadcast source stream:

uart:~$ audio init
uart:~$ audio create_broadcast
uart:~$ audio start_broadcast

Stop and release a broadcast source stream:

uart:~$ audio stop_broadcast
uart:~$ audio delete_broadcast

Example Broadcast Sink

Scan for and establish a broadcast sink stream:

uart:~$ audio init
uart:~$ audio broadcast_scan on
Found broadcaster with ID 0xB91CD4
uart:~$ audio accept_broadcast 0xB91CD4
PA syncing to broadcaster
Broadcast scan was terminated: 0
PA synced to broadcaster with ID 0xB91CD4 as sink 0x2000d09c
Sink 0x2000d09c is set as default
Sink 0x2000d09c is ready to sync without encryption
Received BASE from sink 0x2000d09c:
Subgroup[0]:
codec 0x06 cid 0x0000 vid 0x0000 count 4

(continues on next page)
Stop and release a broadcast sink stream:

```bash
uart:~$ audio stop_broadcast_sink
uart:~$ audio term_broadcast_sink
```

**Init**

The `init` command register local PAC records which are necessary to be able to configure stream and properly manage capabilities in use.

Table 7.5: State Machine Transitions

<table>
<thead>
<tr>
<th>Depends</th>
<th>Allowed States</th>
<th>Next States</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>any</td>
<td>none</td>
</tr>
</tbody>
</table>

```bash
uart:~$ audio init
```

**Discover PAC(s) and ASE(s)**

Once connected the `discover` command discover PAC records and ASE characteristics representing remote endpoints.

Table 7.6: State Machine Transitions

<table>
<thead>
<tr>
<th>Depends</th>
<th>Allowed States</th>
<th>Next States</th>
</tr>
</thead>
<tbody>
<tr>
<td>init</td>
<td>any</td>
<td>any</td>
</tr>
</tbody>
</table>

**Note:** Use command `gatt exchange-mtu` to make sure the MTU is configured properly.

```bash
uart:~$ gatt exchange-mtu
Exchange pending
Exchange successful
uart:~$ audio discover [type: sink, source]
uart:~$ audio discover sink
cap 0x8175940 type 0x01
codec 0x06 cid 0x0000 vid 0x0000 count 4
data #0: type 0x01 len 1
00000000: 3f | ? |
data #1: type 0x02 len 1
00000000: 03 | . |
```

(continues on next page)
Select preset

The preset command can be used to either print the default preset configuration or set a different one, it is worth noting that it doesn't change any stream previously configured.

```bash
uart:~$ audio preset [preset]
uart:~$ audio preset
16_2_1
codec 0x06 cid 0x0000 vid 0x0000 count 3
data #0: type 0x01 len 1
  00000000: 02 |.. |
data #1: type 0x02 len 1
  00000000: 01 |.. |
data #2: type 0x04 len 2
  00000000: 28 00 |.. |
meta #0: type 0x01 len 2
  00000000: 07 00 |.. |
ep 0x81754e0
ep 0x81755d4
QoS: dir 0x02 interval 10000 framing 0x00 phy 0x02 sdu 40 rtt 2 latency 10 pd 40000
```

Configure Codec

The config command attempts to configure a stream for the given direction using a preset codec configuration which can either be passed directly or in case it is omitted the default preset is used.

```bash
uart:~$ audio config <direction: sink, source> <index> [codec] [preset]
uart:~$ audio config sink 0
ASE Codec Config: conn 0x8173800 ep 0x81754e0 cap 0x816a360
codec 0x06 cid 0x0000 vid 0x0000 count 3
data #0: type 0x01 len 1
  00000000: 02 |.. |
data #1: type 0x02 len 1
  00000000: 01 |.. |
data #2: type 0x04 len 2
  00000000: 28 00 |.. |
meta #0: type 0x02 len 2
  00000000: 02 00 |.. |
QoS: dir 0x02 interval 10000 framing 0x00 phy 0x02 sdu 40 rtt 2 latency 10 pd 40000
ASE Codec Config stream 0x8179e60
```

Table 7.7: State Machine Transitions

<th>Allowed States</th>
<th>Next States</th>
</tr>
</thead>
<tbody>
<tr>
<td>discover</td>
<td>idle/codec-configured/qos-configured</td>
<td>codec-configured</td>
</tr>
</tbody>
</table>

(continues on next page)
Configure QoS

The `qos` command attempts to configure the stream QoS using the preset configuration, each individual QoS parameter can be set with use optional parameters.

Table 7.8: State Machine Transitions

<table>
<thead>
<tr>
<th>Depends</th>
<th>Allowed States</th>
<th>Next States</th>

</table>

```bash
uart:~$ audio qos [preset] [interval] [framing] [latency] [pd] [sdu] [phy] [rtn]
uart:~$ audio qos
ASE config: preset 16_2_1
```

Enable

The `enable` command attempts to enable the stream previously configured, if the remote peer accepts then the ISO connection procedure is also initiated.

Table 7.9: State Machine Transitions

<table>
<thead>
<tr>
<th>Depends</th>
<th>Allowed States</th>
<th>Next States</th>
</tr>
</thead>
<tbody>
<tr>
<td>qos</td>
<td>qos-configured</td>
<td>enabling</td>
</tr>
</tbody>
</table>

```bash
uart:~$ audio enable
```

Start [sink only]

The `start` command is only necessary when acting as a sink as it indicates to the source the stack is ready to start receiving data.

Table 7.10: State Machine Transitions

<thead>
<tr>
<th>Depends</th>
<th>Allowed States</th>
<th>Next States</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>enabling</td>
<td>streaming</td>
</tr>
</tbody>
</table>

```bash
uart:~$ audio start
```

Disable

The `disable` command attempts to disable the stream previously enabled, if the remote peer accepts then the ISO disconnection procedure is also initiated.

Table 7.11: State Machine Transitions

<table>
<thead>
<tr>
<th>Depends</th>
<th>Allowed States</th>
<th>Next States</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>enabling/streaming</td>

<th>Allowed States</th>
<th>Next States</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>any</td>
<td>none</td>
</tr>
</tbody>
</table>

uart:~$ audio list

*0: ase 0x01 dir 0x01 state 0x01

**Select Unicast**

The `select_unicast` command set a unicast stream as default.

<table>
<thead>
<tr>
<th>Depends</th>
<th>Allowed States</th>
<th>Next States</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>any</td>
<td>none</td>
</tr>
</tbody>
</table>

uart:~$ audio select <ase>
uart:~$ audio select 0x01

Default stream: 1

To select a broadcast stream:
uart:$ audio select 0x01 broadcast
Default stream: 1 (broadcast)

Connect

The `connect` command combines `config`, `qos` and `enable` commands in one so it can be used to quickly configure and enable a stream.

<table>
<thead>

7.5 Controller Area Network (CAN)

7.5.1 CAN Controller

- Overview
- Sending
- Receiving
- Setting the bitrate
- SocketCAN
- Samples
- API Reference

Overview

Controller Area Network is a two-wire serial bus specified by the Bosch CAN Specification, Bosch CAN with Flexible Data-Rate specification and the ISO 11898-1:2003 standard. CAN is mostly known for its application in the automotive domain. However, it is also used in home and industrial automation and other products.

A CAN transceiver is an external device that converts the logic level signals from the CAN controller to the bus-levels. The bus lines are called CAN High (CAN H) and CAN Low (CAN L). The transmit wire from the controller to the transceiver is called CAN TX, and the receive wire is called CAN RX. These wires use the logic levels whereas the bus-level is interpreted differentially between CAN H and CAN L. The bus can be either in the recessive (logical one) or dominant (logical zero) state. The recessive state is when both lines, CAN H and CAN L, are at roughly the same voltage level. This state is also the idle state. To write a dominant bit to the bus, open-drain transistors tie CAN H to Vdd and CAN L to ground.

The first and last node use a 120-ohm resistor between CAN H and CAN L to terminate the bus. The dominant state always overrides the recessive state. This structure is called a wired-AND.

Warning: CAN controllers can only initialize when the bus is in the idle (recessive) state for at least 11 recessive bits. Therefore you have to make sure that CAN RX is high, at least for a short time. This is also necessary for loopback mode.

The bit-timing as defined in ISO 11898-1:2003 looks as following:
A single bit is split into four segments.

- **Sync_Seg**: The nodes synchronize at the edge of the Sync_Seg. It is always one time quantum in length.
- **Prop_Seg**: The signal propagation delay of the bus and other delays of the transceiver and node.
- **Phase_Seg1** and **Phase_Seg2**: Define the sampling point. The bit is sampled at the end of Phase_Seg1.

The bit-rate is calculated from the time of a time quantum and the values defined above. A bit has the length of Sync_Seg plus Prop_Seg plus Phase_Seg1 plus Phase_Seg2 multiplied by the time of single time quantum. The bit-rate is the inverse of the length of a single bit.

A bit is sampled at the sampling point. The sample point is between Phase_Seg1 and Phase_Seg2 and therefore is a parameter that the user needs to choose. The CiA recommends setting the sample point to 87.5% of the bit.

The resynchronization jump width (SJW) defines the amount of time quantum the sample point can be moved. The sample point is moved when resynchronization is needed.

The timing parameters (SJW, bitrate and sampling point, or bitrate, Prop_Seg, Phase_Seg1 and Phase_Seg2) are initially set from the device-tree and can be changed at run-time from the timing-API.

CAN uses so-called identifiers to identify the frame instead of addresses to identify a node. This identifier can either have 11-bit width (Standard or Basic Frame) or 29-bit in case of an Extended Frame. The Zephyr CAN API supports both Standard and Extended identifiers concurrently. A CAN frame starts with a dominant Start Of Frame bit. After that, the identifiers follow. This phase is called the arbitration phase. During the arbitration phase, write collisions are allowed. They resolve by the fact that dominant bits override recessive bits. Nodes monitor the bus and notice when their transmission is being overridden and in case, abort their transmission. This effectively gives lower number identifiers priority over higher number identifiers.

Filters are used to whitelist identifiers that are of interest for the specific node. An identifier that doesn't match any filter is ignored. Filters can either match exactly or a specified part of the identifier. This method is called masking. As an example, a mask with 11 bits set for standard or 29 bits set for extended identifiers must match perfectly. Bits that are set to zero in the mask are ignored when matching an identifier. Most CAN controllers implement a limited number of filters in hardware. The number of filters is also limited in Kconfig to save memory.

Errors may occur during transmission. In case a node detects an erroneous frame, it partially overrides the current frame with an error-frame. Error-frames can either be error passive or error active, depending on the state of the controller. In case the controller is in error active state, it sends six consecutive dominant bits, which is a violation of the stuffing rule that all nodes can detect. The sender may reseed the frame right after.

An initialized node can be in one of the following states:

- Error-active
- Error-passive
- Bus-off

After initialization, the node is in the error-active state. In this state, the node is allowed to send active error frames, ACK, and overload frames. Every node has a receive- and transmit-error counter. If either the receive- or the transmit-error counter exceeds 127, the node changes to error-passive state. In this state, the node is not allowed to send error-active frames anymore. If the transmit-error counter increases further to 255, the node changes to the bus-off state. In this state, the node is not allowed to send any dominant bits to the bus. Nodes in the bus-off state may recover after receiving 128 occurrences of 11 concurrent recessive bits.
You can read more about CAN bus in this [CAN Wikipedia article](https://en.wikipedia.org/wiki/Controller_Area_Network).

Zephyr supports following CAN features:

- Standard and Extended Identifiers
- Filters with Masking
- Loopback and Silent mode
- Remote Request

## Sending

The following code snippets show how to send data.

This basic sample sends a CAN frame with standard identifier 0x123 and eight bytes of data. When passing NULL as the callback, as shown in this example, the send function blocks until the frame is sent and acknowledged by at least one other node or an error occurred. The timeout only takes effect on acquiring a mailbox. When a transmitting mailbox is assigned, sending cannot be canceled.

```c
struct zcan_frame frame = {
    .id_type = CAN_STANDARD_IDENTIFIER,
    .rtr = CAN_DATAFRAME,
    .id = 0x123,
    .dlc = 8,
    .data = {1,2,3,4,5,6,7,8}
};
const struct device *can_dev;
int ret;

can_dev = device_get_binding("CAN_0");

ret = can_send(can_dev, &frame, K_MSEC(100), NULL, NULL);
if (ret != 0) {
    LOG_ERR("Sending failed [%d]", ret);
}
```

This example shows how to send a frame with extended identifier 0x1234567 and two bytes of data. The provided callback is called when the message is sent, or an error occurred. Passing `K_FOREVER` to the timeout causes the function to block until a transfer mailbox is assigned to the frame or an error occurred. It does not block until the message is sent like the example above.

```c
void tx_irq_callback(int error, void *arg)
{
    char *sender = (char *)arg;
    if (error != 0) {
        LOG_ERR("Sendig failed [%d]\nSender: %s\n", error, sender);
    }
}

int send_function(const struct device *can_dev)
{
    struct zcan_frame frame = {
        .id_type = CAN_EXTENDED_IDENTIFIER,
        .rtr = CAN_DATAFRAME,
        .id = 0x1234567,
        .dlc = 2
    };
    (continues on next page)
```
frame.data[0] = 1;
frame.data[1] = 2;

return can_send(can_dev, &frame, K_FOREVER, tx_irq_callback, "Sender 1");

Receiving

Frames are only received when they match a filter. The following code snippets show how to receive frames by adding filters.

Here we have an example for a receiving callback as used for can_add_rx_filter(). The user data argument is passed when the filter is added.

```c
void rx_callback_function(struct zcan_frame *frame, void *user_data)
{
    ... do something with the frame ...
}
```

The following snippet shows how to add a filter with a callback function. It is the most efficient but also the most critical way to receive messages. The callback function is called from an interrupt context, which means that the callback function should be as short as possible and must not block. Adding callback functions is not allowed from userspace context.

The filter for this example is configured to match the identifier 0x123 exactly.

```c
const struct zcan_filter my_filter = {
    .id_type = CAN_STANDARD_IDENTIFIER,
    .rtr = CAN_DATAFRAME,
    .id = 0x123,
    .rtr_mask = 1,
    .id_mask = CAN_STD_ID_MASK
};
int filter_id;
const struct device *can_dev;

can_dev = device_get_binding("CAN_0");

filter_id = can_add_rx_filter(can_dev, rx_callback_function, callback_arg, &my_filter);
if (filter_id < 0) {
    LOG_ERR("Unable to add rx filter [%d]", filter_id);
}
```

Here an example for can_add_rx_filter_msgq() is shown. With this function, it is possible to receive frames synchronously. This function can be called from userspace context. The size of the message queue should be as big as the expected backlog.

The filter for this example is configured to match the extended identifier 0x1234567 exactly.

```c
const struct zcan_filter my_filter = {
    .id_type = CAN_EXTENDED_IDENTIFIER,
    .rtr = CAN_DATAFRAME,
    .id = 0x1234567,
    .rtr_mask = 1,
    .id_mask = CAN_EXT_ID_MASK
```

(continues on next page)
\{ \}
CAN_MSGQ_DEFINE(my_can_msgq, 2);
struct zcan_frame rx_frame;
int filter_id;
const struct device *can_dev;

can_dev = device_get_binding("CAN_0");

filter_id = can_add_rx_filter_msgq(can_dev, &my_can_msgq, &my_filter);
if (filter_id < 0) {
    LOG_ERR("Unable to add rx msgq [%d]", filter_id);
    return;
}

while (true) {
    k_msgq_get(&my_can_msgq, &rx_frame, K_FOREVER);
    ... do something with the frame ...
}

\textit{can_remove_rx_filter()} removes the given filter.

\textit{can_remove_rx_filter(can_dev, filter_id)};

\section*{Setting the bitrate}

The bitrate and sampling point is initially set at runtime. To change it from the application, one can use the \textit{can_set_timing()} API. This function takes three arguments. The first timing parameter sets the timing for classic CAN and arbitration phase for CAN-FD. The second parameter sets the timing of the data phase for CAN-FD. For classic CAN, you can use only the first parameter and put NULL to the second one. The \textit{can_calc_timing()} function can calculate timing from a bitrate and sampling point in permille. The following example sets the bitrate to 250k baud with the sampling point at 87.5%.

\begin{verbatim}
struct can_timing timing;
const struct device *can_dev;
int ret;

can_dev = device_get_binding("CAN_0");

ret = can_calc_timing(can_dev, &timing, 250000, 875);
if (ret > 0) {
    LOG_INF("Sample-Point error: %d", ret);
}
if (ret < 0) {
    LOG_ERR("Failed to calc a valid timing");
    return;
}
ret = can_set_timing(can_dev, &timing, NULL);
if (ret != 0) {
    LOG_ERR("Failed to set timing");
}
\end{verbatim}
Zephyr Project Documentation, Release 3.0.99

SocketCAN

Zephyr additionally supports SocketCAN, a BSD socket implementation of the Zephyr CAN API. SocketCAN brings the convenience of the well-known BSD Socket API to Controller Area Networks. It is compatible with the Linux SocketCAN implementation, where many other high-level CAN projects build on top. Note that frames are routed to the network stack instead of passed directly, which adds some computation and memory overhead.

Samples

We have two ready-to-build samples demonstrating use of the Zephyr CAN API Zephyr CAN sample and SocketCAN sample.

API Reference

group can_interface

CAN Interface.

Linux SocketCAN compatibility

The following structures and functions provide compatibility with the CAN frame and CAN filter formats used by Linux SocketCAN.

typedef uint32_t canid_t

CAN Identifier structure for Linux SocketCAN compatibility.

The fields in this type are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-28</td>
<td>CAN identifier (11/29 bit)</td>
</tr>
<tr>
<td>29</td>
<td>Error message frame flag (0 = data frame, 1 = error message)</td>
</tr>
<tr>
<td>30</td>
<td>Remote transmission request flag (1 = RTR frame)</td>
</tr>
<tr>
<td>31</td>
<td>Frame format flag (0 = standard 11 bit, 1 = extended 29 bit)</td>
</tr>
</tbody>
</table>

static inline void can_copy_frame_to_zframe(const struct can_frame *frame, struct zcan_frame *zframe)

Translate a can_frame struct to a zcan_frame struct.

Parameters

- frame – Pointer to can_frame struct.
- zframe – Pointer to zcan_frame struct.

static inline void can_copy_zframe_to_frame(const struct zcan_frame *zframe, struct can_frame *frame)

Translate a zcan_frame struct to a can_frame struct.

Parameters

- zframe – Pointer to zcan_frame struct.
• frame – Pointer to can_frame struct.

static inline void can_copy_filter_to_zfilter(const struct can_filter *filter, struct zcan_filter *zfilter)
Translate a can_filter struct to a zcan_filter struct.

Parameters
• filter – Pointer to can_filter struct.
• zfilter – Pointer to zcan_filter struct.

static inline void can_copy_zfilter_to_filter(const struct zcan_filter *zfilter, struct can_filter *filter)
Translate a zcan_filter struct to a can_filter struct.

Parameters
• zfilter – Pointer to zcan_filter struct.
• filter – Pointer to can_filter struct.

CAN controller configuration

int can_get_core_clock(const struct device *dev, uint32_t *rate)
Get the CAN core clock rate.

Returns the CAN core clock rate. One time quantum is 1/(core clock rate).

Parameters
• dev – Pointer to the device structure for the driver instance.
• rate – [out] CAN core clock rate in Hz.

Returns 0 on success, or a negative error code on error

int can_calc_timing(const struct device *dev, struct can_timing *res, uint32_t bitrate, uint16_t sample_pnt)
Calculate timing parameters from bitrate and sample point.

Calculate the timing parameters from a given bitrate in bits/s and the sampling point in permill (1/1000) of the entire bit time. The bitrate must alway match perfectly. If no result can be reached for the given parameters, -EINVAL is returned.

Note: The requested sample_pnt will not always be matched perfectly. The algorithm calculates the best possible match.

Parameters
• dev – Pointer to the device structure for the driver instance.
• res – [out] Result is written into the can_timing struct provided.
• bitrate – Target bitrate in bits/s.
• sample_pnt – Sampling point in permill of the entire bit time.

Return values
• 0 – or positive sample point error on success.
• -EINVAL – if there is no solution for the desired values.
• -EIO – if can_get_core_clock() is not available.
int can_calc_timing_data(const struct device *dev, struct can_timing *res, uint32_t bitrate, uint16_t sample_pnt)
Calculate timing parameters for the data phase.
Same as can_calc_timing() but with the maximum and minimum values from the data phase.

Note: CONFIG_CAN_FD_MODE must be selected for this function to be available.

Parameters
• dev – Pointer to the device structure for the driver instance.
• res – [out] Result is written into the can_timing struct provided.
• bitrate – Target bitrate for the data phase in bits/s
• sample_pnt – Sampling point for the data phase in permille of the entire bit time.

Return values
• 0 – or positive sample point error on success.
• -EINVAL – if there is no solution for the desired values.
• -EIO – if can_get_core_clock() is not available.

int can_calc_prescaler(const struct device *dev, struct can_timing *timing, uint32_t bitrate)
Fill in the prescaler value for a given bitrate and timing.
Fill the prescaler value in the timing struct. The sjw, prop_seg, phase_seg1 and phase_seg2 must be given.
The returned bitrate error is reminder of the deviation of the clock rate by the bitrate times the timing segments.

Parameters
• dev – Pointer to the device structure for the driver instance.
• timing – Result is written into the can_timing struct provided.
• bitrate – Target bitrate.

Return values
• 0 – or positive bitrate error.
• Negative – error code on error.

int can_set_timing(const struct device *dev, const struct can_timing *timing, const struct can_timing *timing_data)
Configure the bus timing of a CAN controller.
If the sjw equals CAN_SJW_NO_CHANGE, the sjw parameter is not changed.

Note: The parameter timing_data is only relevant for CAN-FD. If the controller does not support CAN-FD or if CONFIG_CAN_FD_MODE is not selected, the value of this parameter is ignored.

Parameters
• dev – Pointer to the device structure for the driver instance.
• timing – Bus timings.
• timing_data – Bus timings for data phase (CAN-FD only).
Return values

• 0 – If successful.
• -EIO – General input/output error, failed to configure device.

int can_set_mode(const struct device *dev, enum can_mode mode)
Set the CAN controller to the given operation mode.

Parameters

• dev – Pointer to the device structure for the driver instance.
• mode – Operation mode.

Return values

• 0 – If successful.
• -EIO – General input/output error, failed to configure device.

static inline int can_set_bitrate(const struct device *dev, uint32_t bitrate, uint32_t bitrate_data)
Set the bitrate of the CAN controller.

The sample point is set to the CiA DS 301 recommended value of 87.5%.

Note: The parameter bitrate_data is only relevant for CAN-FD. If the controller does not support CAN-FD or if CONFIG_CAN_FD_MODE is not selected, the value of this parameter is ignored.

Parameters

• dev – Pointer to the device structure for the driver instance.
• bitrate – Desired arbitration phase bitrate.
• bitrate_data – Desired data phase bitrate.

Return values

• 0 – If successful.
• -EINVAL – bitrate cannot be met.
• -EIO – General input/output error, failed to set bitrate.

CAN_SJW_NO_CHANGE
Synchronization Jump Width (SJW) value to indicate that the SJW should not be changed by the timing calculation.

Transmitting CAN frames

int can_send(const struct device *dev, const struct zcan_frame *frame, k_timeout_t timeout,
        can_tx_callback_t callback, void *user_data)
Queue a CAN frame for transmission on the CAN bus.

Queue a CAN frame for transmission on the CAN bus with optional timeout and completion callback function.

Queued CAN frames are transmitted in order according to their priority:

• The lower the CAN-ID, the higher the priority.
• Data frames have higher priority than Remote Transmission Request (RTR) frames with identical CAN-IDs.
Frames with standard (11-bit) identifiers have higher priority than frames with extended (29-bit) identifiers with identical base IDs (the higher 11 bits of the extended identifier).

Transmission order for queued frames with the same priority is hardware dependent.

By default, the CAN controller will automatically retry transmission in case of lost bus arbitration or missing acknowledge. Some CAN controllers support disabling automatic retransmissions ("one-shot" mode) via a devicetree property.

**Note:** If transmitting segmented messages spanning multiple CAN frames with identical CAN-IDs, the sender must ensure to only queue one frame at a time if FIFO order is required.

### Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **frame** – CAN frame to transmit.
- **timeout** – Timeout waiting for an empty TX mailbox or `K_FOREVER`.
- **callback** – Optional callback for when the frame was sent or a transmission error occurred. If `NULL`, this function is blocking until frame is sent. The callback must be `NULL` if called from user mode.
- **user_data** – User data to pass to callback function.

### Return values

- **0** – if successful.
- **-EINVAL** – if an invalid parameter was passed to the function.
- **-ENETDOWN** – if the CAN controller is in bus-off state.
- **-EBUSY** – if CAN bus arbitration was lost (only applicable if automatic retransmissions are disabled).
- **-EIO** – if a general transmit error occurred (e.g. missing ACK if automatic retransmissions are disabled).
- **-EAGAIN** – on timeout.

### Receiving CAN frames

```c
can_add_rx_filter(const struct device *dev, can_rx_callback_t callback, void *user_data, const struct zcan_filter *filter)
```

Add a callback function for a given CAN filter.

Add a callback to CAN identifiers specified by a filter. When a received CAN frame matching the filter is received by the CAN controller, the callback function is called in interrupt context.

If a frame matches more than one attached filter, the priority of the match is hardware dependent.

The same callback function can be used for multiple filters.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance.
- **callback** – This function is called by the CAN controller driver whenever a frame matching the filter is received.
- **user_data** – User data to pass to callback function.
• filter – Pointer to a `zcan_filter` structure defining the filter.

**Return values**

• `filter_id` – on success.
• `-ENOSPC` – if there are no free filters.

```c
default_value: int can_addRxFilterMsgq(const device *dev, struct k_msgq *msgq, const struct zcan_filter *filter)
```

Wrapper function for adding a message queue for a given filter.

Wrapper function for `can_add_rx_filter()` which puts received CAN frames matching the filter in a message queue instead of calling a callback.

If a frame matches more than one attached filter, the priority of the match is hardware dependent.

The same message queue can be used for multiple filters.

**Note:** The message queue must be initialized before calling this function and the caller must have appropriate permissions on it.

**Parameters**

• `dev` – Pointer to the device structure for the driver instance.
• `msgq` – Pointer to the already initialized `k_msgq` struct.
• `filter` – Pointer to a `zcan_filter` structure defining the filter.

**Return values**

• `filter_id` – on success.
• `-ENOSPC` – if there are no free filters.

```c
default_value: void canRemoveRxFilter(const device *dev, int filter_id)
```

Remove a CAN RX filter.

This routine removes a CAN RX filter based on the filter ID returned by `can_add_rx_filter()` or `can_add_rx_filter_msgq()`.

**Parameters**

• `dev` – Pointer to the device structure for the driver instance.
• `filter_id` – Filter ID

```c
default_value: int canGetMaxFilters(const device *dev, enum can_ide id_type)
```

Get maximum number of RX filters.

Get the maximum number of concurrent RX filters for the CAN controller.

**Parameters**

• `dev` – Pointer to the device structure for the driver instance.
• `id_type` – CAN identifier type (standard or extended).

**Return values**

• Positive – number of maximum concurrent filters.
• `-EIO` – General input/output error.
• `-ENOSYS` – If this function is not implemented by the driver.
**CAN_MSGQ_DEFINE**

Statically define and initialize a CAN RX message queue.

The message queue's ring buffer contains space for `max_frames` CAN frames.

**See also:**

can_add_rx_filter_msgq()

**Parameters**

- **name** – Name of the message queue.
- **max_frames** – Maximum number of CAN frames that can be queued.

---

**CAN bus error reporting and handling**

**int can_get_state(const struct device *dev, enum can_state *state, struct can_bus_err_cnt *err_cnt)**

Get current CAN controller state.

Returns the current state and optionally the error counter values of the CAN controller.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance.
- **state** – [out] Pointer to the state destination enum or NULL.
- **err_cnt** – [out] Pointer to the err_cnt destination structure or NULL.

**Return values**

- **0** – If successful.
- **-EIO** – General input/output error, failed to get state.

**int can_recover(const struct device *dev, k_timeout_t timeout)**

Recover from bus-off state.

Recover the CAN controller from bus-off state to error-active state.

**Note:** CONFIG_CAN_AUTO_BUS_OFF_RECOVERY must be deselected for this function to be available.

**Parameters**

- **dev** – Pointer to the device structure for the driver instance.
- **timeout** – Timeout for waiting for the recovery or K_FOREVER.

**Return values**

- **0** – on success.
- **-EAGAIN** – on timeout.

**static inline void can_set_state_change_callback(const struct device *dev,**

```c
can_state_change_callback_t callback, void *
user_data)
```

Set a callback for CAN controller state change events.

Set the callback for CAN controller state change events. The callback function will be called in interrupt context.
Only one callback can be registered per controller. Calling this function again overrides any previously registered callback.

Parameters

- `dev` – Pointer to the device structure for the driver instance.
- `callback` – Callback function.
- `user_data` – User data to pass to callback function.

**CAN utility functions**

```c
static inline uint8_t can_dlc_to_bytes(uint8_t dlc)
Convert from Data Length Code (DLC) to the number of data bytes.

Parameters

- `dlc` – Data Length Code (DLC).

Return values

Number of bytes.
```

```c
static inline uint8_t can_bytes_to_dlc(uint8_t num_bytes)
Convert from number of bytes to Data Length Code (DLC)

Parameters

- `num_bytes` – Number of bytes.

Return values

Data Length Code (DLC).
```

**CAN frame definitions**

- `CAN_STD_ID_MASK` – Bit mask for a standard (11-bit) CAN identifier.
- `CAN_MAX_STD_ID` – Maximum value for a standard (11-bit) CAN identifier.
- `CAN_EXT_ID_MASK` – Bit mask for an extended (29-bit) CAN identifier.
- `CAN_MAX_EXT_ID` – Maximum value for an extended (29-bit) CAN identifier.
- `CAN_MAX_DLC` – Maximum data length code for CAN 2.0A/2.0B.
- `CANFD_MAX_DLC` – Maximum data length code for CAN-FD.

**Defines**

```c
CAN_STATS_BIT0_ERROR_INC(dev)
Increment the bit0 error counter for a CAN device.

The bit0 error counter is incremented when the CAN controller is unable to transmit a dominant bit.

Parameters
```
• dev_ – Pointer to the device structure for the driver instance.

**CAN_STATS_BIT1_ERROR_INC(dev_)**
Increment the bit1 (recessive) error counter for a CAN device.

The bit1 error counter is incremented when the CAN controller is unable to transmit a recessive bit.

**Parameters**
• dev_ – Pointer to the device structure for the driver instance.

**CAN_STATS_STUFF_ERROR_INC(dev_)**
Increment the stuffing error counter for a CAN device.

The stuffing error counter is incremented when the CAN controller detects a bit stuffing error.

**Parameters**
• dev_ – Pointer to the device structure for the driver instance.

**CAN_STATS_CRC_ERROR_INC(dev_)**
Increment the CRC error counter for a CAN device.

The CRC error counter is incremented when the CAN controller detects a frame with an invalid CRC.

**Parameters**
• dev_ – Pointer to the device structure for the driver instance.

**CAN_STATS_FORM_ERROR_INC(dev_)**
Increment the form error counter for a CAN device.

The form error counter is incremented when the CAN controller detects a fixed-form bit field containing illegal bits.

**Parameters**
• dev_ – Pointer to the device structure for the driver instance.

**CAN_STATS_ACK_ERROR_INC(dev_)**
Increment the acknowledge error counter for a CAN device.

The acknowledge error counter is incremented when the CAN controller does not monitor a dominant bit in the ACK slot.

**Parameters**
• dev_ – Pointer to the device structure for the driver instance.

**CAN_DEVICE_DT_DEFINE(node_id, init_fn, pm_device, data_ptr, cfg_ptr, level, prio, api_ptr, ...)**
Like **DEVICE_DT_DEFINE()** with CAN device specifics.

Defines a device which implements the CAN API. May generate a custom device_state container struct and init_fn wrapper when needed depending on CONFIG_CAN_STATS.

**Parameters**
• node_id – The devicetree node identifier.
• init_fn – Name of the init function of the driver.
• pm_device – PM device resources reference (NULL if device does not use PM).
• data_ptr – Pointer to the device's private data.
• cfg_ptr – The address to the structure containing the configuration information for this instance of the driver.
• level – The initialization level. See **SYS_INIT()** for details.
• **prio** – Priority within the selected initialization level. See `SYS_INIT()` for details.

• **api_ptr** – Provides an initial pointer to the API function struct used by the driver. Can be NULL.

```
CAN_DEVICE_DT_INST_DEFINE(inst, ...)
```

Like `CAN_DEVICE_DT_DEFINE()` for an instance of a DT_DRV_COMPAT compatible.

**Parameters**

• **inst** – Instance number. This is replaced by `DT_DRV_COMPAT(inst)` in the call to `CAN_DEVICE_DT_DEFINE()`.

• **...** – Other parameters as expected by `CAN_DEVICE_DT_DEFINE()`.

**Typedefs**

typedef void (*can_tx_callback_t)(int error, void *user_data)

Defines the application callback handler function signature.

- **Param error** Status of the performed send operation. See the list of return values for `can_send()` for value descriptions.

- **Param user_data** User data provided when the frame was sent.

```
typedef void (*can_rx_callback_t)(struct zcan_frame *frame, void *user_data)
```

Defines the application callback handler function signature for receiving.

- **Param frame** Received frame.

- **Param user_data** User data provided when the filter was added.

```
typedef void (*can_state_change_callback_t)(enum can_state state, struct can_bus_err_cnt err_cnt, void *user_data)
```

Defines the state change callback handler function signature.

- **Param state** State of the CAN controller.

- **Param err_cnt** CAN controller error counter values.

- **Param user_data** User data provided the callback was set.

**Enums**

```
enum can_mode
```

Defines the mode of the CAN controller.

**Values:**

- **enumerator CAN_NORMAL_MODE** Normal mode.

- **enumerator CAN_SILENT_MODE** Controller is not allowed to send dominant bits.

- **enumerator CAN_LOOPBACK_MODE** Controller is in loopback mode (receives own frames).
enumerator CAN_SILENT_LOOPBACK_MODE
    Combination of loopback and silent modes.

enum can_state
    Defines the state of the CAN bus.
    Values:

    enumerator CAN_ERROR_ACTIVE
        Error-active state (RX/TX error count < 96).

    enumerator CAN_ERROR_WARNING
        Error-warning state (RX/TX error count < 128).

    enumerator CAN_ERROR_PASSIVE
        Error-passive state (RX/TX error count < 256).

    enumerator CAN_BUS_OFF
        Bus-off state (RX/TX error count >= 256).

enum can_ide
    Defines if the CAN frame has a standard (11-bit) or extended (29-bit) CAN identifier.
    Values:

    enumerator CAN_STANDARD_IDENTIFIER
        Standard (11-bit) CAN identifier.

    enumerator CAN_EXTENDED_IDENTIFIER
        Extended (29-bit) CAN identifier.

enum can_rtr
    Defines if the CAN frame is a data frame or a Remote Transmission Request (RTR) frame.
    Values:

    enumerator CAN_DATAFRAME
        Data frame.

    enumerator CAN_REMOTEREQUEST
        Remote Transmission Request (RTR) frame.

struct zcan_frame
    #include <can.h> CAN frame structure.

    Public Members

    uint32_t id
        Standard (11-bit) or extended (29-bit) CAN identifier.

    uint32_t fd
        Frame is in the CAN-FD frame format if set to true.

    uint32_t rtr
        Remote Transmission Request (RTR) flag. Use can_rtr enum for assignment.
uint32_t id_type
    CAN identifier type (standard or extended). Use can_ide enum for assignment.

uint8_t dlc
    Data Length Code (DLC) indicating data length in bytes.

uint8_t brs
    Baud Rate Switch (BRS). Only valid for CAN-FD.

uint16_t timestamp
    Captured value of the free-running timer in the CAN controller when this frame was received. The timer is incremented every bit time and captured at the start of frame bit (SOF).

Note: CONFIG_CAN_RX_TIMESTAMP must be selected for this field to be available.

union zcan_frame.
    The frame payload data.

struct zcan_filter
#include <can.h>
    CAN filter structure.

Public Members

uint32_t id
    CAN identifier to match.

uint32_t rtr
    Match data frame or Remote Transmission Request (RTR) frame.

uint32_t id_type
    Standard or extended CAN identifier. Use can_ide enum for assignment.

uint32_t id_mask
    CAN identifier matching mask. If a bit in this mask is 0, the value of the corresponding bit in the id field is ignored by the filter.

uint32_t rtr_mask
    Data frame/Remote Transmission Request (RTR) bit matching mask. If this bit is 0, the value of the rtr field is ignored by the filter.

struct can_bus_err_cnt
#include <can.h>
    CAN controller error counters.

Public Members

uint8_t tx_err_cnt
    Value of the CAN controller transmit error counter.

uint8_t rx_err_cnt
    Value of the CAN controller receive error counter.
struct can_timing
#include <can.h> CAN bus timing structure.

This struct is used to pass bus timing values to the configuration and bitrate calculation functions.

The propagation segment represents the time of the signal propagation. Phase segment 1 and phase segment 2 define the sampling point. The prop_seg and phase_seg1 values affect the sampling point in the same way and some controllers only have a register for the sum of those two. The sync segment always has a length of 1 time quantum (see below).

<table>
<thead>
<tr>
<th>sync_seg</th>
<th>prop_seg</th>
<th>phase_seg1</th>
<th>phase_seg2</th>
</tr>
</thead>
<tbody>
<tr>
<td>+--------+----------+------------+------------</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| Sampling-Point

1 time quantum (tq) has the length of 1/(core_clock / prescaler). The bitrate is defined by the core clock divided by the prescaler and the sum of the segments:

\[ br = \frac{\text{core_clock}}{\text{prescaler}} \div \left( 1 + \text{prop}_\text{seg} + \text{phase}_\text{seg1} + \text{phase}_\text{seg2} \right) \]

The Synchronization Jump Width (SJW) defines the amount of time quanta the sample point can be moved. The sample point is moved when resynchronization is needed.

**Public Members**

- **uint16_t sjw**
  Synchronisation jump width.

- **uint16_t prop_seg**
  Propagation segment.

- **uint16_t phase_seg1**
  Phase segment 1.

- **uint16_t phase_seg2**
  Phase segment 2.

- **uint16_t prescaler**
  Prescaler value.

**struct can_device_state**
#include <can.h> CAN specific device state which allows for CAN device class specific additions.

**struct can_frame**
#include <can.h> CAN frame for Linux SocketCAN compatibility.

**Public Members**

- **canid_t can_id**
  32-bit CAN ID + EFF/RTR/ERR flags.
The data length code (DLC).

The payload data.

#include <can.h>

A filter is considered a match when `received_can_id & mask == can_id & can_mask`.

Public Members

The CAN identifier to match.

The mask applied to `can_id` for matching.

7.5.2 ISO-TP Transport Protocol

Overview

ISO-TP is a transport protocol defined in the ISO-Standard ISO15765-2 Road vehicles - Diagnostic communication over Controller Area Network (DoCAN). Part2: Transport protocol and network layer services. As its name already implies, it is originally designed, and still used in road vehicle diagnostic over Controller Area Networks. Nevertheless, it’s not limited to applications in road vehicles or the automotive domain.

This transport protocol extends the limited payload data size for classical CAN (8 bytes) and CAN-FD (64 bytes) to theoretically four gigabytes. Additionally, it adds a flow control mechanism to influence the sender’s behavior. ISO-TP segments packets into small fragments depending on the payload size of the CAN frame. The header of those segments is called Protocol Control Information (PCI).

Packets smaller or equal to seven bytes on Classical CAN are called single-frames (SF). They don’t need to fragment and do not have any flow-control.

Packets larger than that are segmented into a first-frame (FF) and as many consecutive-frames as required. The FF contains information about the length of the entire payload data and additionally, the first few bytes of payload data. The receiving peer sends back a flow-control-frame (FC) to either deny, postpone, or accept the following consecutive frames. The FC also defines the conditions of sending, namely the block-size (BS) and the minimum separation time between frames (STmin). The block size defines how many CF the sender is allowed to send, before he has to wait for another FC.
API Reference

*group can_isotp*

CAN ISO-TP Interf.

**Defines**

**ISOTP_N_OK**

Completed successfully

**ISOTP_N_TIMEOUT_A**

Ar/As has timed out

**ISOTP_N_TIMEOUT_BS**

Reception of next FC has timed out

**ISOTP_N_TIMEOUT_CR**

Cr has timed out

**ISOTP_N_WRONG_SN**

Unexpected sequence number

**ISOTP_N_INVALID_FS**

Invalid flow status received

**ISOTP_N_UNEXP_PDU**

Unexpected PDU received

**ISOTP_N_WFT_OVRN**

Maximum number of WAIT flowStatus PDUs exceeded

**ISOTP_N_BUFFER_OVFLW**

FlowStatus OVFLW PDU was received

**ISOTP_N_ERROR**

General error

**ISOTP_NO_FREE_FILTER**

Implementation specific errors Can't bind or send because the CAN device has no filter left

**ISOTP_NO_NET_BUF_LEFT**

No net buffer left to allocate
ISOTP_NO_BUF_DATA_LEFT
   Not sufficient space in the buffer left for the data

ISOTP_NO_CTX_LEFT
   No context buffer left to allocate

ISOTP_RECV_TIMEOUT
   Timeout for recv

ISOTP_FIXED_ADDR_SA_POS
   Position of fixed source address (SA)

ISOTP_FIXED_ADDR_SA_MASK
   Mask to obtain fixed source address (SA)

ISOTP_FIXED_ADDR_TA_POS
   Position of fixed target address (TA)

ISOTP_FIXED_ADDR_TA_MASK
   Mask to obtain fixed target address (TA)

ISOTP_FIXED_ADDR_PRIO_POS
   Position of priority in fixed addressing mode

ISOTP_FIXED_ADDR_PRIO_MASK
   Mask for priority in fixed addressing mode

ISOTP_FIXED_ADDR_RX_MASK

Typedefs

typedef void (*isotp_tx_callback_t)(int error_nr, void *arg)

Functions

int isotp_bind(struct isotp_recv_ctx *ctx, const struct device *can_dev, const struct isotp_msg_id *rx_addr, const struct isotp_msg_id *tx_addr, const struct isotp_fc_opts *opts, k_timeout_t timeout)

Bind an address to a receiving context.

This function binds an RX and TX address combination to an RX context. When data arrives from the specified address, it is buffered and can be read by calling isotp_recv. When calling this routine, a filter is applied in the CAN device, and the context is initialized. The context must be valid until calling unbind.

Parameters

- ctx – Context to store the internal states.
- can_dev – The CAN device to be used for sending and receiving.
- rx_addr – Identifier for incoming data.
- tx_addr – Identifier for FC frames.
• opts – Flow control options.
• timeout – Timeout for FF SF buffer allocation.

Return values
• ISOTP_N_OK – on success
• ISOTP_NO_FREE_FILTER – if CAN device has no filters left.

void isotp.unbind(struct isotp_recv_ctx *ctx)
Unbind a context from the interface.

This function removes the binding from isotp_bind. The filter is detached from the CAN device, and if a transmission is ongoing, buffers are freed. The context can be discarded safely after calling this function.

Parameters
• ctx – Context that should be unbound.

int isotp.recv(struct isotp_recv_ctx *ctx, uint8_t *data, size_t len, k_timeout_t timeout)
Read out received data from fifo.

This function reads the data from the receive FIFO of the context. It blocks if the FIFO is empty. If an error occurs, the function returns a negative number and leaves the data buffer unchanged.

Parameters
• ctx – Context that is already bound.
• data – Pointer to a buffer where the data is copied to.
• len – Size of the buffer.
• timeout – Timeout for incoming data.

Return values
• Number – of bytes copied on success
• ISOTP_WAIT_TIMEOUT – when “timeout” timed out
• ISOTP_N_* – on error

int isotp.recv.net(struct isotp_recv_ctx *ctx, struct net_buf **buffer, k_timeout_t timeout)
Get the net buffer on data reception.

This function reads incoming data into net-buffers. It blocks until the entire packet is received, BS is reached, or an error occurred. If BS was zero, the data is in a single net_buf. Otherwise, the data is fragmented in chunks of BS size. The net-buffers are referenced and must be freed with net_buf_unref after the data is processed.

Parameters
• ctx – Context that is already bound.
• buffer – Pointer where the net_buf pointer is written to.
• timeout – Timeout for incoming data.

Return values
• Remaining – data length for this transfer if BS > 0, 0 for BS = 0
• ISOTP_WAIT_TIMEOUT – when “timeout” timed out
• ISOTP_N_* – on error
int isotp_send(struct isotp_send_ctx *ctx, const struct device *can_dev, const uint8_t *data,
               size_t len, const struct isotp_msg_id *tx_addr, const struct isotp_msg_id *rx_addr,
               isotp_tx_callback_t complete_cb, void *cb_arg)

Send data.

This function is used to send data to a peer that listens to the tx_addr. An internal work-queue is used to transfer the segmented data. Data and context must be valid until the transmission has finished. If a complete_cb is given, this function is non-blocking, and the callback is called on completion with the return value as a parameter.

Parameters
- **ctx** – Context to store the internal states.
- **can_dev** – The CAN device to be used for sending and receiving.
- **data** – Data to be sent.
- **len** – Length of the data to be sent.
- **rx_addr** – Identifier for FC frames.
- **tx_addr** – Identifier for outgoing frames the receiver listens on.
- **complete_cb** – Function called on completion or NULL.
- **cb_arg** – Argument passed to the complete callback.

Return values
- **ISOTP_N_OK** – on success
- **ISOTP_N_*** – on error

struct isotp_msg_id
   #include <isotp.h> ISO-TP message id struct.

Used to pass addresses to the bind and send functions.

Public Members

union isotp_msg_id [anonymous] [anonymous]
   CAN identifier

If ISO-TP fixed addressing is used, isotp_bind ignores SA and priority sections and modifies TA section in flow control frames.

uint8_t ext_addr
   ISO-TP extended address (if used)

uint8_t id_type
   Indicates the CAN identifier type (standard or extended)

uint8_t use_ext_addr
   Indicates if ISO-TP extended addressing is used

uint8_t use_fixed_addr
   Indicates if ISO-TP fixed addressing (acc. to SAE J1939) is used

struct isotp_fc_opts
   #include <isotp.h> ISO-TP frame control options struct.

Used to pass the options to the bind and send functions.
Public Members

uint8_t bs
Block size. Number of CF PDUs before next CF is sent

uint8_t stmin
Minimum separation time. Min time between frames

7.6 Crypto

7.6.1 Overview

7.6.2 API Reference

Generic API for crypto drivers

group crypto
Crypto APIs.

Defines

CAP_OPAQUE_KEY_HNDL

CAP_RAW_KEY

CAP_KEY_LOADING_API

CAP_INPLACE_OPS
Whether the output is placed in separate buffer or not

CAP_SEPARATE_IO_BUFS

CAP_SYNC_OPS
These denote if the output (completion of a cipher_xxx_op) is conveyed by the op function returning, or it is conveyed by an async notification

CAP_ASYNC_OPS

CAP_AUTONONCE
Whether the hardware/driver supports autononce feature

CAP_NO_IV_PREFIX
Don’t prefix IV to cipher blocks
Functions

static inline int crypto_query_hwcaps(const struct device *dev)
    Query the crypto hardware capabilities.

This API is used by the app to query the capabilities supported by the crypto device. Based on
this the app can specify a subset of the supported options to be honored for a session during
cipher_begin_session().

Parameters

• dev – Pointer to the device structure for the driver instance.

Returns bitmask of supported options.

struct crypto_driver_api
    #include <crypto.h> Crypto driver API definition.

Ciphers API

group crypto_cipher
    Crypto Cipher APIs.

Typedefs

typedef int (*block_op_t)(struct cipher_ctx *ctx, struct cipher_pkt *pkt)

typedef int (*cbc_op_t)(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *iv)

typedef int (*ctr_op_t)(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *ctr)

typedef int (*ccm_op_t)(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)

typedef int (*gcm_op_t)(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)

typedef void (*cipher_completion_cb)(struct cipher_pkt *completed, int status)

Enums

enum cipher_algo
    Cipher Algorithm

Values:

    enumerator CRYPTO_CIPHER_ALGO_AES = 1
enum cipher_op
Cipher Operation
Values:

cryptographer CRYPTO_CIPHER_OP_DECRYPT = 0

cryptographer CRYPTO_CIPHER_OP_ENCRYPT = 1

enum cipher_mode
Possible cipher mode options.
More to be added as required.
Values:

cryptographer CRYPTO_CIPHER_MODE_ECB = 1

cryptographer CRYPTO_CIPHER_MODE_CBC = 2

cryptographer CRYPTO_CIPHER_MODE_CTR = 3

cryptographer CRYPTO_CIPHER_MODE_CCM = 4

cryptographer CRYPTO_CIPHER_MODE_GCM = 5

Functions

static inline int cipher_begin_session(const struct device *dev, struct cipher_ctx *ctx, enum cipher_algo algo, enum cipher_mode mode, enum cipher_op optype)

Setup a crypto session.
Initializes one time parameters, like the session key, algorithm and cipher mode which may remain constant for all operations in the session. The state may be cached in hardware and/or driver data state variables.

Parameters

• dev – Pointer to the device structure for the driver instance.
• ctx – Pointer to the context structure. Various one time parameters like key, keylength, etc. are supplied via this structure. The structure documentation specifies which fields are to be populated by the app before making this call.
• algo – The crypto algorithm to be used in this session. e.g AES
• mode – The cipher mode to be used in this session. e.g CBC, CTR
• optype – Whether we should encrypt or decrypt in this session

Returns 0 on success, negative errno code on fail.
static inline int cipher_free_session(const struct device *dev, struct cipher_ctx *ctx)
Cleanup a crypto session.

Clears the hardware and/or driver state of a previous session.

Parameters

• dev – Pointer to the device structure for the driver instance.
• ctx – Pointer to the crypto context structure of the session to be freed.

Returns 0 on success, negative errno code on fail.

static inline int cipher_callback_set(const struct device *dev, cipher_completion_cb cb)
Registers an async crypto op completion callback with the driver.

The application can register an async crypto op completion callback handler to be invoked by
the driver, on completion of a prior request submitted via cipher_do_op(). Based on crypto
device hardware semantics, this is likely to be invoked from an ISR context.

Parameters

• dev – Pointer to the device structure for the driver instance.
• cb – Pointer to application callback to be called by the driver.

Returns 0 on success, -ENOTSUP if the driver does not support async op, negative
errno code on other error.

static inline int cipher_block_op(struct cipher_ctx *ctx, struct cipher_pkt *pkt)
Perform single-block crypto operation (ECB cipher mode). This should not be overloaded to
operate on multiple blocks for security reasons.

Parameters

• ctx – Pointer to the crypto context of this op.
• pkt – Structure holding the input/output buffer pointers.

Returns 0 on success, negative errno code on fail.

static inline int cipher_cbc_op(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *iv)
Perform Cipher Block Chaining (CBC) crypto operation.

Parameters

• ctx – Pointer to the crypto context of this op.
• pkt – Structure holding the input/output buffer pointers.
• iv – Initialization Vector (IV) for the operation. Same IV value should not be
reused across multiple operations (within a session context) for security.

Returns 0 on success, negative errno code on fail.

static inline int cipher_ctr_op(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *iv)
Perform Counter (CTR) mode crypto operation.

Parameters

• ctx – Pointer to the crypto context of this op.
• pkt – Structure holding the input/output buffer pointers.
• iv – Initialization Vector (IV) for the operation. We use a split counter formed
by appending IV and ctr. Consequently ivlen = keylen - ctrlen. 'ctrlen' is spec-
ified during session setup through the 'ctx.mode_params.ctr_params.ctr_len'
parameter. IV should not be reused across multiple operations (within a ses-
sion context) for security. The non-IV part of the split counter is transparent to
the caller and is fully managed by the crypto provider.

Returns 0 on success, negative errno code on fail.
static inline int cipher_ccm_op(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)
    Perform Counter with CBC-MAC (CCM) mode crypto operation.
    Parameters
    • ctx – Pointer to the crypto context of this op.
    • pkt – Structure holding the input/output, Associated Data (AD) and auth tag buffer pointers.
    • nonce – Nonce for the operation. Same nonce value should not be reused across multiple operations (within a session context) for security.
    Returns 0 on success, negative errno code on fail.

static inline int cipher_gcm_op(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)
    Perform Galois/Counter Mode (GCM) crypto operation.
    Parameters
    • ctx – Pointer to the crypto context of this op.
    • pkt – Structure holding the input/output, Associated Data (AD) and auth tag buffer pointers.
    • nonce – Nonce for the operation. Same nonce value should not be reused across multiple operations (within a session context) for security.
    Returns 0 on success, negative errno code on fail.

struct cipher_ops
    #include <cipher.h>

struct ccm_params
    #include <cipher.h>

struct ctr_params
    #include <cipher.h>

struct gcm_params
    #include <cipher.h>

struct cipher_ctx
    #include <cipher.h> Structure encoding session parameters.
    Refer to comments for individual fields to know the contract in terms of who fills what and when w.r.t begin_session() call.

Public Members

struct cipher_ops ops
    Place for driver to return function pointers to be invoked per cipher operation. To be populated by crypto driver on return from begin_session() based on the algo/mode chosen by the app.

union cipher_ctx.[anonymous] key
    To be populated by the app before calling begin_session()
const struct device *device
   The device driver instance this crypto context relates to. Will be populated by the begin_session() API.

void *drv_sessn_state
   If the driver supports multiple simultaneously crypto sessions, this will identify the specific driver state this crypto session relates to. Since dynamic memory allocation is not possible, it is suggested that at build time drivers allocate space for the max simultaneous sessions they intend to support. To be populated by the driver on return from begin_session().

void *app_sessn_state
   Place for the user app to put info relevant stuff for resuming when completion callback happens for async ops. Totally managed by the app.

union cipher_ctx.[anonymous] mode_params
   Cypher mode parameters, which remain constant for all ops in a session. To be populated by the app before calling begin_session().

uint16_t keylen
   Cryptographic keylength in bytes. To be populated by the app before calling begin_session()

uint16_t flags
   How certain fields are to be interpreted for this session. (A bitmask of CAP_* below.) To be populated by the app before calling begin_session(). An app can obtain the capability flags supported by a hw/driver by calling crypto_query_hwcaps().

struct cipher_pkt
#include <cipher.h> Structure encoding IO parameters of one cryptographic operation like encrypt/decrypt.

The fields which has not been explicitly called out has to be filled up by the app before making the cipher_xxx_op() call.

Public Members

uint8_t *in_buf
   Start address of input buffer

int in_len
   Bytes to be operated upon

uint8_t *out_buf
   Start of the output buffer, to be allocated by the application. Can be NULL for in-place ops. To be populated with contents by the driver on return from op / async callback.

int out_buf_max
   Size of the out_buf area allocated by the application. Drivers should not write past the size of output buffer.

int out_len
   To be populated by driver on return from cipher_xxx_op() and holds the size of the actual result.
struct cipher_ctx *ctx
    Context this packet relates to. This can be useful to get the session details, especially for async ops. Will be populated by the cipher_xxx_op() API based on the ctx parameter.

struct cipher_aead_pkt
    #include <cipher.h> Structure encoding IO parameters in AEAD (Authenticated Encryption with Associated Data) scenario like in CCM.
    App has to furnish valid contents prior to making cipher_ccm_op() call.

Public Members

uint8_t *ad
    Start address for Associated Data. This has to be supplied by app.

uint32_t ad_len
    Size of Associated Data. This has to be supplied by the app.

uint8_t *tag
    Start address for the auth hash. For an encryption op this will be populated by the driver when it returns from cipher_ccm_op call. For a decryption op this has to be supplied by the app.

7.7 Devicetree

This is reference documentation for devicetree as it is used for Zephyr development. For a high-level guide, see Devicetree Guide. For a platform-independent specification, see the Devicetree specification.

7.7.1 Devicetree API

This is a reference page for the <devicetree.h> API. The API is macro based. Use of these macros has no impact on scheduling. They can be used from any calling context and at file scope.

Some of these require a special macro named DT_DRV_COMPAT to be defined before they can be used; these are discussed individually below. These macros are generally meant for use within device drivers, though they can be used outside of drivers with appropriate care.

Generic APIs

The APIs in this section can be used anywhere and do not require DT_DRV_COMPAT to be defined.

Node identifiers and helpers A node identifier is a way to refer to a devicetree node at C preprocessor time. While node identifiers are not C values, you can use them to access devicetree data in C rvalue form using, for example, the Property access API.

The root node / has node identifier DT_ROOT. You can create node identifiers for other devicetree nodes using DT_PATH(), DT_NODELABEL(), DT_ALIAS(), and DT_INST().

There are also DT_PARENT() and DT_CHILD() macros which can be used to create node identifiers for a given node's parent node or a particular child node, respectively.

The following macros create or operate on node identifiers.

7.7. Devicetree
group devicetree-generic-id

Defines

**DT_INVALID_NODE**
Name for an invalid node identifier.

This supports cases where factored macros can be invoked from paths where devicetree data may or may not be available. It is a preprocessor identifier that does not match any valid devicetree node identifier.

**DT_ROOT**
Node identifier for the root node in the devicetree.

**DT_PATH(…)**
Get a node identifier for a devicetree path.

(This macro returns a node identifier from path components. To get a path string from a node identifier, use `DT_NODE_PATH()` instead.)

The arguments to this macro are the names of non-root nodes in the tree required to reach the desired node, starting from the root. Non-alphanumeric characters in each name must be converted to underscores to form valid C tokens, and letters must be lowercased.

Example devicetree fragment:

```c
/ {
    soc {
        serial1: serial@40001000 {
            status = “okay”;
            current-speed = <115200>;
            ... 
        }
    };
};
```

You can use `DT_PATH(soc, serial_40001000)` to get a node identifier for the serial@40001000 node. Node labels like “serial1” cannot be used as `DT_PATH()` arguments; use `DT_NODELABEL()` for those instead.

Example usage with `DT_PROP()` to get the current-speed property:

```c
DT_PROP(DT_PATH(soc, serial_40001000), current_speed) // 115200
```

(The current-speed property is also in “lowercase-and-underscores” form when used with this API.)

When determining arguments to `DT_PATH()`:

- the first argument corresponds to a child node of the root (“soc” above)
- a second argument corresponds to a child of the first argument (“serial_40001000” above, from the node name “serial@40001000” after lowercasing and changing “@” to “_”)
- and so on for deeper nodes in the desired node's path

**Parameters**

- ... – lowercase-and-underscores node names along the node's path, with each name given as a separate argument
**Returns** node identifier for the node with that path

**DT_NODELABEL**(label)
Get a node identifier for a node label.

Convert non-alphanumeric characters in the node label to underscores to form valid C tokens, and lowercase all letters. Note that node labels are not the same thing as label properties.

Example devicetree fragment:
```
serial1: serial@40001000 {
    label = "UART_0";
    status = "okay";
    current-speed = <115200>;
    ...
};
```

The only node label in this example is “serial1”.
The string “UART_0” is not a node label; it’s the value of a property named label.

You can use **DT_NODELABEL**(serial1) to get a node identifier for the serial@40001000 node.

Example usage with **DT_PROP()** to get the current-speed property:
```
DT_PROP(DT_NODELABEL(serial1), current_speed) // 115200
```

Another example devicetree fragment:
```
cpu@0 {
    L2_0: l2-cache {
        cache-level = <2>;
        ...
    };
};
```

Example usage to get the cache-level property:
```
DT_PROP(DT_NODELABEL(L2_0), cache_level) // 2
```

Notice how “L2_0” in the devicetree is lowercased to “l2_0” in the **DT_NODELABEL()** argument.

**Parameters**
- label – lowercase-and-underscores node label name

**Returns** node identifier for the node with that label

**DT_ALIAS**(alias)
Get a node identifier from /aliases.

This macro’s argument is a property of the /aliases node. It returns a node identifier for the node which is aliased. Convert non-alphanumeric characters in the alias property to underscores to form valid C tokens, and lowercase all letters.

Example devicetree fragment:
```
/ {
    aliases {
        my-serial = &serial1;
    };
    soc {
        serial1: serial@40001000 {
```

(continues on next page)
You can use `DT_ALIAS(my_serial)` to get a node identifier for the serial@40001000 node. Notice how my-serial in the devicetree becomes my_serial in the `DT_ALIAS()` argument. Example usage with `DT_PROP()` to get the current-speed property:

```
DT_PROP(DT_ALIAS(my_serial), current_speed) // 115200
```

**Parameters**

- `alias` - lowercase-and-underscores alias name.

**Returns** node identifier for the node with that alias

`DT_INST(inst, compat)`

Get a node identifier for an instance of a compatible.

All nodes with a particular compatible property value are assigned instance numbers, which are zero-based indexes specific to that compatible. You can get a node identifier for these nodes by passing `DT_INST()` an instance number, “inst”, along with the lowercase-and-underscores version of the compatible, “compat”.

Instance numbers have the following properties:

- for each compatible, instance numbers start at 0 and are contiguous
- exactly one instance number is assigned for each node with a compatible, including disabled nodes
- enabled nodes (status property is “okay” or missing) are assigned the instance numbers starting from 0, and disabled nodes have instance numbers which are greater than those of any enabled node

No other guarantees are made. In particular:

- instance numbers in no way reflect any numbering scheme that might exist in SoC documentation, node labels or unit addresses, or properties of the /aliases node (use `DT_NODELABEL()` or `DT_ALIAS()` for those)
- there is no general guarantee that the same node will have the same instance number between builds, even if you are building the same application again in the same build directory

Example devicetree fragment:

```
serial1: serial@40001000 {
    compatible = "vnd,soc-serial";
    status = "okay";
    current-speed = <115200>;
    ...
};

serial2: serial@40002000 {
    compatible = "vnd,soc-serial";
    ...
};
```

(continues on next page)
status = "okay";
current-speed = <57600>;

serial3: serial@40003000 {
    compatible = "vnd,soc-serial";
current-speed = <115200>;
}

Assuming no other nodes in the devicetree have compatible “vnd,soc-serial”, that compatible has nodes with instance numbers 0, 1, and 2.

The nodes serial@40002000 and serial@40003000 are both enabled, so their instance numbers are 0 and 1, but no guarantees are made regarding which node has which instance number.

Since serial@40001000 is the only disabled node, it has instance number 2, since disabled nodes are assigned the largest instance numbers. Therefore:

// Could be 57600 or 115200. There is no way to be sure:
// either serial@40002000 or serial@40003000 could
// have instance number 0, so this could be the current-speed
// property of either of those nodes.
DT_PROP(DT_INST(0, vnd_soc_serial), current_speed)

// Could be 57600 or 115200, for the same reason.
// If the above expression expands to 57600, then
// this expands to 115200, and vice-versa.
DT_PROP(DT_INST(1, vnd_soc_serial), current_speed)

// 9600, because there is only one disabled node, and
// disabled nodes are "at the the end" of the instance
// number "list".
DT_PROP(DT_INST(2, vnd_soc_serial), current_speed)

Notice how “vnd,soc-serial” in the devicetree becomes vnd_soc_serial (without quotes) in the DT_INST() arguments. (As usual, current-speed in the devicetree becomes current_speed as well.)

Nodes whose “compatible” property has multiple values are assigned independent instance numbers for each compatible.

**Parameters**
- **inst** – instance number for compatible “compat”
- **compat** – lowercase-and-underscores compatible, without quotes

**Returns** node identifier for the node with that instance number and compatible

DT_PARENT(node_id)
Get a node identifier for a parent node.

Example devicetree fragment:

parent: parent-node {
    child: child-node {
        ...
}
The following are equivalent ways to get the same node identifier:

```
DT_NODELABEL(parent)
DT_PARENT(DT_NODELABEL(child))
```

**Parameters**

- node_id – node identifier

**Returns** a node identifier for the node’s parent

```
DT_INST_PARENT(inst)
```

Get a DT_DRV_COMPAT parent’s node identifier.

**Parameters**

- inst – instance number

**Returns** a node identifier for the instance’s parent

```
DT_GPARENT(node_id)
```

Get a node identifier for a grandparent node.

Example devicetree fragment:

```
gparent: grandparent-node {
    parent: parent-node {
        child: child-node {
        }
    }
};
```

The following are equivalent ways to get the same node identifier:

```
DT_GPARENT(DT_NODELABEL(child))
DT_PARENT(DT_PARENT(DT_NODELABEL(child))
```

**Parameters**

- node_id – node identifier

**Returns** a node identifier for the node’s parent’s parent

```
DT_CHILD(node_id, child)
```

Get a node identifier for a child node.

Example devicetree fragment:

```
/ {
    soc-label: soc {
        serial1: serial@40001000 {
            status = "okay";
            current-speed = <115200>;
            ...
        }
    }
};
```

Example usage with `DT_PROP()` to get the status of the serial@40001000 node:
Node labels like “serial1” cannot be used as the “child” argument to this macro. Use `DT_NODELABEL()` for that instead.

You can also use `DT_FOREACH_CHILD()` to iterate over node identifiers for all of a node's children.

**Parameters**
- `node_id` – node identifier
- `child` – lowercase-and-underscores child node name

**Returns**
node identifier for the node with the name referred to by ‘child’

**Example devicetree fragment:**
```
node-a {
    compatible = "vnd,device";
    status = "okay";
};

node-b {
    compatible = "vnd,device";
    status = "okay";
};

node-c {
    compatible = "vnd,device";
    status = "disabled";
};
```

**Example usage:**
```
DT_COMPAT_GET_ANY_STATUS_OKAY(vnd_device)
```
This expands to a node identifier for either `node-a` or `node-b`. It will not expand to a node identifier for `node-c`, because that node does not have status “okay”.

**Parameters**
- `compat` – lowercase-and-underscores compatible, without quotes

**Returns**
node identifier for a node with that compatible, or `DT_INVALID_NODE`

**DT_NODE_PATH(node_id)**
Get a devicetree node's full path as a string literal.

This returns the path to a node from a node identifier. To get a node identifier from path components instead, use `DT_PATH()`.

**Example devicetree fragment:**
```
/ {
    soc {
        node: my-node@12345678 { ... }
    }
```
Example usage:

```
DT_NODE_PATH(DT_NODELABEL(node)) // "soc/my-node@12345678"
DT_NODE_PATH(DT_PATH(soc)) // "soc" DT_NODE_PATH(DT_ROOT) // "/
```

**Parameters**
- `node_id` – node identifier

**Returns**
the node's full path in the devicetree

### DT_NODE_FULL_NAME(node_id)

Get a devicetree node’s name with unit-address as a string literal.
This returns the node name and unit-address from a node identifier.

Example devicetree fragment:

```
/ {
   soc {
      node: my-node@12345678 { ... }
   }
};
```

Example usage:

```
DT_NODE_FULL_NAME(DT_NODELABEL(node)) // "my-node@12345678"
```

**Parameters**
- `node_id` – node identifier

**Returns**
the node's name with unit-address as a string in the devicetree

### DT_SAME_NODE(node_id1, node_id2)

Do `node_id1` and `node_id2` refer to the same node?

Both “node_id1” and “node_id2” must be node identifiers for nodes that exist in the devicetree
(if unsure, you can check with `DT_NODE_EXISTS()`).

The expansion evaluates to 0 or 1, but may not be a literal integer 0 or 1.

**Parameters**
- `node_id1` – first node identifier
- `node_id2` – second node identifier

**Returns**
an expression that evaluates to 1 if the node identifiers refer to the same
node, and evaluates to 0 otherwise

---

**Property access**
The following general-purpose macros can be used to access node properties. There
are special-purpose APIs for accessing the `ranges property`, `reg property` and `interrupts property`.

Property values can be read using these macros even if the node is disabled, as long as it has a matching
binding.

```
group devicetree-generic-prop
```
Defines

**DT_PROP(node_id, prop)**
Get a devicetree property value.

For properties whose bindings have the following types, this macro expands to:

- string: a string literal
- boolean: 0 if the property is false, or 1 if it is true
- int: the property's value as an integer literal
- array, uint8-array, string-array: an initializer expression in braces, whose elements are integer or string literals (like {0, 1, 2}, {"hello", "world"}, etc.)
- phandle: a node identifier for the node with that phandle

A property's type is usually defined by its binding. In some special cases, it has an assumed type defined by the devicetree specification even when no binding is available: “compatible” has type string-array, “status” and “label” have type string, and “interrupt-controller” has type boolean.

For other properties or properties with unknown type due to a missing binding, behavior is undefined.

For usage examples, see **DT_PATH**, **DT_ALIAS**, **DT_NODELABEL**, and **DT_INST** above.

**Parameters**

- node_id – node identifier
- prop – lowercase-and-underscores property name

**Returns** a representation of the property's value

**DT_PROP_LEN(node_id, prop)**
Get a property's logical length.

Here, “length” is a number of elements, which may differ from the property's size in bytes.

The return value depends on the property's type:

- for types array, string-array, and uint8-array, this expands to the number of elements in the array
- for type phandles, this expands to the number of phandles
- for type phandle-array, this expands to the number of phandle and specifier blocks in the property

These properties are handled as special cases:

- reg property: use **DT_NUM_REGS(node_id)** instead
- interrupts property: use **DT_NUM_IRQS(node_id)** instead

It is an error to use this macro with the ranges, dma-ranges, reg or interrupts properties.

For other properties, behavior is undefined.

**Parameters**

- node_id – node identifier
- prop – a lowercase-and-underscores property with a logical length
**Returns** the property’s length

DT_PROP_LEN_OR(node_id, prop, default_value)

Like DT_PROP_LEN(), but with a fallback to default_value.

If the property is defined (as determined by DT_NODE_HAS_PROP()), this expands to DT_PROP_LEN(node_id, prop). The default_value parameter is not expanded in this case.

Otherwise, this expands to default_value.

**Parameters**
- node_id – node identifier
- prop – a lowercase-and-underscores property with a logical length
- default_value – a fallback value to expand to

**Returns** the property's length or the given default value

DT_PROP_HAS_IDX(node_id, prop, idx)

Is index “idx” valid for an array type property?

If this returns 1, then DT_PROP_BY_IDX(node_id, prop, idx) or DT_PHA_BY_IDX(node_id, prop, idx, ...) are valid at index “idx”. If it returns 0, it is an error to use those macros with that index.

These properties are handled as special cases:

- reg property: use DT_REG_HAS_IDX(node_id, idx) instead
- interrupts property: use DT_IRQ_HAS_IDX(node_id, idx) instead

It is an error to use this macro with the reg or interrupts properties.

**Parameters**
- node_id – node identifier
- prop – a lowercase-and-underscores property with a logical length
- idx – index to check

**Returns** An expression which evaluates to 1 if “idx” is a valid index into the given property, and 0 otherwise.

DT_PROP_HAS_NAME(node_id, prop, name)

Is name “name” available in a foo-names property?

This property is handled as special case:

- interrupts property: use DT_IRQ_HAS_NAME(node_id, idx) instead

It is an error to use this macro with the interrupts property.

Example devicetree fragment:

```c
nx: node-x {
    foos = <&bar xx yy>, <&baz xx zz>;
    foo-names = "event", "error";
    status = "okay";
};
```

Example usage:

```c
DT_PROP_HAS_NAME(nx, foos, event)   // 1
DT_PROP_HAS_NAME(nx, foos, failure) // 0
```
Parameters
- node_id – node identifier
- prop – a lowercase-and-underscores "prop-names" type property
- name – a lowercase-and-underscores name to check

Returns An expression which evaluates to 1 if “name” is an available name into the given property, and 0 otherwise.

DT_PROP_BY_IDX(node_id, prop, idx)
Get the value at index “idx” in an array type property.
It might help to read the argument order as being similar to “node->property[index]”.
When the property’s binding has type array, string-array, uint8-array, or phandles, this expands to the idx-th array element as an integer, string literal, or node identifier respectively.
These properties are handled as special cases:

- reg property: use DT_REG_ADDR_BY_IDX() or DT_REG_SIZE_BY_IDX() instead
- interrupts property: use DT_IRQ_BY_IDX() instead

For non-array properties, behavior is undefined.

Parameters
- node_id – node identifier
- prop – lowercase-and-underscores property name
- idx – the index to get

Returns a representation of the idx-th element of the property

DT_PROP_OR(node_id, prop, default_value)
Like DT_PROP(), but with a fallback to default_value.
If the value exists, this expands to DT_PROP(node_id, prop). The default_value parameter is not expanded in this case.
Otherwise, this expands to default_value.

Parameters
- node_id – node identifier
- prop – lowercase-and-underscores property name
- default_value – a fallback value to expand to

Returns the property's value or default_value

DT_LABEL(node_id)
Equivalent to DT_PROP(node_id, label)
This is a convenience for the Zephyr device API, which uses label properties as device_get_binding() arguments.

Parameters
- node_id – node identifier

Returns node’s label property value

DT_ENUM_IDX(node_id, prop)
Get a property value's index into its enumeration values.
The return values start at zero.
Example devicetree fragment:

```c
usb1: usb@12340000 {
    maximum-speed = "full-speed";
};
usb2: usb@12341000 {
    maximum-speed = "super-speed";
};
```

Example bindings fragment:

```c
properties:
    maximum-speed:
        type: string
        enum:
            - "low-speed"
            - "full-speed"
            - "high-speed"
            - "super-speed"
```

Example usage:

```c
DT_ENUM_IDX(DT_NODELABEL(usb1), maximum_speed) // 1
DT_ENUM_IDX(DT_NODELABEL(usb2), maximum_speed) // 3
```

Parameters

- `node_id` – node identifier
- `prop` – lowercase-and-underscores property name

Returns

zero-based index of the property's value in its enum: list

```c
DT_ENUM_IDX_OR(node_id, prop, default_idx_value)
```

Like `DT_ENUM_IDX()`, but with a fallback to a default enum index.

If the value exists, this expands to its zero based index value thanks to `DT_ENUM_IDX(node_id, prop)`.

Otherwise, this expands to provided default index enum value.

Parameters

- `node_id` – node identifier
- `prop` – lowercase-and-underscores property name
- `default_idx_value` – a fallback index value to expand to

Returns

zero-based index of the property's value in its enum if present, default_idx_value otherwise

```c
DT_STRING_TOKEN(node_id, prop)
```

Get a string property's value as a token.

This removes “the quotes” from string-valued properties, and converts non-alphanumeric characters to underscores. That can be useful, for example, when programmatically using the value to form a C variable or code.

`DT_STRING_TOKEN()` can only be used for properties with string type.

It is an error to use `DT_STRING_TOKEN()` in other circumstances.

Example devicetree fragment:
Example bindings fragment:

```c
properties:
  prop:
    type: string
```

Example usage:

```c
DT_STRING_TOKEN(DT_NODELABEL(n1), prop) // foo
DT_STRING_TOKEN(DT_NODELABEL(n2), prop) // FOO
DT_STRING_TOKEN(DT_NODELABEL(n3), prop) // 123_foo
```

Notice how:

- Unlike C identifiers, the property values may begin with a number. It’s the user’s responsibility not to use such values as the name of a C identifier.
- The uppercased “FOO” in the DTS remains FOO as a token. It is not converted to foo.
- The whitespace in the DTS “123 foo” string is converted to 123_foo as a token.

### Parameters

- `node_id` – node identifier
- `prop` – lowercase-and-underscores property string name

### Returns

The value of `prop` as a token, i.e. without any quotes and with special characters converted to underscores

```c
DT_STRING_UPPER_TOKEN(node_id, prop)
```

Like `DT_STRING_TOKEN()`, but uppercased.

This removes “the quotes and capitalize” from string-valued properties, and converts non-alphanumeric characters to underscores. That can be useful, for example, when programmatically using the value to form a C variable or code.

`DT_STRING_UPPER_TOKEN()` can only be used for properties with string type.

It is an error to use `DT_STRING_UPPER_TOKEN()` in other circumstances.

Example devicetree fragment:

```c
n1: node-1 {
    prop = "foo";
}
```

Example bindings fragment:

```c
7.7. Devicetree
473
```
properties:
  prop:
    type: string

Example usage:

```
DT_STRING_UPPER_TOKEN(DT_NODELABEL(n1), prop) // FOO
DT_STRING_UPPER_TOKEN(DT_NODELABEL(n2), prop) // 123_FOO
```

Notice how:

- Unlike C identifiers, the property values may begin with a number. It's the user's responsibility not to use such values as the name of a C identifier.
- The lowercased “foo” in the DTS becomes FOO as a token, i.e. it is uppercased.
- The whitespace in the DTS “123 foo” string is converted to 123_FOO as a token, i.e. it is uppercased and whitespace becomes an underscore.

**Parameters**

- **node_id** – node identifier
- **prop** – lowercase-and-underscores property string name

**Returns** the value of prop as a token, i.e. without any quotes and with special characters converted to underscores

```
DT_PROP_BY_PHANDLE_IDX(node_id, phs, idx, prop)
```

Get a property value from a phandle in a property.

This is a shorthand for:

```
DT_PROP(DT_PHANDLE_BY_IDX(node_id, phs, idx), prop)
```

That is, “prop” is a property of the phandle's node, not a property of “node_id”.

Example devicetree fragment:

```
n1: node-1 {
    foo = <&n2 &n3>;
};
n2: node-2 {
    bar = <42>;
};
n3: node-3 {
    baz = <43>;
};
```

Example usage:

```
#define N1 DT_NODELABEL(n1)

DT_PROP_BY_PHANDLE_IDX(N1, foo, 0, bar) // 42
DT_PROP_BY_PHANDLE_IDX(N1, foo, 1, baz) // 43
```

**Parameters**

- **node_id** – node identifier
• `phs` – lowercase-and-underscores property with type “phandle”, “phandles”, or “phandle-array”
• `idx` – logical index into “phs”, which must be zero if “phs” has type “phandle”
• `prop` – lowercase-and-underscores property of the phandle’s node

**Returns** the property’s value

\[
\text{DT_PROP_BY_PHANDLE_IDX_OR(node_id, phs, idx, prop, default_value)}
\]

Like \textit{DT_PROP_BY_PHANDLE_IDX()}, but with a fallback to `default_value`.

If the value exists, this expands to \text{DT_PROP_BY_PHANDLE_IDX(node_id, phs, idx, prop)}. The `default_value` parameter is not expanded in this case.

Otherwise, this expands to `default_value`.

**Parameters**

• `node_id` – node identifier
• `phs` – lowercase-and-underscores property with type “phandle”, “phandles”, or “phandle-array”
• `idx` – logical index into “phs”, which must be zero if “phs” has type “phandle”
• `prop` – lowercase-and-underscores property of the phandle’s node
• `default_value` – a fallback value to expand to

**Returns** the property’s value

\[
\text{DT_PROP_BY_PHANDLE(node_id, ph, prop)}
\]

Get a property value from a phandle’s node.

This is equivalent to \textit{DT_PROP_BY_PHANDLE_IDX(node_id, ph, 0, prop)}.

**Parameters**

• `node_id` – node identifier
• `ph` – lowercase-and-underscores property of “node_id” with type “phandle”
• `prop` – lowercase-and-underscores property of the phandle’s node

**Returns** the property’s value

\[
\text{DT_PHA_BY_IDX(node_id, pha, idx, cell)}
\]

Get a phandle-array specifier cell value at an index.

It might help to read the argument order as being similar to “node->phandle_array[index].cell”. That is, the cell value is in the “pha” property of “node_id”, inside the specifier at index “idx”.

Example devicetree fragment:

```plaintext
gpio0: gpio0... {
    #gpio-cells = <2>;
}/tty; 

gpio1: gpio1... {
    #gpio-cells = <2>;
} 
led: led_0 {
    gpis = <&gpio0 17 0x1>, <&gpio1 5 0x3>;
}
```

Bindings fragment for the gpio0 and gpio1 nodes:
gpio-cells:
  - pin
  - flags

Above, “gpios” has two elements:

  • index 0 has specifier <17 0x1>, so its “pin” cell is 17, and its “flags” cell is 0x1
  • index 1 has specifier <5 0x3>, so “pin” is 5 and “flags” is 0x3

Example usage:

```c
#define LED DT_NODELABEL(led)
DT_PHA_BY_IDX(LED, gpios, 0, pin) // 17
DT_PHA_BY_IDX(LED, gpios, 1, flags) // 0x3
```

### Parameters

- **node_id** – node identifier
- **pha** – lowercase-and-underscores property with type “phandle-array”
- **idx** – logical index into “pha”
- **cell** – lowercase-and-underscores cell name within the specifier at “pha” index “idx”

### Returns

The cell's value

Like `DT_PHA_BY_IDX(node_id, pha, idx, cell)`, but with a fallback to `default_value`.

If the value exists, this expands to `DT_PHA_BY_IDX(node_id, pha, idx, cell)`. The `default_value` parameter is not expanded in this case.

Otherwise, this expands to `default_value`.

### Parameters

- **node_id** – node identifier
- **pha** – lowercase-and-underscores property with type “phandle-array”
- **idx** – logical index into “pha”
- **cell** – lowercase-and-underscores cell name within the specifier at “pha” index “idx”
- **default_value** – a fallback value to expand to

### Returns

The cell's value or “default_value”

Equivalent to `DT_PHA_BY_IDX(node_id, pha, 0, cell)`

### Parameters

- **node_id** – node identifier
- **pha** – lowercase-and-underscores property with type “phandle-array”
- **cell** – lowercase-and-underscores cell name

### Returns

The cell's value
DT_PHA_OR(node_id, pha, cell, default_value)
Like DT_PHA(), but with a fallback to default_value.
If the value exists, this expands to DT_PHA(node_id, pha, cell). The default_value parameter is not expanded in this case.
Otherwise, this expands to default_value.

Parameters
• node_id – node identifier
• pha – lowercase-and-underscores property with type “phandle-array”
• cell – lowercase-and-underscores cell name
• default_value – a fallback value to expand to

Returns
the cell’s value or default_value

DT_PHA_BY_NAME(node_id, pha, name, cell)
Get a value within a phandle-array specifier by name.
This is like DT_PHA_BY_IDX(), except it treats “pha” as a structure where each array element has a name.

It might help to read the argument order as being similar to “node->phandle_struct.name.cell”. That is, the cell value is in the “pha” property of “node_id”, treated as a data structure where each array element has a name.

Example devicetree fragment:

```plaintext
n: node {
  io-channels = <&adc1 10>, <&adc2 20>;
  io-channel-names = "SENSOR", "BANDGAP";
};
```

Bindings fragment for the “adc1” and “adc2” nodes:

```plaintext
io-channel-cells:
- input
```

Example usage:

```plaintext
DT_PHA_BY_NAME(DT_NODELABEL(n), io_channels, sensor, input) // 10
DT_PHA_BY_NAME(DT_NODELABEL(n), io_channels, bandgap, input) // 20
```

Parameters
• node_id – node identifier
• pha – lowercase-and-underscores property with type “phandle-array”
• name – lowercase-and-underscores name of a specifier in “pha”
• cell – lowercase-and-underscores cell name in the named specifier

Returns
the cell’s value

DT_PHA_BY_NAME_OR(node_id, pha, name, cell, default_value)
Like DT_PHA_BY_NAME(), but with a fallback to default_value.
If the value exists, this expands to DT_PHA_BY_NAME(node_id, pha, name, cell). The default_value parameter is not expanded in this case.
Otherwise, this expands to default_value.

Parameters
• **node_id** – node identifier
• **pha** – lowercase-and-underscores property with type “phandle-array”
• **name** – lowercase-and-underscores name of a specifier in “pha”
• **cell** – lowercase-and-underscores cell name in the named specifier
• **default_value** – a fallback value to expand to

**Returns** the cell’s value or default_value

```
DT_PHANDLE_BY_NAME(node_id, pha, name)
```

Get a phandle's node identifier from a phandle array by name.

It might help to read the argument order as being similar to “node->phandle_struct.name.phandle”. That is, the phandle array is treated as a structure with named elements. The return value is the node identifier for a phandle inside the structure.

Example devicetree fragment:

```plaintext
adc1: adc@... {
    label = "ADC_1";
};
adc2: adc@... {
    label = "ADC_2";
};

n: node {
    io-channels = &adc1 10, &adc2 20;
    io-channel-names = "SENSOR", "BANDGAP";
};
```

Above, “io-channels” has two elements:

• the element named “SENSOR” has phandle &adc1
• the element named “BANDGAP” has phandle &adc2

Example usage:

```
#define NODE DT_NODELABEL(n)

DT_LABEL(DT_PHANDLE_BY_NAME(NODE, io_channels, sensor)) // "ADC_1"
DT_LABEL(DT_PHANDLE_BY_NAME(NODE, io_channels, bandgap)) // "ADC_2"
```

Notice how devicetree properties and names are lowercased, and non-alphanumeric characters are converted to underscores.

**Parameters**

• **node_id** – node identifier
• **pha** – lowercase-and-underscores property with type “phandle-array”
• **name** – lowercase-and-underscores name of an element in “pha”

**Returns** a node identifier for the node with that phandle

```
DT_PHANDLE_BY_IDX(node_id, prop, idx)
```

Get a node identifier for a phandle in a property.

When a node's value at a logical index contains a phandle, this macro returns a node identifier for the node with that phandle.
Therefore, if “prop” has type “phandle”, “idx” must be zero. (A “phandle” type is treated as a “phandles” with a fixed length of 1).

Example devicetree fragment:

```c
n1: node-1 {
    foo = &n2 &n3;
};

n2: node-2 {
    ...
};
n3: node-3 {
    ...
};
```

Above, “foo” has type phandles and has two elements:

- index 0 has phandle &n2, which is node-2’s phandle
- index 1 has phandle &n3, which is node-3’s phandle

Example usage:

```c
#define N1 DT_NODELABEL(n1)

DT_PHANDLE_BY_IDX(N1, foo, 0) // node identifier for node-2
DT_PHANDLE_BY_IDX(N1, foo, 1) // node identifier for node-3
```

Behavior is analogous for phandle-arrays.

**Parameters**

- `node_id` – node identifier
- `prop` – lowercase-and-underscores property name in “node_id” with type “phandle”, “phandles” or “phandle-array”
- `idx` – index into “prop”

**Returns** node identifier for the node with the phandle at that index

**DT_PHANDLE**(`node_id`, `prop`)

Get a node identifier for a phandle property’s value.

This is equivalent to `DT_PHANDLE_BY_IDX(node_id, prop, 0)`. Its primary benefit is readability when “prop” has type “phandle”.

**Parameters**

- `node_id` – node identifier
- `prop` – lowercase-and-underscores property of “node_id” with type “phandle”

**Returns** a node identifier for the node pointed to by “ph”

**ranges property** Use these APIs instead of `Property access` to access the ranges property. Because this property’s semantics are defined by the devicetree specification, these macros can be used even for nodes without matching bindings. However, they take on special semantics when the node's binding indicates it is a PCIe bus node, as defined in the PCI Bus Binding to: IEEE Std 1275-1994 Standard for Boot (Initialization Configuration) Firmware

**group devicetree-ranges-prop**
Defines

**DT_NUM_RANGES(node_id)**
Get the number of range blocks in the ranges property.
Use this instead of **DT_PROP_LEN(node_id, ranges)**.

Example devicetree fragment:

```plaintext
pcie0: pcie@0 {
    compatible = "intel,pcie";
    reg = <0 1>;
    #address-cells = <3>;
    #size-cells = <2>;

    ranges = <0x1000000 0 0 0x3eff0000 0 0x10000>,
             <0x2000000 0x10000000 0 0x10000000 0 0x2eff0000>,
             <0x3000000 0x80 0x80 0x80 0x80 0x80>;
};

other: other@1 {
    reg = <1 1>;

    ranges = <0x0 0x0 0x0 0x3eff0000 0x10000>,
             <0x0 0x10000000 0x0 0x10000000 0x2eff0000>;
};
```

Example usage:

```
DT_NUM_RANGES(DT_NODELABEL(pcie0)) // 3
DT_NUM_RANGES(DT_NODELABEL(other)) // 2
```

Parameters

- **node_id** – node identifier

**DT_RANGES_HAS_IDX(node_id, idx)**
Is "idx" a valid range block index?
If this returns 1, then **DT_RANGES_CHILD_BUS_ADDRESS_BY_IDX(node_id, idx)**, **DT_RANGES_PARENT_BUS_ADDRESS_BY_IDX(node_id, idx)** or **DT_RANGES_LENGTH_BY_IDX(node_id, idx)** are valid. For **DT_RANGES_CHILD_BUS_FLAGS_BY_IDX(node_id, idx)** or **DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(node_id, idx)** the return value of **DT_RANGES_CHILD_BUS_FLAGS_BY_IDX(node_id, idx)** will indicate validity.
If it returns 0, it is an error to use those macros with index "idx", including **DT_RANGES_CHILD_BUS_FLAGS_BY_IDX(node_id, idx)**.

Example devicetree fragment:

```plaintext
pcie0: pcie@0 {
    compatible = "intel,pcie";
    reg = <0 1>;
    #address-cells = <3>;
    #size-cells = <2>;

    ranges = <0x1000000 0 0 0x3eff0000 0 0x10000>,
             <0x2000000 0x10000000 0 0x10000000 0 0x2eff0000>,
             <0x3000000 0x80 0x80 0x80 0x80 0x80>;
};
```
Example usage:

```
DT_RANGES_HAS_IDX(DT_NODELABEL(pcie0), 0) // 1
DT_RANGES_HAS_IDX(DT_NODELABEL(pcie0), 1) // 1
DT_RANGES_HAS_IDX(DT_NODELABEL(pcie0), 2) // 1
DT_RANGES_HAS_IDX(DT_NODELABEL(pcie0), 3) // 0
DT_RANGES_HAS_IDX(DT_NODELABEL(other), 0) // 1
DT_RANGES_HAS_IDX(DT_NODELABEL(other), 1) // 1
DT_RANGES_HAS_IDX(DT_NODELABEL(other), 2) // 0
DT_RANGES_HAS_IDX(DT_NODELABEL(other), 3) // 0
```

**Parameters**

- node_id – node identifier
- idx – index to check

**Returns** 1 if “idx” is a valid register block index, 0 otherwise.

`DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(node_id, idx)`

Does a ranges property have child bus flags at index?

If this returns 1, then `DT_RANGES_CHILD_BUS_FLAGS_BY_IDX(node_id, idx)` is valid. If it returns 0, it is an error to use this macro with index “idx”. This macro only returns 1 for PCIe buses (i.e. nodes whose bindings specify they are “pcie” bus nodes.)

Example devicetree fragment:

```
parent {
    #address-cells = <2>;

    pcie0: pcie00 {
        compatible = "intel.pcie";
        reg = <0 0 1>;
        #address-cells = <3>;
        #size-cells = <2>;
        ranges = <0x1000000 0 0 0x3eff0000 0x10000>,
                 <0x2000000 0x10000000 0x10000000 0x2eff0000>,
                 <0x3000000 0x80 0 0x80 0x80 0x80 0>;
    };

    other: other01 {
        reg = <0 1 1>;
        ranges = <0x0 0x0 0x3eff0000 0x10000>,
                 <0x0 0x10000000 0x0 0x10000000 0x2eff0000>;
    };
};
```
Example usage:

```c
DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(DT_NODELABEL(pcie0), 0) // 1
DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(DT_NODELABEL(pcie0), 1) // 1
DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(DT_NODELABEL(pcie0), 2) // 1
DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(DT_NODELABEL(pcie0), 3) // 0
DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(DT_NODELABEL(other), 0) // 0
DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(DT_NODELABEL(other), 1) // 0
DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(DT_NODELABEL(other), 2) // 0
DT_RANGES_HAS_CHILD_BUS_FLAGS_AT_IDX(DT_NODELABEL(other), 3) // 0
```

**Parameters**

- **node_id** – node identifier
- **idx** – logical index into the ranges array

**Returns** 1 if “idx” is a valid child bus flags index, 0 otherwise.

```c
DT_RANGES_CHILD_BUS_FLAGS_BY_IDX(node_id, idx)
```

Get the ranges property child bus flags at index.

When the node is a PCIe bus, the Child Bus Address has an extra cell used to store some flags, thus this cell is extracted from the Child Bus Address as Child Bus Flags field.

Example devicetree fragments:

```devicetree
parent {
    #address-cells = <2>;

    pcie0: pcie@0 {
        compatible = "intel,pcie";
        reg = <0 0 1>;
        #address-cells = <3>;
        #size-cells = <2>;

        ranges = <0x1000000 0 0 0x3eff0000 0 0x10000>,
                  <0x2000000 0x10000000 0 0x10000000 0 0x2eff0000>,
                  <0x3000000 0x80 0 0x80 0 0x80 0>;
    }
};
```

Example usage:

```c
DT_RANGES_CHILD_BUS_FLAGS_BY_IDX(DT_NODELABEL(pcie0), 0) // 0x1000000
DT_RANGES_CHILD_BUS_FLAGS_BY_IDX(DT_NODELABEL(pcie0), 1) // 0x2000000
DT_RANGES_CHILD_BUS_FLAGS_BY_IDX(DT_NODELABEL(pcie0), 2) // 0x3000000
```

**Parameters**

- **node_id** – node identifier
- **idx** – logical index into the ranges array

**Returns** range child bus flags field at idx

```c
DT_RANGES_CHILD_BUS_ADDRESS_BY_IDX(node_id, idx)
```

Get the ranges property child bus address at index.

When the node is a PCIe bus, the Child Bus Address has an extra cell used to store some flags, thus this cell is removed from the Child Bus Address.

Example devicetree fragments:
parent {
    #address-cells = <2>;
    pcie0: pcie00 {
        compatible = "intel,pcie";
        reg = <0 0 1>;
        #address-cells = <3>;
        #size-cells = <2>;
        ranges = <0x1000000 0 0 0x3eff0000 0 0x10000>,
                  <0x2000000 0x10000000 0 0x10000000 0 0x2eff0000>,
                  <0x3000000 0x80 0 0x80 0 0x80 0>;
    };
    other: other@1 {
        reg = <0 1 1>;
        ranges = <0x0 0x0 0x0 0x3eff0000 0x10000>,
                  <0x0 0x10000000 0x0 0x10000000 0x2eff0000>;
    };
};

Example usage:

DT_RANGES_CHILD_BUS_ADDRESS_BY_IDX(DT_NODELABEL(pcie0), 0) // 0
DT_RANGES_CHILD_BUS_ADDRESS_BY_IDX(DT_NODELABEL(pcie0), 1) // 0x10000000
DT_RANGES_CHILD_BUS_ADDRESS_BY_IDX(DT_NODELABEL(pcie0), 2) // 0x8000000000
DT_RANGES_CHILD_BUS_ADDRESS_BY_IDX(DT_NODELABEL(other), 0) // 0
DT_RANGES_CHILD_BUS_ADDRESS_BY_IDX(DT_NODELABEL(other), 1) // 0x10000000

Parameters

• node_id – node identifier
• idx – logical index into the ranges array

Returns range child bus address field at idx

DT_RANGES_PARENT_BUS_ADDRESS_BY_IDX(node_id, idx)
Get the ranges property parent bus address at index.

Similarly to DT_RANGES_CHILD_BUS_ADDRESS_BY_IDX(), this properly accounts for child
bus flags cells when the node is a PCIe bus.

Example devicetree fragment:

parent {
    #address-cells = <2>;
    pcie0: pcie00 {
        compatible = "intel,pcie";
        reg = <0 0 1>;
        #address-cells = <3>;
        #size-cells = <2>;
        ranges = <0x1000000 0 0 0x3eff0000 0 0x10000>,
                  <0x2000000 0x10000000 0 0x10000000 0 0x2eff0000>,
                  <0x3000000 0x80 0 0x80 0 0x80 0>;
    };
}
other: other@1 {
    reg = <0 1 1>;
    ranges = <0x0 0x0 0x0 0x3eff0000 0x10000>,
             <0x0 0x10000000 0x0 0x10000000 0x2eff0000>;
};
}

Example usage:

DT_RANGES_PARENT_BUS_ADDRESS_BY_IDX(DT_NODELABEL(pcie0), 0) // 0x3eff0000
DT_RANGES_PARENT_BUS_ADDRESS_BY_IDX(DT_NODELABEL(pcie0), 1) // 0x10000000
DT_RANGES_PARENT_BUS_ADDRESS_BY_IDX(DT_NODELABEL(pcie0), 2) // 0x8000000000
DT_RANGES_PARENT_BUS_ADDRESS_BY_IDX(DT_NODELABEL(other), 0) // 0x3eff0000
DT_RANGES_PARENT_BUS_ADDRESS_BY_IDX(DT_NODELABEL(other), 1) // 0x10000000

Parameters
- node_id – node identifier
- idx – logical index into the ranges array

Returns range parent bus address field at idx

DT_RANGES_LENGTH_BY_IDX(node_id, idx)
Get the ranges property length at index.

Similarly to DT_RANGES_CHILD_BUS_ADDRESS_BY_IDX(), this properly accounts for child
bus flags cells when the node is a PCIe bus.

Example devicetree fragment:

parent {
    #address-cells = <2>;

    pcie0: pcie00 {
        compatible = "intel,pcie";
        reg = <0 0 1>;
        #address-cells = <3>;
        #size-cells = <2>;
        ranges = <0x10000000 0 0 0x3eff0000 0 0x10000>,
                 <0x20000000 0x10000000 0x10000000 0 0x2eff0000>,
                 <0x30000000 0x80 0 0x80 0 0x80 0>;
    }

    other: other@1 {
        reg = <0 1 1>;
        ranges = <0x0 0x0 0x0 0x3eff0000 0x10000>,
                  <0x0 0x10000000 0x0 0x10000000 0x2eff0000>;
    }
};

Example usage:

DT_RANGES_LENGTH_BY_IDX(DT_NODELABEL(pcie0), 0) // 0x10000
DT_RANGES_LENGTH_BY_IDX(DT_NODELABEL(pcie0), 1) // 0x2eff0000

(continues on next page)
DT_RANGES_LENGTH_BY_IDX(DT_NODELABEL(pcie0), 2) // 0x8000000000
DT_RANGES_LENGTH_BY_IDX(DT_NODELABEL(other), 0) // 0x10000
DT_RANGES_LENGTH_BY_IDX(DT_NODELABEL(other), 1) // 0x2eff0000

Parameters

- node_id – node identifier
- idx – logical index into the ranges array

Returns range length field at idx

DT_FOREACH_RANGE(node_id, fn)

Invokes “fn” for each entry of “node_id” ranges property.

The macro “fn” must take two parameters, “node_id” which will be the node identifier of the node with the ranges property and “idx” the index of the ranges block.

Example devicetree fragment:

```
n: node@0 {
    reg = <0 0 1>;
    ranges = <0x0 0x0 0x0 0x3eff0000 0x10000>,
             <0x0 0x10000000 0x0 0x10000000 0x2eff0000>;
}
```

Example usage:

```
#define RANGE_LENGTH(node_id, idx) DT_RANGES_LENGTH_BY_IDX(node_id, idx),
const uint64_t *ranges_length[] = {
    DT_FOREACH_RANGE(DT_NODELABEL(n), RANGE_LENGTH)
};
```

This expands to:

```
const char *ranges_length[] = {
    0x10000, 0x2eff0000,
};
```

Parameters

- node_id – node identifier
- fn – macro to invoke

reg property Use these APIs instead of Property access to access the reg property. Because this property’s semantics are defined by the devicetree specification, these macros can be used even for nodes without matching bindings.

group devicetree-reg-prop

Defines

```
DT_NUM_REGS(node_id)
Get the number of register blocks in the reg property.
Use this instead of DT_PROP_LEN(node_id, reg).
```

7.7. Devicetree
Parameters

- node_id – node identifier

Returns

Number of register blocks in the node’s “reg” property.

`DT_REG_HAS_IDX(node_id, idx)`

Is “idx” a valid register block index?

If this returns 1, then `DT_REG_ADDR_BY_IDX(node_id, idx)` or `DT_REG_SIZE_BY_IDX(node_id, idx)` are valid. If it returns 0, it is an error to use those macros with index “idx”.

Parameters

- node_id – node identifier
  - idx – index to check

Returns

1 if “idx” is a valid register block index, 0 otherwise.

`DT_REG_ADDR_BY_IDX(node_id, idx)`

Get the base address of the register block at index “idx”.

Parameters

- node_id – node identifier
  - idx – index of the register whose address to return

Returns

address of the idx-th register block

`DT_REG_SIZE_BY_IDX(node_id, idx)`

Get the size of the register block at index “idx”.

This is the size of an individual register block, not the total number of register blocks in the property; use `DT_NUM_REGS()` for that.

Parameters

- node_id – node identifier
  - idx – index of the register whose size to return

Returns

size of the idx-th register block

`DT_REG_ADDR(node_id)`

Get a node’s (only) register block address.

Equivalent to `DT_REG_ADDR_BY_IDX(node_id, 0)`.

Parameters

- node_id – node identifier

Returns

node’s register block address

`DT_REG_SIZE(node_id)`

Get a node’s (only) register block size.

Equivalent to `DT_REG_SIZE_BY_IDX(node_id, 0)`.

Parameters

- node_id – node identifier

Returns

node’s only register block’s size

`DT_REG_ADDR_BY_NAME(node_id, name)`

Get a register block’s base address by name.

Parameters

- node_id – node identifier
  - name – lowercase-and-underscores register specifier name
Returns address of the register block specified by name

\[ \text{DT_REG_SIZE_BY_NAME}(\text{node}_\text{id}, \text{name}) \]

Get a register block's size by name.

**Parameters**

- \text{node}_\text{id} – node identifier
- \text{name} – lowercase-and-underscores register specifier name

**Returns** size of the register block specified by name

**interrupts property**  Use these APIs instead of *Property access* to access the interrupts property.

Because this property's semantics are defined by the devicetree specification, some of these macros can be used even for nodes without matching bindings. This does not apply to macros which take cell names as arguments.

**group devicetree-interrupts-prop**

**Defines**

\[ \text{DT_NUM_IRQS}(\text{node}_\text{id}) \]

Get the number of interrupt sources for the node.

Use this instead of \[ \text{DT_PROP_LEN}(\text{node}_\text{id}, \text{interrupts}) \].

**Parameters**

- \text{node}_\text{id} – node identifier

**Returns** Number of interrupt specifiers in the node's "interrupts" property.

\[ \text{DT_IRQ_HAS_IDX}(\text{node}_\text{id}, \text{idx}) \]

Is "idx" a valid interrupt index?

If this returns 1, then \[ \text{DT_IRQ_BY_IDX}(\text{node}_\text{id}, \text{idx}) \] is valid. If it returns 0, it is an error to use that macro with this index.

**Parameters**

- \text{node}_\text{id} – node identifier
- \text{idx} – index to check

**Returns** 1 if the \text{idx} is valid for the interrupt property 0 otherwise.

\[ \text{DT_IRQ_HAS_CELL_AT_IDX}(\text{node}_\text{id}, \text{idx}, \text{cell}) \]

Does an interrupts property have a named cell specifier at an index? If this returns 1, then \[ \text{DT_IRQ_BY_IDX}(\text{node}_\text{id}, \text{idx}, \text{cell}) \] is valid. If it returns 0, it is an error to use that macro.

**Parameters**

- \text{node}_\text{id} – node identifier
- \text{idx} – index to check
- \text{cell} – named cell value whose existence to check

**Returns** 1 if the named cell exists in the interrupt specifier at index \text{idx} 0 otherwise.

\[ \text{DT_IRQ_HAS_CELL}(\text{node}_\text{id}, \text{cell}) \]

Equivalent to \[ \text{DT_IRQ_HAS_CELL_AT_IDX}(\text{node}_\text{id}, 0, \text{cell}) \]

**Parameters**

- \text{node}_\text{id} – node identifier
cell – named cell value whose existence to check

Returns 1 if the named cell exists in the interrupt specifier at index 0 0 otherwise.

DT_IRQ_HAS_NAME(node_id, name)

Does an interrupts property have a named specifier value at an index? If this returns 1, then DT_IRQ_BY_NAME(node_id, name, cell) is valid. If it returns 0, it is an error to use that macro.

Parameters
- node_id – node identifier
- name – lowercase-and-underscores interrupt specifier name

Returns 1 if “name” is a valid named specifier 0 otherwise.

DT_IRQ_BY_IDX(node_id, idx, cell)

Get a value within an interrupt specifier at an index.

It might help to read the argument order as being similar to “node->interrupts[idx].cell”.

This can be used to get information about an individual interrupt when a device generates more than one.

Example devicetree fragment:

```plaintext
my-serial: serial@... {
    interrupts = < 33 0 >, < 34 1 >;
}
```

Assuming the node’s interrupt domain has “#interrupt-cells = <2>;” and the individual cells in each interrupt specifier are named “irq” and “priority” by the node’s binding, here are some examples:

```
#define SERIAL DT_NODELABEL(my_serial)
```

<table>
<thead>
<tr>
<th>Example usage</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DT_IRQ_BY_IDX(SERIAL, 0, irq)</td>
<td>33</td>
</tr>
<tr>
<td>DT_IRQ_BY_IDX(SERIAL, 0, priority)</td>
<td>0</td>
</tr>
<tr>
<td>DT_IRQ_BY_IDX(SERIAL, 1, irq,)</td>
<td>34</td>
</tr>
<tr>
<td>DT_IRQ_BY_IDX(SERIAL, 1, priority)</td>
<td>1</td>
</tr>
</tbody>
</table>

Parameters
- node_id – node identifier
- idx – logical index into the interrupt specifier array
- cell – cell name specifier

Returns the named value at the specifier given by the index

DT_IRQ_BY_NAME(node_id, name, cell)

Get a value within an interrupt specifier by name.

It might help to read the argument order as being similar to “node->interrupts.name.cell”.

This can be used to get information about an individual interrupt when a device generates more than one, if the bindings give each interrupt specifier a name.

Parameters
- node_id – node identifier
- name – lowercase-and-underscores interrupt specifier name
- cell – cell name specifier
**Returns** the named value at the specifier given by the index

\texttt{DT_IRQ(node\_id, cell)}

Get an interrupt specifier's value Equivalent to \texttt{DT_IRQ\_BY\_IDX(node\_id, 0, cell)}.

**Parameters**

- node\_id – node identifier
- cell – cell name specifier

**Returns** the named value at that index

\texttt{DT_IRQN(node\_id)}

Get a node’s (only) irq number.

Equivalent to \texttt{DT_IRQ(node\_id, irq)}. This is provided as a convenience for the common case where a node generates exactly one interrupt, and the IRQ number is in a cell named “irq”.

**Parameters**

- node\_id – node identifier

**Returns** the interrupt number for the node’s only interrupt

---

**For-each macros** There is currently only one “generic” for-each macro, \texttt{DT\_FOREACH\_CHILD()}, which allows iterating over the children of a devicetree node.

There are special-purpose for-each macros, like \texttt{DT\_INST\_FOREACH\_STATUS\_OKAY()}, but these require \texttt{DT\_DRV\_COMPAT} to be defined before use.

\texttt{group devicetree-generic-foreach}

**Defines**

\texttt{DT\_FOREACH\_CHILD(node\_id, fn)}

Invokes “fn” for each child of “node\_id”.

The macro “fn” must take one parameter, which will be the node identifier of a child node of “node\_id”.

Example devicetree fragment:

```
n: node {
  child-1 {
    label = "foo";
  };
  child-2 {
    label = "bar";
  };
};
```

Example usage:

```
#define LABEL\_AND\_COMMA(node\_id) DT\_LABEL(node\_id),

const char *child\_labels[] = {
  DT\_FOREACH\_CHILD(DT\_NODELABEL(n), LABEL\_AND\_COMMA)
};
```

This expands to:
```c
const char *child_labels[] = {
    "foo", "bar",
};
```

**Parameters**
- `node_id` – node identifier
- `fn` – macro to invoke

**DT_FOREACH_CHILD_VARGS**
Invokes “fn” for each child of “node_id” with multiple arguments.

The macro “fn” takes multiple arguments. The first should be the node identifier for the child node. The remaining are passed-in by the caller.

**See also:**

**DT_FOREACH_CHILD**

**Parameters**
- `node_id` – node identifier
- `fn` – macro to invoke

**DT_FOREACH_CHILD_STATUS_OKAY**
Call “fn” on the child nodes with status “okay”.

As usual, both a missing status and an “ok” status are treated as “okay”.

**Parameters**
- `node_id` – node identifier
- `fn` – macro to invoke

**DT_FOREACH_CHILD_STATUS_OKAY_VARGS**
Call “fn” on the child nodes with status “okay” with multiple arguments.

The macro “fn” takes multiple arguments. The first should be the node identifier for the child node. The remaining are passed-in by the caller.

As usual, both a missing status and an “ok” status are treated as “okay”.

**See also:**

**DT_FOREACH_CHILD_STATUS_OKAY**

**Parameters**
- `node_id` – node identifier
- `fn` – macro to invoke

- `...` – variable number of arguments to pass to fn
DT_FOREACH_PROP_ELEM(node_id, prop, fn)
Invokes “fn” for each element in the value of property “prop”.

The macro “fn” must take three parameters: fn(node_id, prop, idx). “node_id” and “prop” are the same as what is passed to DT_FOREACH_PROP_ELEM, and “idx” is the current index into the array. The “idx” values are integer literals starting from 0.

Example devicetree fragment:

```devicetree
n: node {
    my-ints = <1 2 3>;
};
```

Example usage:

```c
#define TIMES_TWO(node_id, prop, idx) 
(2 * DT_PROP_BY_IDX(node_id, prop, idx)),
int array[] = {
    DT_FOREACH_PROP_ELEM(DT_NODELABEL(n), my_ints, TIMES_TWO)
};
```

This expands to:

```c
int array[] = {
    (2 * 1), (2 * 2), (2 * 3),
};
```

In general, this macro expands to:

```c
fn(node_id, prop, 0) fn(node_id, prop, 1) [...] fn(node_id, prop, n-1)
```

where “n” is the number of elements in “prop”, as it would be returned by DT_PROP_LEN(node_id, prop).

The “prop” argument must refer to a property with type string, array, uint8-array, string-array, phandles, or phandle-array. It is an error to use this macro with properties of other types.

**Parameters**

- node_id – node identifier
- prop – lowercase-and-underscores property name
- fn – macro to invoke

DT_FOREACH_PROP_ELEM_VARGS(node_id, prop, fn, ...)
Invokes “fn” for each element in the value of property “prop” with multiple arguments.

The macro “fn” must take multiple parameters: fn(node_id, prop, idx, ...). “node_id” and “prop” are the same as what is passed to DT_FOREACH_PROP_ELEM, and “idx” is the current index into the array. The “idx” values are integer literals starting from 0. The remaining arguments are passed-in by the caller.

**See also:**

* DT_FOREACH_PROP_ELEM

**Parameters**

- node_id – node identifier
- prop – lowercase-and-underscores property name
- fn – macro to invoke
DT_FOREACH_STATUS_OKAY(compat, fn)

Invokes “fn” for each status “okay” node of a compatible.

This macro expands to:

fn(node_id_1) fn(node_id_2) ... fn(node_id_n)

where each “node_id_<i>” is a node identifier for some node with compatible “compat” and status “okay”. Whitespace is added between expansions as shown above.

Example devicetree fragment:

```
/ {
  a {
    compatible = "foo";
    status = "okay";
  };
  b {
    compatible = "foo";
    status = "disabled";
  };
  c {
    compatible = "foo";
  };
};
```

Example usage:

DT_FOREACH_STATUS_OKAY(foo, DT_NODE_PATH)

This expands to one of the following:

```
"/a" "/c"
"/c" "/a"
```

“One of the following” is because no guarantees are made about the order that node identifiers are passed to “fn” in the expansion.

(The “/c” string literal is present because a missing status property is always treated as if the status were set to “okay”.)

Note also that “fn” is responsible for adding commas, semicolons, or other terminators as needed.

**Parameters**

- compat – lowercase-and-underscores devicetree compatible
- fn – Macro to call for each enabled node. Must accept a node_id as its only parameter.

DT_FOREACH_STATUS_OKAY_VARGS(compat, fn, ...)

Invokes “fn” for each status “okay” node of a compatible with multiple arguments.

This is like DT_FOREACH_STATUS_OKAY() except you can also pass additional arguments to “fn”.

Example devicetree fragment:

```
/ {
  a {
    compatible = "foo";
  }
```
Example usage:

```c
#define MY_FN(node_id, operator) DT_PROP(node_id, val) operator
x = DT_FOREACH_STATUS_OKAY_VARGS(foo, MY_FN, +) 0;
```

This expands to one of the following:

```
x = 3 + 4 + 0;
x = 4 + 3 + 0;
```

i.e. it sets x to 7. As with `DT_FOREACH_STATUS_OKAY()`, there are no guarantees about the order nodes appear in the expansion.

### Parameters

- `compat` – lowercase-and-underscores devicetree compatible
- `fn` – Macro to call for each enabled node. Must accept a `node_id` as its only parameter.
- `...` – Additional arguments to pass to “fn”

### Existence checks

This section documents miscellaneous macros that can be used to test if a node exists, how many nodes of a certain type exist, whether a node has certain properties, etc. Some macros used for special purposes (such as `DT_IRQ_HAS_IDX()` and all macros which require `DT_DRV_COMPAT`) are documented elsewhere on this page.

**DT_NODE_EXISTS(node_id)**

Does a node identifier refer to a node?

Tests whether a node identifier refers to a node which exists, i.e. is defined in the devicetree. It doesn’t matter whether or not the node has a matching binding, or what the node’s status value is. This is purely a check of whether the node exists at all.

**Parameters**

- `node_id` – a node identifier

**Returns** 1 if the node identifier refers to a node, 0 otherwise.

**DT_NODE_HAS_STATUS(node_id, status)**

Does a node identifier refer to a node with a status?

Example uses:

```
DT_NODE_HAS_STATUS(DT_PATH(soc, i2c_12340000), okay)
DT_NODE_HAS_STATUS(DT_PATH(soc, i2c_12340000), disabled)
```
Tests whether a node identifier refers to a node which:

- exists in the devicetree, and
- has a status property matching the second argument (except that either a missing status or an “ok” status in the devicetree is treated as if it were “okay” instead)

**Parameters**
- `node_id` – a node identifier
- `status` – a status as one of the tokens okay or disabled, not a string

**Returns** 1 if the node has the given status, 0 otherwise.

`DT_HAS_COMPAT_STATUS_OKAY(compat)`

Does the devicetree have a status “okay” node with a compatible?

Test for whether the devicetree has any nodes with status “okay” and the given compatible. That is, this returns 1 if and only if there is at least one “node_id” for which both of these expressions return 1:

```
DT_NODE_HAS_STATUS(node_id, okay)
DT_NODE_HAS_COMPAT(node_id, compat)
```

As usual, both a missing status and an “ok” status are treated as “okay”.

**Parameters**
- `compat` – lowercase-and-underscores compatible, without quotes

**Returns** 1 if both of the above conditions are met, 0 otherwise

`DT_NUM_INST_STATUS_OKAY(compat)`

Get the number of instances of a given compatible with status “okay”.

**Parameters**
- `compat` – lowercase-and-underscores compatible, without quotes

**Returns** Number of instances with status “okay”

`DT_NODE_HAS_COMPAT(node_id, compat)`

Does a devicetree node match a compatible?

Example devicetree fragment:

```
n: node {
    compatible = "vnd,specific-device", "generic-device";
}
```

Example usages which evaluate to 1:

```
DT_NODE_HAS_COMPAT(DT_NODELABEL(n), vnd_specific_device)
DT_NODE_HAS_COMPAT(DT_NODELABEL(n), generic_device)
```

This macro only uses the value of the compatible property. Whether or not a particular compatible has a matching binding has no effect on its value, nor does the node's status.

**Parameters**
- `node_id` – node identifier
- `compat` – lowercase-and-underscores compatible, without quotes

**Returns** 1 if the node's compatible property contains compat, 0 otherwise.
DT_NODE_HAS_COMPAT_STATUS(node_id, compat, status)
Does a devicetree node have a compatible and status?
This is equivalent to:

```
(DT_NODE_HAS_COMPAT(node_id, compat) &&
DT_NODE_HAS_STATUS(node_id, status))
```

**Parameters**
- `node_id` – node identifier
- `compat` – lowercase-and-underscores compatible, without quotes
- `status` – okay or disabled as a token, not a string

DT_NODE_HAS_PROP(node_id, prop)
Does a devicetree node have a property?
Tests whether a devicetree node has a property defined.
This tests whether the property is defined at all, not whether a boolean property is true or false. To get a boolean property's truth value, use `DT_PROP(node_id, prop)` instead.

**Parameters**
- `node_id` – node identifier
- `prop` – lowercase-and-underscores property name

**Returns** 1 if the node has the property, 0 otherwise.

DT_PHA_HAS_CELL_AT_IDX(node_id, pha, idx, cell)
Does a phandle array have a named cell specifier at an index?
If this returns 1, then the phandle-array property “pha” has a cell named “cell” at index “idx”, and therefore `DT_PHA_BY_IDX(node_id, pha, idx, cell)` is valid. If it returns 0, it’s an error to use `DT_PHA_BY_IDX()` with the same arguments.

**Parameters**
- `node_id` – node identifier
- `pha` – lowercase-and-underscores property with type “phandle-array”
- `idx` – index to check within “pha”
- `cell` – lowercase-and-underscores cell name whose existence to check at index “idx”

**Returns** 1 if the named cell exists in the specifier at index idx, 0 otherwise.

DT_PHA_HAS_CELL(node_id, pha, cell)
Equivalent to `DT_PHA_HAS_CELL_AT_IDX(node_id, pha, 0, cell)`

**Parameters**
- `node_id` – node identifier
- `pha` – lowercase-and-underscores property with type “phandle-array”
- `cell` – lowercase-and-underscores cell name whose existence to check at index “idx”

**Returns** 1 if the named cell exists in the specifier at index 0, 0 otherwise.
Inter-node dependencies  The `devicetree.h` API has some support for tracking dependencies between nodes. Dependency tracking relies on a binary “depends on” relation between devicetree nodes, which is defined as the transitive closure of the following “directly depends on” relation:

- every non-root node directly depends on its parent node
- a node directly depends on any nodes its properties refer to by phandle
- a node directly depends on its `interrupt-parent` if it has an `interrupts` property

A dependency ordering of a devicetree is a list of its nodes, where each node n appears earlier in the list than any nodes that depend on n. A node’s dependency ordinal is then its zero-based index in that list. Thus, for two distinct devicetree nodes n1 and n2 with dependency ordinals d1 and d2, we have:

- d1 ≠ d2
- if n1 depends on n2, then d1 > d2
- d1 > d2 does not necessarily imply that n1 depends on n2

The Zephyr build system chooses a dependency ordering of the final devicetree and assigns a dependency ordinal to each node. Dependency related information can be accessed using the following macros. The exact dependency ordering chosen is an implementation detail, but cyclic dependencies are detected and cause errors, so it's safe to assume there are none when using these macros.

There are instance number-based conveniences as well; see `DT_INST_DEP_ORD()` and subsequent documentation.

```c
#define DT_DEP_ORD(node_id)    
    Get a node's dependency ordinal.

#define DT.Requires_Dep_Ords(node_id) 
    Get a list of dependency ordinals of a node's direct dependencies.
    There is a comma after each ordinal in the expansion, including the last one:

    DT.Requires_Dep_Ords(my_node) // required_ord_1, ..., required_ord_n,

    The one case DT.Requires_Dep_Ords() expands to nothing is when given the root node identifier `DT_ROOT` as argument. The root has no direct dependencies; every other node at least depends on its parent.

#define DT.Supports_Dep_Ords(node_id) 
    Get a list of dependency ordinals of what depends directly on a node.
    There is a comma after each ordinal in the expansion, including the last one:

    DT.Supports_Dep_Ords(my_node) // supported_ord_1, ..., supported_ord_n,
```

496 Chapter 7. API Reference
DT_SUPPORTS_DEP_ORDS() may expand to nothing. This happens when node_id refers to a leaf node that nothing else depends on.

**Parameters**

- node_id – Node identifier

**Returns** a list of dependency ordinals, with each ordinal followed by a comma (,), or an empty expansion

DT_INST_DEP_ORD(inst)

Get a DT_DRV_COMPAT instance's dependency ordinal.

Equivalent to DT_DEP_ORD(DT_DRV_INST(inst)).

**Parameters**

- inst – instance number

**Returns** The instance's dependency ordinal

DT_INST_REQUIRES_DEP_ORDS(inst)

Get a list of dependency ordinals of a DT_DRV_COMPAT instance’s direct dependencies.

Equivalent to DT_REQUIRES_DEP_ORDS(DT_DRV_INST(inst)).

**Parameters**

- inst – instance number

**Returns** a list of dependency ordinals for the nodes the instance depends on directly

DT_INST_SUPPORTS_DEP_ORDS(inst)

Get a list of dependency ordinals of what depends directly on a DT_DRV_COMPAT instance.

Equivalent to DT_SUPPORTS_DEP_ORDS(DT_DRV_INST(inst)).

**Parameters**

- inst – instance number

**Returns** a list of node identifiers for the nodes that depend directly on the instance

**Bus helpers** Zephyr's devicetree bindings language supports a bus: key which allows bindings to declare that nodes with a given compatible describe system buses. In this case, child nodes are considered to be on a bus of the given type, and the following APIs may be used.

**group devicetree-generic-bus**

**Defines**

DT_BUS(node_id)

Node's bus controller.

Get the node identifier of the node's bus controller. This can be used with DT_PROP() to get properties of the bus controller.

It is an error to use this with nodes which do not have bus controllers.

Example devicetree fragment:

```c
i2c@deadbeef {
    label = "I2C_CTLR";
    status = "okay";
    clock-frequency = < 100000 >;
}```

(continues on next page)
i2c_device: accelerometer@12 {
    ...
};;

Example usage:

```
DT_PROP(DT_BUS(DT_NODELABEL(i2c_device)), clock_frequency) // 100000
```

**Parameters**
- node_id – node identifier

**Returns** a node identifier for the node's bus controller

```
DT_BUS_LABEL(node_id)
```

Node's bus controller's label property.

**Parameters**
- node_id – node identifier

**Returns** the label property of the node's bus controller `DT_BUS(node)`

```
DT_ON_BUS(node_id, bus)
```

Is a node on a bus of a given type?

Example devicetree overlay:

```
&i2c0 {
    temp: temperature-sensor@76 {
        compatible = "vnd,some-sensor";
        reg = <0x76>;
    }
};
```

Example usage, assuming “i2c0” is an I2C bus controller node, and therefore “temp” is on an I2C bus:

```
DT_ON_BUS(DT_NODELABEL(temp), i2c) // 1
DT_ON_BUS(DT_NODELABEL(temp), spi) // 0
```

**Parameters**
- node_id – node identifier
- bus – lowercase-and-underscores bus type as a C token (i.e. without quotes)

**Returns** 1 if the node is on a bus of the given type, 0 otherwise

### Instance-based APIs

These are recommended for use within device drivers. To use them, define `DT_DRV_COMPAT` to the lowercase-and-underscores compatible the device driver implements support for. Here is an example devicetree fragment:

```
serial@40001000 {
    compatible = "vnd,serial";
    status = "okay";
    current-speed = <115200>;
};
```
Example usage, assuming serial@40001000 is the only enabled node with compatible “vnd,serial”:

```
#define DT_DRV_COMPAT vnd_serial
DT_DRV_INST(0)    // node identifier for serial@40001000
DT_INST_PROP(0, current_speed) // 115200
```

**Warning:** Be careful making assumptions about instance numbers. See `DT_INST()` for the API guarantees.

As shown above, the DT_INST_* APIs are conveniences for addressing nodes by instance number. They are almost all defined in terms of one of the **Generic APIs**. The equivalent generic API can be found by removing INST_ from the macro name. For example, DT_INST_PROP(inst, prop) is equivalent to DT_PROP(DT_DRV_INST(inst), prop). Similarly, DT_INST_REG_ADDR(inst) is equivalent to DT_REG_ADDR(DT_DRV_INST(inst)), and so on. There are some exceptions: `DT_ANY_INST_ON_BUS_STATUS_OKAY()` and `DT_INST_FOREACH_STATUS_OKAY()` are special-purpose helpers without straightforward generic equivalents.

Since DT_DRV_INST() requires DT_DRV_COMPAT to be defined, it’s an error to use any of these without that macro defined.

Note that there are also helpers available for specific hardware; these are documented in **Hardware specific APIs**.

**group devicetree-inst**

**Defines**

`DT_DRV_INST(inst)`
- Node identifier for an instance of a DT_DRV_COMPAT compatible.

**Parameters**
- inst – instance number

**Returns** a node identifier for the node with DT_DRV_COMPAT compatible and instance number “inst”

`DT_INST_FOREACH_CHILD(inst, fn)`
- Call “fn” on all child nodes of `DT_DRV_INST(inst)`.

The macro “fn” should take one argument, which is the node identifier for the child node.

See also:

`DT_FOREACH_CHILD`

**Parameters**
- inst – instance number
- fn – macro to invoke on each child node identifier

`DT_INST_FOREACH_CHILD_VARGS(inst, fn, ...)`
- Call “fn” on all child nodes of `DT_DRV_INST(inst)`.

The macro “fn” takes multiple arguments. The first should be the node identifier for the child node. The remaining are passed-in by the caller.
See also: `DT_FOREACH_CHILD`

**Parameters**
- *inst* – instance number
- *fn* – macro to invoke on each child node identifier
- ... – variable number of arguments to pass to fn

`DT_INST_ENUM_IDX(inst, prop)`
Get a DT_DRV_COMPAT value’s index into its enumeration values.

**Parameters**
- *inst* – instance number
- *prop* – lowercase-and-underscores property name

**Returns** zero-based index of the property's value in its enum: list

`DT_INST_ENUM_IDX_OR(inst, prop, default_idx_value)`
Like `DT_INST_ENUM_IDX()`, but with a fallback to a default enum index.

**Parameters**
- *inst* – instance number
- *prop* – lowercase-and-underscores property name
- *default_idx_value* – a fallback index value to expand to

**Returns** zero-based index of the property's value in its enum if present, default_idx_value otherwise

`DT_INST_PROP(inst, prop)`
Get a DT_DRV_COMPAT instance property.

**Parameters**
- *inst* – instance number
- *prop* – lowercase-and-underscores property name

**Returns** a representation of the property's value

`DT_INST_PROP_LEN(inst, prop)`
Get a DT_DRV_COMPAT property length.

**Parameters**
- *inst* – instance number
- *prop* – lowercase-and-underscores property name

**Returns** logical length of the property

`DT_INST_PROP_HAS_IDX(inst, prop, idx)`
Is index “idx” valid for an array type property on a DT_DRV_COMPAT instance?

**Parameters**
- *inst* – instance number
- *prop* – lowercase-and-underscores property name
- *idx* – index to check

**Returns** 1 if “idx” is a valid index into the given property, 0 otherwise.

`DT_INST_PROP_HAS_NAME(inst, prop, name)`
Is name “name” available in a foo-names property?
Parameters

- inst – instance number
- prop – a lowercase-and-underscores “prop-names” type property
- name – a lowercase-and-underscores name to check

Returns An expression which evaluates to 1 if “name” is an available name into the given property, and 0 otherwise.

DT_INST_PROP_BY_IDX(inst, prop, idx)
Get a DT_DRV_COMPAT element value in an array property.

Parameters

- inst – instance number
- prop – lowercase-and-underscores property name
- idx – the index to get

Returns a representation of the idx-th element of the property

DT_INST_PROP_OR(inst, prop, default_value)
Like DT_INST_PROP(), but with a fallback to default_value.

Parameters

- inst – instance number
- prop – lowercase-and-underscores property name
- default_value – a fallback value to expand to

Returns DT_INST_PROP(inst, prop) or default_value

DT_INST_LABEL(inst)
Get a DT_DRV_COMPAT instance’s “label” property.

Parameters

- inst – instance number

Returns instance’s label property value

DT_INST_PROP_BY_PHANDLE(inst, ph, prop)
Get a DT_DRV_COMPAT instance’s property value from a phandle’s node.

Parameters

- inst – instance number
- ph – lowercase-and-underscores property of “inst” with type “phandle”
- prop – lowercase-and-underscores property of the phandle’s node

Returns the value of “prop” as described in the DT_PROP() documentation

DT_INST_PROP_BY_PHANDLE_IDX(inst, phs, idx, prop)
Get a DT_DRV_COMPAT instance’s property value from a phandle in a property.

Parameters

- inst – instance number
- phs – lowercase-and-underscores property with type “phandle”, “phandles”, or “phandle-array”
- idx – logical index into “phs”, which must be zero if “phs” has type “phandle”
- prop – lowercase-and-underscores property of the phandle’s node

Returns the value of “prop” as described in the DT_PROP() documentation
DT_INST_PHA_BY_IDX(inst, pha, idx, cell)
Get a DT_DRV_COMPAT instance’s phandle-array specifier value at an index.

Parameters
- inst – instance number
- pha – lowercase-and-underscores property with type “phandle-array”
- idx – logical index into the property “pha”
- cell – binding’s cell name within the specifier at index “idx”

Returns the value of the cell inside the specifier at index “idx”

DT_INST_PHA_BY_IDX_OR(inst, pha, idx, cell, default_value)
Like DT_INST_PHA_BY_IDX(), but with a fallback to default_value.

Parameters
- inst – instance number
- pha – lowercase-and-underscores property with type “phandle-array”
- idx – logical index into the property “pha”
- cell – binding’s cell name within the specifier at index “idx”
- default_value – a fallback value to expand to

Returns DT_INST_PHA_BY_IDX(inst, pha, idx, cell) or default_value

DT_INST_PHA(inst, pha, cell)
Get a DT_DRV_COMPAT instance’s phandle-array specifier value Equivalent to DT_INST_PHA_BY_IDX(inst, pha, 0, cell)

Parameters
- inst – instance number
- pha – lowercase-and-underscores property with type “phandle-array”
- cell – binding’s cell name for the specifier at “pha” index 0

Returns the cell value

DT_INST_PHA_OR(inst, pha, cell, default_value)
Like DT_INST_PHA(), but with a fallback to default_value.

Parameters
- inst – instance number
- pha – lowercase-and-underscores property with type “phandle-array”
- cell – binding’s cell name for the specifier at “pha” index 0
- default_value – a fallback value to expand to

Returns DT_INST_PHA(inst, pha, cell) or default_value

DT_INST_PHA_BY_NAME(inst, pha, name, cell)
Get a DT_DRV_COMPAT instance’s value within a phandle-array specifier by name.

Parameters
- inst – instance number
- pha – lowercase-and-underscores property with type “phandle-array”
- name – lowercase-and-underscores name of a specifier in “pha”
- cell – binding’s cell name for the named specifier

Returns the cell value
DT_INST_PHA_BY_NAME_OR (inst, pha, name, cell, default_value)
   Like DT_INST_PHA_BY_NAME(), but with a fallback to default_value.

Parameters
   • inst – instance number
   • pha – lowercase-and-underscores property with type “phandle-array”
   • name – lowercase-and-underscores name of a specifier in “pha”
   • cell – binding’s cell name for the named specifier
   • default_value – a fallback value to expand to

Returns DT_INST_PHA_BY_NAME(inst, pha, name, cell) or default_value

DT_INST_PHANDLE_BY_NAME (inst, pha, name)
   Get a DT_DRV_COMPAT instance’s phandle node identifier from a phandle array by name.

Parameters
   • inst – instance number
   • pha – lowercase-and-underscores property with type “phandle-array”
   • name – lowercase-and-underscores name of an element in “pha”

Returns node identifier for the phandle at the element named “name”

DT_INST_PHANDLE_BY_IDX (inst, prop, idx)
   Get a DT_DRV_COMPAT instance’s node identifier for a phandle in a property.

Parameters
   • inst – instance number
   • prop – lowercase-and-underscores property name in “inst” with type “phandle”, “phandles” or “phandle-array”
   • idx – index into “prop”

Returns a node identifier for the phandle at index “idx” in “prop”

DT_INST_PHANDLE (inst, prop)
   Get a DT_DRV_COMPAT instance’s node identifier for a phandle property’s value.

Parameters
   • inst – instance number
   • prop – lowercase-and-underscores property of “inst” with type “phandle”

Returns a node identifier for the node pointed to by “ph”

DT_INST_REG_HAS_IDX (inst, idx)
   is “idx” a valid register block index on a DT_DRV_COMPAT instance?

Parameters
   • inst – instance number
   • idx – index to check

Returns 1 if “idx” is a valid register block index, 0 otherwise.

DT_INST_REG_ADDR_BY_IDX (inst, idx)
   Get a DT_DRV_COMPAT instance’s idx-th register block’s address.

Parameters
   • inst – instance number
   • idx – index of the register whose address to return
Returns address of the instance’s idx-th register block

\texttt{DT\_INST\_REG\_SIZE\_BY\_IDX}(\texttt{inst, idx})

Get a DT\_DRV\_COMPAT instance’s idx-th register block’s size.

Parameters
\begin{itemize}
  \item inst – instance number
  \item idx – index of the register whose size to return
\end{itemize}

Returns size of the instance’s idx-th register block

\texttt{DT\_INST\_REG\_ADDR\_BY\_NAME}(\texttt{inst, name})

Get a DT\_DRV\_COMPAT’s register block address by name.

Parameters
\begin{itemize}
  \item inst – instance number
  \item name – lowercase-and-underscores register specifier name
\end{itemize}

Returns address of the register block with the given name

\texttt{DT\_INST\_REG\_SIZE\_BY\_NAME}(\texttt{inst, name})

Get a DT\_DRV\_COMPAT’s register block size by name.

Parameters
\begin{itemize}
  \item inst – instance number
  \item name – lowercase-and-underscores register specifier name
\end{itemize}

Returns size of the register block with the given name

\texttt{DT\_INST\_REG\_ADDR}(\texttt{inst})

Get a DT\_DRV\_COMPAT’s (only) register block address.

Parameters
\begin{itemize}
  \item inst – instance number
\end{itemize}

Returns instance’s register block address

\texttt{DT\_INST\_REG\_SIZE}(\texttt{inst})

Get a DT\_DRV\_COMPAT’s (only) register block size.

Parameters
\begin{itemize}
  \item inst – instance number
\end{itemize}

Returns instance’s register block size

\texttt{DT\_INST\_IRQ\_BY\_IDX}(\texttt{inst, idx, cell})

Get a DT\_DRV\_COMPAT interrupt specifier value at an index.

Parameters
\begin{itemize}
  \item inst – instance number
  \item idx – logical index into the interrupt specifier array
  \item cell – cell name specifier
\end{itemize}

Returns the named value at the specifier given by the index

\texttt{DT\_INST\_IRQ\_BY\_NAME}(\texttt{inst, name, cell})

Get a DT\_DRV\_COMPAT interrupt specifier value by name.

Parameters
\begin{itemize}
  \item inst – instance number
  \item name – lowercase-and-underscores interrupt specifier name
\end{itemize}
• cell – cell name specifier

**Returns** the named value at the specifier given by the index

`DT_INST_IRQ(inst, cell)`
Get a DT_DRV_COMPAT interrupt specifier's value.

**Parameters**
• inst – instance number
• cell – cell name specifier

**Returns** the named value at that index

`DT_INST_IRQN(inst)`
Get a DT_DRV_COMPAT's (only) irq number.

**Parameters**
• inst – instance number

**Returns** the interrupt number for the node's only interrupt

`DT_INST_BUS(inst)`
Get a DT_DRV_COMPAT's bus node identifier.

**Parameters**
• inst – instance number

**Returns** node identifier for the instance's bus node

`DT_INST_BUS_LABEL(inst)`
Get a DT_DRV_COMPAT's bus node's label property.

**Parameters**
• inst – instance number

**Returns** the label property of the instance's bus controller

`DT_INST_ON_BUS(inst, bus)`
Test if a DT_DRV_COMPAT's bus type is a given type.

**Parameters**
• inst – instance number
• bus – a binding's bus type as a C token, lowercased and without quotes

**Returns** 1 if the given instance is on a bus of the given type, 0 otherwise

`DT_ANY_INST_ON_BUS_STATUS_OKAY(bus)`
Test if any DT_DRV_COMPAT node is on a bus of a given type and has status okay.

This is a special-purpose macro which can be useful when writing drivers for devices which can appear on multiple buses. One example is a sensor device which may be wired on an I2C or SPI bus.

Example devicetree overlay:

```markdown
&i2c0 {
    temp: temperature-sensor@76 {
        compatible = "vnd,some-sensor";
        reg = <0x76>;
    };
};
```

Example usage, assuming “i2c0” is an I2C bus controller node, and therefore “temp” is on an I2C bus:
#define DT_DRV_COMPAT vnd_some_sensor

DT_ANY_INST_ON_BUS_STATUS_OKAY(i2c) // 1

**Parameters**

- **bus** – a binding’s bus type as a C token, lowercased and without quotes

**Returns** 1 if any enabled node with that compatible is on that bus type, 0 otherwise

DT_INST_FOREACH_STATUS_OKAY(fn)

Call “fn” on all nodes with compatible DT_DRV_COMPAT and status “okay”.

This macro calls “fn(inst)” on each “inst” number that refers to a node with status “okay”. Whitespace is added between invocations.

Example devicetree fragment:

```plaintext
a {
    compatible = "vnd,device";
    status = "okay";
    label = "DEV_A";
};

b {
    compatible = "vnd,device";
    status = "okay";
    label = "DEV_B";
};

c {
    compatible = "vnd,device";
    status = "disabled";
    label = "DEV_C";
};
```

Example usage:

```plaintext
#define DT_DRV_COMPAT vnd_device
#define MY_FN(inst) DT_INST_LABEL(inst),

DT_INST_FOREACH_STATUS_OKAY(MY_FN)
```

This expands to:

```plaintext
MY_FN(0) MY_FN(1)
```

and from there, to either this:

```plaintext
"DEV_A", "DEV_B",
```

or this:

```plaintext
"DEV_B", "DEV_A",
```

No guarantees are made about the order that a and b appear in the expansion.

Note that “fn” is responsible for adding commas, semicolons, or other separators or termina-

tors.

Device drivers should use this macro whenever possible to instantiate a struct device for each

enabled node in the devicetree of the driver’s compatible DT_DRV_COMPAT.
Parameters

- fn – Macro to call for each enabled node. Must accept an instance number as its only parameter.

\[ \text{DT_INST_FOREACH_STATUS_OKAY\_VARGS}(\text{fn},...) \]

Call “fn” on all nodes with compatible DT_DRV_COMPAT and status “okay” with multiple arguments.

See also:

\[ \text{DT_INST_FOREACH_STATUS_OKAY} \]

Parameters

- fn – Macro to call for each enabled node. Must accept an instance number as its only parameter.
- ... – variable number of arguments to pass to fn

\[ \text{DT_INST_FOREACH\_PROP\_ELEM}(\text{inst}, \text{prop}, \text{fn}) \]

Invokes “fn” for each element of property “prop” for a DT_DRV_COMPAT instance.

Equivalent to \[ \text{DT_FOREACH\_PROP\_ELEM}(\text{DT\_DRV\_INST}(\text{inst}), \text{prop}, \text{fn}) \].

Parameters

- inst – instance number
- prop – lowercase-and-underscores property name
- fn – macro to invoke

\[ \text{DT\_INST\_FOREACH\_PROP\_ELEM\_VARGS}(\text{inst}, \text{prop}, \text{fn},...) \]

Invokes “fn” for each element of property “prop” for a DT_DRV_COMPAT instance with multiple arguments.

Equivalent to \[ \text{DT_FOREACH\_PROP\_ELEM\_VARGS}(\text{DT\_DRV\_INST}(\text{inst}), \text{prop}, \text{fn}, \text{VA\_ARGS}) \].

See also:

\[ \text{DT\_INST\_FOREACH\_PROP\_ELEM} \]

Parameters

- inst – instance number
- prop – lowercase-and-underscores property name
- fn – macro to invoke
- ... – variable number of arguments to pass to fn

\[ \text{DT\_INST\_NODE\_HAS\_PROP}(\text{inst}, \text{prop}) \]

Does a DT_DRV_COMPAT instance have a property?

Parameters

- inst – instance number
- prop – lowercase-and-underscores property name

Returns 1 if the instance has the property, 0 otherwise.

\[ \text{DT\_INST\_PHA\_HAS\_CELL\_AT\_IDX}(\text{inst}, \text{pha}, \text{idx}, \text{cell}) \]

Does a phandle array have a named cell specifier at an index for a DT_DRV_COMPAT instance?

Parameters

- inst – instance number
- pha – phandle array name
- idx – index for phandle array
- cell – cell specifier name
- \text{VA\_ARGS} – variable number of arguments to pass to fn
• inst – instance number
• pha – lowercase-and-underscores property with type “phandle-array”
• idx – index to check
• cell – named cell value whose existence to check

Returns 1 if the named cell exists in the specifier at index idx, 0 otherwise.

DT_INST_PHA_HAS_CELL(inst, pha, cell)
Does a phandle array have a named cell specifier at index 0 for a DT_DRV_COMPAT instance?

Parameters
• inst – instance number
• pha – lowercase-and-underscores property with type “phandle-array”
• cell – named cell value whose existence to check

Returns 1 if the named cell exists in the specifier at index 0, 0 otherwise.

DT_INST_IRQ_HAS_IDX(inst, idx)
is index valid for interrupt property on a DT_DRV_COMPAT instance?

Parameters
• inst – instance number
• idx – logical index into the interrupt specifier array

Returns 1 if the idx is valid for the interrupt property 0 otherwise.

DT_INST_IRQ_HAS_CELL_AT_IDX(inst, idx, cell)
Does a DT_DRV_COMPAT instance have an interrupt named cell specifier?

Parameters
• inst – instance number
• idx – index to check
• cell – named cell value whose existence to check

Returns 1 if the named cell exists in the interrupt specifier at index idx 0 otherwise.

DT_INST_IRQ_HAS_CELL(inst, cell)
Does a DT_DRV_COMPAT instance have an interrupt value?

Parameters
• inst – instance number
• cell – named cell value whose existence to check

Returns 1 if the named cell exists in the interrupt specifier at index 0 0 otherwise.

DT_INST_IRQ_HAS_NAME(inst, name)
Does a DT_DRV_COMPAT instance have an interrupt value?

Parameters
• inst – instance number
• name – lowercase-and-underscores interrupt specifier name

Returns 1 if “name” is a valid named specifier

Hardware specific APIs

The following APIs can also be used by including <devicetree.h>; no additional include is needed.
Clocks  These conveniences may be used for nodes which describe clock sources, and properties related to them.

\textbf{group devicetree-clocks}

\textbf{Defines}

\begin{verbatim}
DT_CLOCKS_HAS_IDX(node_id, idx)
Test if a node has a clocks phandle-array property at a given index.
This expands to 1 if the given index is valid clocks property phandle-array index. Otherwise, it expands to 0.

Example devicetree fragment:

n1: node-1 {
    clocks = <...>, <...>;
};
n2: node-2 {
    clocks = <...>;
};

Example usage:

DT_CLOCKS_HAS_IDX(DT_NODELABEL(n1), 0) // 1
DT_CLOCKS_HAS_IDX(DT_NODELABEL(n1), 1) // 1
DT_CLOCKS_HAS_IDX(DT_NODELABEL(n1), 2) // 0
DT_CLOCKS_HAS_IDX(DT_NODELABEL(n2), 1) // 0
\end{verbatim}

\begin{itemize}
\item \textit{node_id} – node identifier; may or may not have any clocks property
\item \textit{idx} – index of a clocks property phandle-array whose existence to check
\end{itemize}

\begin{itemize}
\item Returns 1 if the index exists, 0 otherwise
\end{itemize}

\begin{verbatim}
DT_CLOCKS_HAS_NAME(node_id, name)
Test if a node has a clock-names array property holds a given name.
This expands to 1 if the name is available as clocks-name array property cell. Otherwise, it expands to 0.

Example devicetree fragment:

n1: node-1 {
    clocks = <...>, <...>;
    clock-names = "alpha", "beta";
};
n2: node-2 {
    clocks = <...>;
    clock-names = "alpha";
};

Example usage:

DT_CLOCKS_HAS_NAME(DT_NODELABEL(n1), alpha) // 1
DT_CLOCKS_HAS_NAME(DT_NODELABEL(n1), beta) // 1
DT_CLOCKS_HAS_NAME(DT_NODELABEL(n2), beta) // 0
\end{verbatim}

\begin{itemize}
\item \textit{name} – name of a clocks-name property cell
\end{itemize}

\begin{itemize}
\item Returns 1 if the name exists, 0 otherwise
\end{itemize}
Parameters

- node_id – node identifier; may or may not have any clock-names property.
- name – lowercase-and-underscores clock-names cell value name to check

Returns 1 if the clock name exists, 0 otherwise

\[ \text{DT\_NUM\_CLOCKS}(\text{node\_id}) \]
Get the number of elements in a clocks property.

Example devicetree fragment:

```plaintext
n1: node-1 {
    clocks = <&foo>, <&bar>;
};
n2: node-2 {
    clocks = <&foo>;
};
```

Example usage:

\[ \text{DT\_NUM\_CLOCKS(DT\_NODELABEL(n1))} \ // \ 2 \]
\[ \text{DT\_NUM\_CLOCKS(DT\_NODELABEL(n2))} \ // \ 1 \]

Parameters

- node_id – node identifier with a clocks property

Returns number of elements in the property

\[ \text{DT\_CLOCKS\_CTLR\_BY\_IDX}(\text{node\_id}, \text{idx}) \]
Get the node identifier for the controller phandle from a “clocks” phandle-array property at an index.

Example devicetree fragment:

```plaintext
clk1: clock-controller@... { ... };
clk2: clock-controller@... { ... };
n: node {
    clocks = <&clk1 10 20>, <&clk2 30 40>;
};
```

Example usage:

\[ \text{DT\_CLOCKS\_CTLR\_BY\_IDX(DT\_NODELABEL(n), 0))} \ // \ DT\_NODELABEL(clk1) \]
\[ \text{DT\_CLOCKS\_CTLR\_BY\_IDX(DT\_NODELABEL(n), 1))} \ // \ DT\_NODELABEL(clk2) \]

See also:

\[ DT\_PHANDLE\_BY\_IDX() \]

Parameters

- node_id – node identifier
- idx – logical index into “clocks”

Returns the node identifier for the clock controller referenced at index “idx”
DT_CLOCKS_CTLR(node_id)
Equivalent to DT_CLOCKS_CTLR_BY_IDX(node_id, 0)

See also:
DT_CLOCKS_CTLR_BY_IDX()

Parameters
• node_id – node identifier

Returns a node identifier for the clocks controller at index 0 in “clocks”

DT_CLOCKS_CTLR_BY_NAME(node_id, name)
Get the node identifier for the controller phandle from a clocks phandle-array property by name.

Example devicetree fragment:

```
clk1: clock-controller@... { ... };
clk2: clock-controller@... { ... };

n: node {
    clocks = <&clk1 10 20>, <&clk2 30 40>;
clock-names = "alpha", "beta";
};
```

Example usage:

```
DT_CLOCKS_CTLR_BY_NAME(DT_NODELABEL(n), beta) // DT_NODELABEL(clk2)
```

See also:
DT_PHANDLE_BY_NAME()

Parameters
• node_id – node identifier
• name – lowercase-and-underscores name of a clocks element as defined by the node's clock-names property

Returns the node identifier for the clock controller referenced by name

DT_CLOCKS_CELL_BY_IDX(node_id, idx, cell)
Get a clock specifier’s cell value at an index.

Example devicetree fragment:

```
clk1: clock-controller@... { 
    compatible = "vnd,clock";
    #clock-cells = < 2 >;
};

n: node {
    clocks = < &clk1 10 20 >, < &clk1 30 40 >;
};
```

Bindings fragment for the vnd,clock compatible:
clock-cells:
- bus
- bits

Example usage:
```
DT_CLOCKS_CELL_BY_IDX(DT_NODELABEL(n), 0, bus) // 10
DT_CLOCKS_CELL_BY_IDX(DT_NODELABEL(n), 1, bits) // 40
```

See also:
`DT_PHA_BY_IDX()`

Parameters
- `node_id` – node identifier for a node with a clocks property
- `idx` – logical index into clocks property
- `cell` – lowercase-and-underscores cell name

Returns
the cell value at index “idx”

```
DT_CLOCKS_CELL_BY_NAME(node_id, name, cell)
Get a clock specifier's cell value by name.
```

Example devicetree fragment:
```
clk1: clock-controller@... {
    compatible = "vnd,clock";
    #clock-cells = < 2 >;
};

n: node {
    clocks = < &clk1 10 20 >, < &clk1 30 40 >;
    clock-names = "alpha", "beta";
};
```

Bindings fragment for the vnd,clock compatible:
```
clock-cells:
- bus
- bits
```

Example usage:
```
DT_CLOCKS_CELL_BY_NAME(DT_NODELABEL(n), alpha, bus) // 10
DT_CLOCKS_CELL_BY_NAME(DT_NODELABEL(n), beta, bits) // 40
```

See also:
`DT_PHA_BY_NAME()`

Parameters
- `node_id` – node identifier for a node with a clocks property
- `name` – lowercase-and-underscores name of a clocks element as defined by the node’s clock-names property
- `cell` – lowercase-and-underscores cell name

Returns
the cell value in the specifier at the named element
DT_CLOCKS_CELL(node_id, cell)
   Equivalent to DT_CLOCKS_CELL_BY_IDX(node_id, 0, cell)

See also:
   DT_CLOCKS_CELL_BY_IDX()

Parameters
   • node_id – node identifier for a node with a clocks property
   • cell – lowercase-and-underscores cell name

Returns the cell value at index 0

DT_INST_CLOCKS_HAS_IDX(inst, idx)
   Equivalent to DT_CLOCKS_HAS_IDX(DT_DRV_INST(inst), idx)

Parameters
   • inst – DT_DRV_COMPAT instance number; may or may not have any clocks property
   • idx – index of a clocks property phandle-array whose existence to check

Returns 1 if the index exists, 0 otherwise

DT_INST_CLOCKS_HAS_NAME(inst, name)
   Equivalent to DT_CLOCK_HAS_NAME(DT_DRV_INST(inst), name)

Parameters
   • inst – DT_DRV_COMPAT instance number; may or may not have any clock-names property.
   • name – lowercase-and-underscores clock-names cell value name to check

Returns 1 if the clock name exists, 0 otherwise

DT_INST_NUM_CLOCKS(inst)
   Equivalent to DT_NUM_CLOCKS(DT_DRV_INST(inst))

Parameters
   • inst – instance number

Returns number of elements in the clocks property

DT_INST_CLOCKS_CTLR_BY_IDX(inst, idx)
   Get the node identifier for the controller phandle from a “clocks” phandle-array property at an index.

See also:
   DT_CLOCKS_CTLR_BY_IDX()

Parameters
   • inst – instance number
   • idx – logical index into “clocks”

Returns the node identifier for the clock controller referenced at index “idx”
DT_INST_CLOCKS_CTLR(inst)
   Equivalent to DT_INST_CLOCKS_CTLR_BY_IDX(inst, 0)

See also:

DT_CLOCKS_CTLR()

Parameters

   • inst – instance number

Returns a node identifier for the clocks controller at index 0 in “clocks”

DT_INST_CLOCKS_CTLR_BY_NAME(inst, name)
   Get the node identifier for the controller phandle from a clocks phandle-array property by
   name.

See also:

DT_CLOCKS_CTLR_BY_NAME()

Parameters

   • inst – instance number
   • name – lowercase-and-underscores name of a clocks element as defined by the
         node’s clock-names property

Returns the node identifier for the clock controller referenced by the named element

DT_INST_CLOCKS_CELL_BY_IDX(inst, idx, cell)
   Get a DT_DRV_COMPAT instance’s clock specifier’s cell value at an index.

See also:

DT_CLOCKS_CELL_BY_IDX()

Parameters

   • inst – DT_DRV_COMPAT instance number
   • idx – logical index into clocks property
   • cell – lowercase-and-underscores cell name

Returns the cell value at index “idx”

DT_INST_CLOCKS_CELL_BY_NAME(inst, name, cell)
   Get a DT_DRV_COMPAT instance’s clock specifier’s cell value by name.

See also:

DT_CLOCKS_CELL_BY_NAME()

Parameters

   • inst – DT_DRV_COMPAT instance number
   • name – lowercase-and-underscores name of a clocks element as defined by the
         node’s clock-names property
   • cell – lowercase-and-underscores cell name
Returns the cell value in the specifier at the named element

\texttt{DT_INST_CLOCKS\_CELL}\texttt{(inst, cell)}

Equivalent to \texttt{DT\_INST\_CLOCKS\_CELL\_BY\_IDX}\texttt{(inst, 0, cell)}

Parameters

\begin{itemize}
\item \texttt{inst} – DT\_DRV\_COMPAT instance number
\item \texttt{cell} – lowercase-and-underscores cell name
\end{itemize}

Returns the value of the cell inside the specifier at index 0

\textbf{DMA} These conveniences may be used for nodes which describe direct memory access controllers or channels, and properties related to them.

\textit{group devicetree-dmas}

\textbf{Defines}

\texttt{DT\_DMAS\_CTLR\_BY\_IDX}\texttt{(node\_id, idx)}

Get the node identifier for the DMA controller from a dmas property at an index.

Example devicetree fragment:

```plaintext
dma1: dma\@... { ... };
dma2: dma\@... { ... };
n: node {
    dmas = &dma1 1 2 0x400 0x3>,
    &dma2 6 3 0x404 0x5>
};
```

Example usage:

\begin{verbatim}
DT\_DMAS\_CTLR\_BY\_IDX(DT\_NODELABEL(n), 0) // DT\_NODELABEL(dma1)
DT\_DMAS\_CTLR\_BY\_IDX(DT\_NODELABEL(n), 1) // DT\_NODELABEL(dma2)
\end{verbatim}

\textbf{See also:}

\textit{DT\_PROP\_BY\_PHANDLE\_IDX()}

Parameters

\begin{itemize}
\item \texttt{node\_id} – node identifier for a node with a dmas property
\item \texttt{idx} – logical index into dmas property
\end{itemize}

Returns the node identifier for the DMA controller referenced at index “idx”

\texttt{DT\_DMAS\_CTLR\_BY\_NAME}\texttt{(node\_id, name)}

Get the node identifier for the DMA controller from a dmas property by name.

Example devicetree fragment:

```plaintext
dma1: dma\@... { ... };
dma2: dma\@... { ... };
n: node {
(continues on next page)
```

7.7. Devicetree
dmas = <&dma1 1 2 0x400 0x3>,
     <&dma2 6 3 0x404 0x5>;
 dma-names = "tx", "rx";
};

Example usage:
DT_DMAS_CTLR_BY_NAME(DT_NODELABEL(n), tx) // DT_NODELABEL(dma1)
DT_DMAS_CTLR_BY_NAME(DT_NODELABEL(n), rx) // DT_NODELABEL(dma2)

See also:
DT_PHANDLE_BY_NAME()

Parameters
• node_id – node identifier for a node with a dmas property
• name – lowercase-and-underscores name of a dmas element as defined by the
  node's dma-names property

Returns the node identifier for the DMA controller in the named element

DT_DMAS_CTLR(node_id)
Equivalent to DT_DMAS_CTLR_BY_IDX(node_id, 0)

See also:
DT_DMAS_CTLR_BY_IDX()

Parameters
• node_id – node identifier for a node with a dmas property

Returns the node identifier for the DMA controller at index 0 in the node's “dmas”
  property

DT_INST_DMAS_CTLR_BY_IDX(inst, idx)
Get the node identifier for the DMA controller from a DT_DRV_COMPAT instance's dmas prop-
erty at an index.

See also:
DT_DMAS_CTLR_BY_IDX()

Parameters
• inst – DT_DRV_COMPAT instance number
• idx – logical index into dmas property

Returns the node identifier for the DMA controller referenced at index “idx”

DT_INST_DMAS_CTLR_BY_NAME(inst, name)
Get the node identifier for the DMA controller from a DT_DRV_COMPAT instance's dmas prop-
erty by name.

See also:
DT_DMAS_CTLR_BY_NAME()
Parameters
- **inst** – DT_DRV_COMPAT instance number
- **name** – lowercase-and-underscores name of a dmas element as defined by the node’s dma-names property

**Returns** the node identifier for the DMA controller in the named element

```
DT_INST_DMAS_CTLR(inst)
```
Equivalent to `DT_INST_DMAS_CTLR_BY_IDX(inst, 0)`

See also:

`DT_DMAS_CTLR_BY_IDX()`

Parameters
- **inst** – DT_DRV_COMPAT instance number

**Returns** the node identifier for the DMA controller at index 0 in the instance’s “dmas” property

```
DT_DMAS_CELL_BY_IDX(node_id, idx, cell)
```
Get a DMA specifier’s cell value at an index.

Example devicetree fragment:
```
dma1: dma@... {
    compatible = "vnd,dma";
    #dma-cells = <2>;
};

dma2: dma@... {
    compatible = "vnd,dma";
    #dma-cells = <2>;
};

n: node {
    dmas = <&dma1 1 0x400>,
          <&dma2 6 0x404>;
};
```

Bindings fragment for the vnd,dma compatible:
```
dma-cells:
  - channel
  - config
```

Example usage:
```
DT_DMAS_CELL_BY_IDX(DT_NODELABEL(n), 0, channel) // 1
DT_DMAS_CELL_BY_IDX(DT_NODELABEL(n), 1, channel) // 6
DT_DMAS_CELL_BY_IDX(DT_NODELABEL(n), 0, config) // 0x400
DT_DMAS_CELL_BY_IDX(DT_NODELABEL(n), 1, config) // 0x404
```

See also:

`DT_PHA_BY_IDX()`

Parameters
• node_id – node identifier for a node with a dmas property
• idx – logical index into dmas property
• cell – lowercase-and-underscores cell name

**Returns** the cell value at index “idx”

```c
DT_INST_DMAS_CELL_BY_IDX(inst, idx, cell)
```
Get a DT_DRV_COMPAT instance’s DMA specifier’s cell value at an index.

**See also:**

`DT_DMAS_CELL_BY_IDX()`

**Parameters**

• inst – DT_DRV_COMPAT instance number
• idx – logical index into dmas property
• cell – lowercase-and-underscores cell name

**Returns** the cell value at index “idx”

```c
DT_DMAS_CELL_BY_NAME(node_id, name, cell)
```
Get a DMA specifier’s cell value by name.

Example devicetree fragment:

```plaintext
dma1: dma@... {
    compatible = "vnd,dma";
    #dma-cells = <2>;
};

dma2: dma@... {
    compatible = "vnd,dma";
    #dma-cells = <2>;
};

n: node {
    dmas = <&dma1 1 0x400>,
         <&dma2 6 0x404>;
    dma-names = "tx", "rx";
};
```

Bindings fragment for the vnd,dma compatible:

```plaintext
dma-cells:
    - channel
    - config
```

Example usage:

```c
DT_DMAS_CELL_BY_NAME(DT_NODELABEL(n), tx, channel) // 1
DT_DMAS_CELL_BY_NAME(DT_NODELABEL(n), rx, channel) // 6
DT_DMAS_CELL_BY_NAME(DT_NODELABEL(n), tx, config) // 0x400
DT_DMAS_CELL_BY_NAME(DT_NODELABEL(n), rx, config) // 0x404
```

**See also:**

`DT_PHA_BY_NAME()`
Parameters

- node_id – node identifier for a node with a dmas property
- name – lowercase-and-underscores name of a dmas element as defined by the node's dma-names property
- cell – lowercase-and-underscores cell name

Returns the cell value in the specifier at the named element

DT_INST_DMAS_CELL_BY_NAME(inst, name, cell)
Get a DT_DRV_COMPAT instance's DMA specifier's cell value by name.

See also:

DT_DMAS_CELL_BY_NAME()

Parameters

- inst – DT_DRV_COMPAT instance number
- name – lowercase-and-underscores name of a dmas element as defined by the node's dma-names property
- cell – lowercase-and-underscores cell name

Returns the cell value in the specifier at the named element

DT_DMAS_HAS_IDX(node_id, idx)
Is index “idx” valid for a dmas property?

Parameters

- node_id – node identifier for a node with a dmas property
- idx – logical index into dmas property

Returns 1 if the “dmas” property has index “idx”, 0 otherwise

DT_INST_DMAS_HAS_IDX(inst, idx)
Is index “idx” valid for a DT_DRV_COMPAT instance's dmas property?

Parameters

- inst – DT_DRV_COMPAT instance number
- idx – logical index into dmas property

Returns 1 if the “dmas” property has a specifier at index “idx”, 0 otherwise

DT_DMAS_HAS_NAME(node_id, name)
Does a dmas property have a named element?

Parameters

- node_id – node identifier for a node with a dmas property
- name – lowercase-and-underscores name of a dmas element as defined by the node's dma-names property

Returns 1 if the dmas property has the named element, 0 otherwise

DT_INST_DMAS_HAS_NAME(inst, name)
Does a DT_DRV_COMPAT instance's dmas property have a named element?

Parameters

- inst – DT_DRV_COMPAT instance number
• name – lowercase-and-underscores name of a dmas element as defined by the node's dma-names property

Returns 1 if the dmas property has the named element, 0 otherwise

Fixed flash partitions These conveniences may be used for the special-purpose fixed-partitions compatible used to encode information about flash memory partitions in the device tree. See See fixed-partition for more details.

group devicetree-fixed-partition

Defines

DT_NODE_BY_FIXED_PARTITION_LABEL(label)
Get a node identifier for a fixed partition with a given label property.

Example devicetree fragment:

```
flash@... {
    partitions {
        compatible = "fixed-partitions";
        boot_partition: partition@0 {
            label = "mcuboot";
        };
        slot0_partition: partition@c000 {
            label = "image-0";
        };
        ...
    }
};
```

Example usage:

```
DT_NODE_BY_FIXED_PARTITION_LABEL(mcuboot) // node identifier for boot_-.partition
DT_NODE_BY_FIXED_PARTITION_LABEL(image_0) // node identifier for slot0_-partition
```

Parameters

• label – lowercase-and-underscores label property value

Returns a node identifier for the partition with that label property

DT_HAS_FIXED_PARTITION_LABEL(label)
Test if a fixed partition with a given label property exists.

Parameters

• label – lowercase-and-underscores label property value

Returns 1 if any “fixed-partitions” child node has the given label, 0 otherwise.

DT_FIXED_PARTITION_ID(node_id)
Get a numeric identifier for a fixed partition.

Parameters

• node_id – node identifier for a fixed-partitions child node

Returns the partition's ID, a unique zero-based index number
DT_MTD_FROM_FIXED_PARTITION(node_id)
  Get the node identifier of the flash device for a partition.

  **Parameters**
  
  • node_id – node identifier for a fixed-partitions child node

  **Returns** the node identifier of the memory technology device that contains the fixed-partitions node.

**GPIO** These conveniences may be used for nodes which describe GPIO controllers/pins, and properties related to them.

  **group devicetree-gpio**

**Defines**

DT_GPIO_CTLR_BY_IDX(node_id, gpio_pha, idx)
  Get the node identifier for the controller phandle from a gpio phandle-array property at an index.

  **Example devicetree fragment:**

  gpio1: gpio@... { };
  gpio2: gpio@... { };
  
  n: node {
      gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
             <&gpio2 30 GPIO_ACTIVE_HIGH>;
  }

  **Example usage:**

  DT_GPIO_CTLR_BY_IDX(DT_NODELABEL(n), gpios, 1) // DT_NODELABEL(gpio2)

  **See also:**

  DT_GPIO_CTLR_BY_IDX()

**DT_PHANDLE_BY_IDX()**

  **Parameters**

  • node_id – node identifier
  
  • gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”
  
  • idx – logical index into “gpio_pha”

  **Returns** the node identifier for the gpio controller referenced at index “idx”

DT_GPIO_CTLR(node_id, gpio_pha)
  Equivalent to DT_GPIO_CTLR_BY_IDX(node_id, gpio_pha, 0)

  **See also:**

  DT_GPIO_CTLR_BY_IDX()

**Parameters**

  • node_id – node identifier
• gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”

**Returns** a node identifier for the gpio controller at index 0 in “gpio_pha”

```c
DT_GPIO_LABEL_BY_IDX(node_id, gpio_pha, idx)
```

Get a label property from a gpio phandle-array property at an index.

It’s an error if the GPIO controller node referenced by the phandle in node_id’s “gpio_pha” property at index “idx” has no label property.

Example devicetree fragment:

```c
gpio1: gpio@... {
    label = "GPIO_1";
};

gpio2: gpio@... {
    label = "GPIO_2";
};

n: node {
    gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
             <&gpio2 30 GPIO_ACTIVE_HIGH>;
};
```

Example usage:

```c
DT_GPIO_LABEL_BY_IDX(DT_NODELABEL(n), gpios, 1) // "GPIO_2"
```

See also:

`DT_PHANDLE_BY_IDX()`

**Parameters**

- node_id – node identifier
- gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”
- idx – logical index into “gpio_pha”

**Returns** the label property of the node referenced at index “idx”

```c
DT_GPIO_LABEL(node_id, gpio_pha)
```

Equivalent to `DT_GPIO_LABEL_BY_IDX(node_id, gpio_pha, 0)`

See also:

`DT_GPIO_LABEL_BY_IDX()`

**Parameters**

- node_id – node identifier
- gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”

**Returns** the label property of the node referenced at index 0
DT_GPIO_PIN_BY_IDX(node_id, gpio_pha, idx)

Get a GPIO specifier's pin cell at an index.

This macro only works for GPIO specifiers with cells named "pin". Refer to the node's binding to check if necessary.

Example devicetree fragment:

```devicetree
gpio1: gpio@... {
    compatible = "vnd/gpio";
    #gpio-cells = <2>;
};

gpio2: gpio@... {
    compatible = "vnd/gpio";
    #gpio-cells = <2>;
};

n: node {
    gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
            <&gpio2 30 GPIO_ACTIVE_HIGH>;
};
```

Bindings fragment for the vnd,gpio compatible:

```devicetree
gpio-cells:
- pin
- flags
```

Example usage:

```c
DT_GPIO_PIN_BY_IDX(DT_NODELABEL(n), gpios, 0) // 10
DT_GPIO_PIN_BY_IDX(DT_NODELABEL(n), gpios, 1) // 30
```

See also:

`DT_PHA_BY_IDX()`

Parameters

- `node_id` – node identifier
- `gpio_pha` – lowercase-and-underscores GPIO property with type “phandle-array”
- `idx` – logical index into “gpio_pha”

Returns the pin cell value at index “idx”

`DT_GPIO_PIN(node_id, gpio_pha)`

Equivalent to `DT_GPIO_PIN_BY_IDX(node_id, gpio_pha, 0)`

See also:

`DT_GPIO_PIN_BY_IDX()`

Parameters

- `node_id` – node identifier
- `gpio_pha` – lowercase-and-underscores GPIO property with type “phandle-array”
Returns the pin cell value at index 0

DT_GPIO_FLAGS_BY_IDX(node_id, gpio_pha, idx)
Get a GPIO specifier’s flags cell at an index.

This macro expects GPIO specifiers with cells named “flags”. If there is no “flags” cell in the GPIO specifier, zero is returned. Refer to the node’s binding to check specifier cell names if necessary.

Example devicetree fragment:

```markdown
gpio1: gpio@... {
    compatible = "vnd,gpio";
    #gpio-cells = <2>;
};

gpio2: gpio@... {
    compatible = "vnd,gpio";
    #gpio-cells = <2>;
};

n: node {
    gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
           <&gpio2 30 GPIO_ACTIVE_HIGH>;
}
```

Bindings fragment for the vnd,gpio compatible:

```markdown
gpio-cells:
- pin
- flags
```

Example usage:

```markdown
DT_GPIO_FLAGS_BY_IDX(DT_NODELABEL(n), gpios, 0) // GPIO_ACTIVE_LOW
DT_GPIO_FLAGS_BY_IDX(DT_NODELABEL(n), gpios, 1) // GPIO_ACTIVE_HIGH
```

See also:

`DT_PHA_BY_IDX()`

Parameters

- node_id – node identifier
- gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”
- idx – logical index into “gpio_pha”

Returns the flags cell value at index “idx”, or zero if there is none

DT_GPIO_FLAGS(node_id, gpio_pha)
Equivalent to `DT_GPIO_FLAGS_BY_IDX(node_id, gpio_pha, 0)`

See also:

`DT_GPIO_FLAGS_BY_IDX()`

Parameters

- node_id – node identifier
• gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”

**Returns** the flags cell value at index 0, or zero if there is none

```
DT_INST_GPIO_LABEL_BY_IDX(inst, gpio_pha, idx)
```

Get a label property from a DT_DRV_COMPAT instance's GPIO property at an index.

**Parameters**

• inst – DT_DRV_COMPAT instance number

• gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”

• idx – logical index into “gpio_pha”

**Returns** the label property of the node referenced at index “idx”

```
DT_INST_GPIO_LABEL(inst, gpio_pha)
```

Equivalent to `DT_INST_GPIO_LABEL_BY_IDX(inst, gpio_pha, 0)`

**Parameters**

• inst – DT_DRV_COMPAT instance number

• gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”

**Returns** the label property of the node referenced at index 0

```
DT_INST_GPIO_PIN_BY_IDX(inst, gpio_pha, idx)
```

Get a DT_DRV_COMPAT instance’s GPIO specifier’s pin cell value at an index.

**See also:**

`DT_GPIO_PIN_BY_IDX()`

**Parameters**

• inst – DT_DRV_COMPAT instance number

• gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”

• idx – logical index into “gpio_pha”

**Returns** the pin cell value at index “idx”

```
DT_INST_GPIO_PIN(inst, gpio_pha)
```

Equivalent to `DT_INST_GPIO_PIN_BY_IDX(inst, gpio_pha, 0)`

**See also:**

`DT_INST_GPIO_PIN_BY_IDX()`

**Parameters**

• inst – DT_DRV_COMPAT instance number

• gpio_pha – lowercase-and-underscores GPIO property with type “phandle-array”

**Returns** the pin cell value at index 0
**DT_INST_GPIO_FLAGS_BY_IDX**(inst, gpio_pha, idx)
Get a DT_DRV_COMPTAT instance's GPIO specifier's flags cell at an index.

**See also:**
**DT_GPIO_FLAGS_BY_IDX()**

**Parameters**
- **inst** – DT_DRV_COMPTAT instance number
- **gpio_pha** – lowercase-and-underscores GPIO property with type “phandle-array”
- **idx** – logical index into “gpio_pha”

**Returns** the flags cell value at index “idx”, or zero if there is none

**DT_INST_GPIO_FLAGS**(inst, gpio_pha)
Equivalent to **DT_INST_GPIO_FLAGS_BY_IDX**(inst, gpio_pha, 0)

**See also:**
**DT_INST_GPIO_FLAGS_BY_IDX()**

**Parameters**
- **inst** – DT_DRV_COMPTAT instance number
- **gpio_pha** – lowercase-and-underscores GPIO property with type “phandle-array”

**Returns** the flags cell value at index 0, or zero if there is none

**IO channels** These are commonly used by device drivers which need to use IO channels (e.g. ADC or DAC channels) for conversion.

**group** devicetree-io-channels

**Defines**

**DT_IO_CHANNELS_CTLR_BY_IDX**(node_id, idx)
Get the node identifier for the node referenced by an io-channels property at an index.

Example devicetree fragment:

```plaintext
adc1: adc@... { ... ;
adc2: adc@... { ... ;

n: node {
    io-channels = <&adc1 10>, <&adc2 20>;
};
```

Example usage:

```plaintext
DT_IO_CHANNELS_CTLR_BY_IDX(DT_NODELABEL(n), 0) // DT_NODELABEL(adc1)
DT_IO_CHANNELS_CTLR_BY_IDX(DT_NODELABEL(n), 1) // DT_NODELABEL(adc2)
```
See also:

\texttt{DT_PROP_BY_PHANDLE_IDX()}

\textbf{Parameters}

- \texttt{node\_id} – node identifier for a node with an io-channels property
- \texttt{idx} – logical index into io-channels property

\textbf{Returns} the node identifier for the node referenced at index “idx”

\texttt{DT\_IO\_CHANNELS\_CTRL\_BY\_NAME(node\_id, name)}
Get the node identifier for the node referenced by an io-channels property by name.

Example devicetree fragment:

```
adc1: adc@... { ... };
adc2: adc@... { ... };
n: node {
    io-channels = &adc1 10, &adc2 20;
    io-channel-names = “SENSOR”, “BANDGAP”;
};
```

Example usage:

\texttt{DT\_IO\_CHANNELS\_CTRL\_BY\_NAME(DT\_NODELABEL(n), sensor)} // DT\_NODELABEL(adc1)
\texttt{DT\_IO\_CHANNELS\_CTRL\_BY\_NAME(DT\_NODELABEL(n), bandgap)} // DT\_NODELABEL(adc2)

See also:

\texttt{DT\_PHANDLE\_BY\_NAME()}

\textbf{Parameters}

- \texttt{node\_id} – node identifier for a node with an io-channels property
- \texttt{name} – lowercase-and-underscores name of an io-channels element as defined by the node's io-channel-names property

\textbf{Returns} the node identifier for the node referenced at the named element

\texttt{DT\_IO\_CHANNELS\_CTRL(node\_id)}
Equivalent to \texttt{DT\_IO\_CHANNELS\_CTRL\_BY\_IDX(node\_id, 0)}

See also:

\texttt{DT\_IO\_CHANNELS\_CTRL\_BY\_IDX()}

\textbf{Parameters}

- \texttt{node\_id} – node identifier for a node with an io-channels property

\textbf{Returns} the node identifier for the node referenced at index 0 in the node's “io-channels” property

\texttt{DT\_INST\_IO\_CHANNELS\_CTRL\_BY\_IDX(inst, idx)}
Get the node identifier from a DT\_DRV\_COMPAT instance's io-channels property at an index.
See also:

`DT_IO_CHANNELS_CTLR_BY_IDX()`

**Parameters**

- `inst` – DT_DRV_COMPAT instance number
- `idx` – logical index into io-channels property

**Returns** the node identifier for the node referenced at index “idx”

`DT_INST_IO_CHANNELS_CTLR_BY_NAME(inst, name)`

Get the node identifier from a DT_DRV_COMPAT instance's io-channels property by name.

See also:

`DT_IO_CHANNELS_CTLR_BY_NAME()`

**Parameters**

- `inst` – DT_DRV_COMPAT instance number
- `name` – lowercase-and-underscores name of an io-channels element as defined by the node's io-channel-names property

**Returns** the node identifier for the node referenced at the named element

`DT_INST_IO_CHANNELS_CTLR(inst)`

Equivalent to `DT_INST_IO_CHANNELS_CTLR_BY_IDX(inst, 0)`

See also:

`DT_IO_CHANNELS_CTLR_BY_IDX()`

**Parameters**

- `inst` – DT_DRV_COMPAT instance number

**Returns** the node identifier for the node referenced at index 0 in the node's “io-channels” property

`DT_IO_CHANNELS_INPUT_BY_IDX(node_id, idx)`

Get an io-channels specifier input cell at an index.

This macro only works for io-channels specifiers with cells named “input”. Refer to the node's binding to check if necessary.

Example devicetree fragment:

```plaintext
adc1: adc@... {
    compatible = "vnd_adsn";
    #io-channel-cells = <1>;
};
adc2: adc@... {
    compatible = "vnd_adsn";
    #io-channel-cells = <1>;
};
```

(continues on next page)
io-channels = <&adc1 10>, <&adc2 20>;

Bindings fragment for the vnd,adc compatible:

io-channel-cells:
  • input

Example usage:

```
DT_IO_CHANNELS_INPUT_BY_IDX(DT_NODELABEL(n), 0)  // 10
DT_IO_CHANNELS_INPUT_BY_IDX(DT_NODELABEL(n), 1)  // 20
```

See also:

- `DT_PHA_BY_IDX()`

Parameters

- `node_id` – node identifier for a node with an io-channels property
- `idx` – logical index into io-channels property

Returns the input cell in the specifier at index “idx”

```
DT_IO_CHANNELS_INPUT_BY_NAME(node_id, name)
```

Get an io-channels specifier input cell by name.

This macro only works for io-channels specifiers with cells named “input”. Refer to the node’s binding to check if necessary.

Example devicetree fragment:

```
adc1: adc@... {
    compatible = "vnd,adc";
    #io-channel-cells = <1>;
};

adc2: adc@... {
    compatible = "vnd,adc";
    #io-channel-cells = <1>;
};

n: node {
    io-channels = <&adc1 10>, <&adc2 20>;
    io-channel-names = "SENSOR", "BANDGAP";
};
```

Bindings fragment for the vnd,adc compatible:

io-channel-cells:
  • input

Example usage:

```
DT_IO_CHANNELS_INPUT_BY_NAME(DT_NODELABEL(n), sensor)  // 10
DT_IO_CHANNELS_INPUT_BY_NAME(DT_NODELABEL(n), bandgap)  // 20
```

See also:

- `DT_PHA_BY_NAME()`

7.7. Devicetree
Parameters

- node_id – node identifier for a node with an io-channels property
- name – lowercase-and-underscores name of an io-channels element as defined by the node’s io-channel-names property

Returns the input cell in the specifier at the named element

`DT_IO_CHANNELS_INPUT(node_id)`

Equivalent to `DT_IO_CHANNELS_INPUT_BY_IDX(node_id, 0)`

See also:

`DT_IO_CHANNELS_INPUT_BY_IDX()`

Parameters

- node_id – node identifier for a node with an io-channels property

Returns the input cell in the specifier at index 0

`DT_INST_IO_CHANNELS_INPUT_BY_IDX(inst, idx)`

Get an input cell from the “DT_DRV_INST(inst)” io-channels property at an index.

See also:

`DT_IO_CHANNELS_INPUT_BY_IDX()`

Parameters

- inst – DT_DRV_COMPAT instance number
- idx – logical index into io-channels property

Returns the input cell in the specifier at index “idx”

`DT_INST_IO_CHANNELS_INPUT_BY_NAME(inst, name)`

Get an input cell from the “DT_DRV_INST(inst)” io-channels property by name.

See also:

`DT_IO_CHANNELS_INPUT_BY_NAME()`

Parameters

- inst – DT_DRV_COMPAT instance number
- name – lowercase-and-underscores name of an io-channels element as defined by the instance’s io-channel-names property

Returns the input cell in the specifier at the named element

`DT_INST_IO_CHANNELS_INPUT(inst)`

Equivalent to `DT_INST_IO_CHANNELS_INPUT_BY_IDX(inst, 0)`

Parameters

- inst – DT_DRV_COMPAT instance number

Returns the input cell in the specifier at index 0
**Pinctrl (pin control)**  These are used to access pin control properties by name or index.

Devicetree nodes may have properties which specify pin control (sometimes known as pin mux) settings. These are expressed using `pinctrl-<index>` properties within the node, where the `<index>` values are contiguous integers starting from 0. These may also be named using the `pinctrl-names` property.

Here is an example:

```
node {
  ...
  pinctrl-0 = <&foo &bar ...>;
  pinctrl-1 = <&baz ...>;
  pinctrl-names = "default", "sleep";
};
```

Above, `pinctrl-0` has name "default", and `pinctrl-1` has name "sleep". The `pinctrl-<index>` property values contain phandles. The `&foo`, `&bar`, etc. phandles within the properties point to nodes whose contents vary by platform, and which describe a pin configuration for the node.

```
group devicetree-pinctrl

Defines

**DT_PINCTRL_BY_IDX(node_id, pc_idx, idx)**
Get a node identifier for a phandle in a pinctrl property by index.

Example devicetree fragment:

```
n: node {
  pinctrl-0 = <&foo &bar>;
  pinctrl-1 = <&baz &blub>;
}
```

Example usage:

```
DT_PINCTRL_BY_IDX(DT_NODELABEL(n), 0, 1) // DT_NODELABEL(bar)
DT_PINCTRL_BY_IDX(DT_NODELABEL(n), 1, 0) // DT_NODELABEL(baz)
```

**Parameters**

- `node_id` – node with a pinctrl-`pc_idx` property
- `pc_idx` – index of the pinctrl property itself
- `idx` – index into the value of the pinctrl property

**Returns** node identifier for the phandle at index ‘idx’ in ‘pinctrl-`pc_idx`”

**DT_PINCTRL_0(node_id, idx)**
Get a node identifier from a pinctrl-0 property.

This is equivalent to:

```
DT_PINCTRL_BY_IDX(node_id, 0, idx)
```

It is provided for convenience since pinctrl-0 is commonly used.

**Parameters**

- `node_id` – node with a pinctrl-0 property
- `idx` – index into the pinctrl-0 property

7.7. Devicetree
Returns  node identifier for the phandle at index idx in the pinctrl-0 property of that node

DT_PINCTRL_BY_NAME(node_id, name, idx)
Get a node identifier for a phandle inside a pinctrl node by name.

Example devicetree fragment:

```markdown
default = "default", "sleep";
```

Example usage:

```
DT_PINCTRL_BY_NAME(DT_NODELABEL(n), default, 1) // DT_NODELABEL(bar)
DT_PINCTRL_BY_NAME(DT_NODELABEL(n), sleep, 0) // DT_NODELABEL(baz)
```

Parameters

- node_id – node with a named pinctrl property
- name – lowercase-and-underscores pinctrl property name
- idx – index into the value of the named pinctrl property

Returns  node identifier for the phandle at that index in the pinctrl property

DT_PINCTRL_NAME_TO_IDX(node_id, name)
Convert a pinctrl name to its corresponding index.

Example devicetree fragment:

```
```

Example usage:

```
DT_PINCTRL_NAME_TO_IDX(DT_NODELABEL(n), default) // 0
DT_PINCTRL_NAME_TO_IDX(DT_NODELABEL(n), sleep) // 1
```

Parameters

- node_id – node identifier with a named pinctrl property
- name – lowercase-and-underscores name name of the pinctrl whose index to get

Returns  integer literal for the index of the pinctrl property with that name

DT_PINCTRL_IDX_TO_NAME_TOKEN(node_id, pc_idx)
Convert a pinctrl property index to its name as a token.

This allows you to get a pinctrl property's name, and “remove the quotes” from it.
DT_PINCTRL_IDX_TO_NAME_TOKEN() can only be used if the node has a pinctrl-'pc_idx' property and a pinctrl-names property element for that index. It is an error to use it in other circumstances.

Example devicetree fragment:

```dt
n: node {
    pinctrl-0 = <...>;
    pinctrl-1 = <...>;
    pinctrl-names = "default", "f.o.o2";
};
```

Example usage:

```c
DT_PINCTRL_IDX_TO_NAME_TOKEN(DT_NODELABEL(n), 0) // default
DT_PINCTRL_IDX_TO_NAME_TOKEN(DT_NODELABEL(n), 1) // f_o_o2
```

The same caveats and restrictions that apply to DT_STRING_TOKEN()'s return value also apply here.

**Parameters**

- node_id – node identifier
- pc_idx – index of a pinctrl property in that node

**Returns** name of the pinctrl property, as a token, without any quotes and with non-alphanumeric characters converted to underscores

DT_PINCTRL_IDX_TO_NAME_UPPER_TOKEN(node_id, pc_idx)

Like DT_PINCTRL_IDX_TO_NAME_TOKEN(), but with an uppercased result.

This does the a similar conversion as DT_PINCTRL_IDX_TO_NAME_TOKEN(node_id, pc_idx).

The only difference is that alphabetical characters in the result are uppercased.

Example devicetree fragment:

```dt
n: node {
    pinctrl-0 = <...>;
    pinctrl-1 = <...>;
    pinctrl-names = "default", "f.o.o2";
};
```

Example usage:

```c
DT_PINCTRL_IDX_TO_NAME_TOKEN(DT_NODELABEL(n), 0) // DEFAULT
DT_PINCTRL_IDX_TO_NAME_TOKEN(DT_NODELABEL(n), 1) // F_O_O2
```

The same caveats and restrictions that apply to DT_STRING_UPPER_TOKEN()'s return value also apply here.

DT_NUM_PINCTRLS_BY_IDX(node_id, pc_idx)

Get the number of phandles in a pinctrl property.

Example devicetree fragment:

```dt
n1: node-1 {
    pinctrl-0 = &foo &bar;
};
n2: node-2 {
    pinctrl-0 = &baz;
};
```
Example usage:

```c
DT_NUM_PINCTRLS_BY_IDX(DT_NODELABEL(n1), 0) // 2
DT_NUM_PINCTRLS_BY_IDX(DT_NODELABEL(n2), 0) // 1
```

**Parameters**

- `node_id` – node identifier with a pinctrl property
- `pc_idx` – index of the pinctrl property itself

**Returns** number of phandles in the property with that index

```c
DT_NUM_PINCTRLS_BY_NAME(node_id, name)
```

Like `DT_NUM_PINCTRLS BY_IDX()`, but by name instead.

Example devicetree fragment:

```
n: node {
    pinctrl-0 = <&foo &bar>;
    pinctrl-1 = <&baz>
    pinctrl-names = "default", "sleep";
};
```

Example usage:

```c
DT_NUM_PINCTRLS_BY_NAME(DT_NODELABEL(n), default) // 2
DT_NUM_PINCTRLS_BY_NAME(DT_NODELABEL(n), sleep) // 1
```

**Parameters**

- `node_id` – node identifier with a pinctrl property
- `name` – lowercase-and-underscores name name of the pinctrl property

**Returns** number of phandles in the property with that name

```c
DT_NUM_PINCTRL_STATES(node_id)
```

Get the number of pinctrl properties in a node.

This expands to 0 if there are no pinctrl-i properties. Otherwise, it expands to the number of such properties.

Example devicetree fragment:

```
n1: node-1 {
    pinctrl-0 = <...>;
    pinctrl-1 = <...>;
};
n2: node-2 {
};
```

Example usage:

```c
DT_NUM_PINCTRL_STATES(DT_NODELABEL(n1)) // 2
DT_NUM_PINCTRL_STATES(DT_NODELABEL(n2)) // 0
```

**Parameters**

- `node_id` – node identifier; may or may not have any pinctrl properties

**Returns** number of pinctrl properties in the node
DT_PINCTRL_HAS_IDX(node_id, pc_idx)
Test if a node has a pinctrl property with an index.
This expands to 1 if the pinctrl-'idx' property exists. Otherwise, it expands to 0.
Example devicetree fragment:

```plaintext
n1: node-1 {
    pinctrl-0 = <...>;
    pinctrl-1 = <...>;
};
n2: node-2 {
};
```

Example usage:

```plaintext
DT_PINCTRL_HAS_IDX(DT_NODELABEL(n1), 0) // 1
DT_PINCTRL_HAS_IDX(DT_NODELABEL(n1), 1) // 1
DT_PINCTRL_HAS_IDX(DT_NODELABEL(n1), 2) // 0
DT_PINCTRL_HAS_IDX(DT_NODELABEL(n2), 0) // 0
```

**Parameters**
- node_id – node identifier; may or may not have any pinctrl properties
- pc_idx – index of a pinctrl property whose existence to check

**Returns** 1 if the property exists, 0 otherwise

DT_PINCTRL_HAS_NAME(node_id, name)
Test if a node has a pinctrl property with a name.
This expands to 1 if the named pinctrl property exists. Otherwise, it expands to 0.
Example devicetree fragment:

```plaintext
n1: node-1 {
    pinctrl-0 = <...>;
    pinctrl-names = "default";
};
n2: node-2 {
};
```

Example usage:

```plaintext
DT_PINCTRL_HAS_NAME(DT_NODELABEL(n1), default) // 1
DT_PINCTRL_HAS_NAME(DT_NODELABEL(n1), sleep) // 0
DT_PINCTRL_HAS_NAME(DT_NODELABEL(n2), default) // 0
```

**Parameters**
- node_id – node identifier; may or may not have any pinctrl properties
- name – lowercase-and-underscores pinctrl property name to check

**Returns** 1 if the property exists, 0 otherwise

DT_INST_PINCTRL_BY_IDX(inst, pc_idx, idx)
Get a node identifier for a phandle in a pinctrl property by index for a DT_DRV_COMPAT instance.
This is equivalent to DT_PINCTRL_BY_IDX(DT_DRV_INST(inst), pc_idx, idx).

7.7. Devicetree
Parameters

- `inst` – instance number
- `pc_idx` – index of the pinctrl property itself
- `idx` – index into the value of the pinctrl property

**Returns** node identifier for the phandle at index `idx` in `pinctrl`-`pc_idx`

`DT_INST_PINCTRL_0(inst, idx)`

Get a node identifier from a `pinctrl-0` property for a `DT_DRV_COMPAT` instance. This is equivalent to:

`DT_PINCTRL_BY_IDX(DT_DRV_INST(inst), 0, idx)`

It is provided for convenience since `pinctrl-0` is commonly used.

**Parameters**

- `inst` – instance number
- `idx` – index into the `pinctrl-0` property

**Returns** node identifier for the phandle at index `idx` in the `pinctrl-0` property of that instance

`DT_INST_PINCTRL_BY_NAME(inst, name, idx)`

Get a node identifier for a phandle inside a pinctrl node for a `DT_DRV_COMPAT` instance. This is equivalent to `DT_PINCTRL_BY_NAME(DT_DRV_INST(inst), name, idx)`.

**Parameters**

- `inst` – instance number
- `name` – lowercase-and-underscores pinctrl property name
- `idx` – index into the value of the named pinctrl property

**Returns** node identifier for the phandle at that index in the pinctrl property

`DT_INST_PINCTRL_NAME_TO_IDX(inst, name)`

Convert a pinctrl name to its corresponding index for a `DT_DRV_COMPAT` instance. This is equivalent to `DT_PINCTRL_NAME_TO_IDX(DT_DRV_INST(inst), name)`.

**Parameters**

- `inst` – instance number
- `name` – lowercase-and-underscores name of the pinctrl whose index to get

**Returns** integer literal for the index of the pinctrl property with that name

`DT_INST_PINCTRL_IDX_TO_NAME_TOKEN(inst, pc_idx)`

Convert a pinctrl index to its name as an uppercased token. This is equivalent to `DT_PINCTRL_IDX_TO_NAME_TOKEN(DT_DRV_INST(inst), idx)`.

**Parameters**

- `inst` – instance number
- `pc_idx` – index of the pinctrl property itself

**Returns** name of the pin control property as a token

`DT_INST_PINCTRL_IDX_TO_NAME_UPPER_TOKEN(inst, pc_idx)`

Convert a pinctrl index to its name as an uppercased token. This is equivalent to `DT_PINCTRL_IDX_TO_NAME_UPPER_TOKEN(DT_DRV_INST(inst), idx)`.
Parameters

- `inst` – instance number
- `pc_idx` – index of the pinctrl property itself

Returns name of the pin control property as an uppercase token

`DT_INST_NUM_PINCTRLS_BY_IDX(inst, pc_idx)`

Get the number of phandles in a pinctrl property for a DT_DRV_COMPAT instance. This is equivalent to `DT_NUM_PINCTRLS_BY_IDX(DT_DRV_INST(inst), pc_idx)`.

Parameters

- `inst` – instance number
- `pc_idx` – index of the pinctrl property itself

Returns number of phandles in the property with that index

`DT_INST_NUM_PINCTRLS_BY_NAME(inst, name)`

Like `DT_INST_NUM_PINCTRLS_BY_IDX()`, but by name instead. This is equivalent to `DT_NUM_PINCTRLS_BY_NAME(DT_DRV_INST(inst), name)`.

Parameters

- `inst` – instance number
- `name` – lowercase-and-underscores name of the pinctrl property

Returns number of phandles in the property with that name

`DT_INST_PINCTRL_HAS_IDX(inst, pc_idx)`

Test if a DT_DRV_COMPAT instance has a pinctrl property with an index. This is equivalent to `DT_PINCTRL_HAS_IDX(DT_DRV_INST(inst), pc_idx)`.

Parameters

- `inst` – instance number
- `pc_idx` – index of a pinctrl property whose existence to check

Returns 1 if the property exists, 0 otherwise

`DT_INST_PINCTRL_HAS_NAME(inst, name)`

Test if a DT_DRV_COMPAT instance has a pinctrl property with a name. This is equivalent to `DT_PINCTRL_HAS_NAME(DT_DRV_INST(inst), name)`.

Parameters

- `inst` – instance number
- `name` – lowercase-and-underscores pinctrl property name to check

Returns 1 if the property exists, 0 otherwise
PWMS

These conveniences may be used for nodes which describe PWM controllers and properties related to them.

group devicetree-pwms

Defines

**DT_PWMS_CTLR_BY_IDX(node_id, idx)**

Get the node identifier for the PWM controller from a pwms property at an index.

Example devicetree fragment:

```plaintext
pwm1: pwm-controller@... { ... };
pwm2: pwm-controller@... { ... };
n: node {
    pwms = <&pwm1 1 PWM_POLARITY_NORMAL>,
           <&pwm2 3 PWM_POLARITY_INVERTED>;
};
```

Example usage:

```plaintext
DT_PWMS_CTLR_BY_IDX(DT_NODELABEL(n), 0) // DT_NODELABEL(pwm1)
DT_PWMS_CTLR_BY_IDX(DT_NODELABEL(n), 1) // DT_NODELABEL(pwm2)
```

**DT_PWMS_CTLR_BY_NAME(node_id, name)**

Get the node identifier for the PWM controller from a pwms property by name.

Example devicetree fragment:

```plaintext
pwm1: pwm-controller@... { ... };
pwm2: pwm-controller@... { ... };
n: node { pwms = <&pwm1 1 PWM_POLARITY_NORMAL>, <&pwm2 3 PWM_POLARITY_INVERTED>; pwm-names = “alpha”, “beta”; };
```

Example usage:

```plaintext
DT_PWMS_CTLR_BY_NAME(DT_NODELABEL(n), alpha) // DT_NODELABEL(pwm1)
DT_PWMS_CTLR_BY_NAME(DT_NODELABEL(n), beta) // DT_NODELABEL(pwm2)
```

See also:

**DT_PROP_BY_PHANDLE_IDX()**

Parameters

- node_id – node identifier for a node with a pwms property
- idx – logical index into pwms property

Returns

the node identifier for the PWM controller referenced at index “idx”

**DT_PWMS_CTLR_BY_NAME()**

Parameters

- node_id – node identifier for a node with a pwms property
• name – lowercase-and-underscores name of a pwms element as defined by the node's pwm-names property

**Returns** the node identifier for the PWM controller in the named element

```
DT_PWMS_CTRLR(node_id)
```
Equivalent to `DT_PWMS_CTRLR_BY_IDX(node_id, 0)`

**See also:**

`DT_PWMS_CTRLR_BY_IDX()`

**Parameters**

• node_id – node identifier for a node with a pwms property

**Returns** the node identifier for the PWM controller at index 0 in the node's “pwms” property

```
DT_PWMS_CELL_BY_IDX(node_id, idx, cell)
```
Get PWM specifier's cell value at an index.

Example devicetree fragment:

```plaintext
pwm1: pwm-controller@... {
    compatible = "vnd,pwm";
    label = "PWM_1";
    #pwm-cells = <2>;
};
pwm2: pwm-controller@... {
    compatible = "vnd,pwm";
    label = "PWM_2";
    #pwm-cells = <2>;
};
n: node {
    pwms = <&pwm1 1 200000 PWM_POLARITY_NORMAL>,
           <&pwm2 3 100000 PWM_POLARITY_INVERTED>;
};
```

**Bindings fragment for the “vnd,pwm” compatible:**

```plaintext
pwm-cells:
- channel
- period
- flags
```

**Example usage:**

```plaintext
DT_PWMS_CELL_BY_IDX(DT_NODELABEL(n), 0, channel) // 1
DT_PWMS_CELL_BY_IDX(DT_NODELABEL(n), 1, channel) // 3
DT_PWMS_CELL_BY_IDX(DT_NODELABEL(n), 0, period)  // 200000
DT_PWMS_CELL_BY_IDX(DT_NODELABEL(n), 1, period)  // 100000
DT_PWMS_CELL_BY_IDX(DT_NODELABEL(n), 0, flags)   // PWM_POLARITY_NORMAL
DT_PWMS_CELL_BY_IDX(DT_NODELABEL(n), 1, flags)   // PWM_POLARITY_INVERTED
```

**See also:**

`DT_PHA_BY_IDX()`
### Parameters

- `node_id` – node identifier for a node with a `pwms` property
- `idx` – logical index into `pwms` property
- `cell` – lowercase-and-underscores cell name

### Returns

the cell value at index “`idx`”

```c
DT_PWMS_CELL_BY_NAME(node_id, name, cell)
```

Get a PWM specifier’s cell value by name.

Example devicetree fragment:

```c
pwm1: pwm-controller@... {  
    compatible = "vnd,pwm";
    label = "PWM_1";
    #pwm-cells = <2>;
};

pwm2: pwm-controller@... {  
    compatible = "vnd,pwm";
    label = "PWM_2";
    #pwm-cells = <2>;
};

n: node {  
    pwms = <&pwm1 1 200000 PWM_POLARITY_NORMAL>,
           <&pwm2 3 100000 PWM_POLARITY_INVERTED>;
    pwm-names = "alpha", "beta";
};
```

Example usage:

- `DT_PWMS_CELL_BY_NAME(DT_NODELABEL(n), alpha, channel) // 1`
- `DT_PWMS_CELL_BY_NAME(DT_NODELABEL(n), beta, channel) // 3`
- `DT_PWMS_CELL_BY_NAME(DT_NODELABEL(n), alpha, period) // 200000`
- `DT_PWMS_CELL_BY_NAME(DT_NODELABEL(n), beta, period) // 100000`
- `DT_PWMS_CELL_BY_NAME(DT_NODELABEL(n), alpha, flags) // PWM_POLARITY_NORMAL`
- `DT_PWMS_CELL_BY_NAME(DT_NODELABEL(n), beta, flags) // PWM_POLARITY_INVERTED`

See also:

`DT_PHA_BY_NAME()`

### Parameters

- `node_id` – node identifier for a node with a `pwms` property
- `name` – lowercase-and-underscores name of a `pwms` element as defined by the node's `pwm-names` property
- `cell` – lowercase-and-underscores cell name

### Returns

the cell value in the specifier at the named element
DT_PWMS_CELL(node_id, cell)
Equivalent to \texttt{DT_PWMS_CELL\_BY\_IDX(node_id, 0, cell)}

\textbf{See also:}

\texttt{DT_PWMS\_CELL\_BY\_IDX()}

\textbf{Parameters}

\begin{itemize}
  \item node\_id – node identifier for a node with a pwms property
  \item cell – lowercase-and-underscores cell name
\end{itemize}

\textbf{Returns} the cell value at index 0

DT_PWMS_CHANNEL\_BY\_IDX(node_id, idx)
Get a PWM specifier's channel cell value at an index.
This macro only works for PWM specifiers with cells named “channel”. Refer to the node's binding to check if necessary.

This is equivalent to \texttt{DT_PWMS\_CELL\_BY\_IDX(node_id, idx, channel)}.

\textbf{See also:}

\texttt{DT_PWMS\_CELL\_BY\_IDX()}

\textbf{Parameters}

\begin{itemize}
  \item node\_id – node identifier for a node with a pwms property
  \item idx – logical index into pwms property
\end{itemize}

\textbf{Returns} the channel cell value at index “idx”

DT_PWMS\_CHANNEL\_BY\_NAME(node_id, name)
Get a PWM specifier's channel cell value by name.
This macro only works for PWM specifiers with cells named “channel”. Refer to the node's binding to check if necessary.

This is equivalent to \texttt{DT_PWMS\_CELL\_BY\_NAME(node_id, name, channel)}.

\textbf{See also:}

\texttt{DT_PWMS\_CELL\_BY\_NAME()}

\textbf{Parameters}

\begin{itemize}
  \item node\_id – node identifier for a node with a pwms property
  \item name – lowercase-and-underscores name of a pwms element as defined by the node's pwm-names property
\end{itemize}

\textbf{Returns} the channel cell value in the specifier at the named element

DT_PWMS\_CHANNEL(node_id)
Equivalent to \texttt{DT_PWMS\_CHANNEL\_BY\_IDX(node_id, 0)}

\textbf{See also:}

\texttt{DT_PWMS\_CHANNEL\_BY\_IDX()}

7.7. Devicetree
Parameters

- `node_id` – node identifier for a node with a pwms property

Returns the channel cell value at index 0

```
DT_PWMS_PERIOD_BY_IDX(node_id, idx)
```

Get PWM specifier's period cell value at an index.

This macro only works for PWM specifiers with cells named “period”. Refer to the node's binding to check if necessary.

This is equivalent to `DT_PWMS_CELL_BY_IDX(node_id, idx, period)`.

See also:

`DT_PWMS_CELL_BY_IDX()`

Parameters

- `node_id` – node identifier for a node with a pwms property
- `idx` – logical index into pwms property

Returns the period cell value at index “idx”

```
DT_PWMS_PERIOD_BY_NAME(node_id, name)
```

Get a PWM specifier's period cell value by name.

This macro only works for PWM specifiers with cells named “period”. Refer to the node's binding to check if necessary.

This is equivalent to `DT_PWMS_CELL_BY_NAME(node_id, name, period)`.

See also:

`DT_PWMS_CELL_BY_NAME()`

Parameters

- `node_id` – node identifier for a node with a pwms property
- `name` – lowercase-and-underscores name of a pwms element as defined by the node's pwm-names property

Returns the period cell value in the specifier at the named element

```
DT_PWMS_PERIOD(node_id)
```

Equivalent to `DT_PWMS_PERIOD_BY_IDX(node_id, 0)`

See also:

`DT_PWMS_PERIOD_BY_IDX()`

Parameters

- `node_id` – node identifier for a node with a pwms property

Returns the period cell value at index 0
DT_PWMS_FLAGS_BY_IDX(node_id, idx)
Get a PWM specifier's flags cell value at an index.

This macro expects PWM specifiers with cells named “flags”. If there is no “flags” cell in the
PWM specifier, zero is returned. Refer to the node's binding to check specifier cell names if
necessary.

This is equivalent to DT_PWMS_CELL_BY_IDX(node_id, idx, flags).

See also:
DT_PWMS_CELL_BY_IDX()

Parameters
• node_id – node identifier for a node with a pwms property
• idx – logical index into pwms property

Returns the flags cell value at index “idx”, or zero if there is none

DT_PWMS_FLAGS_BY_NAME(node_id, name)
Get a PWM specifier's flags cell value by name.

This macro expects PWM specifiers with cells named “flags”. If there is no “flags” cell in the
PWM specifier, zero is returned. Refer to the node's binding to check specifier cell names if
necessary.

This is equivalent to DT_PWMS_CELL_BY_NAME(node_id, name, flags) if there is a flags cell,
but expands to zero if there is none.

See also:
DT_PWMS_CELL_BY_NAME()

Parameters
• node_id – node identifier for a node with a pwms property
• name – lowercase-and-underscores name of a pwms element as defined by the
  node's pwm-names property

Returns the flags cell value in the specifier at the named element, or zero if there is
none

DT_PWMS_FLAGS(node_id)
Equivalent to DT_PWMS_FLAGS_BY_IDX(node_id, 0)

See also:
DT_PWMS_FLAGS_BY_IDX()

Parameters
• node_id – node identifier for a node with a pwms property

Returns the flags cell value at index 0, or zero if there is none

DT_INST_PWMS_CTLR_BY_IDX(inst, idx)
Get the node identifier for the PWM controller from a DT_DRV_COMPAT instance's pwms
property at an index.
See also:

**DT_PWMS_CTRLR_BY_IDX()**

**Parameters**

- `inst` – DT_DRV_COMPAT instance number
- `idx` – logical index into pwms property

**Returns** the node identifier for the PWM controller referenced at index “idx”

**DT_INST_PWMS_CTRLR_BY_NAME**(inst, name)
Get the node identifier for the PWM controller from a DT_DRV_COMPAT instance's pwms property by name.

See also:

**DT_PWMS_CTRLR_BY_NAME()**

**Parameters**

- `inst` – DT_DRV_COMPAT instance number
- `name` – lowercase-and-underscores name of a pwms element as defined by the node's pwm-names property

**Returns** the node identifier for the PWM controller in the named element

**DT_INST_PWMS_CTRLR(inst)**
Equivalent to **DT_INST_PWMS_CTRLR_BY_IDX**(inst, 0)

See also:

**DT_PWMS_CTRLR_BY_IDX()**

**Parameters**

- `inst` – DT_DRV_COMPAT instance number

**Returns** the node identifier for the PWM controller at index 0 in the instance's “pwms” property

**DT_INST_PWMS_CELL_BY_IDX**(inst, idx, cell)
Get a DT_DRV_COMPAT instance's PWM specifier's cell value at an index.

**Parameters**

- `inst` – DT_DRV_COMPAT instance number
- `idx` – logical index into pwms property
- `cell` – lowercase-and-underscores cell name

**Returns** the cell value at index “idx”

**DT_INST_PWMS_CELL_BY_NAME**(inst, name, cell)
Get a DT_DRV_COMPAT instance's PWM specifier's cell value by name.

See also:

**DT_PWMS_CELL_BY_NAME()**

**Parameters**
• inst – DT_DRV_COMPAT instance number
• name – lowercase-and-underscores name of a pwms element as defined by the node’s pwm-names property
• cell – lowercase-and-underscores cell name

Returns the cell value in the specifier at the named element

`DT_INST_PWMS_CELL(inst, cell)`
Equivalent to `DT_INST_PWMS_CELL_BY_IDX(inst, 0, cell)`

Parameters

• inst – DT_DRV_COMPAT instance number
• cell – lowercase-and-underscores cell name

Returns the cell value at index 0

`DT_INST_PWMS_CHANNEL_BY_IDX(inst, idx)`
Equivalent to `DT_INST_PWMS_CELL_BY_IDX(inst, idx, channel)`

See also:

`DT_INST_PWMS_CELL_BY_IDX()`

Parameters

• inst – DT_DRV_COMPAT instance number
• idx – logical index into pwms property

Returns the channel cell value at index “idx”

`DT_INST_PWMS_CHANNEL_BY_NAME(inst, name)`
Equivalent to `DT_INST_PWMS_CELL_BY_NAME(inst, name, channel)`

See also:

`DT_INST_PWMS_CELL_BY_NAME()`

Parameters

• inst – DT_DRV_COMPAT instance number
• name – lowercase-and-underscores name of a pwms element as defined by the node’s pwm-names property

Returns the channel cell value in the specifier at the named element

`DT_INST_PWMS_CHANNEL(inst)`
Equivalent to `DT_INST_PWMS_CHANNEL_BY_IDX(inst, 0)`

See also:

`DT_INST_PWMS_CHANNEL_BY_IDX()`

Parameters

• inst – DT_DRV_COMPAT instance number

Returns the channel cell value at index 0
DT_INST_PWMS_PERIOD_BY_IDX(inst, idx)
   Equivalent to DT_INST_PWMS_CELL_BY_IDX(inst, idx, period)

See also:
DT_INST_PWMS_CELL_BY_IDX()

Parameters
• inst – DT_DRV_COMPAT instance number
• idx – logical index into pwms property

Returns the period cell value at index “idx”

DT_INST_PWMS_PERIOD_BY_NAME(inst, name)
   Equivalent to DT_INST_PWMS_CELL_BY_NAME(inst, name, period)

See also:
DT_INST_PWMS_CELL_BY_NAME()

Parameters
• inst – DT_DRV_COMPAT instance number
• name – lowercase-and-underscores name of a pwms element as defined by the node’s pwm-names property

Returns the period cell value in the specifier at the named element

DT_INST_PWMS_PERIOD(inst)
   Equivalent to DT_INST_PWMS_PERIOD_BY_IDX(inst, 0)

See also:
DT_INST_PWMS_PERIOD_BY_IDX()

Parameters
• inst – DT_DRV_COMPAT instance number

Returns the period cell value at index 0

DT_INST_PWMS_FLAGS_BY_IDX(inst, idx)
   Equivalent to DT_INST_PWMS_CELL_BY_IDX(inst, idx, flags)

See also:
DT_INST_PWMS_CELL_BY_IDX()

Parameters
• inst – DT_DRV_COMPAT instance number
• idx – logical index into pwms property

Returns the flags cell value at index “idx”, or zero if there is none
DT_INST_PWMS_FLAGS_BY_NAME(inst, name)
Equivalent to DT_INST_PWMS_CELL_BY_NAME(inst, name, flags)

See also:
DT_INST_PWMS_CELL_BY_NAME()

Parameters
• inst – DT_DRV_COMPAT instance number
• name – lowercase-and-underscores name of a pwms element as defined by the node's pwm-names property

Returns the flags cell value in the specifier at the named element, or zero if there is none

DT_INST_PWMS_FLAGS(inst)
Equivalent to DT_INST_PWMS_FLAGS_BY_IDX(inst, 0)

See also:
DT_INST_PWMS_FLAGS_BY_IDX()

Parameters
• inst – DT_DRV_COMPAT instance number

Returns the flags cell value at index 0, or zero if there is none

SPI These conveniences may be used for nodes which describe either SPI controllers or devices, depending on the case.

group devicetree-spi

Defines

DT_SPI_HAS_CS_GPIOS(spi)
Does a SPI controller node have chip select GPIOs configured?

SPI bus controllers use the “cs-gpios” property for configuring chip select GPIOs. Its value is a phandle-array which specifies the chip select lines.

Example devicetree fragment:

```
spi1: spi@... {
    compatible = "vnd.spi";
    cs-gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
              <&gpio2 20 GPIO_ACTIVE_LOW>;
};
spi2: spi@... {
    compatible = "vnd.spi";
};
```

Example usage:

```
DT_SPI_HAS_CS_GPIOS(DT_NODELABEL(spi1)) // 1
DT_SPI_HAS_CS_GPIOS(DT_NODELABEL(spi2)) // 0
```
Parameters

- spi – a SPI bus controller node identifier

Returns 1 if “spi” has a cs-gpios property, 0 otherwise

\[ \text{DT_SPI_NUM_CS_GPIOS}(\text{spi}) \]

Number of chip select GPIOs in a SPI controller’s cs-gpios property.

Example devicetree fragment:

```plaintext
spi1: spi@... {
    compatible = "vnd.spi";
    cs-gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
              <&gpio2 20 GPIO_ACTIVE_LOW>;
};

spi2: spi@... {
    compatible = "vnd.spi";
};
```

Example usage:

```plaintext
\[ \text{DT_SPI_NUM_CS_GPIOS(DT_NODELABEL(spi1)) // 2} \]
\[ \text{DT_SPI_NUM_CS_GPIOS(DT_NODELABEL(spi2)) // 0} \]
```

Parameters

- spi – a SPI bus controller node identifier

Returns Logical length of spi’s cs-gpios property, or 0 if “spi” doesn’t have a cs-gpios property

\[ \text{DT_SPI_DEV_HAS_CS_GPIOS}(\text{spi_dev}) \]

Does a SPI device have a chip select line configured? Example devicetree fragment:

```plaintext
spi1: spi@... {
    compatible = "vnd.spi";
    cs-gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
              <&gpio2 20 GPIO_ACTIVE_LOW>;

    a: spi-dev-a@0 { 
        reg = <0>;
    };  

    b: spi-dev-b@1 { 
        reg = <1>;
    };  
};

spi2: spi@... {
    compatible = "vnd.spi";
    c: spi-dev-c@0 { 
        reg = <0>;
    };  
};
```

Example usage:
DT_SPI_DEV_HAS_CS_GPIOS(DT_NODELABEL(a)) // 1
DT_SPI_DEV_HAS_CS_GPIOS(DT_NODELABEL(b)) // 1
DT_SPI_DEV_HAS_CS_GPIOS(DT_NODELABEL(c)) // 0

Parameters

• spi_dev – a SPI device node identifier

Returns 1 if spi_dev's bus node DT_BUS(spi_dev) has a chip select pin at index DT_REG_ADDR(spi_dev), 0 otherwise

DT_SPI_DEV_CS_GPIOS_CTLR(spi_dev)
Get a SPI device's chip select GPIO controller's node identifier.

Example devicetree fragment:

gpio1: gpio@... { ... };
gpio2: gpio@... { ... };
spi... {
    compatible = "vnd,spi";
    cs-gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
              <&gpio2 20 GPIO_ACTIVE_LOW>;
    a: spi-dev-a@0 {
        reg = <0>;
    };
    b: spi-dev-b@1 {
        reg = <1>;
    };
};

Example usage:

DT_SPI_DEV_CS_GPIOS_CTLR(DT_NODELABEL(a)) // DT_NODELABEL(gpio1)
DT_SPI_DEV_CS_GPIOS_CTLR(DT_NODELABEL(b)) // DT_NODELABEL(gpio2)

Parameters

• spi_dev – a SPI device node identifier

Returns node identifier for spi_dev's chip select GPIO controller

DT_SPI_DEV_CS_GPIOS_LABEL(spi_dev)
Get a SPI device's chip select GPIO controller's label property.

Example devicetree fragment:

gpio1: gpio@... {
    label = "GPIO_1";
};
gpio2: gpio@... {
    label = "GPIO_2";
};
spi1: spi@... {
    compatible = "vnd,spi";
}
cs-gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
   <&gpio2 20 GPIO_ACTIVE_LOW>;

a: spi-dev-a@0 {
   reg = <0>;
};
b: spi-dev-b@1 {
   reg = <1>;
};

Example usage:
DT_SPI_DEV_CS_GPIOS_LABEL(DT_NODELABEL(a)) // "GPIO_1"
DT_SPI_DEV_CS_GPIOS_LABEL(DT_NODELABEL(b)) // "GPIO_2"

Parameters
• spi_dev – a SPI device node identifier

Returns label property of spi_dev's chip select GPIO controller

DT_SPI_DEV_CS_GPIOS_PIN(spi_dev)
Get a SPI device's chip select GPIO pin number.
It's an error if the GPIO specifier for spi_dev's entry in its bus node's cs-gpios property has no pin cell.
Example devicetree fragment:
spi1: spi@... {
   compatible = "vnd.spi";
   cs-gpios = <&gpio1 10 GPIO_ACTIVE_LOW>,
      <&gpio2 20 GPIO_ACTIVE_LOW>;

   a: spi-dev-a@0 {
      reg = <0>;
   };

   b: spi-dev-b@1 {
      reg = <1>;
   };
};

Example usage:
DT_SPI_DEV_CS_GPIOS_PIN(DT_NODELABEL(a)) // 10
DT_SPI_DEV_CS_GPIOS_PIN(DT_NODELABEL(b)) // 20

Parameters
• spi_dev – a SPI device node identifier

Returns pin number of spi_dev's chip select GPIO

DT_SPI_DEV_CS_GPIOS_FLAGS(spi_dev)
Get a SPI device's chip select GPIO flags.
Example devicetree fragment:
spi: spi®... {
    compatible = "vnd.spi";
    cs-gpios = <&gpio1 10 GPIO_ACTIVE_LOW>;

    a: spi-dev-a@0 {
        reg = <0>;
    };
};

Example usage:

DT_SPI_DEV_CS_GPIOS_FLAGS(DT_NODELABEL(a)) // GPIO_ACTIVE_LOW

If the GPIO specifier for spi_dev's entry in its bus node's cs-gpios property has no flags cell, this expands to zero.

**Parameters**

- spi_dev – a SPI device node identifier

**Returns** flags value of spi_dev's chip select GPIO specifier, or zero if there is none

DT_INST_SPI_DEV_HAS_CS_GPIOS(inst)

Equivalent to `DT_SPI_DEV_HAS_CS_GPIOS(DT_DRV_INST(inst))`.

See also:

*DT_SPI_DEV_HAS_CS_GPIOS()*

**Parameters**

- inst – DT_DRV_COMPAT instance number

**Returns** 1 if the instance's bus has a CS pin at index `DT_INST_REG_ADDR(inst)`, 0 otherwise

DT_INST_SPI_DEV_CS_GPIOS_CTLR(inst)

Get GPIO controller node identifier for a SPI device instance This is equivalent to `DT_SPI_DEV_CS_GPIOS_CTLR(DT_DRV_INST(inst))`.

See also:

*DT_SPI_DEV_CS_GPIOS_CTLR()*

**Parameters**

- inst – DT_DRV_COMPAT instance number

**Returns** node identifier for instance's chip select GPIO controller

DT_INST_SPI_DEV_CS_GPIOS_LABEL(inst)

Get GPIO controller name for a SPI device instance This is equivalent to `DT_SPI_DEV_CS_GPIOS_LABEL(DT_DRV_INST(inst))`.

See also:

*DT_SPI_DEV_CS_GPIOS_LABEL()*

**Parameters**

- inst – DT_DRV_COMPAT instance number
**Returns** label property of the instance’s chip select GPIO controller

```
DT_INST_SPI_DEV_CS_GPIOS_PIN(inst)
```

Equivalent to `DT_SPI_DEV_CS_GPIOS_PIN(DT_DRV_INST(inst))`.

**See also:**
`DT_SPI_DEV_CS_GPIOS_PIN()`

**Parameters**

- `inst` – DT_DRV_COMPAT instance number

**Returns** pin number of the instance’s chip select GPIO

```
DT_INST_SPI_DEV_CS_GPIOS_FLAGS(inst)
```

```
DT_SPI_DEV_CS_GPIOS_FLAGS(DT_DRV_INST(inst))
```

**See also:**
`DT_SPI_DEV_CS_GPIOS_FLAGS()`

**Parameters**

- `inst` – DT_DRV_COMPAT instance number

**Returns** flags value of the instance’s chip select GPIO specifier, or zero if there is none

**Chosen nodes**

The special `/chosen` node contains properties whose values describe system-wide settings. The `DT_CHOSEN()` macro can be used to get a node identifier for a chosen node.

**group devicetree-generic-chosen**

**Defines**

```
DT_CHOSEN(prop)
```

Get a node identifier for a /chosen node property.

This is only valid to call if `DT_HAS_CHOSEN(prop)` is 1.

**Parameters**

- `prop` – lowercase-and-underscores property name for the /chosen node

**Returns** a node identifier for the chosen node property

```
DT_HAS_CHOSEN(prop)
```

Test if the devicetree has a /chosen node.

**Parameters**

- `prop` – lowercase-and-underscores devicetree property

**Returns** 1 if the chosen property exists and refers to a node, 0 otherwise

There are also conveniences for commonly used zephyr-specific properties of the /chosen node.

**group devicetree-zephyr**
Defines

DT_CHOSEN_ZEPHYR_ENTROPY_LABEL
If there is a chosen node zephyr,entropy property which has a label property, that property’s value. Undefined otherwise.

DT_CHOSEN_ZEPHYR_FLASH_CONTROLLER_LABEL
If there is a chosen node zephyr,flash-controller property which has a label property, that property’s value. Undefined otherwise.

The following table documents some commonly used Zephyr-specific chosen nodes.

Sometimes, a chosen node’s label property will be used to set the default value of a Kconfig option which in turn configures a hardware-specific device. This is usually for backwards compatibility in cases when the Kconfig option predates devicetree support in Zephyr. In other cases, there is no Kconfig option, and the devicetree node is used directly in the source code to select a device.

<table>
<thead>
<tr>
<th>Property</th>
<th>Purpose</th>

7.7.2 Bindings index

This page documents the available devicetree bindings. See Devicetree bindings for an introduction to the Zephyr bindings file format.

Vendor index

This section contains an index of hardware vendors. Click on a vendor's name to go to the list of bindings for that vendor.

- Generic or vendor-independent
- Altera Corp. (altr)
- AMS AG (ams)
- Analog Devices, Inc. (adi)
- Andes Technology Corporation (andestech)
- Apa Electronic Co., Ltd (apa)
- Aptina Imaging (aptina)
- Arduino (arduino)
- ARM Ltd. (arm)
- Asahi Kasei Corp. (asahi-kasei)
- ASMedia Technology Inc. (asmedia)
- Atmel Corporation (atmel)
- Avago Technologies (avago)
- Bosch Sensortec GmbH (bosch)
- Broadcom Corporation (bcm)
- Cadence Design Systems Inc. (cdns)
- Cypress Semiconductor Corporation (cypress)
- Dalian Good Display Co., Ltd. (gooddisplay)
- Espressif Systems (espressif)
- Fairchild Semiconductor (fcs)
- FocalTech Systems Co., Ltd (focaltech)
- Freescale Semiconductor (fsl)
- Future Technology Devices International Ltd. (ftdi)
- Gaisler (gaisler)
- GigaDevice Semiconductor (gd)
- GreeLed Electronic Ltd. (greeled)
- Guangzhou Aosong Electronic Co., Ltd. (aosong)
- Holtek Semiconductor, Inc. (holtek)
- Honeywell (honeywell)
- HOPERF Microelectronics Co. Ltd (hoperf)
- Hynitron (hynitron)
- ILI Technology Corporation (ILITEK) (ili)
- Imagination Technologies Ltd. (formerly MIPS Technologies Inc.) (mti)
- Infineon Technologies (infineon)
- Intel Corporation (intel)
- Intersil (isil)
- InvenSense Inc. (invensense)
- Inventek Systems (inventek)
- ITE Tech. Inc. (ite)
- JEDEC Solid State Technology Association (jedec)
- Linaro Limited (linaro)
- LiteX SoC builder (litex)
- Maxim Integrated Products (maxim)
- Measurement Specialties (meas)

- Nuclei System Technology (nuclei)
- Nuvoton Technology Corporation (nuvoton)
- NXP Semiconductors (nxp)
- OmniVision Technologies (ovti)
- open-isa.org (openisa)
- OpenCores.org (opencores)
- Panasonic Corporation (panasonic)
- Plantower Co., Ltd (plantower)
- QEMU, a generic and open source machine emulator and virtualizer (qemu)
- Qorvo, Inc (formerly Decawave) (decawave)
- Quectel Wireless Solutions Co., Ltd. (quectel)
- QuickLogic Corp. (quicklogic)
- Raspberry Pi Foundation (raspberrypi)
- Renesas Electronics Corporation (renesas)
- RISC-V Foundation (riscv)
- ROCKTECH DISPLAYS LIMITED (rocktech)
- Seeed Technology Co., Ltd (seeed)
- SEgger Microcontroller GmbH (segger)
- Semtech Corporation (semtech)
- Sensirion AG (sensirion)
- Sharp Corporation (sharp)
- Sierra Wireless (swir)
- SiFive, Inc. (sifive)
• Silicon Laboratories (silabs)
• SIMCom Wireless Solutions Co., LTD (simcom)
• Sitronix Technology Corporation (sitronix)
• Skyworks Solutions, Inc. (skyworks)
• Smart Battery System (sbs)
• Solomon Systech Limited (solomon)
• Standard Microsystems Corporation (smsc)
• STMicroelectronics (st)
• Synopsys, Inc. (snps)
• Synopsys, Inc. (formerly ARC International PLC) (arc)
• Telink Semiconductor (telink)
• Texas Instruments (ti)
• u-blox (u-blox)
• Vishay Intertechnology, Inc (vishay)
• Wistron NeWeb Corporation (wnc)
• WIZNet Co., Ltd. (wisnet)
• Worldsemi Co., Limited (worldsemi)
• Würth Elektronik GmbH. (we)
• Xilinx (xlnx)
• Zephyr-specific binding (zephyr)
• Zhengzhou Winsen Electronics Technology Co., Ltd. (wensen)
• Unknown vendor

Bindings by vendor

This section contains available bindings, grouped by vendor. Within each group, bindings are listed by the “compatible” property they apply to, like this:

Vendor name (vendor prefix)

• <compatible-A>
• <compatible-B> (on <bus-name> bus)
• <compatible-C>
  ...

The text “(on <bus-name> bus)” appears when bindings may behave differently depending on the bus the node appears on. For example, this applies to some sensor device nodes, which may appear as children of either I2C or SPI bus nodes.

7.8  Device Driver Model

7.8.1  Introduction

The Zephyr kernel supports a variety of device drivers. Whether a driver is available depends on the board and the driver.

The Zephyr device model provides a consistent device model for configuring the drivers that are part of a system. The device model is responsible for initializing all the drivers configured into the system.

Each type of driver (e.g. UART, SPI, I2C) is supported by a generic type API.

In this model the driver fills in the pointer to the structure containing the function pointers to its API functions during driver initialization. These structures are placed into the RAM section in initialization level order.

7.8.2  Standard Drivers

Device drivers which are present on all supported board configurations are listed below.

- **Interrupt controller**: This device driver is used by the kernel’s interrupt management subsystem.
- **Timer**: This device driver is used by the kernel’s system clock and hardware clock subsystem.
- **Serial communication**: This device driver is used by the kernel’s system console subsystem.
- **Entropy**: This device driver provides a source of entropy numbers for the random number generator subsystem.

**Important**: Use the *random API functions* for random values. *Entropy functions* should not be directly used as a random number generator source as some hardware implementations are designed...
to be an entropy seed source for random number generators and will not provide cryptographically secure random number streams.

7.8.3 Synchronous Calls

Zephyr provides a set of device drivers for multiple boards. Each driver should support an interrupt-based implementation, rather than polling, unless the specific hardware does not provide any interrupt.

High-level calls accessed through device-specific APIs, such as i2c.h or spi.h, are usually intended as synchronous. Thus, these calls should be blocking.

7.8.4 Driver APIs

The following APIs for device drivers are provided by device.h. The APIs are intended for use in device drivers only and should not be used in applications.

DEVICE_DEFINE() Create device object and related data structures including setting it up for boot-time initialization.

DEVICE_NAME_GET() Converts a device identifier to the global identifier for a device object.

DEVICE_GET() Obtain a pointer to a device object by name.

DEVICE_DECLARE() Declare a device object. Use this when you need a forward reference to a device that has not yet been defined.

7.8.5 Driver Data Structures

The device initialization macros populate some data structures at build time which are split into read-only and runtime-mutable parts. At a high level we have:

```c
struct device {
    const char *name;
    const void *config;
    const void *api;
    void * const data;
};
```

The `config` member is for read-only configuration data set at build time. For example, base memory mapped IO addresses, IRQ line numbers, or other fixed physical characteristics of the device. This is the `config` pointer passed to `DEVICE_DEFINE()` and related macros.

The `data` struct is kept in RAM, and is used by the driver for per-instance runtime housekeeping. For example, it may contain reference counts, semaphores, scratch buffers, etc.

The `api` struct maps generic subsystem APIs to the device-specific implementations in the driver. It is typically read-only and populated at build time. The next section describes this in more detail.

7.8.6 Subsystems and API Structures

Most drivers will be implementing a device-independent subsystem API. Applications can simply program to that generic API, and application code is not specific to any particular driver implementation.

A subsystem API definition typically looks like this:
typedef int (*subsystem_do_this_t)(const struct device *dev, int foo, int bar);
typedef void (*subsystem_do_that_t)(const struct device *dev, void *baz);

struct subsystem_api {
    subsystem_do_this_t do_this;
    subsystem_do_that_t do_that;
};

static inline int subsystem_do_this(const struct device *dev, int foo, int bar) {
    struct subsystem_api *api;
    api = (struct subsystem_api *)dev->api;
    return api->do_this(dev, foo, bar);
}

static inline void subsystem_do_that(const struct device *dev, void *baz) {
    struct subsystem_api *api;
    api = (struct subsystem_api *)dev->api;
    api->do_that(dev, baz);
}

A driver implementing a particular subsystem will define the real implementation of these APIs, and populate an instance of subsystem_api structure:

static int my_driver_do_this(const struct device *dev, int foo, int bar) {
    ...
}

static void my_driver_do_that(const struct device *dev, void *baz) {
    ...
}

static struct subsystem_api my_driver_api_funcs = {
    .do_this = my_driver_do_this,
    .do_that = my_driver_do_that
};

The driver would then pass my_driver_api_funcs as the api argument to DEVICE_DEFINE().

**Note:** Since pointers to the API functions are referenced in the api struct, they will always be included in the binary even if unused; gc-sections linker option will always see at least one reference to them. Providing for link-time size optimizations with driver APIs in most cases requires that the optional feature be controlled by a Kconfig option.

### 7.8.7 Device-Specific API Extensions

Some devices can be cast as an instance of a driver subsystem such as GPIO, but provide additional functionality that cannot be exposed through the standard API. These devices combine subsystem operations with device-specific APIs, described in a device-specific header.

A device-specific API definition typically looks like this:
```c
#include <drivers/subsystem.h>

/* When extensions need not be invoked from user mode threads */
int specific_do_that(const struct device *dev, int foo);

/* When extensions must be invokable from user mode threads */
__syscall int specific_from_user(const struct device *dev, int bar);

/* Only needed when extensions include syscalls */
#include <syscalls/specific.h>

A driver implementing extensions to the subsystem will define the real implementation of both the subsystem API and the specific APIs:

```c
static int generic_do_this(const struct device *dev, void *arg)
{
  ...
}

static struct generic_api api {
  ...
  .do_this = generic_do_this,
  ...
};

/* supervisor-only API is globally visible */
int specific_do_that(const struct device *dev, int foo)
{
  ...
}

/* syscall API passes through a translation */
int z_impl_specific_from_user(const struct device *dev, int bar)
{
  ...
}

#ifdef CONFIG_USERSPACE
#include <syscall_handler.h>

int z_vrfy_specific_from_user(const struct device *dev, int bar)
{
  Z_OOPS(Z_SYSCALL_SPECIFIC_DRIVER(dev, K_OBJ_DRIVER_GENERIC, &api));
  return z_impl_specific_do_that(dev, bar)
}

#include <syscalls/specific_from_user_mrsh.c>
#endif /* CONFIG_USERSPACE */
```

Applications use the device through both the subsystem and specific APIs.

**Note:** Public API for device-specific extensions should be prefixed with the compatible for the device to which it applies. For example, if adding special functions to support the Maxim DS3231 the identifier fragment `specific` in the examples above would be `maxim_ds3231`. 

588 Chapter 7. API Reference
7.8.8 Single Driver, Multiple Instances

Some drivers may be instantiated multiple times in a given system. For example, there can be multiple GPIO banks, or multiple UARTS. Each instance of the driver will have a different config struct and data struct.

Configuring interrupts for multiple drivers instances is a special case. If each instance needs to configure a different interrupt line, this can be accomplished through the use of per-instance configuration functions, since the parameters to IRQ_CONNECT() need to be resolvable at build time.

For example, let’s say we need to configure two instances of my_driver, each with a different interrupt line. In drivers/subsystem/subsystem_my_driver.h:

```c
typedef void (*my_driver_config_irq_t)(const struct device *dev);

struct my_driver_config {
    DEVICE_MMIO_ROM;
    my_driver_config_irq_t config_func;
};
```

In the implementation of the common init function:

```c
void my_driver_isr(const struct device *dev) {
    /* Handle interrupt */
    ...
}

int my_driver_init(const struct device *dev) {
    const struct my_driver_config *config = dev->config;
    DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);
    /* Do other initialization stuff */
    ...
    config->config_func(dev);
    return 0;
}
```

Then when the particular instance is declared:

```c
#if CONFIG_MY_DRIVER_0
DEVICE_DECLARE(my_driver_0);

static void my_driver_config_irq_0(void) {
    IRQ_CONNECT(MY_DRIVER_0_IRQ, MY_DRIVER_0_PRI, my_driver_isr,
                DEVICE_GET(my_driver_0), MY_DRIVER_0_FLAGS);
}

const static struct my_driver_config my_driver_config_0 = {
    DEVICE_MMIO_ROM_INIT(DT_DRV_INST(0)),
    .config_func = my_driver_config_irq_0
}
```

(continues on next page)
Note the use of DEVICE_DECLARE() to avoid a circular dependency on providing the IRQ handler argument and the definition of the device itself.

### 7.8.9 Initialization Levels

Drivers may depend on other drivers being initialized first, or require the use of kernel services. DEVICE_DEFINE() and related APIs allow the user to specify at what time during the boot sequence the init function will be executed. Any driver will specify one of four initialization levels:

**PRE_KERNEL_1** Used for devices that have no dependencies, such as those that rely solely on hardware present in the processor/SOC. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. The interrupt subsystem will be configured however so it's OK to set up interrupts. Init functions at this level run on the interrupt stack.

**PRE_KERNEL_2** Used for devices that rely on the initialization of devices initialized as part of the PRE_KERNEL_1 level. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. Init functions at this level run on the interrupt stack.

**POST_KERNEL** Used for devices that require kernel services during configuration. Init functions at this level run in context of the kernel main task.

**APPLICATION** Used for application components (i.e. non-kernel components) that need automatic configuration. These devices can use all services provided by the kernel during configuration. Init functions at this level run on the kernel main task.

Within each initialization level you may specify a priority level, relative to other devices in the same initialization level. The priority level is specified as an integer value in the range 0 to 99; lower values indicate earlier initialization. The priority level must be a decimal integer literal without leading zeroes or sign (e.g. 32), or an equivalent symbolic name (e.g. \#define MY_INIT_PRIO 32); symbolic expressions are not permitted (e.g. CONFIG_KERNEL_INIT_PRIORITY_DEFAULT + 5).

Drivers and other system utilities can determine whether startup is still in pre-kernel states by using the k_is_pre_kernel() function.

### 7.8.10 System Drivers

In some cases you may just need to run a function at boot. For such cases, the SYS_INIT can be used. This macro does not take any config or runtime data structures and there isn't a way to later get a device pointer by name. The same device policies for initialization level and priority apply.

### 7.8.11 Error handling

In general, it's best to use _ASSERT() macros instead of propagating return values unless the failure is expected to occur during the normal course of operation (such as a storage device full). Bad parameters, programming errors, consistency checks, pathological/unrecoverable failures, etc., should be handled by assertions.
When it is appropriate to return error conditions for the caller to check, 0 should be returned on success and a POSIX `errno.h` code returned on failure. See https://github.com/zephyrproject-rtos/zephyr/wiki/Naming-Conventions#return-codes for details about this.

### 7.8.12 Memory Mapping

On some systems, the linear address of peripheral memory-mapped I/O (MMIO) regions cannot be known at build time:

- The I/O ranges must be probed at runtime from the bus, such as with PCI express
- A memory management unit (MMU) is active, and the physical address of the MMIO range must be mapped into the page tables at some virtual memory location determined by the kernel.

These systems must maintain storage for the MMIO range within RAM and establish the mapping within the driver's init function. Other systems do not care about this and can use MMIO physical addresses directly from DTS and do not need any RAM-based storage for it.

For drivers that may need to deal with this situation, a set of APIs under the DEVICE_MMIO scope are defined, along with a mapping function `device_map()`.

#### Device Model Drivers with one MMIO region

The simplest case is for drivers which need to maintain one MMIO region. These drivers will need to use the `DEVICE_MMIO_ROM` and `DEVICE_MMIO_RAM` macros in the definitions for their `config_info` and `driver_data` structures, with initialization of the `config_info` from DTS using `DEVICE_MMIO_ROM_INIT`. A call to `DEVICE_MMIO_MAP()` is made within the init function:

```c
struct my_driver_config {
    DEVICE_MMIO_ROM; /* Must be first */
    ...
}

struct my_driver_dev_data {
    DEVICE_MMIO_RAM; /* Must be first */
    ...
}

const static struct my_driver_config my_driver_config_0 = {
    DEVICE_MMIO_ROM_INIT(DT_DRV_INST(...)),
    ...
}

int my_driver_init(const struct device *dev)
{
    ...
    DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);
    ...
}

int my_driver_some_function(const struct device *dev)
{
    ...
    /* Write some data to the MMIO region */
    sys_write32(0xDEADBEEF, DEVICE_MMIO_GET(dev));
    ...
}
```
The particular expansion of these macros depends on configuration. On a device with no MMU or PCI-e, `DEVICE_MMIO_MAP` and `DEVICE_MMIO_RAM` expand to nothing.

### Device Model Drivers with multiple MMIO regions

Some drivers may have multiple MMIO regions. In addition, some drivers may already be implementing a form of inheritance which requires some other data to be placed first in the `config_info` and `driver_data` structures.

This can be managed with the `DEVICE_MMIO_NAMED` variant macros. These require that `DEV_CFG()` and `DEV_DATA()` macros be defined to obtain a properly typed pointer to the driver's `config_info` or `dev_data` structs. For example:

```c
struct my_driver_config {
    ...
    DEVICE_MMIO_NAMED_ROM(corge);
    DEVICE_MMIO_NAMED_ROM(grault);
    ...
}

struct my_driver_dev_data {
    ...
    DEVICE_MMIO_NAMED_RAM(corge);
    DEVICE_MMIO_NAMED_RAM(grault);
    ...
}

#define DEV_CFG(_dev) \
    ((const struct my_driver_config *)((dev)->config))

#define DEV_DATA(_dev) \
    ((struct my_driver_dev_data *)((dev)->data))

const static struct my_driver_config my_driver_config_0 = {
    ...
    DEVICE_MMIO_NAMED_ROM_INIT(corge, DT_DRV_INST(...)),
    DEVICE_MMIO_NAMED_ROM_INIT(grault, DT_DRV_INST(...)),
    ...
}

int my_driver_init(const struct device *dev)
{
    ...
    DEVICE_MMIO_NAMED_MAP(dev, corge, K_MEM_CACHE_NONE);
    DEVICE_MMIO_NAMED_MAP(dev, grault, K_MEM_CACHE_NONE);
    ...
}

int my_driver_some_function(const struct device *dev)
{
    /* Write some data to the MMIO regions */
    sys_write32(0xDEADBEEF, DEVICE_MMIO_GET(dev, grault));
    sys_write32(0xF0CCAC1A, DEVICE_MMIO_GET(dev, corge));
    ...
}
```
Drivers that do not use Zephyr Device Model

Some drivers or driver-like code may not use Zephyr’s device model, and alternative storage must be arranged for the MMIO data. An example of this are timer drivers, or interrupt controller code.

This can be managed with the \texttt{DEVICE\_MMIO\_TOPLEVEL} set of macros, for example:

\begin{lstlisting}[language=C]
DEVICE\_MMIO\_TOPLEVEL\_STATIC(my_regs, DT\_DRV\_INST(..));

void some_init_code(...) {
    ...
    DEVICE\_MMIO\_TOPLEVEL\_MAP(my_regs, K\_MEM\_CACHE\_NONE);
    ...
}

void some_function(...) {
    ...
    sys_write32(DEVICE\_MMIO\_TOPLEVEL\_GET(my_regs), 0xDEADBEEF);
    ...
}
\end{lstlisting}

Drivers that do not use DTS

Some drivers may not obtain the MMIO physical address from DTS, such as is the case with PCI-E. In this case the \texttt{device\_map()} function may be used directly:

\begin{lstlisting}[language=C]
void some_init_code(...) {
    ...
    struct pcie\_mbar mbar;
    bool bar_found = pcie\_get\_mbar(bdf, index, &mbar);

    device\_map(DEVICE\_MMIO\_RAM\_PTR(dev), mbar.phys\_addr, mbar.size, K\_MEM\_CACHE\_NONE);
    ...
}
\end{lstlisting}

For these cases, \texttt{DEVICE\_MMIO\_ROM} directives may be omitted.

7.8.13 API Reference

\begin{verbatim}
group device_model
    Device Model APIs.

Defines

DEVICE\_HANDLE\_SEP
    Flag value used in lists of device handles to separate distinct groups.
    This is the minimum value for the device\_handle\_t type.

DEVICE\_HANDLE\_ENDS
    Flag value used in lists of device handles to indicate the end of the list.
    This is the maximum value for the device\_handle\_t type.
\end{verbatim}
DEVICE_HANDLE_NULL
Flag value used to identify an unknown device.

DEVICE_NAME_GET(name)
Expands to the name of a global device object.

Return the full name of a device object symbol created by DEVICE_DEFINE(), using the dev_name provided to DEVICE_DEFINE(). This is the name of the global variable storing the device structure, not a pointer to the string in the device's name field.

It is meant to be used for declaring extern symbols pointing to device objects before using the DEVICE_GET macro to get the device object.

This macro is normally only useful within device driver source code. In other situations, you are probably looking for device_get_binding().

Parameters
• name – The same dev_name token given to DEVICE_DEFINE()

Returns The full name of the device object defined by DEVICE_DEFINE()

SYS_DEVICE_DEFINE(drv_name, init_fn, level, prio)
Run an initialization function at boot at specified priority.

Deprecated:
Use SYS_INIT() instead.

Parameters
• drv_name – A string name for the pseudo-device (unused).
• init_fn – Pointer to the function which should run at boot time.
• level – Initialization level to run the function in.
• prio – Function's priority within its initialization level.

DEVICE_DEFINE(dev_name, drv_name, init_fn, pm_device, data_ptr, cfg_ptr, level, prio, api_ptr)
Create a device object and set it up for boot time initialization.

This macro defines a struct device that is automatically configured by the kernel during system initialization. This macro should only be used when the device is not being allocated from a devicetree node. If you are allocating a device from a devicetree node, use DEVICE_DT_DEFINE() or DEVICE_DT_INST_DEFINE() instead.

Parameters
• dev_name – A unique token which is used in the name of the global device structure as a C identifier.
• drv_name – A string name for the device, which will be stored in the device structure's name field. This name can be used to look up the device with device_get_binding(). This must be less than Z_DEVICE_MAX_NAME_LEN characters (including terminating NUL) in order to be looked up from user mode.
• init_fn – Pointer to the device's initialization function, which will be run by the kernel during system initialization.
• pm_device – Pointer to the device's power management resources, a struct pm_device, which will be stored in the device structure's pm field. Use NULL if the device does not use PM.
• data_ptr – Pointer to the device's private mutable data, which will be stored in the device structure's data field.
• `cfg_ptr` – Pointer to the device's private constant data, which will be stored in the device structure's `config` field.

• `level` – The device's initialization level. See `SYS_INIT()` for details.

• `prio` – The device's priority within its initialization level. See `SYS_INIT()` for details.

• `api_ptr` – Pointer to the device's API structure. Can be NULL.

**DEVICE_DT_NAME(node_id)**

Return a string name for a devicetree node.

This macro returns a string literal usable as a device's `name` field from a devicetree node identifier.

**Parameters**

• `node_id` – The devicetree node identifier.

**Returns** The value of the node's "label" property, if it has one. Otherwise, the node's full name in "node-name@@unit-address" form.

**DEVICE_DT_DEFINE(node_id, init_fn, pm_device, data_ptr, cfg_ptr, level, prio, api_ptr, ...)**

Create a device object from a devicetree node identifier and set it up for boot time initialization.

This macro defines a `struct device` that is automatically configured by the kernel during system initialization. The global device object's name as a C identifier is derived from the node's dependency ordinal. The device structure's `name` field is set to `DEVICE_DT_NAME(node_id)`.

The device is declared with extern visibility, so a pointer to a global device object can be obtained with `DEVICE_DT_GET(node_id)` from any source file that includes device.h. Before using the pointer, the referenced object should be checked using `device_is_ready()`.

**Parameters**

• `node_id` – The devicetree node identifier.

• `init_fn` – Pointer to the device's initialization function, which will be run by the kernel during system initialization.

• `pm_device` – Pointer to the device's power management resources, a `struct pm_device`, which will be stored in the device structure's `pm` field. Use `NULL` if the device does not use PM.

• `data_ptr` – Pointer to the device's private mutable data, which will be stored in the device structure's `data` field.

• `cfg_ptr` – Pointer to the device's private constant data, which will be stored in the device structure's `config` field.

• `level` – The device's initialization level. See `SYS_INIT()` for details.

• `prio` – The device's priority within its initialization level. See `SYS_INIT()` for details.

• `api_ptr` – Pointer to the device's API structure. Can be NULL.

**DEVICE_DT_INST_DEFINE(inst, ...)**

Like `DEVICE_DT_DEFINE()`, but uses an instance of a `DT_DRV_COMPAT` compatible instead of a node identifier.

**Parameters**

• `inst` – instance number. The `node_id` argument to `DEVICE_DT_DEFINE` is set to `DT_DRV_INST(inst)`.

• `...` – other parameters as expected by `DEVICE_DT_DEFINE`.
**DEVICE_DT_NAME_GET(node_id)**

The name of the global device object for `node_id`.

Returns the name of the global device structure as a C identifier. The device must be allocated using `DEVICE_DT_DEFINE()` or `DEVICE_DT_INST_DEFINE()` for this to work.

This macro is normally only useful within device driver source code. In other situations, you are probably looking for `DEVICE_DT_GET()`.

**Parameters**

- `node_id` – Devicetree node identifier

**Returns** The name of the device object as a C identifier

**DEVICE_DT_GET(node_id)**

Get a `const struct device*` from a devicetree node identifier.

Returns a pointer to a device object created from a devicetree node, if any device was allocated by a driver.

If no such device was allocated, this will fail at linker time. If you get an error that looks like `undefined reference to __device_dts_ord_<N>`, that is what happened. Check to make sure your device driver is being compiled, usually by enabling the Kconfig options it requires.

**Parameters**

- `node_id` – A devicetree node identifier

**Returns** A pointer to the device object created for that node

**DEVICE_DT_INST_GET(inst)**

Get a `const struct device*` for an instance of a DT_DRV_COMPAT compatible.

This is equivalent to `DEVICE_DT_GET(DT_DRV_INST(inst))`.

**Parameters**

- `inst` – DT_DRV_COMPAT instance number

**Returns** A pointer to the device object created for that instance

**DEVICE_DT_GET_ANY(compat)**

Get a `const struct device*` from a devicetree compatible.

If an enabled devicetree node has the given compatible and a device object was created from it, this returns a pointer to that device.

If there no such devices, this returns NULL.

If there are multiple, this returns an arbitrary one.

If this returns non-NULL, the device must be checked for readiness before use, e.g. with `device_is_ready()`.

**Parameters**

- `compat` – lowercase-and-underscores devicetree compatible

**Returns** a pointer to a device, or NULL

**DEVICE_DT_GET_ONE(compat)**

Get a `const struct device*` from a devicetree compatible.

If an enabled devicetree node has the given compatible and a device object was created from it, this returns a pointer to that device.

If there no such devices, this will fail at compile time.

If there are multiple, this returns an arbitrary one.

If this returns non-NULL, the device must be checked for readiness before use, e.g. with `device_is_ready()`.
Parameters

• compat – lowercase-and-underscores devicetree compatible

Returns a pointer to a device

DEVICE_DT_GET_OR_NULL(node_id)
Utility macro to obtain an optional reference to a device.

If the node identifier refers to a node with status “okay”, this returns DEVICE_DT_GET(node_id). Otherwise, it returns NULL.

Parameters

• node_id – devicetree node identifier

Returns a const struct device* for the node identifier, which may be NULL.

DEVICE_GET(name)
Obtain a pointer to a device object by name.

Return the address of a device object created by DEVICE_DEFINE(), using the dev_name provided to DEVICE_DEFINE().

Parameters

• name – The same as dev_name provided to DEVICE_DEFINE()

Returns a pointer to the device object created by DEVICE_DEFINE()

DEVICE_DECLARE(name)
Declare a static device object.

This macro can be used at the top-level to declare a device, such that DEVICE_GET() may be used before the full declaration in DEVICE_DEFINE().

This is often useful when configuring interrupts statically in a device's init or per-instance config function, as the init function itself is required by DEVICE_DEFINE() and use of DEVICE_GET() inside it creates a circular dependency.

Parameters

• name – Device name

SYS_INIT(_init_fn, _level, _prio)
Run an initialization function at boot at specified priority.

This macro lets you run a function at system boot.

Parameters

• _init_fn – Pointer to the boot function to run
• _level – The initialization level at which configuration occurs. Must be one of the following symbols, which are listed in the order they are performed by the kernel:
  – PRE_KERNEL_1: Used for initialization objects that have no dependencies, such as those that rely solely on hardware present in the processor/SOC. These objects cannot use any kernel services during configuration, since they are not yet available.
  – PRE_KERNEL_2: Used for initialization objects that rely on objects initialized as part of the PRE_KERNEL_1 level. These objects cannot use any kernel services during configuration, since they are not yet available.
  – POST_KERNEL: Used for initialization objects that require kernel services during configuration.
  – POST_KERNEL_SMP: Used for initialization objects that require kernel services during configuration after SMP initialization.
– APPLICATION: Used for application components (i.e. non-kernel components) that need automatic configuration. These objects can use all services provided by the kernel during configuration.

- _prio – The initialization priority of the object, relative to other objects of the same initialization level. Specified as an integer value in the range 0 to 99; lower values indicate earlier initialization. Must be a decimal integer literal without leading zeroes or sign (e.g. 32), or an equivalent symbolic name (e.g. #define MY_INIT_PRIORITY 32); symbolic expressions are not permitted (e.g. CONFIG_KERNEL_INIT_PRIORITY_DEFAULT + 5).

**Typedefs**

typedef int16_t device_handle_t

Type used to represent a “handle” for a device.

Every struct device has an associated handle. You can get a pointer to a device structure from its handle and vice versa, but the handle uses less space than a pointer. The device.h API mainly uses handles to store lists of multiple devices in a compact way.

The extreme values and zero have special significance. Negative values identify functionality that does not correspond to a Zephyr device, such as the system clock or a SYS_INIT() function.

See also:

device_handle_get()

See also:

device_from_handle()

typedef int (*device_visitor_callback_t)(const struct device *dev, void *context)

Prototype for functions used when iterating over a set of devices.

Such a function may be used in API that identifies a set of devices and provides a visitor API supporting caller-specific interaction with each device in the set.

The visit is said to succeed if the visitor returns a non-negative value.

See also:

device_required_foreach()

See also:

device_supported_foreach()

Param dev a device in the set being iterated

Param context state used to support the visitor function

Return A non-negative number to allow walking to continue, and a negative error code to case the iteration to stop.

**Functions**

static inline device_handle_t device_handle_get(const struct device *dev)

Get the handle for a given device.

Parameters
• dev – the device for which a handle is desired.

**Returns** the handle for the device, or DEVICE_HANDLE_NULL if the device does not have an associated handle.

static inline const struct device *device_from_handle(device_handle_t dev_handle)

Get the device corresponding to a handle.

**Parameters**

- dev_handle – the device handle

**Returns** the device that has that handle, or a null pointer if dev_handle does not identify a device.

static inline const device_handle_t *device_required_handles_get(const struct device *dev, size_t *count)

Get the device handles for devicetree dependencies of this device.

This function returns a pointer to an array of device handles. The length of the array is stored in the count parameter.

The array contains a handle for each device that dev requires directly, as determined from the devicetree. This does not include transitive dependencies; you must recursively determine those.

**Parameters**

- dev – the device for which dependencies are desired.
- count – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if the device has no devicetree dependencies.

**Returns** a pointer to a sequence of *count device handles, or a null pointer if dev does not have any dependency data.

static inline const device_handle_t *device_supported_handles_get(const struct device *dev, size_t *count)

Get the set of handles that this device supports.

This function returns a pointer to an array of device handles. The length of the array is stored in the count parameter.

The array contains a handle for each device that dev “supports” that is, devices that require dev directly as determined from the devicetree. This does not include transitive dependencies; you must recursively determine those.

**Parameters**

- dev – the device for which supports are desired.
- count – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if nothing in the devicetree depends on dev.

**Returns** a pointer to a sequence of *count device handles, or a null pointer if dev does not have any dependency data.

int device_required_foreach(const struct device *dev, device_visitor_callback_t visitor_cb, void *context)

Visit every device that dev directly requires.

Zephyr maintains information about which devices are directly required by another device; for example an I2C-based sensor driver will require an I2C controller for communication. Required devices can derive from statically-defined devicetree relationships or dependencies registered at runtime.
This API supports operating on the set of required devices. Example uses include making sure required devices are ready before the requiring device is used, and releasing them when the requiring device is no longer needed.

There is no guarantee on the order in which required devices are visited.

If the visitor function returns a negative value iteration is halted, and the returned value from the visitor is returned from this function.

**Note:** This API is not available to unprivileged threads.

**Parameters**
- `dev` – a device of interest. The devices that this device depends on will be used as the set of devices to visit. This parameter must not be null.
- `visitor_cb` – the function that should be invoked on each device in the dependency set. This parameter must not be null.
- `context` – state that is passed through to the visitor function. This parameter may be null if visitor tolerates a null context.

**Returns** The number of devices that were visited if all visits succeed, or the negative value returned from the first visit that did not succeed.

```c
int device_supported_foreach(const struct device *dev, device_visitor_callback_t visitor_cb, void *context)
```

Zephyr maintains information about which devices are directly supported by another device; for example an I2C controller will support an I2C-based sensor driver. Supported devices can derive from statically-defined devicetree relationships.

This API supports operating on the set of supported devices. Example uses include iterating over the devices connected to a regulator when it is powered on.

There is no guarantee on the order in which required devices are visited.

If the visitor function returns a negative value iteration is halted, and the returned value from the visitor is returned from this function.

**Note:** This API is not available to unprivileged threads.

**Parameters**
- `dev` – a device of interest. The devices that this device supports will be used as the set of devices to visit. This parameter must not be null.
- `visitor_cb` – the function that should be invoked on each device in the support set. This parameter must not be null.
- `context` – state that is passed through to the visitor function. This parameter may be null if visitor tolerates a null context.

**Returns** The number of devices that were visited if all visits succeed, or the negative value returned from the first visit that did not succeed.

```c
const struct device *device_get_binding(const char *name)
```

Get a *const struct device* from its `name` field.

This function iterates through the devices on the system. If a device with the given `name` field is found, and that device initialized successfully at boot time, this function returns a pointer to the device.
If no device has the given name, this function returns NULL.

This function also returns NULL when a device is found, but it failed to initialize successfully at boot time. (To troubleshoot this case, set a breakpoint on your device driver's initialization function.)

**Parameters**

- `name` – device name to search for. A null pointer, or a pointer to an empty string, will cause NULL to be returned.

**Returns** pointer to device structure with the given name; NULL if the device is not found or if the device with that name's initialization function failed.

```c
bool device_is_ready(const struct device *dev)
```

Verify that a device is ready for use.

Indicates whether the provided device pointer is for a device known to be in a state where it can be used with its standard API.

This can be used with device pointers captured from `DEVICE_DT_GET()`, which does not include the readiness checks of `device_get_binding()`. At minimum this means that the device has been successfully initialized.

**Parameters**

- `dev` – pointer to the device in question.

**Return values**

- `true` – If the device is ready for use.
- `false` – If the device is not ready for use or if a NULL device pointer is passed as argument.

```c
static inline int device_usable_check(const struct device *dev)
```

Determine whether a device is ready for use.

**Deprecated:**

Use `device_is_ready()` instead.

**Parameters**

- `dev` – Device instance.

**Return values**

- `0` – If device is usable.
- `-ENODEV` – If device is not usable.

```c
struct device_state
```

#include <device.h> Runtime device dynamic structure (in RAM) per driver instance.

Fields in this are expected to be default-initialized to zero. The kernel driver infrastructure and driver access functions are responsible for ensuring that any non-zero initialization is done before they are accessed.

**Public Members**

- `unsigned int init_res` Non-negative result of initializing the device.
The absolute value returned when the device initialization function was invoked, or
UINT8_MAX if the value exceeds an 8-bit integer. If initialized is also set, a zero value
indicates initialization succeeded.

bool initialized
Indicates the device initialization function has been invoked.

#include <device.h> Runtime device structure (in ROM) per driver instance.

Public Members

const char *name
Name of the device instance

cost void *config
Address of device instance config information

cost void *api
Address of the API structure exposed by the device instance

struct device_state *const state
Address of the common device state

void *const data
Address of the device instance private data

cost device_handle_t *const handles
optional pointer to handles associated with the device.

This encodes a sequence of sets of device handles that have some relationship
to this node. The individual sets are extracted with dedicated API, such as
device_required_handles_get().

7.9 Display Interface

7.9.1 API Reference

Generic Display Interface

typedef int (*display_blanking_on_api)(const struct device *dev)
Callback API to turn on display blanking See display_blanking_on() for argument description.

typedef int (*display_blanking_off_api)(const struct device *dev)
Callback API to turn off display blanking See display_blanking_off() for argument description.
typedef int (*display_write_api)(const struct device *dev, const uint16_t x, const uint16_t y, const struct display_buffer_descriptor *desc, const void *buf)
  Callback API for writing data to the display See display_write() for argument description.

typedef int (*display_read_api)(const struct device *dev, const uint16_t x, const uint16_t y, const struct display_buffer_descriptor *desc, void *buf)
  Callback API for reading data from the display See display_read() for argument description.

typedef void *(*display_get_framebuffer_api)(const struct device *dev)
  Callback API to get framebuffer pointer See display_get_framebuffer() for argument description.

typedef int (*display_set_brightness_api)(const struct device *dev, const uint8_t brightness)
  Callback API to set display brightness See display_set_brightness() for argument description.

typedef int (*display_set_contrast_api)(const struct device *dev, const uint8_t contrast)
  Callback API to set display contrast See display_set_contrast() for argument description.

typedef void *(*display_get_capabilities_api)(const struct device *dev, struct display_capabilities *capabilities)
  Callback API to get display capabilities See display_get_capabilities() for argument description.

typedef int (*display_set_pixel_format_api)(const struct device *dev, const enum display_pixel_format pixel_format)
  Callback API to set pixel format used by the display See display_set_pixel_format() for argument description.

typedef int (*display_set_orientation_api)(const struct device *dev, const enum display_orientation orientation)
  Callback API to set orientation used by the display See display_set_orientation() for argument description.

Enums

enum display_pixel_format
  Display pixel formats.
  Display pixel format enumeration.
  In case a pixel format consists out of multiple bytes the byte order is big endian.
  Values:

  enumerator PIXEL_FORMAT_RGB_888 = BIT(0)

  enumerator PIXEL_FORMAT_MONO01 = BIT(1)

  enumerator PIXEL_FORMAT_MONO10 = BIT(2)

  enumerator PIXEL_FORMAT_ARGB_8888 = BIT(3)
enumerator PIXEL_FORMAT_RGB_565 = \texttt{BIT}(4)

enumerator PIXEL_FORMAT_BGR_565 = \texttt{BIT}(5)

enum display_screen_info

\textbf{Values:}

enumerator SCREEN_INFO_MONO_VTILED = \texttt{BIT}(0)
If selected, one octet represents 8 pixels ordered vertically, otherwise ordered horizontally.

enumerator SCREEN_INFO_MONO_MSB_FIRST = \texttt{BIT}(1)
If selected, the MSB represents the first pixel, otherwise MSB represents the last pixel.

enumerator SCREEN_INFO_EPD = \texttt{BIT}(2)
Electrophoretic Display.

enumerator SCREEN_INFO_DOUBLE_BUFFER = \texttt{BIT}(3)
Screen has two alternating ram buffers

enumerator SCREEN_INFO_X_ALIGNMENT_WIDTH = \texttt{BIT}(4)
Screen has x alignment constrained to width.

enum display_orientation

\textbf{Enumeration with possible display orientation.}

\textbf{Values:}

enumerator DISPLAY_ORIENTATION_NORMAL

enumerator DISPLAY_ORIENTATION_ROTATED_90

enumerator DISPLAY_ORIENTATION_ROTATED_180

enumerator DISPLAY_ORIENTATION_ROTATED_270

\textbf{Functions}

static inline int display_write(const struct device *dev, const uint16_t x, const uint16_t y, const struct display_buffer_descriptor *desc, const void *buf)

\textbf{Write data to display.}

\textbf{Parameters}

\begin{itemize}
  \item \texttt{dev} – Pointer to device structure
  \item \texttt{x} – x Coordinate of the upper left corner where to write the buffer
  \item \texttt{y} – y Coordinate of the upper left corner where to write the buffer
  \item \texttt{desc} – Pointer to a structure describing the buffer layout
  \item \texttt{buf} – Pointer to buffer array
\end{itemize}
Return values 0 – on success else negative errno code.

static inline int display_read(const struct device *dev, const uint16_t x, const uint16_t y, const struct display_buffer_descriptor *desc, void *buf)

Read data from display.

Parameters

• dev – Pointer to device structure
• x – x Coordinate of the upper left corner where to read from
• y – y Coordinate of the upper left corner where to read from
• desc – Pointer to a structure describing the buffer layout
• buf – Pointer to buffer array

Return values 0 – on success else negative errno code.

static inline void *display_get_framebuffer(const struct device *dev)

Get pointer to framebuffer for direct access.

Parameters

• dev – Pointer to device structure

Return values Pointer – to frame buffer or NULL if direct framebuffer access is not supported

static inline int display_blanking_on(const struct device *dev)

Turn display blanking on.

This function blanks the complete display. The content of the frame buffer will be retained while blanking is enabled and the frame buffer will be accessible for read and write operations.

In case backlight control is supported by the driver the backlight is turned off. The backlight configuration is retained and accessible for configuration.

In case the driver supports display blanking the initial state of the driver would be the same as if this function was called.

Parameters

• dev – Pointer to device structure

Return values 0 – on success else negative errno code.

static inline int display_blanking_off(const struct device *dev)

Turn display blanking off.

Restore the frame buffer content to the display. In case backlight control is supported by the driver the backlight configuration is restored.

Parameters

• dev – Pointer to device structure

Return values 0 – on success else negative errno code.

static inline int display_set_brightness(const struct device *dev, uint8_t brightness)

Set the brightness of the display.

Set the brightness of the display in steps of 1/256, where 255 is full brightness and 0 is minimal.

Parameters

• dev – Pointer to device structure
• brightness – Brightness in steps of 1/256

Return values 0 – on success else negative errno code.
static inline int display_set_contrast(const struct device *dev, uint8_t contrast)
    
Set the contrast of the display.

Set the contrast of the display in steps of 1/256, where 255 is maximum difference and 0 is minimal.

Parameters

• dev – Pointer to device structure
• contrast – Contrast in steps of 1/256

Return values 0 – on success else negative errno code.

static inline void display_get_capabilities(const struct device *dev, struct display_capabilities *capabilities)

Get display capabilities.

Parameters

• dev – Pointer to device structure
• capabilities – Pointer to capabilities structure to populate

static inline int display_set_pixel_format(const struct device *dev, const enum display_pixel_format pixel_format)

Set pixel format used by the display.

Parameters

• dev – Pointer to device structure
• pixel_format – Pixel format to be used by display

Return values 0 – on success else negative errno code.

static inline int display_set_orientation(const struct device *dev, const enum display_orientation orientation)

Set display orientation.

Parameters

• dev – Pointer to device structure
• orientation – Orientation to be used by display

Return values 0 – on success else negative errno code.

struct display_capabilities
#include <display.h> Structure holding display capabilities.

Public Members

uint16_t x_resolution
    Display resolution in the X direction

uint16_t y_resolution
    Display resolution in the Y direction

uint32_t supported_pixel_formats
    Bitwise or of pixel formats supported by the display

uint32_t screen_info
    Information about display panel
enum display_pixel_format current_pixel_format
    Currently active pixel format for the display

enum display_orientation current_orientation
    Current display orientation

struct display_buffer_descriptor
    #include <display.h> Structure to describe display data buffer layout.

    Public Members

    uint32_t buf_size
        Data buffer size in bytes

    uint16_t width
        Data buffer row width in pixels

    uint16_t height
        Data buffer column height in pixels

    uint16_t pitch
        Number of pixels between consecutive rows in the data buffer

struct display_driver_api
    #include <display.h> Display driver API API which a display driver should expose.

Grove LCD Display

    group grove_display
        Grove display APIs.

    Defines

    GLCD_DS_DISPLAY_ON

    GLCD_DS_DISPLAY_OFF

    GLCD_DS_CURSOR_ON

    GLCD_DS_CURSOR_OFF

    GLCD_DS_BLINK_ON

    GLCD_DS_BLINK_OFF
Functions

void glcd_print(const struct device *dev, char *data, uint32_t size)
    Send text to the screen.
    Parameters
    • dev – Pointer to device structure for driver instance.
    • data – the ASCII text to display
    • size – the length of the text in bytes

void glcd_cursor_pos_set(const struct device *dev, uint8_t col, uint8_t row)
    Set text cursor position for next additions.
    Parameters
    • dev – Pointer to device structure for driver instance.
• col – the column for the cursor to be moved to (0-15)
• row – the row it should be moved to (0 or 1)

void glcd_clear(const struct device *dev)
            Clear the current display.

Parameters
• dev – Pointer to device structure for driver instance.

void glcd_display_state_set(const struct device *dev, uint8_t opt)
            Function to change the display state.

This function provides the user the ability to change the state of the display as per needed. Controlling things like powering on or off the screen, the option to display the cursor or not, and the ability to blink the cursor.

Parameters
• dev – Pointer to device structure for driver instance.
• opt – An 8bit bitmask of GLCD_DS_* options.

uint8_t glcd_display_state_get(const struct device *dev)
            return the display feature set associated with the device

Parameters
• dev – the Grove LCD to get the display features set

Returns the display feature set associated with the device.

void glcd_input_state_set(const struct device *dev, uint8_t opt)
            Function to change the input state.

This function provides the user the ability to change the state of the text input. Controlling things like text entry from the left or right side, and how far to increment on new text

Parameters
• dev – Pointer to device structure for driver instance.
• opt – A bitmask of GLCD_IS_* options

uint8_t glcd_input_state_get(const struct device *dev)
            return the input set associated with the device

Parameters
• dev – the Grove LCD to get the input features set

Returns the input set associated with the device.

void glcd_function_set(const struct device *dev, uint8_t opt)
            Function to set the functional state of the display.

This function provides the user the ability to change the state of the display as per needed. Controlling things like the number of rows, dot size, and text display quality.

Parameters
• dev – Pointer to device structure for driver instance.
• opt – A bitmask of GLCD_FS_* options

uint8_t glcd_function_get(const struct device *dev)
            return the function set associated with the device

Parameters
• dev – the Grove LCD to get the functions set

7.9. Display Interface
Returns the function features set associated with the device.

```c
void glcd_color_select(const struct device *dev, uint8_t color)

Set LCD background to a predefined color.
```

**Parameters**

- `dev` – Pointer to device structure for driver instance.
- `color` – One of the predefined color options

```c
void glcd_color_set(const struct device *dev, uint8_t r, uint8_t g, uint8_t b)

Set LCD background to custom RGB color value.
```

**Parameters**

- `dev` – Pointer to device structure for driver instance.
- `r` – A numeric value for the red color (max is 255)
- `g` – A numeric value for the green color (max is 255)
- `b` – A numeric value for the blue color (max is 255)

## BBC micro:bit Display

**group mb_display**

BBC micro:bit display APIs.

### Defines

```c
MB_IMAGE(_rows...)

Generate an image object from a given array rows/columns.
```

This helper takes an array of 5 rows, each consisting of 5 0/1 values which correspond to the columns of that row. The value 0 means the pixel is disabled whereas a 1 means the pixel is enabled.

The pixels go from left to right and top to bottom, i.e. top-left corner is the first row's first value, top-right is the first row's last value, and bottom-right corner is the last value of the last (5th) row. As an example, the following would create a smiley face image:

#### Parameters

- `_rows` – Each of the 5 rows represented as a 5-value column array.

#### Returns

Image bitmap that can be passed e.g. to `mb_display_image()`.

### Enums

```c
eenum mb_display_mode

Display mode.
```

First 16 bits are reserved for modes, last 16 for flags.

#### Values:

- `MB_DISPLAY_MODE_SINGLE` – Display images sequentially, one at a time.
enumerator MB_DISPLAY_MODE_SCROLL
Display images by scrolling.

enumerator MB_DISPLAY_FLAG_LOOP = BIT(16)
Loop back to the beginning when reaching the last image.

Functions

struct mb_display *mb_display_get(void)
Get a pointer to the BBC micro:bit display object.

Returns Pointer to display object.

void mb_display_image(struct mb_display *disp, uint32_t mode, int32_t duration, const struct mb_image *img, uint8_t img_count)
Display one or more images on the BBC micro:bit LED display.
This function takes an array of one or more images and renders them sequentially on the
micro:bit display. The call is asynchronous, i.e. the processing of the display happens in the
background. If there is another image being displayed it will be canceled and the new one
takes over.

Parameters
• disp – Display object.
• mode – One of the MB_DISPLAY_MODE_* options.
• duration – Duration how long to show each image (in milliseconds), or SYS_FOREVER_MS.
• img – Array of image bitmaps (struct mb_image objects).
• img_count – Number of images in ‘img’ array.

void mb_display_print(struct mb_display *disp, uint32_t mode, int32_t duration, const char *fmt, ...)
Print a string of characters on the BBC micro:bit LED display.
This function takes a printf-style format string and outputs it in a scrolling fashion to the
display.
The call is asynchronous, i.e. the processing of the display happens in the background. If
there is another image or string being displayed it will be canceled and the new one takes over.

Parameters
• disp – Display object.
• mode – One of the MB_DISPLAY_MODE_* options.
• duration – Duration how long to show each character (in milliseconds), or SYS_FOREVER_MS.
• fmt – printf-style format string
• ... – Optional list of format arguments.

void mb_display_stop(struct mb_display *disp)
Stop the ongoing display of an image.

Parameters
• disp – Display object.
struct mb_image
#include <mb_display.h> Representation of a BBC micro:bit display image.

This struct should normally not be used directly, rather created using the MB_IMAGE() macro.

Monochrome Character Framebuffer

group monochrome_character_framebuffer
Public Monochrome Character Framebuffer API.

Defines

FONT_ENTRY_DEFINE(_name, _width, _height, _caps, _data, _fc, _lc)
Macro for creating a font entry.

Parameters

• _name – Name of the font entry.
• _width – Width of the font in pixels
• _height – Height of the font in pixels.
• _caps – Font capabilities.
• _data – Raw data of the font.
• _fc – Character mapped to first font element.
• _lc – Character mapped to last font element.

Enums

eenum cfb_display_param
Values:

enumerator CFB_DISPLAY_HEIGH = 0

eenumerator CFB_DISPLAY_WIDTH

eenumerator CFB_DISPLAY_PPT

eenumerator CFB_DISPLAY_ROWS

eenumerator CFB_DISPLAY_COLS

eenum cfb_font_caps
Values:

enumerator CFB_FONT_MONO_VPACKED = BIT(0)
enumerator CFB_FONT_MONO_HPACKED = \textbf{BIT}(1)

everenumerator CFB_FONT_MSB_FIRST = \textbf{BIT}(2)

Functions

\texttt{int \ cf{\textunderscore}b\_print(const \ struct \ device *dev, \ char *str, \ uint16_t x, \ uint16_t y)}

Print a string into the framebuffer.

\textbf{Parameters}
- \texttt{dev} – Pointer to device structure for driver instance
- \texttt{str} – String to print
- \texttt{x} – Position in X direction of the beginning of the string
- \texttt{y} – Position in Y direction of the beginning of the string

\textbf{Returns} 0 on success, negative value otherwise

\texttt{int \ cf{\textunderscore}b\_framebuffer\_clear(const \ struct \ device *dev, \ bool clear\_display)}

Clear framebuffer.

\textbf{Parameters}
- \texttt{dev} – Pointer to device structure for driver instance
- \texttt{clear\_display} – Clear the display as well

\textbf{Returns} 0 on success, negative value otherwise

\texttt{int \ cf{\textunderscore}b\_framebuffer\_invert(const \ struct \ device *dev)}

Invert Pixels.

\textbf{Parameters}
- \texttt{dev} – Pointer to device structure for driver instance

\textbf{Returns} 0 on success, negative value otherwise

\texttt{int \ cf{\textunderscore}b\_framebuffer\_finalize(const \ struct \ device *dev)}

Finalize framebuffer and write it to display RAM, invert or reorder pixels if necessary.

\textbf{Parameters}
- \texttt{dev} – Pointer to device structure for driver instance

\textbf{Returns} 0 on success, negative value otherwise

\texttt{int \ cf{\textunderscore}b\_get\_display\_parameter(const \ struct \ device *dev, \ enum \ cfb\_display\_param)}

Get display parameter.

\textbf{Parameters}
- \texttt{dev} – Pointer to device structure for driver instance
- \texttt{cfb\_display\_param} – One of the display parameters

\textbf{Returns} Display parameter value

\texttt{int \ cf{\textunderscore}b\_framebuffer\_set\_font(const \ struct \ device *dev, \ uint8_t idx)}

Set font.

\textbf{Parameters}
- \texttt{dev} – Pointer to device structure for driver instance
• idx – Font index

Returns 0 on success, negative value otherwise

```c
int cfb_get_font_size(const struct device *dev, uint8_t idx, uint8_t *width, uint8_t *height)
```
Get font size.

Parameters
• dev – Pointer to device structure for driver instance
• idx – Font index
• width – Pointers to the variable where the font width will be stored.
• height – Pointers to the variable where the font height will be stored.

Returns 0 on success, negative value otherwise

```c
int cfb_get_numof_fonts(const struct device *dev)
```
Get number of fonts.

Parameters
• dev – Pointer to device structure for driver instance

Returns number of fonts

```c
int cfb_framebuffer_init(const struct device *dev)
```
Initialize Character Framebuffer.

Parameters
• dev – Pointer to device structure for driver instance

Returns 0 on success, negative value otherwise

```c
struct cfb_font
#include <cfb.h>
```

### 7.10  Error Detection And Correction (EDAC)

#### 7.10.1  API Reference

*group edac*

** Enums **

```c
enum edac_error_type
```
EDAC error type.

Values:

- enumerator EDAC_ERROR_TYPE_DRAM_COR = BIT(0)
  Correctable error type

- enumerator EDAC_ERROR_TYPE_DRAM_UC = BIT(1)
  Uncorrectable error type
Functions

static inline int edac_inject_set_param1(const struct device *dev, uint64_t value)
Set injection parameter param1.
Set first error injection parameter value.

Parameters
• dev – Pointer to the device structure
• value – First injection parameter

Return values
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, other error code otherwise

static inline int edac_inject_get_param1(const struct device *dev, uint64_t *value)
Get injection parameter param1.
Get first error injection parameter value.

Parameters
• dev – Pointer to the device structure
• value – Pointer to the first injection parameter

Return values
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_inject_set_param2(const struct device *dev, uint64_t value)
Set injection parameter param2.
Set second error injection parameter value.

Parameters
• dev – Pointer to the device structure
• value – Second injection parameter

Return values
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_inject_get_param2(const struct device *dev, uint64_t *value)
Get injection parameter param2.
Get second error injection parameter value.

Parameters
• dev – Pointer to the device structure
• value – Pointer to the second injection parameter

Return values
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_inject_set_error_type(const struct device *dev, uint32_t error_type)
Set error type value.
Set the value of error type to be injected

Parameters
• dev – Pointer to the device structure
• error_type – Error type value

**Return values**
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_inject_get_error_type(const struct device *dev, uint32_t *error_type)
Get error type value.

Get the value of error type to be injected

**Parameters**
• dev – Pointer to the device structure
• error_type – Pointer to error type value

**Return values**
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_inject_error_trigger(const struct device *dev)
Set injection control.

Trigger error injection.

**Parameters**
• dev – Pointer to the device structure

**Return values**
• -ENOSYS – if the optional interface is not implemented
• 0 – on success, error code otherwise

static inline int edac_ecc_error_log_get(const struct device *dev, uint64_t *value)
Get ECC Error Log.

Read value of ECC Error Log.

**Parameters**
• dev – Pointer to the device structure
• value – Pointer to the ECC Error Log value

**Return values**
• 0 – on success, error code otherwise
• -ENOSYS – if the mandatory interface is not implemented

static inline int edac_ecc_error_log_clear(const struct device *dev)
Clear ECC Error Log.

Clear value of ECC Error Log.

**Parameters**
• dev – Pointer to the device structure

**Return values**
• 0 – on success, error code otherwise
• -ENOSYS – if the mandatory interface is not implemented
static inline int edac_parity_error_log_get(const struct device *dev, uint64_t *value)
Get Parity Error Log.

Parameters
• dev – Pointer to the device structure
• value – Pointer to the parity Error Log value

Return values
• 0 – on success, error code otherwise
• -ENOSYS – if the mandatory interface is not implemented

static inline int edac_parity_error_log_clear(const struct device *dev)
Clear Parity Error Log.

Parameters
• dev – Pointer to the device structure

Return values
• 0 – on success, error code otherwise
• -ENOSYS – if the mandatory interface is not implemented

static inline int edac_errors_cor_get(const struct device *dev)
Get number of correctable errors.

Parameters
• dev – Pointer to the device structure

Return values
• num – Number of correctable errors
• -ENOSYS – if the mandatory interface is not implemented

static inline int edac_errors_uc_get(const struct device *dev)
Get number of uncorrectable errors.

Parameters
• dev – Pointer to the device structure

Return values
• num – Number of uncorrectable errors
• -ENOSYS – if the mandatory interface is not implemented

static inline int edac_notify_callback_set(const struct device *dev, edac_notify_callback_f cb)
Register callback function for memory error exception

This callback runs in interrupt context

Parameters
• dev – EDAC driver device to install callback
• cb – Callback function pointer

Return values
• 0 – on success, error code otherwise
• -ENOSYS – if the mandatory interface is not implemented
struct edac_driver_api
    #include <edac.h> EDAC driver API.

This is the mandatory API any EDAC driver needs to expose.

### 7.11 File Systems

Zephyr RTOS Virtual Filesystem Switch (VFS) allows applications to mount multiple file systems at different mount points (e.g., /fatfs and /lfs). The mount point data structure contains all the necessary information required to instantiate, mount, and operate on a file system. The File system Switch decouples the applications from directly accessing an individual file system's specific API or internal functions by introducing file system registration mechanisms.

In Zephyr, any file system implementation or library can be plugged into or pulled out through a file system registration API. Each file system implementation must have a globally unique integer identifier; use `FS_TYPE_EXTERNAL_BASE` to avoid clashes with in-tree identifiers.

```c
int fs_register(int type, const struct fs_file_system_t *fs);
int fs_unregister(int type, const struct fs_file_system_t *fs);
```

Zephyr RTOS supports multiple instances of a file system by making use of the mount point as the disk volume name, which is used by the file system library while formatting or mounting a disk.

A file system is declared as:

```c
static struct fs_mount_t mp = {
    .type = FS_FATFS,
    .mnt_point = FATFS_MNTP,
    .fs_data = &fat_fs,
};
```

where

- `FS_FATFS` is the file system type like FATFS or LittleFS.
- `FATFS_MNTP` is the mount point where the file system will be mounted.
- `fat_fs` is the file system data which will be used by `fs_mount()` API.

#### 7.11.1 Samples

Samples for the VFS are mainly supplied in `samples/subsys/fs`, although various examples of the VFS usage are provided as important functionalities in samples for different subsystems. Here is the list of samples worth looking at:

- `samples/subsys/fs/fat_fs` is an example of FAT file system usage with SDHC media;
- `samples/subsys/shell/fs` is an example of Shell fs subsystem, using internal flash partition formatted to LittleFS;
- `samples/subsys/usb/mass/` example of USB Mass Storage device that uses FAT FS driver with RAM or SPI connected FLASH, or LittleFS in flash, depending on the sample configuration.

#### 7.11.2 API Reference

`group file_system_api`

File System APIs.
fs_open open and creation mode flags

FS_O_READ
Open for read flag

FS_O_WRITE
Open for write flag

FS_O_RDWR
Open for read-write flag combination

FS_O_MODE_MASK
Bitmask for read and write flags

FS_O_CREATE
Create file if it does not exist

FS_O_APPEND
Open/create file for append

FS_O_FLAGS_MASK
Bitmask for open/create flags

FS_O_MASK
Bitmask for open flags

fs_seek whence parameter values

FS_SEEK_SET
Seek from the beginning of file

FS_SEEK_CUR
Seek from a current position

FS_SEEK_END
Seek from the end of file

Defines

FS_MOUNT_FLAG_NO_FORMAT
Flag prevents formatting device if requested file system not found

FS_MOUNT_FLAG_READ_ONLY
Flag makes mounted file system read-only

FS_MOUNT_FLAG_AUTOMOUNT
Flag used in pre-defined mount structures that are to be mounted on startup.
This flag has no impact in user-defined mount structures.
FS_MOUNT_FLAG_USE_DISK_ACCESS
Flag requests file system driver to use Disk Access API. When the flag is set to the
fs_mount_t.flags prior to fs_mount call, a file system needs to use the Disk Access API, other-
wise mount callback for the driver should return -ENOSUP; when the flag is not set the file
system driver should use Flash API by default, unless it only supports Disc Access API. When
file system will use Disk Access API and the flag is not set, the mount callback for the file
system should set the flag on success.

FSTAB_ENTRY_DT_MOUNT_FLAGS(node_id)

FS_FSTAB_ENTRY(node_id)
The name under which a zephyr,fstab entry mount structure is defined.

FS_FSTAB_DECLARE_ENTRY(node_id)
Generate a declaration for the externally defined fstab entry.
This will evaluate to the name of a struct fs_mount_t object.

Enums

enum fs_dir_entry_type
   Values:
   
   enumerator FS_DIR_ENTRY_FILE = 0
      Identifier for file entry
   
   enumerator FS_DIR_ENTRY_DIR
      Identifier for directory entry

enum [anonymous]
Enumeration to uniquely identify file system types.

   Zephyr supports in-tree file systems and external ones. Each requires a unique identifier used
to register the file system implementation and to associate a mount point with the file system
type. This anonymous enum defines global identifiers for the in-tree file systems.

   External file systems should be registered using unique identifiers starting at
FS_TYPE_EXTERNAL_BASE. It is the responsibility of applications that use external file
systems to ensure that these identifiers are unique if multiple file system implementations are
used by the application.

   Values:

   enumerator FS_FATFS = 0
      Identifier for in-tree FatFS file system.

   enumerator FS_LITTLEFS
      Identifier for in-tree LittleFS file system.

   enumerator FS_TYPE_EXTERNAL_BASE
      Base identifier for external file systems.

Functions

   static inline void fs_file_t_init(struct fs_file_t *zfp)
   Initialize fs_file_t object.
Initializes the `fs_file_t` object; the function needs to be invoked on object before first use with `fs_open`.

**Parameters**

- `zfp` – Pointer to file object

```c
static inline void fs_dir_t_init(struct fs_dir_t *zdp)
```

Initialize `fs_dir_t` object.

**Parameters**

- `zdp` – Pointer to file object

```c
int fs_open(struct fs_file_t *zfp, const char *file_name, fs_mode_t flags)
```

Open or create file.

Opens or possibly creates a file and associates a stream with it.

`flags` can be 0 or a binary combination of one or more of the following identifiers:

- `FS_O_READ` open for read
- `FS_O_WRITE` open for write
- `FS_O_RDWR` open for read/write (`FS_O_READ | FS_O_WRITE`)
- `FS_O_CREATE` create file if it does not exist
- `FS_O_APPEND` move to end of file before each write

If `flags` are set to 0 the function will attempt to open an existing file with no read/write access; this may be used to e.g. check if the file exists.

**Parameters**

- `zfp` – Pointer to a file object
- `file_name` – The name of a file to open
- `flags` – The mode flags

**Return values**

- 0 – on success;
- -EBUSY – when `zfp` is already used;
- EINVAL – when a bad file name is given;
- -EROFS – when opening read-only file for write, or attempting to create a file on a system that has been mounted with the `FS_MOUNT_FLAG_READ_ONLY` flag;
- -ENOENT – when the file path is not possible (bad mount point);
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – an other negative errno code, depending on a file system back-end.

```c
int fs_close(struct fs_file_t *zfp)
```

Close file.

Flushes the associated stream and closes the file.

**Parameters**

- `zfp` – Pointer to the file object

**Return values**

- 0 – on success;
### fs_unlink

**Description:** Unlink file.

Deletes the specified file or directory

**Parameters**

- `path` – Path to the file or directory to delete

**Return values**

- 0 – on success;
- -EINVAL – when a bad file name is given;
- -EROFS – if file is read-only, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – a negative errno code on error.

### fs_rename

**Description:** Rename file or directory.

Performs a rename and / or move of the specified source path to the specified destination. The source path can refer to either a file or a directory. All intermediate directories in the destination path must already exist. If the source path refers to a file, the destination path must contain a full filename path, rather than just the new parent directory. If an object already exists at the specified destination path, this function causes it to be unlinked prior to the rename (i.e., the destination gets clobbered).

**Parameters**

- `from` – The source path
- `to` – The destination path

**Return values**

- 0 – on success;
- -EINVAL – when a bad file name is given, or when rename would cause move between mount points;
- -EROFS – if file is read-only, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – an other negative errno code on error.

### fs_read

**Description:** Read file.

Reads up to `size` bytes of data to `ptr` pointed buffer, returns number of bytes read. A returned value may be lower than `size` if there were fewer bytes available than requested.

**Parameters**

- `zfp` – Pointer to the file object
- `ptr` – Pointer to the data buffer
• **size** – Number of bytes to be read

**Return values**
• >=0 – a number of bytes read, on success;
• -EBADF – when invoked on zfp that represents unopened/closed file;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – a negative errno code on error.

```c
ssize_t fs_write(struct fs_file_t *zfp, const void *ptr, size_t size)
```

Write file.

Attempts to write `size` number of bytes to the specified file. If a negative value is returned from the function, the file pointer has not been advanced. If the function returns a non-negative number that is lower than `size`, the global `errno` variable should be checked for an error code, as the device may have no free space for data.

**Parameters**
• `zfp` – Pointer to the file object
• `ptr` – Pointer to the data buffer
• `size` – Number of bytes to be written

**Return values**
• >=0 – a number of bytes written, on success;
• -EBADF – when invoked on zfp that represents unopened/closed file;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – an other negative errno code on error.

```c
int fs_seek(struct fs_file_t *zfp, off_t offset, int whence)
```

Seek file.

Moves the file position to a new location in the file. The `offset` is added to file position based on the `whence` parameter.

**Parameters**
• `zfp` – Pointer to the file object
• `offset` – Relative location to move the file pointer to
• `whence` – Relative location from where offset is to be calculated.
  – FS_SEEK_SET for the beginning of the file;
  – FS_SEEK_CUR for the current position;
  – FS_SEEK_END for the end of the file.

**Return values**
• 0 – on success;
• -EBADF – when invoked on zfp that represents unopened/closed file;
• -ENOTSUP – if not supported by underlying file system driver;
• <0 – an other negative errno code on error.

```c
off_t fs_tell(struct fs_file_t *zfp)
```

Get current file position.

Retrieves and returns the current position in the file stream.
The current revision does not validate the file object.

**Parameters**

- `zfp` – Pointer to the file object

**Return values**

- `>= 0` a current position in file;
- `-EBADF` – when invoked on `zfp` that represents unopened/closed file;
- `-ENOTSUP` – if not supported by underlying file system driver;
- `< 0` – an other negative errno code on error.

```
int fs_truncate(struct fs_file_t *zfp, off_t length)
```

Truncate or extend an open file to a given size.

Truncates the file to the new length if it is shorter than the current size of the file. Expands the file if the new length is greater than the current size of the file. The expanded region would be filled with zeroes.

**Note:** In the case of expansion, if the volume got full during the expansion process, the function will expand to the maximum possible length and return success. Caller should check if the expanded size matches the requested length.

**Parameters**

- `zfp` – Pointer to the file object
- `length` – New size of the file in bytes

**Return values**

- `0` – on success;
- `-EBADF` – when invoked on `zfp` that represents unopened/closed file;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `< 0` – an other negative errno code on error.

```
int fs_sync(struct fs_file_t *zfp)
```

Flush cached write data buffers of an open file.

The function flushes the cache of an open file; it can be invoked to ensure data gets written to the storage media immediately, e.g. to avoid data loss in case if power is removed unexpectedly.

**Note:** Closing a file will cause caches to be flushed correctly so the function need not be called when the file is being closed.

**Parameters**

- `zfp` – Pointer to the file object

**Return values**

- `0` – on success;
- `-EBADF` – when invoked on `zfp` that represents unopened/closed file;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `< 0` – a negative errno code on error.
int fs_mkdir(const char *path)
Directory create.

Creates a new directory using specified path.

Parameters
• path – Path to the directory to create

Return values
• 0 – on success;
• -EROFS – if file is read-only, or when file system has been mounted with the
  FS_MOUNT_FLAG_READ_ONLY flag;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – an other negative errno code on error

int fs_opendir(struct fs_dir_t *zdp, const char *path)
Directory open.

Opens an existing directory specified by the path.

Parameters
• zdp – Pointer to the directory object
• path – Path to the directory to open

Return values
• 0 – on success;
• -EINVAL – when a bad directory path is given;
• -EBUSY – when zdp is already used;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – a negative errno code on error.

int fs_readdir(struct fs_dir_t *zdp, struct fs_dirent *entry)
Directory read entry.

Reads directory entries of an open directory. In end-of-dir condition, the function will return
0 and set the entry->name[0] to 0.

Note: : Most existing underlying file systems do not generate POSIX special directory entries
“.” or “..”. For consistency the abstraction layer will remove these from lower layer results so
higher layers see consistent results.

Parameters
• zdp – Pointer to the directory object
• entry – Pointer to zfs_dirent structure to read the entry into

Return values
• 0 – on success or end-of-dir;
• -ENOTENT – when no such directory found;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – a negative errno code on error.
int fs_closedir(struct fs_dir_t *zdp)
Directory close.
Closes an open directory.

Parameters

• zdp – Pointer to the directory object

Return values

• 0 – on success;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – a negative errno code on error.

int fs_mount(struct fs_mount_t *mp)
Mount filesystem.
Perform steps needed for mounting a file system like calling the file system specific mount function and adding the mount point to mounted file system list.

Note: Current implementation of ELM FAT driver allows only following mount points: 
"/RAM:","/NAND:","/CF:"","/SD:","/SD2:"","/USB:","/USB2:","/USB3:" or mount points that consist of single digit, e.g: "/0:","/1:" and so forth.

Parameters

• mp – Pointer to the fs_mount_t structure. Referenced object is not changed if the mount operation failed. A reference is captured in the fs infrastructure if the mount operation succeeds, and the application must not mutate the structure contents until fs_unmount is successfully invoked on the same pointer.

Return values

• 0 – on success;
• -ENOTENT – when file system type has not been registered;
• -ENOTSUP – when not supported by underlying file system driver; when FS_MOUNT_FLAG_USE_DISK_ACCESS is set but driver does not support it.
• -EROFS – if system requires formatting but FS_MOUNT_FLAG_READ_ONLY has been set;
• <0 – an other negative errno code on error.

int fsUnmount (struct fs_mount_t *mp)
Unmount filesystem.
Perform steps needed to unmount a file system like calling the file system specific unmount function and removing the mount point from mounted file system list.

Parameters

• mp – Pointer to the fs_mount_t structure

Return values

• 0 – on success;
• -EINVAL – if no system has been mounted at given mount point;
• -ENOTSUP – when not supported by underlying file system driver;
• <0 – an other negative errno code on error.
int fs_readmount(int *index, const char **name)
Get path of mount point at index.
This function iterates through the list of mount points and returns the directory name of the
mount point at the given index. On success index is incremented and name is set to the mount
directory name. If a mount point with the given index does not exist, name will be set to NULL.

Parameters
• index – Pointer to mount point index
• name – Pointer to pointer to path name

Return values
• 0 – on success;
• -ENOENT – if there is no mount point with given index.

int fs_stat(const char *path, struct fs_dirent *entry)
File or directory status.
Checks the status of a file or directory specified by the path.

Note: The file on a storage device may not be updated until it is closed.

Parameters
• path – Path to the file or directory
• entry – Pointer to the zfs_dirent structure to fill if the file or directory exists.

Return values
• 0 – on success;
• -EINVAL – when a bad directory or file name is given;
• -ENOENT – when no such directory or file is found;
• -ENOTSUP – when not supported by underlying file system driver;
• <0 – negative errno code on error.

int fs_statvfs(const char *path, struct fs_statvfs *stat)
Retrieves statistics of the file system volume.
Returns the total and available space in the file system volume.

Parameters
• path – Path to the mounted directory
• stat – Pointer to the zfs_statvfs structure to receive the fs statistics.

Return values
• 0 – on success;
• -EINVAL – when a bad path to a directory, or a file, is given;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – an other negative errno code on error.

int fs_register(int type, const struct fs_file_system_t *fs)
Register a file system.
Register file system with virtual file system. Number of allowed file system types to be regis-
tered is controlled with the CONFIG_FILE_SYSTEM_MAX_TYPES Kconfig option.
Parameters

- **type** – Type of file system (ex: FS_FATFS)
- **fs** – Pointer to File system

Return values

- 0 – on success;
- -EALREADY – when a file system of a given type has already been registered;
- -ENOSCP – when there is no space left, in file system registry, to add this file system type.

```c
int fs_unregister(int type, const struct fs_file_system_t *fs)
```

Unregister a file system.

Unregister file system from virtual file system.

Parameters

- **type** – Type of file system (ex: FS_FATFS)
- **fs** – Pointer to File system

Return values

- 0 – on success;
- -EINVAL – when file system of a given type has not been registered.

```c
struct fs_mount_t
```

#include <fs.h> File system mount info structure.

- **node** Entry for the fs_mount_list list
- **type** File system type
- **mnt_point** Mount point directory name (ex: “/fatfs”)
- **fs_data** Pointer to file system specific data
- **storage_dev** Pointer to backend storage device
- **mountp_len** Length of Mount point string
- **fs** Pointer to File system interface of the mount point
- **flags** Mount flags

```c
struct fs_dirent
```

#include <fs.h> Structure to receive file or directory information.

Used in functions that reads the directory entries to get file or directory information.

- **dir_entry_type** Whether file or directory
  - FS_DIR_ENTRY_FILE
  - FS_DIR_ENTRY_DIR
- **name** Name of directory or file
- **size** Size of file. 0 if directory

```c
struct fs_statvfs
```

#include <fs.h> Structure to receive volume statistics.

Used to retrieve information about total and available space in the volume.

- **f_bsize** Optimal transfer block size
Param f_frsize  Allocation unit size
Param f_blocks  Size of FS in f_frsize units
Param f_bfree  Number of free blocks

struct fs_file_t
#include <fs_interface.h>  File object representing an open file.
The object needs to be initialized with function fs_file_t_init().

  Param Pointer  to FATFS file object structure
  Param mp  Pointer to mount point structure

struct fs_dir_t
#include <fs_interface.h>  Directory object representing an open directory.
The object needs to be initialized with function fs_dir_t_init().

  Param dirp  Pointer to directory object structure
  Param mp  Pointer to mount point structure

struct fs_file_system_t
#include <fs_sys.h>  File System interface structure.

  Param open  Opens or creates a file, depending on flags given
  Param read  Reads nbytes number of bytes
  Param write  Writes nbytes number of bytes
  Param lseek  Moves the file position to a new location in the file
  Param tell  Retrieves the current position in the file
  Param truncate  Truncates/expands the file to the new length
  Param sync  Flushes the cache of an open file
  Param close  Flushes the associated stream and closes the file
  Param opendir  Opens an existing directory specified by the path
  Param readdir  Reads directory entries of an open directory
  Param closedir  Closes an open directory
  Param mount  Mounts a file system
  Param unmount  Unmounts a file system
  Param unlink  Deletes the specified file or directory
  Param rename  Renames a file or directory
  Param mkdir  Creates a new directory using specified path
  Param stat  Checks the status of a file or directory specified by the path
  Param statvfs  Returns the total and available space on the file system volume

7.12  Iterable Sections

This page contains the reference documentation for the iterable sections APIs, which can be used for defining iterable areas of equally-sized data structures, that can be iterated on using STRUCT_SECTION_FOREACH.

7.12. Iterable Sections
7.12.1 Usage

Iterable section elements are typically used by defining the data structure and associated initializer in a common header file, so that they can be instantiated anywhere in the code base.

```c
struct my_data {
    int a, b;
};

#define DEFINE_DATA(name, _a, _b) 
    STRUCT_SECTION_ITERABLE(my_data, name) = {
        .a = _a,
        .b = _b,
    }

DEFINE_DATA(d1, 1, 2);
DEFINE_DATA(d2, 3, 4);
DEFINE_DATA(d3, 5, 6);
```

Then the linker has to be setup to place the place the structure in a contiguous segment using one of the linker macros such as `ITERABLE_SECTION_RAM` or `ITERABLE_SECTION_ROM`. Custom linker snippets are normally declared using one of the `zephyr_linker_sources()` CMake functions, using the appropriate section identifier, `DATA_SECTIONS` for RAM structures and `SECTIONS` for ROM ones.

```cmake
# CMakeLists.txt
zephyr_linker_sources(DATA_SECTIONS iterables.ld)
```

```ld
ITERABLE_SECTION_RAM(my_data, 4)
```

The data can then be accessed using `STRUCT_SECTION_FOREACH`.

```c
STRUCT_SECTION_FOREACH(my_data, data) {
    printk("%p: a: %d, b: %d\n", data, data->a, data->b);
}
```

**Note:** The linker is going to place the entries sorted by name, so the example above would visit `d1`, `d2` and `d3` in that order, regardless of how they were defined in the code.

7.12.2 API Reference

**group iterable_section_apis**

Iterable Sections APIs.

**Defines**

`ITERABLE_SECTION_ROM(struct_type, subalign)`

Define a read-only iterable section output.

Define an output section which will set up an iterable area of equally-sized data structures. For use with `STRUCT_SECTION_ITERABLE()`. Input sections will be sorted by name, per ld's `SORT_BY_NAME`.

630 Chapter 7. API Reference
This macro should be used for read-only data.

Note that this keeps the symbols in the image even though they are not being directly referenced. Use this when symbols are indirectly referenced by iterating through the section.

\texttt{ITERABLE\_SECTION\_ROM\_GC\_ALLOWED(\texttt{struct}\_\texttt{type}, \texttt{subalign})}

Define a garbage collectable read-only iterable section output.

Define an output section which will set up an iterable area of equally-sized data structures. For use with \texttt{STRUCT\_SECTION\_ITERABLE()}. Input sections will be sorted by name, per ld's \texttt{SORT\_BY\_NAME}.

This macro should be used for read-only data.

Note that the symbols within the section can be garbage collected.

\texttt{ITERABLE\_SECTION\_RAM(\texttt{struct}\_\texttt{type}, \texttt{subalign})}

Define a read-write iterable section output.

Define an output section which will set up an iterable area of equally-sized data structures. For use with \texttt{STRUCT\_SECTION\_ITERABLE()}. Input sections will be sorted by name, per ld's \texttt{SORT\_BY\_NAME}.

This macro should be used for read-write data that is modified at runtime.

Note that this keeps the symbols in the image even though they are not being directly referenced. Use this when symbols are indirectly referenced by iterating through the section.

\texttt{ITERABLE\_SECTION\_RAM\_GC\_ALLOWED(\texttt{struct}\_\texttt{type}, \texttt{subalign})}

Define a garbage collectable read-write iterable section output.

Define an output section which will set up an iterable area of equally-sized data structures. For use with \texttt{STRUCT\_SECTION\_ITERABLE()}. Input sections will be sorted by name, per ld's \texttt{SORT\_BY\_NAME}.

This macro should be used for read-write data that is modified at runtime.

Note that the symbols within the section can be garbage collected.

\texttt{STRUCT\_SECTION\_ITERABLE(\texttt{struct}\_\texttt{type}, \texttt{name})}

Defines a new iterable section.

Convenience helper combining \texttt{\_\_in\_section()} and \texttt{Z\_DECL\_ALIGN()}. The section name is the struct type prepended with an underscore. The subsection is "static" and the subsubsection is the variable name.

In the linker script, create output sections for these using \texttt{ITERABLE\_SECTION\_ROM()} or \texttt{ITERABLE\_SECTION\_RAM()}.

\texttt{STRUCT\_SECTION\_ITERABLE\_ALTERNATE(\texttt{out}\_\texttt{type}, \texttt{struct}\_\texttt{type}, \texttt{name})}

Defines an alternate data type iterable section.

Special variant of \texttt{STRUCT\_SECTION\_ITERABLE()}, for placing alternate data types within the iterable section of a specific data type. The data type sizes and semantics must be equivalent!

\texttt{STRUCT\_SECTION\_FOREACH(\texttt{struct}\_\texttt{type}, \texttt{iterator})}

Iterate over a specified iterable section.

Iterator for structure instances gathered by \texttt{STRUCT\_SECTION\_ITERABLE()}. The linker must provide a \texttt{\_\_<\texttt{struct}\_\texttt{type}>\_list\_start} symbol and a \texttt{\_\_<\texttt{struct}\_\texttt{type}>\_list\_end} symbol to mark the start and the end of the list of struct objects to iterate over. This is normally done using \texttt{ITERABLE\_SECTION\_ROM()} or \texttt{ITERABLE\_SECTION\_RAM()} in the linker script.
7.13 Formatted Output

Applications as well as Zephyr itself requires infrastructure to format values for user consumption. The standard C99 library *printf() functionality fulfills this need for streaming output devices or memory buffers, but in an embedded system devices may not accept streamed data and memory may not be available to the formatted output.

Internal Zephyr API traditionally provided this both for printk() and for Zephyr's internal minimal libc, but with separate internal interfaces. Logging, tracing, shell, and other applications made use of either these APIs or standard libc routines based on build options.

The cbprintf() public APIs convert C99 format strings and arguments, providing output produced one character at a time through a callback mechanism, replacing the original internal functions and providing support for almost all C99 format specifications. Existing use of *printf() C libraries in Zephyr can be converted to snprintfc() to avoid pulling in libc implementations.

Several Kconfig options control the set of features that are enabled, allowing some control over features and memory usage:

- CONFIG_CBPRINTF_FULL_INTEGRAL or CONFIG_CBPRINTF_REDUCED_INTEGRAL
- CONFIG_CBPRINTF_FP_SUPPORT
- CONFIG_CBPRINTF_FP_A_SUPPORT
- CONFIG_CBPRINTF_FP_ALWAYS_A
- CONFIG_CBPRINTF_N_SPECIFIER

CONFIG_CBPRINTF_LIBC_SUBSTS can be used to provide functions that behave like standard libc functions but use the selected cbprintf formatter rather than pulling in another formatter from libc.

In addition CONFIG_CBPRINTF_NANO can be used to revert back to the very space-optimized but limited formatter used for printk() before this capability was added.

7.13.1 Cbprintf Packaging

Typically, strings are formatted synchronously when a function from printf family is called. However, there are cases when it is beneficial that formatting is deferred. In that case, a state (format string and arguments) must be captured. Such state forms a self-contained package which contains format string and arguments. Additionally, package contains copies of all strings which are part of a format string (format string or any %s argument) and are identified as the one located in the read write memory. Package primary content resembles va_list stack frame thus standard formatting functions are used to process a package. Since package contains data which is processed as va_list frame, strict alignment must be maintained. Due to required padding, size of the package depends on alignment. When package is copied, it should be copied to a memory block with the same alignment as origin.

Package can be created using two methods:

- runtime - using cbprintf_package() or cbvprintf_package(). This method scans format string and based on detected format specifiers builds the package.

- static - types of arguments are detected at compile time by the preprocessor and package is created as simple assignments to a provided memory. This method is significantly faster than runtime (more than 15 times) but has following limitations: requires _Generic keyword (C11 feature) to be supported by the compiler and can only create a package that is known to have no string arguments (%s). CBPRINTF_MUST_RUNTIME_PACKAGE can be used to determine at compile time if static packaging can be applied. Macro determines need for runtime packaging based on presence of char pointers in the argument list so there are cases when it will be false positive, e.g. %p with char pointer.

Several Kconfig options control behavior of the packaging:

- CONFIG_CBPRINTF_PACKAGE_LONDDOUBLE
• CONFIG_CBPRINTF_STATIC_PACKAGE_CHECK_ALIGNMENT

Cbprintf package format

Format of the package contains paddings which are platform specific. Package consists of header which contains size of package (excluding appended strings) and number of appended strings. It is followed by the arguments which contains alignment paddings and resembles va_list stack frame. Finally, package optionally contains appended strings. Each string contains 1 byte header which contains index of the location where address argument is stored. During packaging address is set to null and before string formatting it is updated to point to the current string location within the package. Updating address argument must happen just before string formatting since address changes whenever package is copied.

| Header | 1 byte: Argument list size including header and fmt (in 32 bit words) |
|        | 1 byte: Number of appended strings in writable memory |
|        | 1 byte: Number of appended strings in read-only memory |
|        | platform specific padding to sizeof(void *) |
| Arguments | Pointer to fmt (or null if fmt is appended to the package) |
|           | (optional padding for platform specific alignment) |
|           | argument 0 |
|           | (optional padding for platform specific alignment) |
|           | argument 1 |
|           | ... |
| Appended strings | 1 byte: Index within the package to the location of associated argument |
|                  | Null terminated string |
|                  | ... |

**Warning:** If CONFIG_MINIMAL_LIBC is selected in combination with CONFIG_CBPRINTF_NANO formatting with C standard library functions like printf or snprintf is limited. Among other things the %n specifier, most format flags, precision control, and floating point are not supported.

7.13.2 API Reference

`group cbprintf_apis`

**Defines**

- CBPRINTF_PACKAGE_ALIGNMENT
  Required alignment of the buffer used for packaging.
- CBPRINTF_MUST_RUNTIME_PACKAGE(skip, flags, ...)
  Determine if string must be packaged in run time.

Static packaging can be applied if size of the package can be determined at compile time. In general, package size can be determined at compile time if there are no string arguments which might be copied into package body if they are considered transient.
Note: By default any char pointers are considered to be pointing at transient strings. This can be narrowed down to non const pointers by using CBPRINTF_MUST_RUNTIME_PACKAGE_CONST_CHAR.

Parameters

- **skip** – number of read only string arguments in the parameter list. It shall be non-zero if there are known read only string arguments present in the string (e.g. function name prefix in the log message).
- **...** – String with arguments.
- **flags** – option flags. See Package flags.

Return values

- **1** – if string must be packaged in run time.
- **0** – string can be statically packaged.

```c
CBPRINTF_STATIC_PACKAGE(packaged, inlen, outlen, align_offset, flags, ...)
```

Statically package string.

Build string package from formatted string. It assumes that formatted string is in the read only memory.

If _Generic is not supported then runtime packaging is performed.

Parameters

- **packaged** – pointer to where the packaged data can be stored. Pass a null pointer to skip packaging but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. It must be aligned to the size of the longest argument. It is recommended to use CBPRINTF_PACKAGE_ALIGNMENT for alignment.
- **inlen** – set to the number of bytes available at packaged. If packaged is NULL the value is ignored.
- **outlen** – variable updated to the number of bytes required to completely store the packed information. If input buffer was too small it is set to -ENOSPC.
- **align_offset** – input buffer alignment offset in bytes. Where offset 0 means that buffer is aligned to CBPRINTF_PACKAGE_ALIGNMENT. Xtensa requires that packaged is aligned to CBPRINTF_PACKAGE_ALIGNMENT so it must be multiply of CBPRINTF_PACKAGE_ALIGNMENT or 0.
- **flags** – option flags. See Package flags.
- **...** – formatted string with arguments. Format string must be constant.

TypeDefs

typedef int (*cbprintf_cb)()

Signature for a cbprintf callback function.

This function expects two parameters:

- **c** a character to output. The output behavior should be as if this was cast to an unsigned char.
- **ctx** a pointer to an object that provides context for the output operation.
The declaration does not specify the parameter types. This allows a function like `fputc` to be used without requiring all context pointers to be to a `FILE` object.

**Return** the value of `c` cast to an unsigned char then back to int, or a negative error code that will be returned from `cbprintf()`.

typedef int (*cbvprintf_external_formatter_func)(cbprintf_cb out, void *ctx, const char *fmt, va_list ap)

Signature for a external formatter function identical to `cbvprintf`.

This function expects the following parameters:

**Param out** the function used to emit each generated character.

**Param ctx** a pointer to an object that provides context for the external formatter.

**Param fmt** a standard ISO C format string with characters and conversion specifications.

**Param ap** captured stack arguments corresponding to the conversion specifications found within `fmt`.

**Return** `vprintf` like return values: the number of characters printed, or a negative error value returned from external formatter.

**Functions**

```c
int cbprintf_package(void *packaged, size_t len, uint32_t flags, const char *format, ...)
```

Capture state required to output formatted data later.

Like `cbprintf()` but instead of processing the arguments and emitting the formatted results immediately all arguments are captured so this can be done in a different context, e.g. when the output function can block.

In addition to the values extracted from arguments this will ensure that copies are made of the necessary portions of any string parameters that are not confirmed to be stored in read-only memory (hence assumed to be safe to refer to directly later).

**Parameters**

- **packaged** – pointer to where the packaged data can be stored. Pass a null pointer to store nothing but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. However, under condition that alignment is maintained. It must be aligned to at least the size of a pointer.

- **len** – this must be set to the number of bytes available at `packaged` if it is not null. If `packaged` is null then it indicates hypothetical buffer alignment offset in bytes compared to `CBPRINTF_PACKAGE_ALIGNMENT` alignment. Buffer alignment offset impacts returned size of the package. Xtensa requires that buffer is always aligned to `CBPRINTF_PACKAGE_ALIGNMENT` so it must be multiply of `CBPRINTF_PACKAGE_ALIGNMENT` or 0 when `packaged` is null.

- **flags** – option flags. See Package flags.

- **format** – a standard ISO C format string with characters and conversion specifications.

- **...** – arguments corresponding to the conversion specifications found within `format`.

**Return values**

- **nonnegative** – the number of bytes successfully stored at `packaged`. This will not exceed `len`. 
• -EINVAL – if format is not acceptable
• -EFAULT – if packaged alignment is not acceptable
• -ENOSPC – if packaged was not null and the space required to store exceed len.

int cbvprintf_package(void *packaged, size_t len, uint32_t flags, const char *format, va_list ap)
Capture state required to output formatted data later.

Like cbprintf() but instead of processing the arguments and emitting the formatted results immediately all arguments are captured so this can be done in a different context, e.g. when the output function can block.

In addition to the values extracted from arguments this will ensure that copies are made of the necessary portions of any string parameters that are not confirmed to be stored in read-only memory (hence assumed to be safe to refer to directly later).

**Parameters**

- **packaged** – pointer to where the packaged data can be stored. Pass a null pointer to store nothing but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. The pointer must be aligned to a multiple of the largest element in the argument list.
- **len** – this must be set to the number of bytes available at packaged. Ignored if packaged is NULL.
- **flags** – option flags. See Package flags.
- **format** – a standard ISO C format string with characters and conversion specifications.
- **ap** – captured stack arguments corresponding to the conversion specifications found within format.

**Return values**

- nonegative – the number of bytes successfully stored at packaged. This will not exceed len.
- -EINVAL – if format is not acceptable
- -ENOSPC – if packaged was not null and the space required to store exceed len.

int cbprintf_fsc_package(void *in_packaged, size_t in_len, void *packaged, size_t len)
Convert package to fully self-contained (fsc) package.

By default, package does not contain read only strings. However, if needed it may be converted to a fully self-contained package which contains all strings. In order to allow such conversion, original package must be created with CBPRINTF_PACKAGE_ADD_STRINGIDX flag. Such package will contain necessary data to find read only strings in the package and copy them into package body.

**Parameters**

- **in_packaged** – pointer to original package created with CBPRINTF_PACKAGE_ADD_STRINGIDX.
- **in_len** – in_packaged length.
- **packaged** – pointer to location where fully self-contained version of the input package will be written. Pass a null pointer to calculate space required.
- **len** – must be set to the number of bytes available at packaged. Not used if packaged is null.

**Return values**
• nonegative – the number of bytes successfully stored at packaged. This will not exceed len. If packaged is null, calculated length.
• -ENOSPC – if packaged was not null and the space required to store exceed len.
• -EINVAL – if in_packaged is null.

```c
int cbprintf_external(cbprintf_cb out, cbprintf_external_formatter_func formatter, void *ctx, void *packaged)
```

Generate the output for a previously captured format operation using an external formatter.

**Note:** Memory indicated by packaged will be modified in a non-destructive way, meaning that it could still be reused with this function again.

**Parameters**

- **out** – the function used to emit each generated character.
- **formatter** – external formatter function.
- **ctx** – a pointer to an object that provides context for the external formatter.
- **packaged** – the data required to generate the formatted output, as captured by cbprintf_package() or cbvprintf_package(). The alignment requirement on this data is the same as when it was initially created.

**Returns** printf like return values: the number of characters printed, or a negative error value returned from external formatter.

```c
int cbprintf(cbprintf_cb out, void *ctx, const char *format, ...)
```

*printf-like output through a callback.

This is essentially printf() except the output is generated character-by-character using the provided out function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.

All formatting specifiers of C99 are recognized, and most are supported if the functionality is enabled.

**Note:** The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

**Parameters**

- **out** – the function used to emit each generated character.
- **ctx** – context provided when invoking out
- **format** – a standard ISO C format string with characters and conversion specifications.
- **...** – arguments corresponding to the conversion specifications found within format.

**Returns** the number of characters printed, or a negative error value returned from invoking out.

```c
int cbvprintf(cbprintf_cb out, void *ctx, const char *format, va_list ap)
```

varargs-aware *printf-like output through a callback.

This is essentially vsprintf() except the output is generated character-by-character using the provided out function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.
Note: This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

Note: The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

• out – the function used to emit each generated character.
• ctx – context provided when invoking out
• format – a standard ISO C format string with characters and conversion specifications.
• ap – a reference to the values to be converted.

Returns the number of characters generated, or a negative error value returned from invoking out.

static inline int cbpprintf(cbprintf_cb out, void *ctx, void *packaged)
Generate the output for a previously captured format operation.

Note: Memory indicated by packaged will be modified in a non-destructive way, meaning that it could still be reused with this function again.

Parameters

• out – the function used to emit each generated character.
• ctx – context provided when invoking out
• packaged – the data required to generate the formatted output, as captured by cbprintf_package() or cbvprintf_package(). The alignment requirement on this data is the same as when it was initially created.

Returns the number of characters printed, or a negative error value returned from invoking out.

int fprintfcb(FILE *stream, const char *format, ...)
fprintf using Zephyrs cbprintf infrastructure.

return The number of characters printed.

Note: This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

Note: The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

• stream – the stream to which the output should be written.
• format – a standard ISO C format string with characters and conversion specifications.
• ... – arguments corresponding to the conversion specifications found within format.

```c
int vfprintfcb(FILE *stream, const char *format, va_list ap)
    vfprintf using Zephyrs cbprintf infrastructure.
```

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

### Parameters
- `stream` – the stream to which the output should be written.
- `format` – a standard ISO C format string with characters and conversion specifications.
- `ap` – a reference to the values to be converted.

**Returns** The number of characters printed.

```c
int printfcb(const char *format, ...)
    printf using Zephyrs cbprintf infrastructure.
```

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

### Parameters
- `format` – a standard ISO C format string with characters and conversion specifications.
- `...` – arguments corresponding to the conversion specifications found within `format`.

**Returns** The number of characters printed.

```c
int vprintfcb(const char *format, va_list ap)
    vprintf using Zephyrs cbprintf infrastructure.
```

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

### Parameters
- `format` – a standard ISO C format string with characters and conversion specifications.
- `ap` – a reference to the values to be converted.
Returns The number of characters printed.

```
int snprintfcb(char *str, size_t size, const char *format, ...)

snprintf using Zephyrs cbprintf infrastructure.
```

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

### Parameters

- **str** – where the formatted content should be written
- **size** – maximum number of characters for the formatted output, including the terminating null byte.
- **format** – a standard ISO C format string with characters and conversion specifications.
- **...** – arguments corresponding to the conversion specifications found within `format`.

### Returns

The number of characters that would have been written to `str`, excluding the terminating null byte. This is greater than the number actually written if `size` is too small.

```
int vsnprintfcb(char *str, size_t size, const char *format, va_list ap)

vsnprintf using Zephyrs cbprintf infrastructure.
```

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

### Parameters

- **str** – where the formatted content should be written
- **size** – maximum number of characters for the formatted output, including the terminating null byte.
- **format** – a standard ISO C format string with characters and conversion specifications.
- **ap** – a reference to the values to be converted.

### Returns

The number of characters that would have been written to `str`, excluding the terminating null byte. This is greater than the number actually written if `size` is too small.

## 7.14 Kernel Services

The Zephyr kernel lies at the heart of every Zephyr application. It provides a low footprint, high performance, multi-threaded execution environment with a rich set of available features. The rest of the
Zephyr ecosystem, including device drivers, networking stack, and application-specific code, uses the kernel’s features to create a complete application.

The configurable nature of the kernel allows you to incorporate only those features needed by your application, making it ideal for systems with limited amounts of memory (as little as 2 KB!) or with simple multi-threading requirements (such as a set of interrupt handlers and a single background task). Examples of such systems include: embedded sensor hubs, environmental sensors, simple LED wearable, and store inventory tags.

Applications requiring more memory (50 to 900 KB), multiple communication devices (like Wi-Fi and Bluetooth Low Energy), and complex multi-threading, can also be developed using the Zephyr kernel. Examples of such systems include: fitness wearables, smart watches, and IoT wireless gateways.

### 7.14.1 Scheduling, Interrupts, and Synchronization

These pages cover basic kernel services related to thread scheduling and synchronization.

**Threads**

**Note:** There is also limited support for using Zephyr Without Threads.
This section describes kernel services for creating, scheduling, and deleting independently executable threads of instructions.

A thread is a kernel object that is used for application processing that is too lengthy or too complex to be performed by an ISR.

Any number of threads can be defined by an application (limited only by available RAM). Each thread is referenced by a thread id that is assigned when the thread is spawned.

A thread has the following key properties:

- A **stack area**, which is a region of memory used for the thread’s stack. The **size** of the stack area can be tailored to conform to the actual needs of the thread’s processing. Special macros exist to create and work with stack memory regions.

- A **thread control block** for private kernel bookkeeping of the thread’s metadata. This is an instance of type `k_thread`.

- An **entry point function**, which is invoked when the thread is started. Up to 3 **argument values** can be passed to this function.

- A **scheduling priority**, which instructs the kernel’s scheduler how to allocate CPU time to the thread. (See **Scheduling**.)

- A set of **thread options**, which allow the thread to receive special treatment by the kernel under specific circumstances. (See **Thread Options**.)

- A **start delay**, which specifies how long the kernel should wait before starting the thread.

- An **execution mode**, which can either be supervisor or user mode. By default, threads run in supervisor mode and allow access to privileged CPU instructions, the entire memory address space, and peripherals. User mode threads have a reduced set of privileges. This depends on the `CONFIG_USERSPACE` option. See **User Mode**.

**Lifecycle**

**Thread Creation** A thread must be created before it can be used. The kernel initializes the thread control block as well as one end of the stack portion. The remainder of the thread’s stack is typically left uninitialized.

Specifying a start delay of `K_NO_WAIT` instructs the kernel to start thread execution immediately. Alternatively, the kernel can be instructed to delay execution of the thread by specifying a timeout value – for example, to allow device hardware used by the thread to become available.

The kernel allows a delayed start to be canceled before the thread begins executing. A cancellation request has no effect if the thread has already started. A thread whose delayed start was successfully canceled must be re-spawned before it can be used.

**Thread Termination** Once a thread is started it typically executes forever. However, a thread may synchronously end its execution by returning from its entry point function. This is known as **termination**.

A thread that terminates is responsible for releasing any shared resources it may own (such as mutexes and dynamically allocated memory) prior to returning, since the kernel does not reclaim them automatically.

In some cases a thread may want to sleep until another thread terminates. This can be accomplished with the `k_thread_join()` API. This will block the calling thread until either the timeout expires, the target thread self-exits, or the target thread aborts (either due to a `k_thread_abort()` call or triggering a fatal error).

Once a thread has terminated, the kernel guarantees that no use will be made of the thread struct. The memory of such a struct can then be re-used for any purpose, including spawning a new thread. Note that the thread must be fully terminated, which presents race conditions where a thread’s own logic signals
completion which is seen by another thread before the kernel processing is complete. Under normal circumstances, application code should use \texttt{k_thread_join()} or \texttt{k_thread_abort()} to synchronize on thread termination state and not rely on signaling from within application logic.

\textbf{Thread Aborting} A thread may asynchronously end its execution by \texttt{aborting}. The kernel automatically aborts a thread if the thread triggers a fatal error condition, such as dereferencing a null pointer. A thread can also be aborted by another thread (or by itself) by calling \texttt{k_thread_abort()}. However, it is typically preferable to signal a thread to terminate itself gracefully, rather than aborting it. As with thread termination, the kernel does not reclaim shared resources owned by an aborted thread.

\textbf{Note:} The kernel does not currently make any claims regarding an application's ability to respawn a thread that aborts.

\textbf{Thread Suspension} A thread can be prevented from executing for an indefinite period of time if it becomes \texttt{suspended}. The function \texttt{k_thread_suspend()} can be used to suspend any thread, including the calling thread. Suspending a thread that is already suspended has no additional effect. Once suspended, a thread cannot be scheduled until another thread calls \texttt{k_thread_resume()} to remove the suspension.

\textbf{Note:} A thread can prevent itself from executing for a specified period of time using \texttt{k_sleep()}. However, this is different from suspending a thread since a sleeping thread becomes executable automatically when the time limit is reached.

\textbf{Thread States} A thread that has no factors that prevent its execution is deemed to be \texttt{ready}, and is eligible to be selected as the current thread. A thread that has one or more factors that prevent its execution is deemed to be \texttt{unready}, and cannot be selected as the current thread. The following factors make a thread unready:

- The thread has not been started.
- The thread is waiting for a kernel object to complete an operation. (For example, the thread is taking a semaphore that is unavailable.)
- The thread is waiting for a timeout to occur.
- The thread has been suspended.
- The thread has terminated or aborted.
Thread Stack objects Every thread requires its own stack buffer for the CPU to push context. Depending on configuration, there are several constraints that must be met:

- There may need to be additional memory reserved for memory management structures
- If guard-based stack overflow detection is enabled, a small write-protected memory management region must immediately precede the stack buffer to catch overflows.
- If userspace is enabled, a separate fixed-size privilege elevation stack must be reserved to serve as a private kernel stack for handling system calls.
- If userspace is enabled, the thread's stack buffer must be appropriately sized and aligned such that a memory protection region may be programmed to exactly fit.

The alignment constraints can be quite restrictive, for example some MPUs require their regions to be of some power of two in size, and aligned to its own size.

Because of this, portable code can’t simply pass an arbitrary character buffer to `k_thread_create()`. Special macros exist to instantiate stacks, prefixed with `K_KERNEL_STACK` and `K_THREAD_STACK`.

Kernel-only Stacks If it is known that a thread will never run in user mode, or the stack is being used for special contexts like handling interrupts, it is best to define stacks using the `K_KERNEL_STACK` macros.

These stacks save memory because an MPU region will never need to be programmed to cover the stack buffer itself, and the kernel will not need to reserve additional room for the privilege elevation stack, or memory management data structures which only pertain to user mode threads.

Attempts from user mode to use stacks declared in this way will result in a fatal error for the caller.

If `CONFIG_USERSPACE` is not enabled, the set of `K_THREAD_STACK` macros have an identical effect to the `K_KERNEL_STACK` macros.

Thread stacks If it is known that a stack will need to host user threads, or if this cannot be determined, define the stack with `K_THREAD_STACK` macros. This may use more memory but the stack object is suitable for hosting user threads.
If `CONFIG_USERSPACE` is not enabled, the set of `K_THREAD_STACK` macros have an identical effect to the `K_KERNEL_STACK` macros.

**Thread Priorities** A thread’s priority is an integer value, and can be either negative or non-negative. Numerically lower priorities takes precedence over numerically higher values. For example, the scheduler gives thread A of priority 4 higher priority over thread B of priority 7; likewise thread C of priority -2 has higher priority than both thread A and thread B.

The scheduler distinguishes between two classes of threads, based on each thread’s priority.

- A *cooperative thread* has a negative priority value. Once it becomes the current thread, a cooperative thread remains the current thread until it performs an action that makes it unready.
- A *preemptible thread* has a non-negative priority value. Once it becomes the current thread, a preemptible thread may be supplanted at any time if a cooperative thread, or a preemptible thread of higher or equal priority, becomes ready.

A thread’s initial priority value can be altered up or down after the thread has been started. Thus it is possible for a preemptible thread to become a cooperative thread, and vice versa, by changing its priority.

**Note:** The scheduler does not make heuristic decisions to re-prioritize threads. Thread priorities are set and changed only at the application’s request.

The kernel supports a virtually unlimited number of thread priority levels. The configuration options `CONFIG_NUM_COOP_PRIORITIES` and `CONFIG_NUM_PREEMPT_PRIORITIES` specify the number of priority levels for each class of thread, resulting in the following usable priority ranges:

- cooperative threads: `(-CONFIG_NUM_COOP_PRIORITIES)` to `-1`
- preemptive threads: `0` to `(``CONFIG_NUM_PREEMPT_PRIORITIES` `- 1`)`

For example, configuring 5 cooperative priorities and 10 preemptive priorities results in the ranges `-5` to `-1` and `0` to `9`, respectively.

**Meta-IRQ Priorities** When enabled (see `CONFIG_NUM_METAIRQ_PRIORITIES`), there is a special sub-class of cooperative priorities at the highest (numerically lowest) end of the priority space: meta-IRQ threads. These are scheduled according to their normal priority, but also have the special ability to preempt all other threads (and other meta-IRQ threads) at lower priorities, even if those threads are cooperative and/or have taken a scheduler lock. Meta-IRQ threads are still threads, however, and can still be interrupted by any hardware interrupt.

This behavior makes the act of unblocking a meta-IRQ thread (by any means, e.g. creating it, calling `k_sem_give()`, etc.) into the equivalent of a synchronous system call when done by a lower priority thread, or an ARM-like “pended IRQ” when done from true interrupt context. The intent is that this feature will be used to implement interrupt “bottom half” processing and/or “tasklet” features in driver
subsystems. The thread, once woken, will be guaranteed to run before the current CPU returns into application code.

Unlike similar features in other OSes, meta-IRQ threads are true threads and run on their own stack (which must be allocated normally), not the per-CPU interrupt stack. Design work to enable the use of the IRQ stack on supported architectures is pending.

Note that because this breaks the promise made to cooperative threads by the Zephyr API (namely that the OS won’t schedule other thread until the current thread deliberately blocks), it should be used only with great care from application code. These are not simply very high priority threads and should not be used as such.

**Thread Options**  The kernel supports a small set of thread options that allow a thread to receive special treatment under specific circumstances. The set of options associated with a thread are specified when the thread is spawned.

A thread that does not require any thread option has an option value of zero. A thread that requires a thread option specifies it by name, using the | character as a separator if multiple options are needed (i.e. combine options using the bitwise OR operator).

The following thread options are supported.

- **K_ESSENTIAL**  This option tags the thread as an essential thread. This instructs the kernel to treat the termination or aborting of the thread as a fatal system error.

  By default, the thread is not considered to be an essential thread.

- **K_SSE_REGS**  This x86-specific option indicate that the thread uses the CPU’s SSE registers. Also see K_FP_REGS.

  By default, the kernel does not attempt to save and restore the contents of these registers when scheduling the thread.

- **K_FP_REGS**  This option indicate that the thread uses the CPU’s floating point registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. (For more information see Floating Point Services.)

  By default, the kernel does not attempt to save and restore the contents of this register when scheduling the thread.

- **K_USER**  If CONFIG_USERSPACE is enabled, this thread will be created in user mode and will have reduced privileges. See User Mode. Otherwise this flag does nothing.

- **K_INHERIT_PERMS**  If CONFIG_USERSPACE is enabled, this thread will inherit all kernel object permissions that the parent thread had, except the parent thread object. See User Mode.

**Thread Custom Data**  Every thread has a 32-bit custom data area, accessible only by the thread itself, and may be used by the application for any purpose it chooses. The default custom data value for a thread is zero.

**Note:**  Custom data support is not available to ISRs because they operate within a single shared kernel interrupt handling context.

By default, thread custom data support is disabled. The configuration option CONFIG_THREAD_CUSTOM_DATA can be used to enable support.

The k_thread_custom_data_set() and k_thread_custom_data_get() functions are used to write and read a thread’s custom data, respectively. A thread can only access its own custom data, and not that of another thread.

The following code uses the custom data feature to record the number of times each thread calls a specific routine.
Note: Obviously, only a single routine can use this technique, since it monopolizes the use of the custom data feature.

```c
int call_tracking_routine(void)
{
    uint32_t call_count;

    if (k_is_in_isr()) {
        /* ignore any call made by an ISR */
    } else {
        call_count = (uint32_t)k_thread_custom_data_get();
        call_count++;
        k_thread_custom_data_set((void *)call_count);
    }

    /* do rest of routine's processing */
    ...
}
```

Use thread custom data to allow a routine to access thread-specific information, by using the custom data as a pointer to a data structure owned by the thread.

**Implementation**

**Spawning a Thread**  A thread is spawned by defining its stack area and its thread control block, and then calling `k_thread_create()`.

The stack area must be defined using `K_THREAD_STACK_DEFINE` or `K_KERNEL_STACK_DEFINE` to ensure it is properly set up in memory.

The size parameter for the stack must be one of three values:

- The original requested stack size passed to `K_THREAD_STACK` or `K_KERNEL_STACK` family of stack instantiation macros.
- For a stack object defined with the `K_THREAD_STACK` family of macros, the return value of `K_THREAD_STACK_SIZEOF()` for that object.
- For a stack object defined with the `K_KERNEL_STACK` family of macros, the return value of `K_KERNEL_STACK_SIZEOF()` for that object.

The thread spawning function returns its thread id, which can be used to reference the thread.

The following code spawns a thread that starts immediately:

```c
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);
struct k_thread my_thread_data;

k_tid_t my_tid = k_thread_create(&my_thread_data, my_stack_area,
                                K_THREAD_STACK_SIZEOF(my_stack_area),
                                my_entry_point,
                                NULL, NULL, NULL,
                                MY_PRIORITY, 0, K_NO_WAIT);
```
Alternatively, a thread can be declared at compile time by calling `K_THREAD_DEFINE`. Observe that the macro defines the stack area, control block, and thread id variables automatically.

The following code has the same effect as the code segment above.

```c
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_DEFINE(my_tid, MY_STACK_SIZE,
    my_entry_point, NULL, NULL, NULL,
    MY_PRIORITY, 0, 0);
```

Note: The delay parameter to `k_thread_create()` is a `k_timeout_t` value, so `K_NO_WAIT` means to start the thread immediately. The corresponding parameter to `K_THREAD_DEFINE` is a duration in integral milliseconds, so the equivalent argument is 0.

User Mode Constraints  This section only applies if `CONFIG_USERSPACE` is enabled, and a user thread tries to create a new thread. The `k_thread_create()` API is still used, but there are additional constraints which must be met or the calling thread will be terminated:

- The calling thread must have permissions granted on both the child thread and stack parameters; both are tracked by the kernel as kernel objects.
- The child thread and stack objects must be in an uninitialized state, i.e. it is not currently running and the stack memory is unused.
- The stack size parameter passed in must be equal to or less than the bounds of the stack object when it was declared.
- The `K_USER` option must be used, as user threads can only create other user threads.
- The `K_ESSENTIAL` option must not be used, user threads may not be considered essential threads.
- The priority of the child thread must be a valid priority value, and equal to or lower than the parent thread.

Dropping Permissions  If `CONFIG_USERSPACE` is enabled, a thread running in supervisor mode may perform a one-way transition to user mode using the `k_thread_user_mode_enter()` API. This is a one-way operation which will reset and zero the thread’s stack memory. The thread will be marked as non-essential.

Terminating a Thread  A thread terminates itself by returning from its entry point function.

The following code illustrates the ways a thread can terminate.

```c
void my_entry_point(int unused1, int unused2, int unused3)
{
    while (1) {
        ...
        if (<some condition>) {
            return; /* thread terminates from mid-entry point function */
        }
        ...
    }
}
```

(continues on next page)
If CONFIG_USERSPACE is enabled, aborting a thread will additionally mark the thread and stack objects as uninitialized so that they may be re-used.

**Runtime Statistics** Thread runtime statistics can be gathered and retrieved if CONFIG_THREAD_RUNTIME_STATS is enabled, for example, total number of execution cycles of a thread.

By default, the runtime statistics are gathered using the default kernel timer. For some architectures, SoCs or boards, there are timers with higher resolution available via timing functions. Using of these timers can be enabled via CONFIG_THREAD_RUNTIME_STATS_USE_TIMING_FUNCTIONS.

Here is an example:

```c
k_thread_runtime_stats_t rt_stats_thread;

k_thread_runtime_stats_get(k_current_get(), &rt_stats_thread);

printk("Cycles: %llu\n", rt_stats_thread.execution_cycles);
```

**Suggested Uses** Use threads to handle processing that cannot be handled in an ISR.

Use separate threads to handle logically distinct processing operations that can execute in parallel.

**Configuration Options** Related configuration options:

- CONFIG_MAIN_THREAD_PRIORITY
- CONFIG_MAIN_STACK_SIZE
- CONFIG_IDLE_STACK_SIZE
- CONFIG_THREAD_CUSTOM_DATA
- CONFIG_NUM_COOP_PRIORITIES
- CONFIG_NUM_PREEMPT_PRIORITIES
- CONFIG_TIMESLICING
- CONFIG_TIMESLICE_SIZE
- CONFIG_TIMESLICE_PRIORITY
- CONFIG_USERSPACE

**API Reference**

group thread_apis

**Defines**

- K_ESSENTIAL
  system thread that must not abort
K_FP_REGS
FPU registers are managed by context switch.
This option indicates that the thread uses the CPU's floating point registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. No effect if CONFIG_FPU_SHARING is not enabled.

K_USER
user mode thread
This thread has dropped from supervisor mode to user mode and consequently has additional restrictions

K_INHERIT_PERMS
Inherit Permissions.
Indicates that the thread being created should inherit all kernel object permissions from the thread that created it. No effect if CONFIG_USERSPACE is not enabled.

K_CALLBACK_STATE
Callback item state.
This is a single bit of state reserved for “callback manager” utilities (p4wq initially) who need to track operations invoked from within a user-provided callback they have been invoked. Effectively it serves as a tiny bit of zero-overhead TLS data.

k_thread_access_grant(thread, ...)
Grant a thread access to a set of kernel objects.
This is a convenience function. For the provided thread, grant access to the remaining arguments, which must be pointers to kernel objects.
The thread object must be initialized (i.e. running). The objects don’t need to be. Note that NULL shouldn’t be passed as an argument.

Parameters
• thread – Thread to grant access to objects
• ... – list of kernel object pointers

K_THREAD_DEFINE(name, stack_size, entry, p1, p2, p3, prio, options, delay)
Statically define and initialize a thread.
The thread may be scheduled for immediate execution or a delayed start.
Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using “|” (the logical OR operator).
The ID of the thread can be accessed using:

extern const k_tid_t <name>;

Parameters
• name – Name of the thread.
• stack_size – Stack size in bytes.
• entry – Thread entry function.
• p1 – 1st entry point parameter.
• p2 – 2nd entry point parameter.
• p3 – 3rd entry point parameter.
• prio – Thread priority.
• options – Thread options.
• delay – Scheduling delay (in milliseconds), zero for no delay.

**Typedefs**

typedef void (*k_thread_user_cb_t)(const struct k_thread *thread, void *user_data)

**Functions**

void k_thread_foreach(k_thread_user_cb_t user_cb, void *user_data)
Iterate over all the threads in the system.
This routine iterates over all the threads in the system and calls the user_cb function for each thread.

**Note:** CONFIG_THREAD_MONITOR must be set for this function to be effective.

**Note:** This API uses k_spin_lock to protect the _kernel.threads list which means creation of new threads and terminations of existing threads are blocked until this API returns.

**Parameters**
• user_cb – Pointer to the user callback function.
• user_data – Pointer to user data.

void k_thread_foreach_unlocked(k_thread_user_cb_t user_cb, void *user_data)
Iterate over all the threads in the system without locking.
This routine works exactly the same like k_thread_foreach but unlocks interrupts when user_cb is executed.

**Note:** CONFIG_THREAD_MONITOR must be set for this function to be effective.

**Note:** This API uses k_spin_lock only when accessing the _kernel.threads queue elements. It unlocks it during user callback function processing. If a new task is created when this foreach function is in progress, the added new task would not be included in the enumeration. If a task is aborted during this enumeration, there would be a race here and there is a possibility that this aborted task would be included in the enumeration.

**Note:** If the task is aborted and the memory occupied by its k_thread structure is reused when this k_thread_foreach_unlocked is in progress it might even lead to the system behave unstable. This function may never return, as it would follow some next task pointers treating given pointer as a pointer to the k_thread structure while it is something different right now. Do not reuse the memory that was occupied by k_thread structure of aborted task if it was aborted after this function was called in any context.
k_tid_t k_thread_create(struct k_thread *new_thread, k_thread_stack_t *stack, size_t stack_size, k_thread_entry_t entry, void *p1, void *p2, void *p3, int prio, uint32_t options, k_timeout_t delay)

Create a thread.

This routine initializes a thread, then schedules it for execution.

The new thread may be scheduled for immediate execution or a delayed start. If the newly spawned thread does not have a delayed start the kernel scheduler may preempt the current thread to allow the new thread to execute.

Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using “|” (the logical OR operator).

Stack objects passed to this function must be originally defined with either of these macros in order to be portable:

- K_THREAD_STACK_DEFINE() - For stacks that may support either user or supervisor threads.
- K_KERNEL_STACK_DEFINE() - For stacks that may support supervisor threads only. These stacks use less memory if CONFIG_USERSPACE is enabled.

The stack_size parameter has constraints. It must either be:

- The original size value passed to K_THREAD_STACK_DEFINE() or K_KERNEL_STACK_DEFINE()
- The return value of K_THREAD_STACK_SIZEOF(stack) if the stack was defined with K_THREAD_STACK_DEFINE()
- The return value of K_KERNEL_STACK_SIZEOF(stack) if the stack was defined with K_KERNEL_STACK_DEFINE().

Using other values, or sizeof(stack) may produce undefined behavior.

### Parameters

- **new_thread** – Pointer to uninitialized struct k_thread
- **stack** – Pointer to the stack space.
- **stack_size** – Stack size in bytes.
- **entry** – Thread entry function.
- **p1** – 1st entry point parameter.
- **p2** – 2nd entry point parameter.
- **p3** – 3rd entry point parameter.
- **prio** – Thread priority.
- **options** – Thread options.
- **delay** – Scheduling delay, or K_NO_WAIT (for no delay).

### Returns

ID of new thread.
FUNC_NORETURN void k_thread_user_mode_enter(k_thread_entry_t entry, void *p1, void *p2, void *p3)

Drop a thread’s privileges permanently to user mode.

This allows a supervisor thread to be re-used as a user thread. This function does not return, but control will transfer to the provided entry point as if this was a new user thread.

The implementation ensures that the stack buffer contents are erased. Any thread-local storage will be reverted to a pristine state.

Memory domain membership, resource pool assignment, kernel object permissions, priority, and thread options are preserved.

A common use of this function is to re-use the main thread as a user thread once all supervisor mode-only tasks have been completed.

Parameters
- entry – Function to start executing from
- p1 – 1st entry point parameter
- p2 – 2nd entry point parameter
- p3 – 3rd entry point parameter

static inline void k_thread_heap_assign(struct k_thread *thread, struct k_heap *heap)

Assign a resource memory pool to a thread.

By default, threads have no resource pool assigned unless their parent thread has a resource pool, in which case it is inherited. Multiple threads may be assigned to the same memory pool.

Changing a thread’s resource pool will not migrate allocations from the previous pool.

Parameters
- thread – Target thread to assign a memory pool for resource requests.
- heap – Heap object to use for resources, or NULL if the thread should no longer have a memory pool.

void k_thread_system_pool_assign(struct k_thread *thread)

Assign the system heap as a thread’s resource pool.

Similar to z_thread_heap_assign(), but the thread will use the kernel heap to draw memory.

Use with caution, as a malicious thread could perform DoS attacks on the kernel heap.

Parameters
- thread – Target thread to assign the system heap for resource requests

int k_thread_join(struct k_thread *thread, k_timeout_t timeout)

Sleep until a thread exits.

The caller will be put to sleep until the target thread exits, either due to being aborted, self-exiting, or taking a fatal error. This API returns immediately if the thread isn’t running.

This API may only be called from ISRs with a K_NO_WAIT timeout, where it can be useful as a predicate to detect when a thread has aborted.

Parameters
- thread – Thread to wait to exit
- timeout – upper bound time to wait for the thread to exit.

Return values
- 0 – success, target thread has exited or wasn’t running
- -EBUSY – returned without waiting
- **EAGAIN** – waiting period timed out
- **EDeadLK** – target thread is joining on the caller, or target thread is the caller

```c
int32_t k_sleep(k_timeout_t timeout)
```

Put the current thread to sleep.

This routine puts the current thread to sleep for duration, specified as a `k_timeout_t` object.

**Note:** if `timeout` is set to K_FOREVER then the thread is suspended.

**Parameters**

- **timeout** – Desired duration of sleep.

**Returns** Zero if the requested time has elapsed or the number of milliseconds left to sleep, if thread was woken up by `k_wakeup` call.

```c
static inline int32_t k_msleep(int32_t ms)
```

Put the current thread to sleep.

This routine puts the current thread to sleep for `duration` milliseconds.

**Parameters**

- **ms** – Number of milliseconds to sleep.

**Returns** Zero if the requested time has elapsed or the number of milliseconds left to sleep, if thread was woken up by `k_wakeup` call.

```c
int32_t k_usleep(int32_t us)
```

Put the current thread to sleep with microsecond resolution.

This function is unlikely to work as expected without kernel tuning. In particular, because the lower bound on the duration of a sleep is the duration of a tick, `CONFIG_SYS_CLOCK_TICKS_PER_SEC` must be adjusted to achieve the resolution desired. The implications of doing this must be understood before attempting to use `k_usleep()`. Use with caution.

**Parameters**

- **us** – Number of microseconds to sleep.

**Returns** Zero if the requested time has elapsed or the number of microseconds left to sleep, if thread was woken up by `k_wakeup` call.

```c
void k_busy_wait(uint32_t usec_to_wait)
```

Cause the current thread to busy wait.

This routine causes the current thread to execute a “do nothing” loop for `usec_to_wait` microseconds.

**Note:** The clock used for the microsecond-resolution delay here may be skewed relative to the clock used for system timeouts like `k_sleep()`. For example `k_busy_wait(1000)` may take slightly more or less time than `k_sleep(K_MSEC(1))`, with the offset dependent on clock tolerances.

```c
void k_yield(void)
```

Yield the current thread.

This routine causes the current thread to yield execution to another thread of the same or higher priority. If there are no other ready threads of the same or higher priority, the routine returns immediately.
void k_wakeup(k_tid_t thread)
    Wake up a sleeping thread.

This routine prematurely wakes up thread from sleeping.

If thread is not currently sleeping, the routine has no effect.

Parameters

• thread – ID of thread to wake.

__attribute_const__ static inline k_tid_t k_current_get(void)
    Get thread ID of the current thread.

Returns ID of current thread.

void k_thread_abort(k_tid_t thread)
    Abort a thread.

This routine permanently stops execution of thread. The thread is taken off all kernel queues
it is part of (i.e. the ready queue, the timeout queue, or a kernel object wait queue). However,
any kernel resources the thread might currently own (such as mutexes or memory blocks) are
not released. It is the responsibility of the caller of this routine to ensure all necessary cleanup
is performed.

After k_thread_abort() returns, the thread is guaranteed not to be running or to become
runnable anywhere on the system. Normally this is done via blocking the caller (in the same
manner as k_thread_join()), but in interrupt context on SMP systems the implementation is
required to spin for threads that are running on other CPUs. Note that as specified, this
means that on SMP platforms it is possible for application code to create a deadlock condition
by simultaneously aborting a cycle of threads using at least one termination from interrupt
context. Zephyr cannot detect all such conditions.

Parameters

• thread – ID of thread to abort.

void k_thread_start(k_tid_t thread)
    Start an inactive thread.

If a thread was created with K_FOREVER in the delay parameter, it will not be added to the
scheduling queue until this function is called on it.

Parameters

• thread – thread to start

k_ticks_t k_thread_timeout_expires_ticks(const struct k_thread *t)
    Get time when a thread wakes up, in system ticks.

This routine computes the system uptime when a waiting thread next executes, in units of
system ticks. If the thread is not waiting, it returns current system time.

k_ticks_t k_thread_timeout_remaining_ticks(const struct k_thread *t)
    Get time remaining before a thread wakes up, in system ticks.

This routine computes the time remaining before a waiting thread next executes, in units of
system ticks. If the thread is not waiting, it returns zero.

int k_thread_priority_get(k_tid_t thread)
    Get a thread's priority.

This routine gets the priority of thread.

Parameters

• thread – ID of thread whose priority is needed.

Returns Priority of thread.
void k_thread_priority_set(k_tid_t thread, int prio)
   Set a thread's priority.

   This routine immediately changes the priority of thread.
   Rescheduling can occur immediately depending on the priority thread is set to:

   - If its priority is raised above the priority of the caller of this function, and the caller is
     preemptible, thread will be scheduled in.
   - If the caller operates on itself, it lowers its priority below that of other threads in the
     system, and the caller is preemptible, the thread of highest priority will be scheduled in.

   Priority can be assigned in the range of -CONFIG_NUM_COOP_PRIORITIES to
   CONFIG_NUM_PREEMPT_PRIORITIES-1, where -CONFIG_NUM_COOP_PRIORITIES is the
   highest priority.

   Warning: Changing the priority of a thread currently involved in mutex priority inheri-
   tance may result in undefined behavior.

   Parameters
   - thread – ID of thread whose priority is to be set.
   - prio – New priority.

void k_thread_deadline_set(k_tid_t thread, int deadline)
   Set deadline expiration time for scheduler.

   This sets the “deadline” expiration as a time delta from the current time, in the same units
   used by k_cycle_get_32(). The scheduler (when deadline scheduling is enabled) will choose
   the next expiring thread when selecting between threads at the same static priority. Threads
   at different priorities will be scheduled according to their static priority.

   Note: Deadlines are stored internally using 32 bit unsigned integers. The number of cy-
   cles between the “first” deadline in the scheduler queue and the “last” deadline must be less
   than 2^31 (i.e a signed non-negative quantity). Failure to adhere to this rule may result in
   scheduled threads running in an incorrect deadline order.

   Note: Despite the API naming, the scheduler makes no guarantees the the thread WILL be
   scheduled within that deadline, nor does it take extra metadata (like e.g. the “runtime” and
   “period” parameters in Linux sched_setattr()) that allows the kernel to validate the scheduling
   for achievability. Such features could be implemented above this call, which is simply input
   to the priority selection logic.

   Note: You should enable CONFIG_SCHED_DEADLINE in your project configuration.

   Parameters
   - thread – A thread on which to set the deadline
   - deadline – A time delta, in cycle units

int k_thread_cpu_mask_clear(k_tid_t thread)
   Sets all CPU enable masks to zero.
After this returns, the thread will no longer be schedulable on any CPUs. The thread must not be currently runnable.

**Note:** You should enable `CONFIG_SCHED_DEADLINE` in your project configuration.

### Parameters
- `thread` – Thread to operate upon

### Returns
Zero on success, otherwise error code

```c
int k_thread_cpu_mask_enable_all(k_tid_t thread);
```
Sets all CPU enable masks to one.

After this returns, the thread will be schedulable on any CPU. The thread must not be currently runnable.

**Note:** You should enable `CONFIG_SCHED_DEADLINE` in your project configuration.

### Parameters
- `thread` – Thread to operate upon

### Returns
Zero on success, otherwise error code

```c
int k_thread_cpu_mask_enable(k_tid_t thread, int cpu);
```
Enable thread to run on specified CPU.

The thread must not be currently runnable.

**Note:** You should enable `CONFIG_SCHED_DEADLINE` in your project configuration.

### Parameters
- `thread` – Thread to operate upon
- `cpu` – CPU index

### Returns
Zero on success, otherwise error code

```c
int k_thread_cpu_mask_disable(k_tid_t thread, int cpu);
```
Prevent thread to run on specified CPU.

The thread must not be currently runnable.

**Note:** You should enable `CONFIG_SCHED_DEADLINE` in your project configuration.

### Parameters
- `thread` – Thread to operate upon
- `cpu` – CPU index

### Returns
Zero on success, otherwise error code

```c
void k_thread_suspend(k_tid_t thread);
```
Suspend a thread.
This routine prevents the kernel scheduler from making `thread` the current thread. All other internal operations on `thread` are still performed; for example, kernel objects it is waiting on are still handed to it. Note that any existing timeouts (e.g. `k_sleep()`, or a timeout argument to `k_sem_take()` et. al.) will be canceled. On resume, the thread will begin running immediately and return from the blocked call.

If `thread` is already suspended, the routine has no effect.

**Parameters**

- `thread` – ID of thread to suspend.

```c
void k_thread_resume(k_tid_t thread)
```

Resume a suspended thread.

This routine allows the kernel scheduler to make `thread` the current thread, when it is next eligible for that role.

If `thread` is not currently suspended, the routine has no effect.

**Parameters**

- `thread` – ID of thread to resume.

```c
void k_sched_time_slice_set(int32_t slice, int prio)
```

Set time-slicing period and scope.

This routine specifies how the scheduler will perform time slicing of preemptible threads.

To enable time slicing, `slice` must be non-zero. The scheduler ensures that no thread runs for more than the specified time limit before other threads of that priority are given a chance to execute. Any thread whose priority is higher than `prio` is exempted, and may execute as long as desired without being preempted due to time slicing.

Time slicing only limits the maximum amount of time a thread may continuously execute. Once the scheduler selects a thread for execution, there is no minimum guaranteed time the thread will execute before threads of greater or equal priority are scheduled.

When the current thread is the only one of that priority eligible for execution, this routine has no effect; the thread is immediately rescheduled after the slice period expires.

To disable timeslicing, set both `slice` and `prio` to zero.

**Parameters**

- `slice` – Maximum time slice length (in milliseconds).
- `prio` – Highest thread priority level eligible for time slicing.

```c
void k_sched_lock(void)
```

Lock the scheduler.

This routine prevents the current thread from being preempted by another thread by instructing the scheduler to treat it as a cooperative thread. If the thread subsequently performs an operation that makes it unready, it will be context switched out in the normal manner. When the thread again becomes the current thread, its non-preemptible status is maintained.

This routine can be called recursively.

**Note:** `k_sched_lock()` and `k_sched_unlock()` should normally be used when the operation being performed can be safely interrupted by ISRs. However, if the amount of processing involved is very small, better performance may be obtained by using `irq_lock()` and `irq_unlock()`.

```c
void k_sched_unlock(void)
```

Unlock the scheduler.

This routine reverses the effect of a previous call to `k_sched_lock()`. A thread must call the routine once for each time it called `k_sched_lock()` before the thread becomes preemptible.
void k_thread_custom_data_set(void *value)
Set current thread's custom data.
This routine sets the custom data for the current thread to @value.
Custom data is not used by the kernel itself, and is freely available for a thread to use as it sees fit. It can be used as a framework upon which to build thread-local storage.

Parameters
• value – New custom data value.

void *k_thread_custom_data_get(void)
Get current thread's custom data.
This routine returns the custom data for the current thread.

Returns Current custom data value.

int k_thread_name_set(k_tid_t thread, const char *str)
Set current thread name.
Set the name of the thread to be used when CONFIG_THREAD_MONITOR is enabled for tracing and debugging.

Parameters
• thread – Thread to set name, or NULL to set the current thread
• str – Name string

Return values
• 0 – on success
• -EFAULT – Memory access error with supplied string
• -ENOSYS – Thread name configuration option not enabled
• -EINVAL – Thread name too long

const char *k_thread_name_get(k_tid_t thread)
Get thread name.

Get the name of a thread.

Parameters
• thread – Thread ID

Return values Thread – name, or NULL if configuration not enabled

int k_thread_name_copy(k_tid_t thread, char *buf, size_t size)
Copy the thread name into a supplied buffer.

Parameters
• thread – Thread to obtain name information
• buf – Destination buffer
• size – Destination buffer size

Return values
• -ENOSPC – Destination buffer too small
• -EFAULT – Memory access error
• -ENOSYS – Thread name feature not enabled
• 0 – Success

7.14. Kernel Services
const char *k_thread_state_str(k_tid_t thread_id)
    Get thread state string.
    Get the human friendly thread state string

    Parameters
    • thread_id – Thread ID

    Return values
    Thread – state string, empty if no state flag is set

struct k_thread
    #include <thread.h> Thread Structure

    Public Members

    struct _callee_saved callee_saved
        defined by the architecture, but all archs need these

    void *init_data
        static thread init data

    _wait_q_t join_queue
        threads waiting in k_thread_join()

    struct __thread_entry entry
        thread entry and parameters description

    struct k_thread *next_thread
        next item in list of all threads

    void *custom_data
        crude thread-local storage

    struct thread_stack_info stack_info
        Stack Info

    struct _mem_domain_info mem_domain_info
        memory domain info of the thread

    k_thread_stack_t *stack_obj
        Base address of thread stack

    void *syscall_frame
        current syscall frame pointer

    int swap_retval
        z_swap() return value

    void *switch_handle
        Context handle returned via arch_switch()

    struct k_heap *resource_pool
        resource pool
struct_thread_arch
arch
arch-specifics: must always be at the end

group thread_stack_api
Thread Stack APIs.

Defines

K_KERNEL_STACK_ARRAY_EXTERN(sym, nmemb, size)
Obtain an extern reference to a stack array.
This macro properly brings the symbol of a stack array declared elsewhere into scope.

Parameters
• sym – Thread stack symbol name
• nmemb – Number of stacks to declare
• size – Size of the stack memory region

K_KERNEL_PINNED_STACK_ARRAY_EXTERN(sym, nmemb, size)
Obtain an extern reference to a pinned stack array.
This macro properly brings the symbol of a pinned stack array declared elsewhere into scope.

Parameters
• sym – Thread stack symbol name
• nmemb – Number of stacks to declare
• size – Size of the stack memory region

K_KERNEL_STACK_DEFINE(sym, size)
Define a toplevel kernel stack memory region.
This declares a region of memory for use as a thread stack, for threads that exclusively run in supervisor mode. This is also suitable for declaring special stacks for interrupt or exception handling.
Stacks declared with this macro may not host user mode threads.
It is legal to precede this definition with the 'static' keyword.
It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of \texttt{k_thread_create()}, it may not be the same as the 'size' parameter. Use \texttt{K_KERNEL_STACK_SIZEOF()} instead.
The total amount of memory allocated may be increased to accommodate fixed-size stack overflow guards.

Parameters
• sym – Thread stack symbol name
• size – Size of the stack memory region

K_KERNEL_PINNED_STACK_DEFINE(sym, size)
Define a toplevel kernel stack memory region in pinned section.
See \texttt{K_KERNEL_STACK_DEFINE()} for more information and constraints.

This puts the stack into the pinned noinit linker section if \texttt{CONFIG_LINKER_USE_PINNED_SECTION} is enabled, or else it would put the stack into the same section as \texttt{K_KERNEL_STACK_DEFINE()}.
• **sym** – Thread stack symbol name
• **size** – Size of the stack memory region

**K_KERNEL_STACK_ARRAY_DEFINE(sym, nmemb, size)**

Define a toplevel array of kernel stack memory regions.

Stacks declared with this macro may not host user mode threads.

**Parameters**

• **sym** – Kernel stack array symbol name
• **nmemb** – Number of stacks to declare
• **size** – Size of the stack memory region

**K_KERNEL_PINNED_STACK_ARRAY_DEFINE(sym, nmemb, size)**

Define a toplevel array of kernel stack memory regions in pinned section.

See **K_KERNEL_STACK_ARRAY_DEFINE()** for more information and constraints.

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as **K_KERNEL_STACK_ARRAY_DEFINE()**.

**Parameters**

• **sym** – Kernel stack array symbol name
• **nmemb** – Number of stacks to declare
• **size** – Size of the stack memory region

**K_KERNEL_STACK_MEMBER(sym, size)**

Declare an embedded stack memory region.

Used for kernel stacks embedded within other data structures.

Stacks declared with this macro may not host user mode threads.

**Parameters**

• **sym** – Thread stack symbol name
• **size** – Size of the stack memory region

**K_KERNEL_STACK_SIZEOF(sym)**

**K_THREAD_STACK_SIZEOF(sym)**

Return the size in bytes of a stack memory region.

Convenience macro for passing the desired stack size to **k_thread_create()** since the underlying implementation may actually create something larger (for instance a guard area).

The value returned here is not guaranteed to match the 'size' parameter passed to **K_THREAD_STACK_DEFINE** and may be larger, but is always safe to pass to **k_thread_create()** for the associated stack object.

**Parameters**

• **sym** – Stack memory symbol

**Returns** Size of the stack buffer

**K_THREAD_STACK_DEFINE(sym, size)**

Declare a toplevel thread stack memory region.

This declares a region of memory suitable for use as a thread's stack.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in ‘noinit’ section so that it isn’t zeroed at boot
The declared symbol will always be a k_thread_stack_t which can be passed to
k_thread_create(), but should otherwise not be manipulated. If the buffer inside needs to be
examined, examine thread->stack_info for the associated thread object to obtain the bound-
daries.

It is legal to precede this definition with the ‘static’ keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize para-
meter of k_thread_create(), it may not be the same as the ‘size’ parameter. Use
K_THREAD_STACK_SIZEOF() instead.

Some arches may round the size of the usable stack region up to satisfy alignment constraints.
K_THREAD_STACK_SIZEOF() will return the aligned size.

Parameters

• sym – Thread stack symbol name
• size – Size of the stack memory region

K_THREAD_PINNED_STACK_DEFINE(sym, size)
Define a toplevel thread stack memory region in pinned section.

This declares a region of memory suitable for use as a thread’s stack.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in
‘noinit’ section so that it isn’t zeroed at boot

The declared symbol will always be a k_thread_stack_t which can be passed to
k_thread_create(), but should otherwise not be manipulated. If the buffer inside needs to be
examined, examine thread->stack_info for the associated thread object to obtain the bound-
daries.

It is legal to precede this definition with the ‘static’ keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize para-
meter of k_thread_create(), it may not be the same as the ‘size’ parameter. Use
K_THREAD_STACK_SIZEOF() instead.

Some arches may round the size of the usable stack region up to satisfy alignment constraints.
K_THREAD_STACK_SIZEOF() will return the aligned size.

This puts the stack into the pinned noinit linker section if CON-
FIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the
same section as K_THREAD_STACK_DEFINE().

Parameters

• sym – Thread stack symbol name
• size – Size of the stack memory region

K_THREAD_STACK_LEN(size)
Calculate size of stacks to be allocated in a stack array.

This macro calculates the size to be allocated for the stacks inside a stack array. It accepts
the indicated “size” as a parameter and if required, pads some extra bytes (e.g. for MPU
scenarios). Refer K_THREAD_STACK_ARRAY_DEFINE definition to see how this is used. The
returned size ensures each array member will be aligned to the required stack base alignment.

Parameters

• size – Size of the stack memory region

Returns Appropriate size for an array member

K_THREAD_STACK_ARRAY_DEFINE(sym, nmemb, size)
Declare a toplevel array of thread stack memory regions.

7.14. Kernel Services
663
Create an array of equally sized stacks. See K_THREAD_STACK_DEFINE definition for additional details and constraints.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in 'noinit' section so that it isn't zeroed at boot

**Parameters**

- **sym** – Thread stack symbol name
- **nmemb** – Number of stacks to declare
- **size** – Size of the stack memory region

```c
K_THREAD_PINNED_STACK_ARRAY_DEFINE(sym, nmemb, size)
```

Declare a toplevel array of thread stack memory regions in pinned section.

Create an array of equally sized stacks. See K_THREAD_STACK_DEFINE definition for additional details and constraints.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in 'noinit' section so that it isn't zeroed at boot

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as K_THREAD_STACK_DEFINE().

**Parameters**

- **sym** – Thread stack symbol name
- **nmemb** – Number of stacks to declare
- **size** – Size of the stack memory region

```c
K_THREAD_STACK_MEMBER(sym, size)
```

Declare an embedded stack memory region.

Used for stacks embedded within other data structures. Use is highly discouraged but in some cases necessary. For memory protection scenarios, it is very important that any RAM preceding this member not be writable by threads else a stack overflow will lead to silent corruption. In other words, the containing data structure should live in RAM owned by the kernel.

A user thread can only be started with a stack defined in this way if the thread starting it is in supervisor mode.

This is now deprecated, as stacks defined in this way are not usable from user mode. Use K_KERNEL_STACK_MEMBER.

**Parameters**

- **sym** – Thread stack symbol name
- **size** – Size of the stack memory region

Scheduling

The kernel’s priority-based scheduler allows an application’s threads to share the CPU.

**Concepts**

The scheduler determines which thread is allowed to execute at any point in time; this thread is known as the **current thread**.

There are various points in time when the scheduler is given an opportunity to change the identity of the current thread. These points are called **reschedule points**. Some potential reschedule points are:

- transition of a thread from running state to a suspended or waiting state, for example by `k_sem_take()` or `k_sleep()`.
• transition of a thread to the *ready state*, for example by `k_sem_give()` or `k_thread_start()`

• return to thread context after processing an interrupt

• when a running thread invokes `k_yield()`

A thread **sleeps** when it voluntarily initiates an operation that transitions itself to a suspended or waiting state.

Whenever the scheduler changes the identity of the current thread, or when execution of the current thread is replaced by an ISR, the kernel first saves the current thread’s CPU register values. These register values get restored when the thread later resumes execution.

**Scheduling Algorithm**

The kernel’s scheduler selects the highest priority ready thread to be the current thread. When multiple ready threads of the same priority exist, the scheduler chooses the one that has been waiting longest.

A thread’s relative priority is primarily determined by its static priority. However, when both earliest-deadline-first scheduling is enabled (`CONFIG_SCHED_DEADLINE`) and a choice of threads have equal static priority, then the thread with the earlier deadline is considered to have the higher priority. Thus, when earliest-deadline-first scheduling is enabled, two threads are only considered to have the same priority when both their static priorities and deadlines are equal. The routine `k_thread_deadline_set()` is used to set a thread’s deadline.

**Note:** Execution of ISRs takes precedence over thread execution, so the execution of the current thread may be replaced by an ISR at any time unless interrupts have been masked. This applies to both cooperative threads and preemptive threads.

The kernel can be built with one of several choices for the ready queue implementation, offering different choices between code size, constant factor runtime overhead and performance scaling when many threads are added.

• Simple linked-list ready queue (`CONFIG_SCHED_DUMB`)

  The scheduler ready queue will be implemented as a simple unordered list, with very fast constant time performance for single threads and very low code size. This implementation should be selected on systems with constrained code size that will never see more than a small number (3, maybe) of runnable threads in the queue at any given time. On most platforms (that are not otherwise using the red/black tree) this results in a savings of ~2k of code size.

• Red/black tree ready queue (`CONFIG_SCHED_SCALABLE`)

  The scheduler ready queue will be implemented as a red/black tree. This has rather slower constant-time insertion and removal overhead, and on most platforms (that are not otherwise using the red/black tree somewhere) requires an extra ~2kb of code. The resulting behavior will scale cleanly and quickly into the many thousands of threads.

  Use this for applications needing many concurrent runnable threads (> 20 or so). Most applications won’t need this ready queue implementation.

• Traditional multi-queue ready queue (`CONFIG_SCHED_MULTIQ`)

  When selected, the scheduler ready queue will be implemented as the classic/textbook array of lists, one per priority (max 32 priorities).

  This corresponds to the scheduler algorithm used in Zephyr versions prior to 1.12.

  It incurs only a tiny code size overhead vs. the “dumb” scheduler and runs in O(1) time in almost all circumstances with very low constant factor. But it requires a fairly large RAM budget to store those list heads, and the limited features make it incompatible with features like deadline scheduling that need to sort threads more finely, and SMP affinity which need to traverse the list of threads.

  Typical applications with small numbers of runnable threads probably want the DUMB scheduler.
The wait_q abstraction used in IPC primitives to pend threads for later wakeup shares the same backend
data structure choices as the scheduler, and can use the same options.

- **Scalable wait_q implementation (CONFIG_WAITQ_SCALABLE)**
  
  When selected, the wait_q will be implemented with a balanced tree. Choose this if you expect
to have many threads waiting on individual primitives. There is a ~2kb code size increase over
CONFIG_WAITQ_DUMB (which may be shared with CONFIG_SCHED_SCALABLE) if the red/black tree
is not used elsewhere in the application, and pend/unpend operations on “small” queues will be
somewhat slower (though this is not generally a performance path).

- **Simple linked-list wait_q (CONFIG_WAITQ_DUMB)**
  
  When selected, the wait_q will be implemented with a doubly-linked list. Choose this if you expect
to have only a few threads blocked on any single IPC primitive.

**Cooperative Time Slicing** Once a cooperative thread becomes the current thread, it remains the cur-
rent thread until it performs an action that makes it unready. Consequently, if a cooperative thread
performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads,
including those of higher priority and equal priority.

![Cooperative Time Slicing Diagram]

To overcome such problems, a cooperative thread can voluntarily relinquish the CPU from time to time
to permit other threads to execute. A thread can relinquish the CPU in two ways:

- **Calling k_yield()** puts the thread at the back of the scheduler’s prioritized list of ready threads,
  and then invokes the scheduler. All ready threads whose priority is higher or equal to that of the
  yielding thread are then allowed to execute before the yielding thread is rescheduled. If no such
  ready threads exist, the scheduler immediately reschedules the yielding thread without context
  switching.

- **Calling k_sleep()** makes the thread unready for a specified time period. Ready threads of all
  priorities are then allowed to execute; however, there is no guarantee that threads whose priority
  is lower than that of the sleeping thread will actually be scheduled before the sleeping thread
  becomes ready once again.

**Preemptive Time Slicing** Once a preemptive thread becomes the current thread, it remains the cur-
rent thread until a higher priority thread becomes ready, or until the thread performs an action that
makes it unready. Consequently, if a preemptive thread performs lengthy computations, it may cause an
unacceptable delay in the scheduling of other threads, including those of equal priority.
To overcome such problems, a preemptive thread can perform cooperative time slicing (as described above), or the scheduler's time slicing capability can be used to allow other threads of the same priority to execute.

The scheduler divides time into a series of time slices, where slices are measured in system clock ticks. The time slice size is configurable, but this size can be changed while the application is running.

At the end of every time slice, the scheduler checks to see if the current thread is preemptible and, if so, implicitly invokes `k_yield()` on behalf of the thread. This gives other ready threads of the same priority the opportunity to execute before the current thread is scheduled again. If no threads of equal priority are ready, the current thread remains the current thread.

Threads with a priority higher than specified limit are exempt from preemptive time slicing, and are never preempted by a thread of equal priority. This allows an application to use preemptive time slicing only when dealing with lower priority threads that are less time-sensitive.

**Note:** The kernel's time slicing algorithm does *not* ensure that a set of equal-priority threads receive an
equitable amount of CPU time, since it does not measure the amount of time a thread actually gets to execute. However, the algorithm does ensure that a thread never executes for longer than a single time slice without being required to yield.

**Scheduler Locking**  A preemptible thread that does not wish to be preempted while performing a critical operation can instruct the scheduler to temporarily treat it as a cooperative thread by calling \texttt{k_sched_lock()}. This prevents other threads from interfering while the critical operation is being performed.

Once the critical operation is complete the preemptible thread must call \texttt{k_sched_unlock()} to restore its normal, preemptible status.

If a thread calls \texttt{k_sched_lock()} and subsequently performs an action that makes it unready, the scheduler will switch the locking thread out and allow other threads to execute. When the locking thread again becomes the current thread, its non-preemptible status is maintained.

**Note:** Locking out the scheduler is a more efficient way for a preemptible thread to prevent preemption than changing its priority level to a negative value.

**Thread Sleeping**  A thread can call \texttt{k_sleep()} to delay its processing for a specified time period. During the time the thread is sleeping the CPU is relinquished to allow other ready threads to execute. Once the specified delay has elapsed the thread becomes ready and is eligible to be scheduled once again.

A sleeping thread can be woken up prematurely by another thread using \texttt{k_wakeup()}. This technique can sometimes be used to permit the secondary thread to signal the sleeping thread that something has occurred \textit{without} requiring the threads to define a kernel synchronization object, such as a semaphore. Waking up a thread that is not sleeping is allowed, but has no effect.

**Busy Waiting**  A thread can call \texttt{k_busy_wait()} to perform a \textit{busy wait} that delays its processing for a specified time period \textit{without} relinquishing the CPU to another ready thread.

A busy wait is typically used instead of thread sleeping when the required delay is too short to warrant having the scheduler context switch from the current thread to another thread and then back again.

**Suggested Uses**  Use cooperative threads for device drivers and other performance-critical work.

Use cooperative threads to implement mutually exclusion without the need for a kernel object, such as a mutex.

Use preemptive threads to give priority to time-sensitive processing over less time-sensitive processing.

**System Threads**

- **Implementation**
  - Writing a \texttt{main()} function
- **Suggested Uses**

A \textit{system thread} is a thread that the kernel spawns automatically during system initialization.

The kernel spawns the following system threads:
Main thread  This thread performs kernel initialization, then calls the application's main() function (if one is defined).

By default, the main thread uses the highest configured preemptible thread priority (i.e. 0). If the kernel is not configured to support preemptible threads, the main thread uses the lowest configured cooperative thread priority (i.e. -1).

The main thread is an essential thread while it is performing kernel initialization or executing the application's main() function; this means a fatal system error is raised if the thread aborts. If main() is not defined, or if it executes and then does a normal return, the main thread terminates normally and no error is raised.

Idle thread  This thread executes when there is no other work for the system to do. If possible, the idle thread activates the board's power management support to save power; otherwise, the idle thread simply performs a "do nothing" loop. The idle thread remains in existence as long as the system is running and never terminates.

The idle thread always uses the lowest configured thread priority. If this makes it a cooperative thread, the idle thread repeatedly yields the CPU to allow the application's other threads to run when they need to.

The idle thread is an essential thread, which means a fatal system error is raised if the thread aborts.

Additional system threads may also be spawned, depending on the kernel and board configuration options specified by the application. For example, enabling the system workqueue spawns a system thread that services the work items submitted to it. (See Workqueue Threads.)

Implementation

Writing a main() function  An application-supplied main() function begins executing once kernel initialization is complete. The kernel does not pass any arguments to the function.

The following code outlines a trivial main() function. The function used by a real application can be as complex as needed.

```c
void main(void)
{
    /* initialize a semaphore */
    ...

    /* register an ISR that gives the semaphore */
    ...

    /* monitor the semaphore forever */
    while (1) {
        /* wait for the semaphore to be given by the ISR */
        ...
        /* do whatever processing is now needed */
        ...
    }
}
```

Suggested Uses  Use the main thread to perform thread-based processing in an application that only requires a single thread, rather than defining an additional application-specific thread.
Workqueue Threads

A workqueue is a kernel object that uses a dedicated thread to process work items in a first in, first out manner. Each work item is processed by calling the function specified by the work item. A workqueue is typically used by an ISR or a high-priority thread to offload non-urgent processing to a lower-priority thread so it does not impact time-sensitive processing.

Any number of workqueues can be defined (limited only by available RAM). Each workqueue is referenced by its memory address.

A workqueue has the following key properties:

- A queue of work items that have been added, but not yet processed.
- A thread that processes the work items in the queue. The priority of the thread is configurable, allowing it to be either cooperative or preemptive as required.

Regardless of workqueue thread priority the workqueue thread will yield between each submitted work item, to prevent a cooperative workqueue from starving other threads.

A workqueue must be initialized before it can be used. This sets its queue to empty and spawns the workqueue's thread. The thread runs forever, but sleeps when no work items are available.

**Note:** The behavior described here is changed from the Zephyr workqueue implementation used prior to release 2.6. Among the changes are:

- Precise tracking of the status of cancelled work items, so that the caller need not be concerned that an item may be processing when the cancellation returns. Checking of return values on cancellation is still required.
- Direct submission of delayable work items to the queue with `K_NO_WAIT` rather than always going through the timeout API, which could introduce delays.
- The ability to wait until a work item has completed or a queue has been drained.
- Finer control of behavior when scheduling a delayable work item, specifically allowing a previous deadline to remain unchanged when a work item is scheduled again.
- Safe handling of work item resubmission when the item is being processed on another workqueue.

Using the return values of `k_work_busy_get()` or `k_work_is_pending()`, or measurements of remaining time until delayable work is scheduled, should be avoided to prevent race conditions of the type observed with the previous implementation. See also Workqueue Best Practices.

**Work Item Lifecycle**

Any number of work items can be defined. Each work item is referenced by its memory address.
A work item is assigned a handler function, which is the function executed by the workqueue's thread when the work item is processed. This function accepts a single argument, which is the address of the work item itself. The work item also maintains information about its status.

A work item must be initialized before it can be used. This records the work item's handler function and marks it as not pending.

A work item may be queued (K_WORK_QUEUE) by submitting it to a workqueue by an ISR or a thread. Submitting a work item appends the work item to the workqueue's queue. Once the workqueue's thread has processed all of the preceding work items in its queue the thread will remove the next work item from the queue and invoke the work item's handler function. Depending on the scheduling priority of the workqueue's thread, and the work required by other items in the queue, a queued work item may be processed quickly or it may remain in the queue for an extended period of time.

A delayable work item may be scheduled (K_WORK_DELAYED) to a workqueue; see Delayable Work.

A work item will be running (K_WORK_RUNNING) when it is running on a work queue, and may also be canceling (K_WORK_CANCELING) if it started running before a thread has requested that it be cancelled.

A work item can be in multiple states; for example it can be:

- running on a queue;
- marked canceling (because a thread used k_work_cancel_sync() to wait until the work item completed);
- queued to run again on the same queue;
- scheduled to be submitted to a (possibly different) queue

all simultaneously. A work item that is in any of these states is pending (k_work_is_pending()) or busy (k_work_busy_get()).

A handler function can use any kernel API available to threads. However, operations that are potentially blocking (e.g. taking a semaphore) must be used with care, since the workqueue cannot process subsequent work items in its queue until the handler function finishes executing.

The single argument that is passed to a handler function can be ignored if it is not required. If the handler function requires additional information about the work it is to perform, the work item can be embedded in a larger data structure. The handler function can then use the argument value to compute the address of the enclosing data structure with CONTAINER_OF, and thereby obtain access to the additional information it needs.

A work item is typically initialized once and then submitted to a specific workqueue whenever work needs to be performed. If an ISR or a thread attempts to submit a work item that is already queued the work item is not affected; the work item remains in its current place in the workqueue's queue, and the work is only performed once.

A handler function is permitted to re-submit its work item argument to the workqueue, since the work item is no longer queued at that time. This allows the handler to execute work in stages, without unduly delaying the processing of other work items in the workqueue's queue.

Important: A pending work item must not be altered until the item has been processed by the workqueue thread. This means a work item must not be re-initialized while it is busy. Furthermore, any additional information the work item's handler function needs to perform its work must not be altered until the handler function has finished executing.

Delayable Work An ISR or a thread may need to schedule a work item that is to be processed only after a specified period of time, rather than immediately. This can be done by scheduling a delayable work item to be submitted to a workqueue at a future time.

A delayable work item contains a standard work item but adds fields that record when and where the item should be submitted.
A delayable work item is initialized and scheduled to a workqueue in a similar manner to a standard work item, although different kernel APIs are used. When the schedule request is made the kernel initiates a timeout mechanism that is triggered after the specified delay has elapsed. Once the timeout occurs the kernel submits the work item to the specified workqueue, where it remains queued until it is processed in the standard manner.

Note that work handler used for delayable still receives a pointer to the underlying non-delayable work structure, which is not publicly accessible from `k_work_delayable`. To get access to an object that contains the delayable work object use this idiom:

```c
static void work_handler(struct k_work *work)
{
    struct k_work_delayable *dwork = k_work_delayable_from_work(work);
    struct work_context *ctx = CONTAINER_OF(dwork, struct work_context, timed_work);
    ...
}
```

### Triggered Work

The `k_work_poll_submit()` interface schedules a triggered work item in response to a **poll event** (see Polling API), that will call a user-defined function when a monitored resource becomes available or poll signal is raised, or a timeout occurs. In contrast to `k_poll()`, the triggered work does not require a dedicated thread waiting or actively polling for a poll event.

A triggered work item is a standard work item that has the following added properties:

- A pointer to an array of poll events that will trigger work item submissions to the workqueue
- A size of the array containing poll events.

A triggered work item is initialized and submitted to a workqueue in a similar manner to a standard work item, although dedicated kernel APIs are used. When a submit request is made, the kernel begins observing kernel objects specified by the poll events. Once at least one of the observed kernel object’s changes state, the work item is submitted to the specified workqueue, where it remains queued until it is processed in the standard manner.

---

**Important:** The triggered work item as well as the referenced array of poll events have to be valid and cannot be modified for a complete triggered work item lifecycle, from submission to work item execution or cancellation.

An ISR or a thread may **cancel** a triggered work item it has submitted as long as it is still waiting for a poll event. In such case, the kernel stops waiting for attached poll events and the specified work is not executed. Otherwise the cancellation cannot be performed.

### System Workqueue

The kernel defines a workqueue known as the **system workqueue**, which is available to any application or kernel code that requires workqueue support. The system workqueue is optional, and only exists if the application makes use of it.

---

**Important:** Additional workqueues should only be defined when it is not possible to submit new work items to the system workqueue, since each new workqueue incurs a significant cost in memory footprint. A new workqueue can be justified if it is not possible for its work items to co-exist with existing system workqueue work items without an unacceptable impact; for example, if the new work items perform blocking operations that would delay other system workqueue processing to an unacceptable degree.

### How to Use Workqueues
**Defining and Controlling a Workqueue**  A workqueue is defined using a variable of type `k_work_q`. The workqueue is initialized by defining the stack area used by its thread, initializing the `k_work_q`, either zeroing its memory or calling `k_work_queue_init()`, and then calling `k_work_queue_start()`. The stack area must be defined using `K_THREAD_STACK_DEFINE` to ensure it is properly set up in memory.

The following code defines and initializes a workqueue:

```c
#define MY_STACK_SIZE 512
#define MY_PRIORITY 5

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);

struct k_work_q my_work_q;

k_work_queue_init(&my_work_q);

k_work_queue_start(&my_work_q, my_stack_area,
                   K_THREAD_STACK_SIZEOF(my_stack_area), MY_PRIORITY,
                   NULL);
```

In addition the queue identity and certain behavior related to thread rescheduling can be controlled by the optional final parameter; see `k_work_queue_start()` for details.

The following API can be used to interact with a workqueue:

- `k_work_queue_drain()` can be used to block the caller until the work queue has no items left. Work items resubmitted from the workqueue thread are accepted while a queue is draining, but work items from any other thread or ISR are rejected. The restriction on submitting more work can be extended past the completion of the drain operation in order to allow the blocking thread to perform additional work while the queue is “plugged”. Note that draining a queue has no effect on scheduling or processing delayable items, but if the queue is plugged and the deadline expires the item will silently fail to be submitted.

- `k_work_queue_unplug()` removes any previous block on submission to the queue due to a previous drain operation.

**Submitting a Work Item**  A work item is defined using a variable of type `k_work`. It must be initialized by calling `k_work_init()`, unless it is defined using `K_WORK_DEFINE` in which case initialization is performed at compile-time.

An initialized work item can be submitted to the system workqueue by calling `k_work_submit()`, or to a specified workqueue by calling `k_work_submit_to_queue()`.

The following code demonstrates how an ISR can offload the printing of error messages to the system workqueue. Note that if the ISR attempts to resubmit the work item while it is still queued, the work item is left unchanged and the associated error message will not be printed.

```c
struct device_info {
    struct k_work work;
    char name[16]
} my_device;

void my_isr(void *arg)
{
    ...
    if (error detected) {
        k_work_submit(&my_device.work);
    }
    ...
}
```

(continues on next page)
void print_error(struct k_work *item)
{
    struct device_info *the_device = CONTAINER_OF(item, struct device_info, work);
    printk("Got error on device %s\n", the_device->name);
}

/* initialize name info for a device */
strcpy(my_device.name, "FOO_dev");

/* initialize work item for printing device's error messages */
k_work_init(&my_device.work, print_error);

/* install my_isr() as interrupt handler for the device (not shown) */
...

The following API can be used to check the status of or synchronize with the work item:

- k_work_busy_get() returns a snapshot of flags indicating work item state. A zero value indicates
  the work is not scheduled, submitted, being executed, or otherwise still being referenced by the
  workqueue infrastructure.

- k_work_is_pending() is a helper that indicates true if and only if the work is scheduled, queued,
  or running.

- k_work_flush() may be invoked from threads to block until the work item has completed. It
  returns immediately if the work is not pending.

- k_work_cancel() attempts to prevent the work item from being executed. This may or may not
  be successful. This is safe to invoke from ISRs.

- k_work_cancel_sync() may be invoked from threads to block until the work completes; it will
  return immediately if the cancellation was successful or not necessary (the work wasn't submitted
  or running). This can be used after k_work_cancel() is invoked (from an ISR) to confirm
  completion of an ISR-initiated cancellation.

Scheduling a Delayable Work Item A delayable work item is defined using a variable of type
k_work_delayable. It must be initialized by calling k_work_init_delayable().

For delayed work there are two common use cases, depending on whether a deadline should be extended
if a new event occurs. An example is collecting data that comes in asynchronously, e.g. characters from
a UART associated with a keyboard. There are two APIs that submit work after a delay:

- k_work_schedule() (or k_work_schedule_for_queue()) schedules work to be executed at a specific
  time or after a delay. Further attempts to schedule the same item with this API before the delay
  completes will not change the time at which the item will be submitted to its queue. Use this if
  the policy is to keep collecting data until a specified delay since the first unprocessed data was
  received;

- k_work_reschedule() (or k_work_reschedule_for_queue()) unconditionally sets the deadline
  for the work, replacing any previous incomplete delay and changing the destination queue if necessary. Use this if the policy is to keep collecting data until a specified delay since the last unprocessed
  data was received.

If the work item is not scheduled both APIs behave the same. If K_NO_WAIT is specified as the delay the
behavior is as if the item was immediately submitted directly to the target queue, without waiting for a
minimal timeout (unless k_work_schedule() is used and a previous delay has not completed).

Both also have variants that allow control of the queue used for submission.
The helper function `k_work_delayable_from_work()` can be used to get a pointer to the containing `k_work_delayable` from a pointer to `k_work` that is passed to a work handler function.

The following additional API can be used to check the status of or synchronize with the work item:

- `k_work_delayable_busy_get()` is the analog to `k_work_busy_get()` for delayable work.
- `k_work_delayable_is_pending()` is the analog to `k_work_is_pending()` for delayable work.
- `k_work_flush_delayable()` is the analog to `k_work_flush()` for delayable work.
- `k_work_cancel_delayable()` is the analog to `k_work_cancel()` for delayable work; similarly with `k_work_cancel_delayable_sync()`.

**Synchronizing with Work Items**  While the state of both regular and delayable work items can be determined from any context using `k_work_busy_get()` and `k_work_delayable_busy_get()` some use cases require synchronizing with work items after they've been submitted. `k_work_flush()`, `k_work_cancel_sync()`, and `k_work_cancel_delayable_sync()` can be invoked from thread context to wait until the requested state has been reached.

These APIs must be provided with a `k_work_sync` object that has no application-inspectable components but is needed to provide the synchronisation objects. These objects should not be allocated on a stack if the code is expected to work on architectures with `CONFIG_KERNEL_COHERENCE`.

**Workqueue Best Practices**

**Avoid Race Conditions**  Sometimes the data a work item must process is naturally thread-safe, for example when it's put into a `k_queue` by some thread and processed in the work thread. More often external synchronization is required to avoid data races: cases where the work thread might inspect or manipulate shared state that's being accessed by another thread or interrupt. Such state might be a flag indicating that work needs to be done, or a shared object that is filled by an ISR or thread and read by the work handler.

For simple flags **Atomic Services** may be sufficient. In other cases spin locks (`k_spinlock_t`) or thread-aware locks (`k_sem`, `k_mutex`, ...) may be used to ensure data races don't occur.

If the selected lock mechanism can `sleep` then allowing the work thread to sleep will starve other work queue items, which may need to make progress in order to get the lock released. Work handlers should try to take the lock with its no-wait path. For example:

```c
static void work_handler(struct work *work)
{
    struct work_context *parent = CONTAINER_OF(work, struct work_context, work_item);

    if (k_mutex_lock(&parent->lock, K_NO_WAIT) != 0) {
        /* NB: Submit will fail if the work item is being cancelled. */
        (void)k_work_submit(work);
        return;
    }

    /* do stuff under lock */
    k_mutex_unlock(&parent->lock);
    /* do stuff without lock */
}
```

Be aware that if the lock is held by a thread with a lower priority than the work queue the resubmission may starve the thread that would release the lock, causing the application to fail. Where the idiom above is required a delayable work item is preferred, and the work should be (re-)scheduled with a non-zero delay to allow the thread holding the lock to make progress.
Note that submitting from the work handler can fail if the work item had been cancelled. Generally this is acceptable, since the cancellation will complete once the handler finishes. If it is not, the code above must take other steps to notify the application that the work could not be performed.

Work items in isolation are self-locking, so you don’t need to hold an external lock just to submit or schedule them. Even if you use external state protected by such a lock to prevent further resubmission, it’s safe to do the resubmit as long as you’re sure that eventually the item will take its lock and check that state to determine whether it should do anything. Where a delayable work item is being rescheduled in its handler due to inability to take the lock some other self-locking state, such as an atomic flag set by the application/driver when the cancel is initiated, would be required to detect the cancellation and avoid the cancelled work item being submitted again after the deadline.

**Check Return Values** All work API functions return status of the underlying operation, and in many cases it is important to verify that the intended result was obtained.

- Submitting a work item (**k_work_submit_to_queue()**) can fail if the work is being cancelled or the queue is not accepting new items. If this happens the work will not be executed, which could cause a subsystem that is animated by work handler activity to become non-responsive.
- Asynchronous cancellation (**k_work_cancel()** or **k_work_cancel_delayable()**) can complete while the work item is still being run by a handler. Proceeding to manipulate state shared with the work handler will result in data races that can cause failures.

Many race conditions have been present in Zephyr code because the results of an operation were not checked.

There may be good reason to believe that a return value indicating that the operation did not complete as expected is not a problem. In those cases the code should clearly document this, by (1) casting the return value to **void** to indicate that the result is intentionally ignored, and (2) documenting what happens in the unexpected case. For example:

```c
/* If this fails, the work handler will check pub->active and
 * exit without transmitting.
 */
(void) k_work_cancel_delayable(&pub->timer);
```

However in such a case the following code must still avoid data races, as it cannot guarantee that the work thread is not accessing work-related state.

**Don’t Optimize Prematurely** The workqueue API is designed to be safe when invoked from multiple threads and interrupts. Attempts to externally inspect a work item's state and make decisions based on the result are likely to create new problems.

So when new work comes in, just submit it. Don’t attempt to “optimize” by checking whether the work item is already submitted by inspecting snapshot state with **k_work_is_pending()** or **k_work_busy_get()**, or checking for a non-zero delay from **k_work_delayable_remaining_get()**.

Those checks are fragile: a “busy” indication can be obsolete by the time the test is returned, and a “not-busy” indication can also be wrong if work is submitted from multiple contexts, or (for delayable work) if the deadline has completed but the work is still in queued or running state.

A general best practice is to always maintain in shared state some condition that can be checked by the handler to confirm whether there is work to be done. This way you can use the work handler as the standard cleanup path: rather than having to deal with cancellation and cleanup at points where items are submitted, you may be able to have everything done in the work handler itself.

A rare case where you could safely use **k_work_is_pending()** is as a check to avoid invoking **k_work_flush()** or **k_work_cancel_sync()**, if you are certain that nothing else might submit the work while you’re checking (generally because you’re holding a lock that prevents access to state used for submission).
Suggested Uses  Use the system workqueue to defer complex interrupt-related processing from an ISR to a shared thread. This allows the interrupt-related processing to be done promptly without compromising the system's ability to respond to subsequent interrupts, and does not require the application to define and manage an additional thread to do the processing.

Configuration Options  Related configuration options:

- `CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE`
- `CONFIG_SYSTEM_WORKQUEUE_PRIORITY`
- `CONFIG_SYSTEM_WORKQUEUE_NO_YIELD`

API Reference

group workqueue_apis

Defines

`K_WORK_DELAYABLE_DEFINE(work, work_handler)`
Initialize a statically-defined delayable work item.
This macro can be used to initialize a statically-defined delayable work item, prior to its first use. For example,

```c
static K_WORK_DELAYABLE_DEFINE(<dwork>, <work_handler>);
```

Note that if the runtime dependencies support initialization with `k_work_init_delayable()` using that will eliminate the initialized object in ROM that is produced by this macro and copied in at system startup.

Parameters

- `work` – Symbol name for delayable work item object
- `work_handler` – Function to invoke each time work item is processed.

`K_WORK_USER_DEFINE(work, work_handler)`
Initialize a statically-defined user work item.
This macro can be used to initialize a statically-defined user work item, prior to its first use. For example,

```c
static K_WORK_USER_DEFINE(<work>, <work_handler>);
```

Parameters

- `work` – Symbol name for work item object
- `work_handler` – Function to invoke each time work item is processed.

`K_WORK_DEFINE(work, work_handler)`
Initialize a statically-defined work item.
This macro can be used to initialize a statically-defined workqueue work item, prior to its first use. For example,
static K_WORK_DEFINE(<work>, <work_handler>);

Parameters

- **work** – Symbol name for work item object
- **work_handler** – Function to invoke each time work item is processed.

K_DELAYED_WORK_DEFINE(work, work_handler)
Initialize a statically-defined delayed work item.
This macro can be used to initialize a statically-defined workqueue delayed work item, prior to its first use. For example,

static K_DELAYED_WORK_DEFINE(<work>, <work_handler>);

Parameters

- **work** – Symbol name for delayed work item object
- **work_handler** – Function to invoke each time work item is processed.

Typedefs

typedef void (*k_work_handler_t)(struct k_work *work)
The signature for a work item handler function.
The function will be invoked by the thread animating a work queue.

**Param work** the work item that provided the handler.

typedef void (*k_work_user_handler_t)(struct k_work_user *work)
Work item handler function type for user work queues.
A work item’s handler function is executed by a user workqueue's thread when the work item is processed by the workqueue.

**Param work** Address of the work item.

Enums

def [anonymous]
Values:

enumerator K_WORK_RUNNING = BIT(K_WORK_RUNNING_BIT)
Flag indicating a work item that is running under a work queue thread.
Accessed via k_work_busy_get(). May co-occur with other flags.

enumerator K_WORK_CANCELING = BIT(K_WORK_CANCELING_BIT)
Flag indicating a work item that is being canceled.

Accessed via k_work_busy_get(). May co-occur with other flags.
enumerator \( \text{K\_WORK\_QUEUED} = \text{BIT}(\text{K\_WORK\_QUEUED\_BIT}) \)
Flag indicating a work item that has been submitted to a queue but has not started running.
Accessed via \( \text{k\_work\_busy\_get}() \). May co-occur with other flags.

enumerator \( \text{K\_WORK\_DELAYED} = \text{BIT}(\text{K\_WORK\_DELAYED\_BIT}) \)
Flag indicating a delayed work item that is scheduled for submission to a queue.
Accessed via \( \text{k\_work\_busy\_get}() \). May co-occur with other flags.

### Functions

**void k\_work\_init\(\text{struct k\_work *work, k\_work\_handler\_t handler}\)**
Initialize a (non-delayable) work structure.
This must be invoked before submitting a work structure for the first time. It need not be invoked again on the same work structure. It can be re-invoked to change the associated handler, but this must be done when the work item is idle.

**Function properties (list may not be complete) isr-ok**

**Parameters**
- \( \text{work} \) – the work structure to be initialized.
- \( \text{handler} \) – the handler to be invoked by the work item.

**int k\_work\_busy\_get\(\text{const struct k\_work *work}\)**
Busy state flags from the work item.
A zero return value indicates the work item appears to be idle.

**Function properties (list may not be complete) isr-ok**

**Note:** This is a live snapshot of state, which may change before the result is checked. Use locks where appropriate.

**Parameters**
- \( \text{work} \) – pointer to the work item.

**Returns** a mask of flags \( \text{K\_WORK\_DELAYED}, \text{K\_WORK\_QUEUED}, \text{K\_WORK\_RUNNING}, \text{K\_WORK\_CANCELING} \).

**static inline bool k\_work\_is\_pending\(\text{const struct k\_work *work}\)**
Test whether a work item is currently pending.
Wrapper to determine whether a work item is in a non-idle dstate.

**Function properties (list may not be complete) isr-ok**

**Note:** This is a live snapshot of state, which may change before the result is checked. Use locks where appropriate.
Parameters

• work – pointer to the work item.

Returns true if and only if \texttt{k\_work\_busy\_get()} returns a non-zero value.

int \texttt{k\_work\_submit\_to\_queue(\ struct k\_work\_q *queue, \ struct k\_work *work)}
Submit a work item to a queue.

Function properties (list may not be complete) \textit{isr-ok}

Parameters

• queue – pointer to the work queue on which the item should run. If NULL the queue from the most recent submission will be used.
• work – pointer to the work item.

Return values

• 0 – if work was already submitted to a queue
• 1 – if work was not submitted and has been queued to \texttt{queue}
• 2 – if work was running and has been queued to the queue that was running it
• -EBUSY –
  – if work submission was rejected because the work item is cancelling; or
  – \texttt{queue} is draining; or
  – \texttt{queue} is plugged.
• -EINVAL – if \texttt{queue} is null and the work item has never been run.
• -ENODEV – if \texttt{queue} has not been started.

int \texttt{k\_work\_submit(\ struct k\_work *work)}
Submit a work item to the system queue.

Function properties (list may not be complete) \textit{isr-ok}

Parameters

• work – pointer to the work item.

Returns as with \texttt{k\_work\_submit\_to\_queue()}.

bool \texttt{k\_work\_flush(\ struct k\_work *work, \ struct k\_work\_sync *sync)}
Wait for last-submitted instance to complete.

Resubmissions may occur while waiting, including chained submissions (from within the handler).

Note: Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

Note: Behavior is undefined if this function is invoked on \texttt{work} from a work queue running \texttt{work}.
Parameters

- `work` – pointer to the work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

Return values

- `true` – if call had to wait for completion
- `false` – if work was already idle

```c
int k_work_cancel(struct k_work *work)
```

Cancel a work item.

This attempts to prevent a pending (non-delayable) work item from being processed by removing it from the work queue. If the item is being processed, the work item will continue to be processed, but resubmissions are rejected until cancellation completes.

If this returns zero cancellation is complete, otherwise something (probably a work queue thread) is still referencing the item.

See also `k_work_cancel_sync()`.

Function properties (list may not be complete) `isr-ok`

Parameters

- `work` – pointer to the work item.

Returns the `k_work_busy_get()` status indicating the state of the item after all cancellation steps performed by this call are completed.

```c
bool k_work_cancel_sync(struct k_work *work, struct k_work_sync *sync)
```

Cancel a work item and wait for it to complete.

Same as `k_work_cancel()` but does not return until cancellation is complete. This can be invoked by a thread after `k_work_cancel()` to synchronize with a previous cancellation.

On return the work structure will be idle unless something submits it after the cancellation was complete.

**Note:** Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

**Note:** Behavior is undefined if this function is invoked on `work` from a work queue running `work`.

Parameters

- `work` – pointer to the work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be
used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

**Return values**

- `true` – if work was pending (call had to wait for cancellation of a running handler to complete, or scheduled or submitted operations were cancelled);
- `false` – otherwise

```c
void k_work_queue_init(struct k_work_q *queue)
Initialize a work queue structure.

This must be invoked before starting a work queue structure for the first time. It need not be invoked again on the same work queue structure.

**Function properties (list may not be complete)** `isr-ok`

**Parameters**

- `queue` – the queue structure to be initialized.

```c
void k_work_queue_start(struct k_work_q *queue, k_thread_stack_t *stack, size_t stack_size, int prio, const struct k_work_queue_config *cfg)
Initialize a work queue.

This configures the work queue thread and starts it running. The function should not be re-invoked on a queue.

**Parameters**

- `queue` – pointer to the queue structure. It must be initialized in zeroed/bss memory or with `k_work_queue_init` before use.
- `stack` – pointer to the work thread stack area.
- `stack_size` – size of the the work thread stack area, in bytes.
- `prio` – initial thread priority
- `cfg` – optional additional configuration parameters. Pass `NULL` if not required, to use the defaults documented in `k_work_queue_config`.

```c
static inline k_tid_t k_work_queue_thread_get(struct k_work_q *queue)
Access the thread that animates a work queue.

This is necessary to grant a work queue thread access to things the work items it will process are expected to use.

**Parameters**

- `queue` – pointer to the queue structure.

**Returns** the thread associated with the work queue.

```c
int k_work_queue_drain(struct k_work_q *queue, bool plug)
Wait until the work queue has drained, optionally plugging it.

This blocks submission to the work queue except when coming from queue thread, and blocks the caller until no more work items are available in the queue.

If `plug` is true then submission will continue to be blocked after the drain operation completes until `k_work_queue_unplug()` is invoked.

Note that work items that are delayed are not yet associated with their work queue. They must be cancelled externally if a goal is to ensure the work queue remains empty. The `plug` feature can be used to prevent delayed items from being submitted after the drain completes.
Parameters

- `queue` – pointer to the queue structure.
- `plug` – if true the work queue will continue to block new submissions after all items have drained.

Return values

- 1 – if call had to wait for the drain to complete
- 0 – if call did not have to wait
- negative – if wait was interrupted or failed

```c
int k_work_queue_unplug(struct k_work_q *queue)
```

Release a work queue to accept new submissions.

This releases the block on new submissions placed when `k_work_queue_drain()` is invoked with the `plug` option enabled. If this is invoked before the drain completes new items may be submitted as soon as the drain completes.

Function properties (list may not be complete) `isr-ok`

Parameters

- `queue` – pointer to the queue structure.

Return values

- 0 – if successfully unplugged
- -EAGAIN – if the work queue was not plugged.

```c
void k_work_init_delayable(struct k_work_delayable *dwork, k_work_handler_t handler)
```

Initialize a delayable work structure.

This must be invoked before scheduling a delayable work structure for the first time. It need not be invoked again on the same work structure. It can be re-invoked to change the associated handler, but this must be done when the work item is idle.

Function properties (list may not be complete) `isr-ok`

Parameters

- `dwork` – the delayable work structure to be initialized.
- `handler` – the handler to be invoked by the work item.

```c
static inline struct k_work_delayable *k_work_delayable_from_work(struct k_work *work)
```

Get the parent delayable work structure from a work pointer.

This function is necessary when a `k_work_handler_t` function is passed to `k_work_schedule_for_queue()` and the handler needs to access data from the container of the containing `k_work_delayable`.

Parameters

- `work` – Address passed to the work handler

Returns

Address of the containing `k_work_delayable` structure.

```c
int k_work_delayable_busy_get(const struct k_work_delayable *dwork)
```

Busy state flags from the delayable work item.
Function properties (list may not be complete)  
isr-ok

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters

• dwork – pointer to the delayable work item.

Returns a mask of flags K_WORK_DELAYED, K_WORK_QUEUED, K_WORK_RUNNING, and K_WORKCANCELING. A zero return value indicates the work item appears to be idle.

static inline bool k_work_delayable_is_pending(const struct k_work_delayable *dwork)
Test whether a delayed work item is currently pending.
Wrapper to determine whether a delayed work item is in a non-idle state.

Function properties (list may not be complete)  
isr-ok

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters

• dwork – pointer to the delayable work item.

Returns true if and only if k_work_delayable_busy_get() returns a non-zero value.

static inline k_ticks_t k_work_delayable_expires_get(const struct k_work_delayable *dwork)
Get the absolute tick count at which a scheduled delayable work will be submitted.

Function properties (list may not be complete)  
isr-ok

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters

• dwork – pointer to the delayable work item.

Returns the tick count when the timer that will schedule the work item will expire, or the current tick count if the work is not scheduled.

static inline k_ticks_t k_work_delayable_remaining_get(const struct k_work_delayable *dwork)
Get the number of ticks until a scheduled delayable work will be submitted.

Function properties (list may not be complete)  
isr-ok

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.
• dwork – pointer to the delayable work item.

**Returns** the number of ticks until the timer that will schedule the work item will expire, or zero if the item is not scheduled.

```c
int k_work_schedule_for_queue(struct k_work_q *queue, struct k_work_delayable *dwork, k_timeout_t delay)
```

Submit an idle work item to a queue after a delay.

Unlike `k_work_reschedule_for_queue()` this is a no-op if the work item is already scheduled or submitted, even if delay is `K_NO_WAIT`.

**Function properties (list may not be complete)** `isr-ok`

**Parameters**

- `queue` – the queue on which the work item should be submitted after the delay.
- `dwork` – pointer to the delayable work item.
- `delay` – the time to wait before submitting the work item. If `K_NO_WAIT` and the work is not pending this is equivalent to `k_work_submit_to_queue()`.

**Return values**

- 0 – if work was already scheduled or submitted.
- 1 – if work has been scheduled.
- -EBUSY – if delay is `K_NO_WAIT` and `k_work_submit_to_queue()` fails with this code.
- -EINVAL – if delay is `K_NO_WAIT` and `k_work_submit_to_queue()` fails with this code.
- -ENODEV – if delay is `K_NO_WAIT` and `k_work_submit_to_queue()` fails with this code.

```c
int k_work_schedule(struct k_work_delayable *dwork, k_timeout_t delay)
```

Submit an idle work item to the system work queue after a delay.

This is a thin wrapper around `k_work_schedule_for_queue()`, with all the API characteristics of that function.

**Parameters**

- `dwork` – pointer to the delayable work item.
- `delay` – the time to wait before submitting the work item. If `K_NO_WAIT` this is equivalent to `k_work_submit_to_queue()`.

**Returns** as with `k_work_schedule_for_queue()`.

```c
int k_work_reschedule_for_queue(struct k_work_q *queue, struct k_work_delayable *dwork, k_timeout_t delay)
```

Reschedule a work item to a queue after a delay.

Unlike `k_work_schedule_for_queue()` this function can change the deadline of a scheduled work item, and will schedule a work item that isn't idle (e.g. is submitted or running). This function does not affect ("unsubmit") a work item that has been submitted to a queue.

**Function properties (list may not be complete)** `isr-ok`
**Note:** If delay is `K_NO_WAIT` (“no delay”) the return values are as with `k_work_submit_to_queue()`.

**Parameters**

- `queue` – the queue on which the work item should be submitted after the delay.
- `dwork` – pointer to the delayable work item.
- `delay` – the time to wait before submitting the work item. If `K_NO_WAIT` this is equivalent to `k_work_submit_to_queue()` after canceling any previous scheduled submission.

**Return values**

- **0** – if delay is `K_NO_WAIT` and work was already on a queue
- **1** – if delay is `K_NO_WAIT` and work was not submitted but has now been queued to queue; or delay not `K_NO_WAIT` and work has been scheduled
- **2** – if delay is `K_NO_WAIT` and work was running and has been queued to the queue that was running it
- `-EBUSY` – if delay is `K_NO_WAIT` and `k_work_submit_to_queue()` fails with this code.
- `-EINVAL` – if delay is `K_NO_WAIT` and `k_work_submit_to_queue()` fails with this code.
- `-ENODEV` – if delay is `K_NO_WAIT` and `k_work_submit_to_queue()` fails with this code.

```c
int k_work_reschedule(struct k_work_delayable *dwork, k_timeout_t delay)
```

Reschedule a work item to the system work queue after a delay.

This is a thin wrapper around `k_work_reschedule_for_queue()`, with all the API characteristics of that function.

**Parameters**

- `dwork` – pointer to the delayable work item.
- `delay` – the time to wait before submitting the work item.

**Returns** as with `k_work_reschedule_for_queue()`.

```c
bool k_work_flush_delayable(struct k_work_delayable *dwork, struct k_work_sync *sync)
```

Flush delayable work.

If the work is scheduled, it is immediately submitted. Then the caller blocks until the work completes, as with `k_work_flush()`.

**Note:** Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

**Note:** Behavior is undefined if this function is invoked on `dwork` from a work queue running `dwork`.  

---

686 Chapter 7. API Reference
Parameters

- `dwork` – pointer to the delayable work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

Return values

- `true` – if call had to wait for completion
- `false` – if work was already idle

```c
int k_work_cancel_delayable(struct k_work_delayable *dwork)
```

Cancel delayable work.

Similar to `k_work_cancel()` but for delayable work. If the work is scheduled or submitted it is canceled. This function does not wait for the cancellation to complete.

Function properties (list may not be complete) `isr-ok`

Note: The work may still be running when this returns. Use `k_work_flush_delayable()` or `k_work_cancel_delayable_sync()` to ensure it is not running.

Note: Canceling delayable work does not prevent rescheduling it. It does prevent submitting it until the cancellation completes.

Parameters

- `dwork` – pointer to the delayable work item.

Returns the `k_work_delayable_busy_get()` status indicating the state of the item after all cancellation steps performed by this call are completed.

```c
bool k_work_cancel_delayable_sync(struct k_work_delayable *dwork, struct k_work_sync *sync)
```

Cancel delayable work and wait.

Like `k_work_cancel_delayable()` but waits until the work becomes idle.

Note: Canceling delayable work does not prevent rescheduling it. It does prevent submitting it until the cancellation completes.

Note: Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

Note: Behavior is undefined if this function is invoked on `dwork` from a work queue running `dwork`.
Parameters

- `dwork` – pointer to the delayable work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with `CONFIG_KERNEL_COHERENCE` the object must be allocated in coherent memory.

Return values

- `true` – if work was not idle (call had to wait for cancellation of a running handler to complete, or scheduled or submitted operations were cancelled);
- `false` – otherwise

static inline bool k_work_pending(const struct k_work *work)
static inline void k_work_q_start(struct k_work_q *work_q, k_thread_stack_t *stack, size_t stack_size, int prio)
static inline void k_delayed_work_init(struct k_delayed_work *work, k_work_handler_t handler)
static inline int k_delayed_work_submit_to_queue(struct k_work_q *work_q, struct k_delayed_work *work, k_timeout_t delay)
static inline int k_delayed_work_submit(struct k_delayed_work *work, k_timeout_t delay)
static inline int k_delayed_work_cancel(struct k_delayed_work *work)
static inline bool k_delayed_work_pending(struct k_delayed_work *work)
static inline int32_t k_delayed_work_remaining_get(struct k_delayed_work *work)
static inline k_ticks_t k_delayed_work_expires_ticks(struct k_delayed_work *work)
static inline k_ticks_t k_delayed_work_remaining_ticks(struct k_delayed_work *work)
static inline void k_work_user_init(struct k_work_user *work, k_work_user_handler_t handler)

Initialize a userspace work item.
This routine initializes a user workqueue work item, prior to its first use.

Parameters

- `work` – Address of work item.
- `handler` – Function to invoke each time work item is processed.

static inline bool k_work_user_is_pending(struct k_work_user *work)
Check if a userspace work item is pending.
This routine indicates if user work item `work` is pending in a workqueue's queue.

Function properties (list may not be complete) \texttt{isr-ok}
Note: Checking if the work is pending gives no guarantee that the work will still be pending when this information is used. It is up to the caller to make sure that this information is used in a safe manner.

Parameters
- work – Address of work item.

Returns true if work item is pending, or false if it is not pending.

static inline int k_work_user_submit_to_queue(struct k_work_user_q *work_q, struct k_work_user *work)
Submit a work item to a user mode workqueue.
Submits a work item to a workqueue that runs in user mode. A temporary memory allocation is made from the caller's resource pool which is freed once the worker thread consumes the k_work item. The workqueue thread must have memory access to the k_work item being submitted. The caller must have permission granted on the work_q parameter's queue object.

Function properties (list may not be complete) isr-ok

Parameters
- work_q – Address of workqueue.
- work – Address of work item.

Return values
- -EBUSY – if the work item was already in some workqueue
- -ENOMEM – if no memory for thread resource pool allocation
- 0 – Success

void k_work_user_queue_start(struct k_work_user_q *work_q, k_thread_stack_t *stack, size_t stack_size, int prio, const char *name)
Start a workqueue in user mode.
This works identically to k_work_queue_start() except it is callable from user mode, and the worker thread created will run in user mode. The caller must have permissions granted on both the work_q parameter's thread and queue objects, and the same restrictions on priority apply as k_thread_create().

Parameters
- work_q – Address of workqueue.
- stack – Pointer to work queue thread's stack space, as defined by K_THREAD_STACK_DEFINE()
- stack_size – Size of the work queue thread's stack (in bytes), which should either be the same constant passed to K_THREAD_STACK_DEFINE() or the value of K_THREAD_STACK_SIZEOF().
- prio – Priority of the work queue's thread.
- name – optional thread name. If not null a copy is made into the thread's name buffer.

void k_work_poll_init(struct k_work_poll *work, k_work_handler_t handler)
Initialize a triggered work item.
This routine initializes a workqueue triggered work item, prior to its first use.

7.14. Kernel Services 689
Parameters

- `work` – Address of triggered work item.
- `handler` – Function to invoke each time work item is processed.

```c
int k_work_poll_submit_to_queue(struct k_work_q *work_q, struct k_work_poll *work, struct k_poll_event *events, int num_events, k_timeout_t timeout)
```
Submit a triggered work item.

This routine schedules work item `work` to be processed by workqueue `work_q` when one of the given `events` is signaled. The routine initiates internal poller for the work item and then returns to the caller. Only when one of the watched events happen the work item is actually submitted to the workqueue and becomes pending.

Submitting a previously submitted triggered work item that is still waiting for the event cancels the existing submission and reschedules it the using the new event list. Note that this behavior is inherently subject to race conditions with the pre-existing triggered work item and work queue, so care must be taken to synchronize such resubmissions externally.

**Function properties (list may not be complete) isr-ok**

**Warning:** Provided array of events as well as a triggered work item must be placed in persistent memory (valid until work handler execution or work cancellation) and cannot be modified after submission.

Parameters

- `work_q` – Address of workqueue.
- `work` – Address of delayed work item.
- `events` – An array of events which trigger the work.
- `num_events` – The number of events in the array.
- `timeout` – Timeout after which the work will be scheduled for execution even if not triggered.

Return values

- 0 – Work item started watching for events.
- -EINVAL – Work item is being processed or has completed its work.
- -EADDRINUSE – Work item is pending on a different workqueue.

```c
int k_work_poll_submit(struct k_work_poll *work, struct k_poll_event *events, int num_events, k_timeout_t timeout)
```
Submit a triggered work item to the system workqueue.

This routine schedules work item `work` to be processed by system workqueue when one of the given `events` is signaled. The routine initiates internal poller for the work item and then returns to the caller. Only when one of the watched events happen the work item is actually submitted to the workqueue and becomes pending.

Submitting a previously submitted triggered work item that is still waiting for the event cancels the existing submission and reschedules it the using the new event list. Note that this behavior is inherently subject to race conditions with the pre-existing triggered work item and work queue, so care must be taken to synchronize such resubmissions externally.

**Function properties (list may not be complete) isr-ok**
Warning: Provided array of events as well as a triggered work item must not be modified until the item has been processed by the workqueue.

Parameters
- `work` – Address of delayed work item.
- `events` – An array of events which trigger the work.
- `num_events` – The number of events in the array.
- `timeout` – Timeout after which the work will be scheduled for execution even if not triggered.

Return values
- 0 – Work item started watching for events.
- -EINVAL – Work item is being processed or has completed its work.
- -EADDRINUSE – Work item is pending on a different workqueue.

```c
int k_work_poll_cancel(struct k_work_poll *work)
```

This routine cancels the submission of triggered work item `work`. A triggered work item can only be canceled if no event triggered work submission.

Function properties (list may not be complete) `isr-ok`

Parameters
- `work` – Address of delayed work item.

Return values
- 0 – Work item canceled.
- -EINVAL – Work item is being processed or has completed its work.

```c
struct k_work
#include <kernel.h> A structure used to submit work.
```

```c
struct k_work_delayable
#include <kernel.h> A structure used to submit work after a delay.
```

```c
struct k_work_sync
#include <kernel.h> A structure holding internal state for a pending synchronous operation on a work item or queue.
```

Instances of this type are provided by the caller for invocation of `k_work_flush()`, `k_work_cancel_sync()` and sibling flush and cancel APIs. A referenced object must persist until the call returns, and be accessible from both the caller thread and the work queue thread.

Note: If CONFIG_KERNEL_COHERENCE is enabled the object must be allocated in coherent memory; see `arch_mem_coherent()`. The stack on these architectures is generally not coherent. be stack-allocated. Violations are detected by runtime assertion.
struct k_work_queue_config
#include <kernel.h> A structure holding optional configuration items for a work queue.

This structure, and values it references, are not retained by k_work_queue_start().

Public Members

const char *name
The name to be given to the work queue thread.
If left null the thread will not have a name.

bool no_yield
Control whether the work queue thread should yield between items.
Yielding between items helps guarantee the work queue thread does not starve other threads, including cooperative ones released by a work item. This is the default behavior.
Set this to true to prevent the work queue thread from yielding between items. This may be appropriate when a sequence of items should complete without yielding control.

struct k_work_q
#include <kernel.h> A structure used to hold work until it can be processed.

struct k_delayed_work
#include <kernel.h>

Zephyr Without Threads

Thread support is not necessary in some applications:

• Bootloaders
• Simple event-driven applications
• Examples intended to demonstrate core functionality

Thread support can be disabled in Zephyr by setting CONFIG_MULTITHREADING to n. Since this configuration has a significant impact on Zephyr's functionality and testing of it has been limited, there are conditions on what can be expected to work in this configuration.

What Can be Expected to Work These core capabilities shall function correctly when CONFIG_MULTITHREADING is disabled:

• The build system
• The ability to boot the application to main()
• Interrupt management
• The system clock including k_uptime_get()
• Timers, i.e. k_timer()
• Non-sleeping delays e.g. k_busy_wait().
• Sleeping k_cpu_idle().
• Pre main() drivers and subsystems initialization e.g. SYS_INIT.
• Memory Management
• Specifically identified drivers in certain subsystems, listed below.

The expectations above affect selection of other features; for example CONFIG_SYS_CLOCK_EXISTS cannot be set to n.

What Cannot be Expected to Work Functionality that will not work with CONFIG_MULTITHREADING includes majority of the kernel API:

• Threads
• Scheduling
• Workqueue Threads
• Polling API
• Semaphores
• Mutexes
• Condition Variables
• Data Passing

Subsystem Behavior Without Thread Support The sections below list driver and functional subsystems that are expected to work to some degree when CONFIG_MULTITHREADING is disabled. Subsystems that are not listed here should not be expected to work.

Some existing drivers within the listed subsystems do not work when threading is disabled, but are within scope based on their subsystem, or may be sufficiently isolated that supporting them on a particular platform is low-impact. Enhancements to add support to existing capabilities that were not originally implemented to work with threads disabled will be considered.

Flash The Flash is expected to work for all SoC flash peripheral drivers. Bus-accessed devices like serial memories may not be supported.

List/table of supported drivers to go here

GPIO The GPIO is expected to work for all SoC GPIO peripheral drivers. Bus-accessed devices like GPIO extenders may not be supported.

List/table of supported drivers to go here

UART A subset of the UART is expected to work for all SoC UART peripheral drivers.

• Applications that select CONFIG_UART_INTERRUPT_DRIVEN may work, depending on driver implementation.

• Applications that select CONFIG_UART_ASYNC_API may work, depending on driver implementation.

• Applications that do not select either CONFIG_UART_ASYNC_API or CONFIG_UART_INTERRUPT_DRIVEN are expected to work.

List/table of supported drivers to go here, including which API options are supported

Interrupts

An interrupt service routine (ISR) is a function that executes asynchronously in response to a hardware or software interrupt. An ISR normally preempts the execution of the current thread, allowing the response to occur with very low overhead. Thread execution resumes only once all ISR work has been completed.
Concepts
Any number of ISRs can be defined (limited only by available RAM), subject to the constraints imposed by underlying hardware.

An ISR has the following key properties:

- An interrupt request (IRQ) signal that triggers the ISR.
- A priority level associated with the IRQ.
- An interrupt handler function that is invoked to handle the interrupt.
- An argument value that is passed to that function.

An IDT (Interrupt Descriptor Table) or a vector table is used to associate a given interrupt source with a given ISR. Only a single ISR can be associated with a specific IRQ at any given time.

Multiple ISRs can utilize the same function to process interrupts, allowing a single function to service a device that generates multiple types of interrupts or to service multiple devices (usually of the same type). The argument value passed to an ISR’s function allows the function to determine which interrupt has been signaled.

The kernel provides a default ISR for all unused IDT entries. This ISR generates a fatal system error if an unexpected interrupt is signaled.

The kernel supports interrupt nesting. This allows an ISR to be preempted in mid-execution if a higher priority interrupt is signaled. The lower priority ISR resumes execution once the higher priority ISR has completed its processing.

An ISR’s interrupt handler function executes in the kernel’s interrupt context. This context has its own dedicated stack area (or, on some architectures, stack areas). The size of the interrupt context stack must be capable of handling the execution of multiple concurrent ISRs if interrupt nesting support is enabled.

Important: Many kernel APIs can be used only by threads, and not by ISRs. In cases where a routine may be invoked by both threads and ISRs the kernel provides the k_is_in_isr() API to allow the routine to alter its behavior depending on whether it is executing as part of a thread or as part of an ISR.

Multi-level Interrupt handling A hardware platform can support more interrupt lines than natively-provided through the use of one or more nested interrupt controllers. Sources of hardware interrupts are combined into one line that is then routed to the parent controller.
If nested interrupt controllers are supported, `CONFIG_MULTI_LEVEL_INTERRUPTS` should be set to 1, and
`CONFIG_2ND_LEVEL_INTERRUPTS` and `CONFIG_3RD_LEVEL_INTERRUPTS` configured as well, based on the
hardware architecture.

A unique 32-bit interrupt number is assigned with information embedded in it to select and invoke the
correct Interrupt Service Routine (ISR). Each interrupt level is given a byte within this 32-bit number,
providing support for up to four interrupt levels using this arch, as illustrated and explained below:

<table>
<thead>
<tr>
<th>9</th>
<th>2</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>(LEVEL 1)</td>
</tr>
<tr>
<td>5</td>
<td>A</td>
<td></td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>B</td>
</tr>
<tr>
<td></td>
<td>D</td>
<td></td>
</tr>
</tbody>
</table>

There are three interrupt levels shown here.

- ‘-’ means interrupt line and is numbered from 0 (right most).
- LEVEL 1 has 12 interrupt lines, with two lines (2 and 9) connected to nested controllers and one
device ‘A’ on line 4.
- One of the LEVEL 2 controllers has interrupt line 5 connected to a LEVEL 3 nested controller and
one device ‘C’ on line 3.
- The other LEVEL 2 controller has no nested controllers but has one device ‘B’ on line 2.
- The LEVEL 3 controller has one device ‘D’ on line 2.

Here’s how unique interrupt numbers are generated for each hardware interrupt. Let’s consider four
interrupts shown above as A, B, C, and D:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00000004</td>
<td>0x00000302</td>
<td>0x00000409</td>
<td>0x00030609</td>
</tr>
</tbody>
</table>

**Note:** The bit positions for LEVEL 2 and onward are offset by 1, as 0 means that interrupt number is not
present for that level. For our example, the LEVEL 3 controller has device D on line 2, connected to the
LEVEL 2 controller’s line 5, that is connected to the LEVEL 1 controller’s line 9 (2 -> 5 -> 9). Because of
the encoding offset for LEVEL 2 and onward, device D is given the number 0x00030609.

**Preventing Interruptions** In certain situations it may be necessary for the current thread to prevent
ISRs from executing while it is performing time-sensitive or critical section operations.

A thread may temporarily prevent all IRQ handling in the system using an **IRQ lock**. This lock can be
applied even when it is already in effect, so routines can use it without having to know if it is already
in effect. The thread must unlock its IRQ lock the same number of times it was locked before interrupts
can be once again processed by the kernel while the thread is running.

**Important:** The IRQ lock is thread-specific. If thread A locks out interrupts then performs an operation
that puts itself to sleep (e.g. sleeping for N milliseconds), the thread’s IRQ lock no longer applies once
thread A is swapped out and the next ready thread B starts to run.

This means that interrupts can be processed while thread B is running unless thread B has also locked
out interrupts using its own IRQ lock. (Whether interrupts can be processed while the kernel is switching
between two threads that are using the IRQ lock is architecture-specific.)
When thread A eventually becomes the current thread once again, the kernel re-establishes thread A's IRQ lock. This ensures thread A won't be interrupted until it has explicitly unlocked its IRQ lock.

If thread A does not sleep but does make a higher-priority thread B ready, the IRQ lock will inhibit any preemption that would otherwise occur. Thread B will not run until the next reschedule point reached after releasing the IRQ lock.

Alternatively, a thread may temporarily disable a specified IRQ so its associated ISR does not execute when the IRQ is signaled. The IRQ must be subsequently enabled to permit the ISR to execute.

**Important:** Disabling an IRQ prevents all threads in the system from being preempted by the associated ISR, not just the thread that disabled the IRQ.

---

**Zero Latency Interrupts**  Preventing interruptions by applying an IRQ lock may increase the observed interrupt latency. A high interrupt latency, however, may not be acceptable for certain low-latency use-cases.

The kernel addresses such use-cases by allowing interrupts with critical latency constraints to execute at a priority level that cannot be blocked by interrupt locking. These interrupts are defined as zero-latency interrupts. The support for zero-latency interrupts requires CONFIG_ZERO_LATENCY_IRQS to be enabled. In addition to that, the flag IRQZERO_LATENCY must be passed to irq_connect or irq_direct_connect macros to configure the particular interrupt with zero latency.

Zero-latency interrupts are expected to be used to manage hardware events directly, and not to interoperate with the kernel code at all. They should treat all kernel APIs as undefined behavior (i.e. an application that uses the APIs inside a zero-latency interrupt context is responsible for directly verifying correct behavior). Zero-latency interrupts may not modify any data inspected by kernel APIs invoked from normal Zephyr contexts and shall not generate exceptions that need to be handled synchronously (e.g. kernel panic).

**Important:** Zero-latency interrupts are supported on an architecture-specific basis. The feature is currently implemented in the ARM Cortex-M architecture variant.

---

**Offloading ISR Work**  An ISR should execute quickly to ensure predictable system operation. If time consuming processing is required the ISR should offload some or all processing to a thread, thereby restoring the kernel's ability to respond to other interrupts.

The kernel supports several mechanisms for offloading interrupt-related processing to a thread.

- An ISR can signal a helper thread to do interrupt-related processing using a kernel object, such as a FIFO, LIFO, or semaphore.

- An ISR can instruct the system workqueue thread to execute a work item. (See Workqueue Threads.)

When an ISR offloads work to a thread, there is typically a single context switch to that thread when the ISR completes, allowing interrupt-related processing to continue almost immediately. However, depending on the priority of the thread handling the load, it is possible that the currently executing cooperative thread or other higher-priority threads may execute before the thread handling the load is scheduled.

---

**Implementation**

**Defining a regular ISR**  An ISR is defined at runtime by calling irq_connect. It must then be enabled by calling irq_enable().
**Important:** IRQ\_CONNECT() is not a C function and does some inline assembly magic behind the scenes. All its arguments must be known at build time. Drivers that have multiple instances may need to define per-instance config functions to configure each instance of the interrupt.

The following code defines and enables an ISR.

```c
#define MY_DEV_IRQ 24 /* device uses IRQ 24 */
#define MY_DEV_PRIO 2 /* device uses interrupt priority 2 */
/* argument passed to my_isr(), in this case a pointer to the device */
#define MY_ISR_ARG DEVICE_GET(my_device)
#define MY_IRQ_FLAGS 0 /* IRQ flags */

void my_isr(void *arg)
{
    /* ISR code */
}

void my_isr_installer(void)
{
    ...
    IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG, MY_IRQ_FLAGS);
    irq_enable(MY_DEV_IRQ);
    ...
}
```

Since the `IRQ\_CONNECT` macro requires that all its parameters be known at build time, in some cases this may not be acceptable. It is also possible to install interrupts at runtime with `irq_connect_dynamic()`. It is used in exactly the same way as `IRQ\_CONNECT`:

```c
void my_isr_installer(void)
{
    ...
    irq_connect_dynamic(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG, MY_IRQ_FLAGS);
    irq_enable(MY_DEV_IRQ);
    ...
}
```

Dynamic interrupts require the `CONFIG_DYNmIC\_INTERRUPTS` option to be enabled. Removing or reconfiguring a dynamic interrupt is currently unsupported.

**Defining a ‘direct’ ISR** Regular Zephyr interrupts introduce some overhead which may be unacceptable for some low-latency use-cases. Specifically:

- The argument to the ISR is retrieved and passed to the ISR
- If power management is enabled and the system was idle, all the hardware will be resumed from low-power state before the ISR is executed, which can be very time-consuming
- Although some architectures will do this in hardware, other architectures need to switch to the interrupt stack in code
- After the interrupt is serviced, the OS then performs some logic to potentially make a scheduling decision.

Zephyr supports so-called ‘direct’ interrupts, which are installed via `IRQ\_DIRECT\_CONNECT`. These direct interrupts have some special implementation requirements and a reduced feature set; see the definition of `IRQ\_DIRECT\_CONNECT` for details.
The following code demonstrates a direct ISR:

```c
#define MY_DEV_IRQ 24 /* device uses IRQ 24 */
#define MY_DEV_PRIO 2 /* device uses interrupt priority 2 */
/* argument passed to my_isr(), in this case a pointer to the device */
#define MY_IRQ_FLAGS 0 /* IRQ flags */
ISR_DIRECT_DECLARE(my_isr)
{
    do_stuff();
    ISR_DIRECT_PM(); /* PM done after servicing interrupt for best latency */
    return 1; /* We should check if scheduling decision should be made */
}
void my_isr_installer(void)
{
    ... 
    IRQ_DIRECT_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_IRQ_FLAGS);
    irq_enable(MY_DEV_IRQ);
    ... 
}
```

Installation of dynamic direct interrupts is supported on an architecture-specific basis. (The feature is currently implemented in ARM Cortex-M architecture variant. Dynamic direct interrupts feature is exposed to the user via an ARM-only API.)

**Implementation Details** Interrupt tables are set up at build time using some special build tools. The details laid out here apply to all architectures except x86, which are covered in the [x86 Details](#) section below.

Any invocation of `IRQ_CONNECT` will declare an instance of struct `_isr_list` which is placed in a special `.intList` section:

```c
struct _isr_list {
    /** IRQ line number */
    int32_t irq;
    /** Flags for this IRQ, see ISR_FLAG_* definitions */
    int32_t flags;
    /** ISR to call */
    void *func;
    /** Parameter for non-direct IRQs */
    void *param;
};
```

Zephyr is built in two phases; the first phase of the build produces `{ZEPHYR_PREBUILT_EXECUTABLE}.elf` which contains all the entries in the `.intList` section preceded by a header:

```c
struct {
    void *spurious_irq_handler;
    void *sw_irq_handler;
    uint32_t num_isrs;
    uint32_t num_vectors;
    struct _isr_list isrs[]; /* of size num_isrs */
};
```

This data consisting of the header and instances of struct `_isr_list` inside `{ZEPHYR_PREBUILT_EXECUTABLE}.elf` is then used by the gen_isr_tables.py script to generate a C file defining a vector table and software ISR table that are then compiled and linked into the final application.
The priority level of any interrupt is not encoded in these tables, instead `IRQ_CONNECT` also has a runtime component which programs the desired priority level of the interrupt to the interrupt controller. Some architectures do not support the notion of interrupt priority, in which case the priority argument is ignored.

**Vector Table**  A vector table is generated when `CONFIG_GEN_IRQ_VECTOR_TABLE` is enabled. This data structure is used natively by the CPU and is simply an array of function pointers, where each element n corresponds to the IRQ handler for IRQ line n, and the function pointers are:

1. For 'direct' interrupts declared with `IRQ_DIRECT_CONNECT`, the handler function will be placed here.
2. For regular interrupts declared with `IRQ_CONNECT`, the address of the common software IRQ handler is placed here. This code does common kernel interrupt bookkeeping and looks up the ISR and parameter from the software ISR table.
3. For interrupt lines that are not configured at all, the address of the spurious IRQ handler will be placed here. The spurious IRQ handler causes a system fatal error if encountered.

Some architectures (such as the Nios II internal interrupt controller) have a common entry point for all interrupts and do not support a vector table, in which case the `CONFIG_GEN_IRQ_VECTOR_TABLE` option should be disabled.

Some architectures may reserve some initial vectors for system exceptions and declare this in a table elsewhere, in which case `CONFIG_GEN_IRQ_START_VECTOR` needs to be set to properly offset the indices in the table.

**SW ISR Table**  This is an array of struct `_isr_table_entry`:

```c
struct _isr_table_entry {
    void *arg;
    void (*isr)(void *);
};
```

This is used by the common software IRQ handler to look up the ISR and its argument and execute it. The active IRQ line is looked up in an interrupt controller register and used to index this table.

**x86 Details**  The x86 architecture has a special type of vector table called the Interrupt Descriptor Table (IDT) which must be laid out in a certain way per the x86 processor documentation. It is still fundamentally a vector table, and the `arch/x86/gen_idt.py` tool uses the `.intList` section to create it. However, on APIC-based systems the indexes in the vector table do not correspond to the IRQ line. The first 32 vectors are reserved for CPU exceptions, and all remaining vectors (up to index 255) correspond to the priority level, in groups of 16. In this scheme, interrupts of priority level 0 will be placed in vectors 32-47, level 1 48-63, and so forth. When the `arch/x86/gen_idt.py` tool is constructing the IDT, when it configures an interrupt it will look for a free vector in the appropriate range for the requested priority level and set the handler there.

On x86 when an interrupt or exception vector is executed by the CPU, there is no foolproof way to determine which vector was fired, so a software ISR table indexed by IRQ line is not used. Instead, the `IRQ_CONNECT` call creates a small assembly language function which calls the common interrupt code in `_interrupt_enter()` with the ISR and parameter as arguments. It is the address of this assembly interrupt stub which gets placed in the IDT. For interrupts declared with `IRQ_DIRECT_CONNECT` the parameterless ISR is placed directly in the IDT.

On systems where the position in the vector table corresponds to the interrupt's priority level, the interrupt controller needs to know at runtime what vector is associated with an IRQ line. `arch/x86/gen_idt.py` additionally creates an `_irq_to_interrupt_vector` array which maps an IRQ line to its configured vector in the IDT. This is used at runtime by `IRQ_CONNECT` to program the IRQ-to-vector association in the interrupt controller.
For dynamic interrupts, the build must generate some 4-byte dynamic interrupt stubs, one stub per dynamic interrupt in use. The number of stubs is controlled by the `CONFIG_X86_DYNAMIC_IRQ_STUBS` option. Each stub pushes an unique identifier which is then used to fetch the appropriate handler function and parameter out of a table populated when the dynamic interrupt was connected.

**Suggested Uses**  Use a regular or direct ISR to perform interrupt processing that requires a very rapid response, and can be done quickly without blocking.

**Note:** Interrupt processing that is time consuming, or involves blocking, should be handed off to a thread. See Offloading ISR Work for a description of various techniques that can be used in an application.

**Configuration Options**  Related configuration options:

- `CONFIG_ISR_STACK_SIZE`

Additional architecture-specific and device-specific configuration options also exist.

**API Reference**

`group isr_apis`

**Defines**

`IRQ_CONNECT(irq_p, priority_p, isr_p, isr_param_p, flags_p)`

Initialize an interrupt handler.

This routine initializes an interrupt handler for an IRQ. The IRQ must be subsequently enabled before the interrupt handler begins servicing interrupts.

**Warning:** Although this routine is invoked at run-time, all of its arguments must be computable by the compiler at build time.

**Parameters**

- `irq_p` – IRQ line number.
- `priority_p` – Interrupt priority.
- `isr_p` – Address of interrupt service routine.
- `isr_param_p` – Parameter passed to interrupt service routine.
- `flags_p` – Architecture-specific IRQ configuration flags..

`IRQ_DIRECT_CONNECT(irq_p, priority_p, isr_p, flags_p)`

Initialize a ‘direct’ interrupt handler.

This routine initializes an interrupt handler for an IRQ. The IRQ must be subsequently enabled via `irq_enable()` before the interrupt handler begins servicing interrupts.

These ISRs are designed for performance-critical interrupt handling and do not go through common interrupt handling code. They must be implemented in such a way that it is safe to put them directly in the vector table. For ISRs written in C, The `ISR DIRECT DECLARE()` macro will do this automatically. For ISRs written in assembly it is entirely up to the developer to ensure that the right steps are taken.

This type of interrupt currently has a few limitations compared to normal Zephyr interrupts:
- No parameters are passed to the ISR.
- No stack switch is done, the ISR will run on the interrupted context's stack, unless the architecture automatically does the stack switch in HW.
- Interrupt locking state is unchanged from how the HW sets it when the ISR runs. On arches that enter ISRs with interrupts locked, they will remain locked.
- Scheduling decisions are now optional, controlled by the return value of ISRs implemented with the `ISR_DIRECT_DECLARE()` macro
- The call into the OS to exit power management idle state is now optional. Normal interrupts always do this before the ISR is run, but when it runs is now controlled by the placement of a `ISR_DIRECT_PM()` macro, or omitted entirely.

**Warning:** Although this routine is invoked at run-time, all of its arguments must be computable by the compiler at build time.

**Parameters**
- irq_p – IRQ line number.
- priority_p – Interrupt priority.
- isr_p – Address of interrupt service routine.
- flags_p – Architecture-specific IRQ configuration flags.

**ISR_DIRECT_HEADER()**
Common tasks before executing the body of an ISR.
This macro must be at the beginning of all direct interrupts and performs minimal architecture-specific tasks before the ISR itself can run. It takes no arguments and has no return value.

**ISR_DIRECT_FOOTER(check_reschedule)**
Common tasks before exiting the body of an ISR.
This macro must be at the end of all direct interrupts and performs minimal architecture-specific tasks like EOI. It has no return value.

In a normal interrupt, a check is done at end of interrupt to invoke z_swap() logic if the current thread is preemptible and there is another thread ready to run in the kernel's ready queue cache. This is now optional and controlled by the check_reschedule argument. If unsure, set to nonzero. On systems that do stack switching and nested interrupt tracking in software, z_swap() should only be called if this was a non-nested interrupt.

**Parameters**
- check_reschedule – If nonzero, additionally invoke scheduling logic

**ISR_DIRECT_PM()**
Perform power management idle exit logic.
This macro may optionally be invoked somewhere in between `ISR_DIRECT_HEADER()` and `ISR_DIRECT_FOOTER()` invocations. It performs tasks necessary to exit power management idle state. It takes no parameters and returns no arguments. It may be omitted, but be careful!

**ISR_DIRECT_DECLARE(name)**
Helper macro to declare a direct interrupt service routine.
This will declare the function in a proper way and automatically include the `ISR_DIRECT_FOOTER()` and `ISR_DIRECT_HEADER()` macros. The function should return nonzero status if a scheduling decision should potentially be made. See `ISR_DIRECT_FOOTER()` for more details on the scheduling decision.
For architectures that support ‘regular’ and ‘fast’ interrupt types, where these interrupt types require different assembly language handling of registers by the ISR, this will always generate code for the ‘fast’ interrupt type.

Example usage:

```c
ISR_DIRECT_DECLARE(my_isr)
{
    bool done = do_stuff();
    ISR_DIRECT_PM(); // done after do_stuff() due to latency concerns
    if (!done) {
        return 0; // don't bother checking if we have to z_swap()
    }

    k_sem_give(some_sem);
    return 1;
}
```

**Parameters**

- **name** – symbol name of the ISR

**irq_lock()**

Lock interrupts.

This routine disables all interrupts on the CPU. It returns an unsigned integer “lock-out key”, which is an architecture-dependent indicator of whether interrupts were locked prior to the call. The lock-out key must be passed to `irq_unlock()` to re-enable interrupts.

This routine can be called recursively, as long as the caller keeps track of each lock-out key that is generated. Interrupts are re-enabled by passing each of the keys to `irq_unlock()` in the reverse order they were acquired. (That is, each call to `irq_lock()` must be balanced by a corresponding call to `irq_unlock()`.)

This routine can only be invoked from supervisor mode. Some architectures (for example, ARM) will fail silently if invoked from user mode instead of generating an exception.

**Note:** This routine must also serve as a memory barrier to ensure the uniprocessor implementation of `k_spinlock_t` is correct.

**Note:** This routine can be called by ISRs or by threads. If it is called by a thread, the interrupt lock is thread-specific; this means that interrupts remain disabled only while the thread is running. If the thread performs an operation that allows another thread to run (for example, giving a semaphore or sleeping for N milliseconds), the interrupt lock no longer applies and interrupts may be re-enabled while other processing occurs. When the thread once again becomes the current thread, the kernel re-establishes its interrupt lock; this ensures the thread won’t be interrupted until it has explicitly released the interrupt lock it established.

**Warning:** The lock-out key should never be used to manually re-enable interrupts or to inspect or manipulate the contents of the CPU’s interrupt bits.

**Returns** An architecture-dependent lock-out key representing the “interrupt disable state” prior to the call.
irq_unlock(key)
Unlock interrupts.

This routine reverses the effect of a previous call to irq_lock() using the associated lock-out key. The caller must call the routine once for each time it called irq_lock(), supplying the keys in the reverse order they were acquired, before interrupts are enabled.

This routine can only be invoked from supervisor mode. Some architectures (for example, ARM) will fail silently if invoked from user mode instead of generating an exception.

Note: This routine must also serve as a memory barrier to ensure the uniprocessor implementation of k_spinlock_t is correct.

Note: Can be called by ISRs.

Parameters
• key – Lock-out key generated by irq_lock().

irq_enable(irq)
Enable an IRQ.

This routine enables interrupts from source irq.

Parameters
• irq – IRQ line.

irq_disable(irq)
Disable an IRQ.

This routine disables interrupts from source irq.

Parameters
• irq – IRQ line.

irq_is_enabled(irq)
Get IRQ enable state.

This routine indicates if interrupts from source irq are enabled.

Parameters
• irq – IRQ line.

Returns interrupt enable state, true or false

Functions

static inline int irq_connect_dynamic(unsigned int irq, unsigned int priority, void (*routine)(const void *parameter), const void *parameter, uint32_t flags)
Configure a dynamic interrupt.

Use this instead of IRQ_CONNECT() if arguments cannot be known at build time.

Parameters
• irq – IRQ line number
• priority – Interrupt priority
• routine – Interrupt service routine
• parameter – ISR parameter
• flags – Arch-specific IRQ configuration flags

Returns The vector assigned to this interrupt

static inline unsigned int irq_get_level(unsigned int irq)

bool k_is_in_isr(void)
Determine if code is running at interrupt level.
This routine allows the caller to customize its actions, depending on whether it is a thread or an ISR.

Function properties (list may not be complete) isr-ok

Returns false if invoked by a thread.
Returns true if invoked by an ISR.

int k_is_preempt_thread(void)
Determine if code is running in a preemptible thread.
This routine allows the caller to customize its actions, depending on whether it can be preempted by another thread. The routine returns a ‘true’ value if all of the following conditions are met:

• The code is running in a thread, not at ISR.
• The thread’s priority is in the preemptible range.
• The thread has not locked the scheduler.

Function properties (list may not be complete) isr-ok

Returns 0 if invoked by an ISR or by a cooperative thread.
Returns Non-zero if invoked by a preemptible thread.

static inline bool k_is_pre_kernel(void)
Test whether startup is in the before-main-task phase.
This routine allows the caller to customize its actions, depending on whether it being invoked before the kernel is fully active.

Function properties (list may not be complete) isr-ok

Returns true if invoked before post-kernel initialization
Returns false if invoked during/after post-kernel initialization

Polling API

The polling API is used to wait concurrently for any one of multiple conditions to be fulfilled.
Concepts

The polling API's main function is `k_poll()`, which is very similar in concept to the POSIX `poll()` function, except that it operates on kernel objects rather than on file descriptors.

The polling API allows a single thread to wait concurrently for one or more conditions to be fulfilled without actively looking at each one individually.

There is a limited set of such conditions:

- a semaphore becomes available
- a kernel FIFO contains data ready to be retrieved
- a poll signal is raised

A thread that wants to wait on multiple conditions must define an array of poll events, one for each condition.

All events in the array must be initialized before the array can be polled on.

Each event must specify which type of condition must be satisfied so that its state is changed to signal the requested condition has been met.

Each event must specify what kernel object it wants the condition to be satisfied.

Each event must specify which mode of operation is used when the condition is satisfied.

Apart from the kernel objects, there is also a poll signal pseudo-object type that be directly signaled.

The `k_poll()` function returns as soon as one of the conditions it is waiting for is fulfilled. It is possible for more than one to be fulfilled when `k_poll()` returns, if they were fulfilled before `k_poll()` was called, or due to the preemptive multi-threading nature of the kernel. The caller must look at the state of all the poll events in the array to figured out which ones were fulfilled and what actions to take.

Currently, there is only one mode of operation available: the object is not acquired. As an example, this means that when `k_poll()` returns and the poll event states that the semaphore is available, the caller of `k_poll()` must then invoke `k_sem_take()` to take ownership of the semaphore. If the semaphore is contested, there is no guarantee that it will be still available when `k_sem_give()` is called.

Implementation

Using `k_poll()` The main API is `k_poll()`, which operates on an array of poll events of type `k_poll_event`. Each entry in the array represents one event a call to `k_poll()` will wait for its condition to be fulfilled.

They can be initialized using either the runtime initializers `K_POLL_EVENT_INITIALIZER()` or `k_poll_event_init()`, or the static initializer `K_POLL_EVENT_STATIC_INITIALIZER()`. An object that matches the type specified must be passed to the initializers. The mode must be set to `K_POLL_MODE_NOTIFY_ONLY`. The state must be set to `K_POLL_STATE_NOT_READY` (the initializers take
care of this). The user tag is optional and completely opaque to the API: it is there to help a user to group similar events together. Being optional, it is passed to the static initializer, but not the runtime ones for performance reasons. If using runtime initializers, the user must set it separately in the k_poll_event data structure. If an event in the array is to be ignored, most likely temporarily, its type can be set to K_POLL_TYPE_IGNORE.

```c
struct k_poll_event events[2] = {
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_SEM_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_sem, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_FIFO_DATA_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_fifo, 0),
};
```

or at runtime

```c
struct k_poll_event events[2];
void some_init(void)
{
    k_poll_event_init(&events[0],
        K_POLL_TYPE_SEM_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_sem);
    k_poll_event_init(&events[1],
        K_POLL_TYPE_FIFO_DATA_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_fifo);

    // tags are left uninitialized if unused
}
```

After the events are initialized, the array can be passed to k_poll(). A timeout can be specified to wait only for a specified amount of time, or the special values K_NO_WAIT and K_FOREVER to either not wait or wait until an event condition is satisfied and not sooner.

A list of pollers is offered on each semaphore or FIFO and as many events can wait in it as the app wants. Notice that the waiters will be served in first-come-first-serve order, not in priority order.

In case of success, k_poll() returns 0. If it times out, it returns -EAGAIN.

```c
// assume there is no contention on this semaphore and FIFO
// -EADDRINUSE will not occur; the semaphore and/or data will be available
void do_stuff(void)
{
    rc = k_poll(events, 2, 1000);
    if (rc == 0) {
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
        } else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        }
    } else {
        // handle timeout
    }
}
```
When `k_poll()` is called in a loop, the events state must be reset to `K_POLL_STATE_NOT_READY` by the user.

```c
void do_stuff(void)
{
    for(;;) {
        rc = k_poll(events, 2, K_FOREVER);
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
        } else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        }
        events[0].state = K_POLL_STATE_NOT_READY;
        events[1].state = K_POLL_STATE_NOT_READY;
    }
}
```

Using `k_poll_signal_raise()`  One of the types of events is `K_POLL_TYPE_SIGNAL`: this is a “direct” signal to a poll event. This can be seen as a lightweight binary semaphore only one thread can wait for.

A poll signal is a separate object of type `k_poll_signal` that must be attached to a `k_poll_event`, similar to a semaphore or FIFO. It must first be initialized either via `K_POLL_SIGNAL_INITIALIZER()` or `k_poll_signal_init()`.

```c
struct k_poll_signal signal;
void do_stuff(void)
{
    k_poll_signal_init(&signal);
}
```

It is signaled via the `k_poll_signal_raise()` function. This function takes a user `result` parameter that is opaque to the API and can be used to pass extra information to the thread waiting on the event.

```c
struct k_poll_signal signal;

// thread A
void do_stuff(void)
{
    k_poll_signal_init(&signal);

    struct k_poll_event events[1] = {
        K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
        K_POLL_MODE_NOTIFY_ONLY,
        &signal),
    };

    k_poll(events, 1, K_FOREVER);

    if (events.signal->result == 0x1337) {
        // A-OK!
    } else {
        // weird error
    }
}
```

(continues on next page)
void signal_do_stuff(void)
{
    k_poll_signal_raise(&signal, 0x1337);
}

If the signal is to be polled in a loop, both its event state and its signaled field must be reset on each iteration if it has been signaled.

struct k_poll_signal signal;

void do_stuff(void)
{
    k_poll_signal_init(&signal);

    struct k_poll_event events[1] = {
        K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
            K_POLL_MODE_NOTIFY_ONLY,
            &signal),
    };

    for (;;) {
        k_poll(events, 1, K_FOREVER);

        if (events[0].signal->result == 0x1337) {
            // A-OK!
        } else {
            // weird error
        }

        events[0].signal->signaled = 0;
        events[0].state = K_POLL_STATE_NOT_READY;
    }
}

Note that poll signals are not internally synchronized. A k_poll call that is passed a signal will return after any code in the system calls k_poll_signal_raise(). But if the signal is being externally managed and reset via k_poll_signal_init(), it is possible that by the time the application checks, the event state may no longer be equal to K_POLL_STATE_SIGNALED, and a (naive) application will miss events. Best practice is always to reset the signal only from within the thread invoking the k_poll() loop, or else to use some other event type which tracks event counts: semaphores and FIFOs more more error-proof in this sense because they can’t “miss” events, architecturally.

**Suggested Uses** Use k_poll() to consolidate multiple threads that would be pending on one object each, saving possibly large amounts of stack space.

Use a poll signal as a lightweight binary semaphore if only one thread pends on it.

**Note:** Because objects are only signaled if no other thread is waiting for them to become available and only one thread can poll on a specific object, polling is best used when objects are not subject of contention between multiple threads, basically when a single thread operates as a main “server” or “dispatcher” for multiple objects and is the only one trying to acquire these objects.

Enums

```c
enum k_poll_modes
{
    enumerator K_POLL_MODE_NOTIFY_ONLY = 0,
    enumerator K_POLL_NUM_MODES
};
```

Functions

```c
void k_poll_event_init(struct k_poll_event *event, uint32_t type, int mode, void *obj)

Initialize one struct `k_poll_event` instance.

After this routine is called on a poll event, the event it ready to be placed in an event array to be passed to `k_poll()`.
```

Parameters

- `event` – The event to initialize.
- `type` – A bitfield of the types of event, from the K_POLL_TYPE_xxx values. Only values that apply to the same object being polled can be used together. Choosing K_POLL_TYPE_IGNORE disables the event.
- `mode` – Future. Use K_POLL_MODE_NOTIFY_ONLY.
- `obj` – Kernel object or poll signal.

```c
int k_poll(struct k_poll_event *events, int num_events, k_timeout_t timeout)

Wait for one or many of multiple poll events to occur.

This routine allows a thread to wait concurrently for one or many of multiple poll events to have occurred. Such events can be a kernel object being available, like a semaphore, or a poll signal event.

When an event notifies that a kernel object is available, the kernel object is not “given” to the thread calling `k_poll()`: it merely signals the fact that the object was available when the `k_poll()` call was in effect. Also, all threads trying to acquire an object the regular way, i.e. by pending on the object, have precedence over the thread polling on the object. This means that the polling thread will never get the poll event on an object until the object becomes available and its pend queue is empty. For this reason, the `k_poll()` call is more effective when the objects being polled only have one thread, the polling thread, trying to acquire them.

When `k_poll()` returns 0, the caller should loop on all the events that were passed to `k_poll()` and check the state field for the values that were expected and take the associated actions.

Before being reused for another call to `k_poll()`, the user has to reset the state field to K_POLL_STATE_NOT_READY.

When called from user mode, a temporary memory allocation is required from the caller’s resource pool.
```

Parameters

- `events` – An array of events to be polled for.
- `num_events` – The number of events in the array.
- `timeout` – Waiting period for an event to be ready, or one of the special values K_NO_WAIT and K_FOREVER.
Return values

- **0** – One or more events are ready.
- **-EAGAIN** – Waiting period timed out.
- **-EINTR** – Polling has been interrupted, e.g. with `k_queue_cancel_wait()`. All output events are still set and valid, cancelled event(s) will be set to K_POLL_STATE_CANCELED. In other words, -EINTR status means that at least one of output events is K_POLL_STATE_CANCELED.
- **-ENOMEM** – Thread resource pool insufficient memory (user mode only)
- **-EINVAL** – Bad parameters (user mode only)

```c
void k_poll_signal_init(struct k_poll_signal *sig)
Initialize a poll signal object.
Ready a poll signal object to be signaled via `k_poll_signal_raise()`.
```

**Parameters**

- **sig** – A poll signal.

```c
void k_poll_signal_reset(struct k_poll_signal *sig)
```

```c
void k_poll_signal_check(struct k_poll_signal *sig, unsigned int *signaled, int *result)
```

Fetch the signaled state and result value of a poll signal.

**Parameters**

- **sig** – A poll signal object
- **signaled** – An integer buffer which will be written nonzero if the object was signaled
- **result** – An integer destination buffer which will be written with the result value if the object was signaled, or an undefined value if it was not.

```c
int k_poll_signal_raise(struct k_poll_signal *sig, int result)
Signal a poll signal object.
```

This routine makes ready a poll signal, which is basically a poll event of type K_POLL_TYPE_SIGNAL. If a thread was polling on that event, it will be made ready to run. A result value can be specified.

The poll signal contains a 'signaled' field that, when set by `k_poll_signal_raise()`, stays set until the user sets it back to 0 with `k_poll_signal_reset()`. It thus has to be reset by the user before being passed again to `k_poll()` or `k_poll()` will consider it being signaled, and will return immediately.

**Note:** The result is stored and the 'signaled' field is set even if this function returns an error indicating that an expiring poll was not notified. The next `k_poll()` will detect the missed raise.

**Parameters**

- **sig** – A poll signal.
- **result** – The value to store in the result field of the signal.

**Return values**

- **0** – The signal was delivered successfully.
- **-EAGAIN** – The polling thread’s timeout is in the process of expiring.

Semaphores

A \textit{semaphore} is a kernel object that implements a traditional counting semaphore.

- \textit{Concepts}
- \textit{Implementation}
  - Defining a Semaphore
  - Giving a Semaphore
Any number of semaphores can be defined (limited only by available RAM). Each semaphore is referenced by its memory address.

A semaphore has the following key properties:

- **A count** that indicates the number of times the semaphore can be taken. A count of zero indicates that the semaphore is unavailable.

- **A limit** that indicates the maximum value the semaphore’s count can reach.

A semaphore must be initialized before it can be used. Its count must be set to a non-negative value that is less than or equal to its limit.

A semaphore may be **given** by a thread or an ISR. Giving the semaphore increments its count, unless the count is already equal to the limit.

A semaphore may be **taken** by a thread. Taking the semaphore decrements its count, unless the semaphore is unavailable (i.e. at zero). When a semaphore is unavailable a thread may choose to wait for it to be given. Any number of threads may wait on an unavailable semaphore simultaneously. When the semaphore is given, it is taken by the highest priority thread that has waited longest.

**Note:** You may initialize a “full” semaphore (count equal to limit) to limit the number of threads able to execute the critical section at the same time. You may also initialize an empty semaphore (count equal to 0, with a limit greater than 0) to create a gate through which no waiting thread may pass until the semaphore is incremented. All standard use cases of the common semaphore are supported.

**Note:** The kernel does allow an ISR to take a semaphore, however the ISR must not attempt to wait if the semaphore is unavailable.

### Implementation

**Defining a Semaphore**  A semaphore is defined using a variable of type `k_sem`. It must then be initialized by calling `k_sem_init()`.

The following code defines a semaphore, then configures it as a binary semaphore by setting its count to 0 and its limit to 1.

```c
struct k_sem my_sem;

k_sem_init(&my_sem, 0, 1);
```

Alternatively, a semaphore can be defined and initialized at compile time by calling `K_SEM_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_SEM_DEFINE(my_sem, 0, 1);
```
Giving a Semaphore  A semaphore is given by calling \texttt{k-sem.give()}. The following code builds on the example above, and gives the semaphore to indicate that a unit of data is available for processing by a consumer thread.

```c
void input_data_interrupt_handler(void *arg)
{
    /* notify thread that data is available */
    k_sem_give(&my_sem);
    ...
}
```

Taking a Semaphore  A semaphore is taken by calling \texttt{k-sem.take()}. The following code builds on the example above, and waits up to 50 milliseconds for the semaphore to be given. A warning is issued if the semaphore is not obtained in time.

```c
void consumer_thread(void)
{
    ...
    if (k_sem_take(&my_sem, K_MSEC(50)) != 0) {
        printk("Input data not available!");
    } else {
        /* fetch available data */
        ...
    }
    ...
}
```

Suggested Uses  Use a semaphore to control access to a set of resources by multiple threads. Use a semaphore to synchronize processing between a producing and consuming threads or ISRs.

Configuration Options  Related configuration options:

- None.

API Reference

\textit{group} semaphore\_apis

\textbf{Defines}

- \texttt{K\_SEM\_MAX\_LIMIT}\hfill\textnormal{Maximum limit value allowed for a semaphore.}

  This is intended for use when a semaphore does not have an explicit maximum limit, and instead is just used for counting purposes.

- \texttt{K\_SEM\_DEFINE(name, initial\_count, count\_limit)}\hfill\textnormal{Statically define and initialize a semaphore.}

  The semaphore can be accessed outside the module where it is defined using:
extern struct k_sem <name>;

Parameters

- **name** – Name of the semaphore.
- **initial_count** – Initial semaphore count.
- **count_limit** – Maximum permitted semaphore count.

Functions

```c
int k_sem_init(struct k_sem *sem, unsigned int initial_count, unsigned int limit)
Initialize a semaphore.
This routine initializes a semaphore object, prior to its first use.
```

See also:

*K_SEM_MAX_LIMIT*

Parameters

- **sem** – Address of the semaphore.
- **initial_count** – Initial semaphore count.
- **limit** – Maximum permitted semaphore count.

Return values

- **0** – Semaphore created successfully
- **-EINVAL** – Invalid values

```c
int k_sem_take(struct k_sem *sem, k_timeout_t timeout)
Take a semaphore.
This routine takes *sem*.
```

Function properties (list may not be complete) **isr-ok**

Note:  *timeout* must be set to K_NO_WAIT if called from ISR.

Parameters

- **sem** – Address of the semaphore.
- **timeout** – Waiting period to take the semaphore, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **0** – Semaphore taken.
- **-EBUSY** – Returned without waiting.
- **-EAGAIN** – Waiting period timed out, or the semaphore was reset during the waiting period.
void k_sem_give(struct k_sem *sem)
    Give a semaphore.

This routine gives `sem`, unless the semaphore is already at its maximum permitted count.

**Function properties (list may not be complete)** `isr-ok`

**Parameters**
- `sem` – Address of the semaphore.

void k_sem_reset(struct k_sem *sem)
    Resets a semaphore’s count to zero.

This routine sets the count of `sem` to zero. Any outstanding semaphore takes will be aborted with -EAGAIN.

**Parameters**
- `sem` – Address of the semaphore.

unsigned int k_sem_count_get(struct k_sem *sem)
    Get a semaphore’s count.

This routine returns the current count of `sem`.

**Parameters**
- `sem` – Address of the semaphore.

**Returns** Current semaphore count.

**User Mode Semaphore API Reference** The `sys_sem` exists in user memory working as counter semaphore for user mode thread when user mode enabled. When user mode isn’t enabled, `sys_sem` behaves like `k_sem`.

**group** user_semaphore_apis

**Defines**

SYS_SEM_DEFINE(_name, _initial_count, _count_limit)
    Statically define and initialize a `sys_sem`.

The semaphore can be accessed outside the module where it is defined using:

```c
extern struct sys_sem <name>;
```

Route this to memory domains using K_APP_DMEM().

**Parameters**
- `_name` – Name of the semaphore.
- `_initial_count` – Initial semaphore count.
- `_count_limit` – Maximum permitted semaphore count.
Functions

int sys_sem_init(struct sys_sem *sem, unsigned int initial_count, unsigned int limit)
Initialize a semaphore.

This routine initializes a semaphore instance, prior to its first use.

Parameters
• sem – Address of the semaphore.
• initial_count – Initial semaphore count.
• limit – Maximum permitted semaphore count.

Return values
• 0 – Initial success.
• -EINVAL – Bad parameters, the value of limit should be located in (0, INT_MAX] and initial_count shouldn’t be greater than limit.

int sys_sem_give(struct sys_sem *sem)
Give a semaphore.

This routine gives sem, unless the semaphore is already at its maximum permitted count.

Parameters
• sem – Address of the semaphore.

Return values
• 0 – Semaphore given.
• -EINVAL – Parameter address not recognized.
• -EACCES – Caller does not have enough access.
• -EAGAIN – Count reached Maximum permitted count and try again.

int sys_sem_take(struct sys_sem *sem, k_timeout_t timeout)
Take a sys_sem.

This routine takes sem.

Parameters
• sem – Address of the sys_sem.
• timeout – Waiting period to take the sys_sem, or one of the special values K_NO_WAIT and K_FOREVER.

Return values
• 0 – sys_sem taken.
• -EINVAL – Parameter address not recognized.
• -ETIMEDOUT – Waiting period timed out.
• -EACCES – Caller does not have enough access.

unsigned int sys_sem_count_get(struct sys_sem *sem)
Get sys_sem’s value.

This routine returns the current value of sem.

Parameters
• sem – Address of the sys_sem.

Returns Current value of sys_sem.
Mutexes

A mutex is a kernel object that implements a traditional reentrant mutex. A mutex allows multiple threads to safely share an associated hardware or software resource by ensuring mutually exclusive access to the resource.

- **Concepts**
  - Reentrant Locking
  - Priority Inheritance
- **Implementation**
  - Defining a Mutex
  - Locking a Mutex
  - Unlocking a Mutex
- **Suggested Uses**
- **Configuration Options**
- **API Reference**
  - Futex API Reference
  - User Mode Mutex API Reference

**Concepts** Any number of mutexes can be defined (limited only by available RAM). Each mutex is referenced by its memory address.

A mutex has the following key properties:

- A **lock count** that indicates the number of times the mutex has been locked by the thread that has locked it. A count of zero indicates that the mutex is unlocked.
- An **owning thread** that identifies the thread that has locked the mutex, when it is locked.

A mutex must be initialized before it can be used. This sets its lock count to zero.

A thread that needs to use a shared resource must first gain exclusive rights to access it by locking the associated mutex. If the mutex is already locked by another thread, the requesting thread may choose to wait for the mutex to be unlocked.

After locking a mutex, the thread may safely use the associated resource for as long as needed; however, it is considered good practice to hold the lock for as short a time as possible to avoid negatively impacting other threads that want to use the resource. When the thread no longer needs the resource it must unlock the mutex to allow other threads to use the resource.

Any number of threads may wait on a locked mutex simultaneously. When the mutex becomes unlocked it is then locked by the highest-priority thread that has waited the longest.

**Note:** Mutex objects are not designed for use by ISRs.

**Reentrant Locking** A thread is permitted to lock a mutex it has already locked. This allows the thread to access the associated resource at a point in its execution when the mutex may or may not already be locked.

A mutex that is repeatedly locked by a thread must be unlocked an equal number of times before the mutex becomes fully unlocked so it can be claimed by another thread.
Priority Inheritance  The thread that has locked a mutex is eligible for *priority inheritance*. This means the kernel will temporarily elevate the thread's priority if a higher priority thread begins waiting on the mutex. This allows the owning thread to complete its work and release the mutex more rapidly by executing at the same priority as the waiting thread. Once the mutex has been unlocked, the unlocking thread resets its priority to the level it had before locking that mutex.

**Note:** The `CONFIG_PRIORITY_CEILING` configuration option limits how high the kernel can raise a thread's priority due to priority inheritance. The default value of 0 permits unlimited elevation.

When two or more threads wait on a mutex held by a lower priority thread, the kernel adjusts the owning thread's priority each time a thread begins waiting (or gives up waiting). When the mutex is eventually unlocked, the unlocking thread's priority correctly reverts to its original non-elevated priority.

The kernel does *not* fully support priority inheritance when a thread holds two or more mutexes simultaneously. This situation can result in the thread's priority not reverting to its original non-elevated priority when all mutexes have been released. It is recommended that a thread lock only a single mutex at a time when multiple mutexes are shared between threads of different priorities.

### Implementation

**Defining a Mutex**  A mutex is defined using a variable of type `k_mutex`. It must then be initialized by calling `k_mutex_init()`.

The following code defines and initializes a mutex.

```c
define k_mutex my_mutex;
k_mutex_init(&my_mutex);
```

Alternatively, a mutex can be defined and initialized at compile time by calling `K_MUTEX_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_MUTEX_DEFINE(my_mutex);
```

**Locking a Mutex**  A mutex is locked by calling `k_mutex_lock()`.

The following code builds on the example above, and waits indefinitely for the mutex to become available if it is already locked by another thread.

```c
k_mutex_lock(&my_mutex, K_FOREVER);
```

The following code waits up to 100 milliseconds for the mutex to become available, and gives a warning if the mutex does not become available.

```c
if (k_mutex_lock(&my_mutex, K_MSEC(100)) == 0) {
    /* mutex successfully locked */
} else {
    printf("Cannot lock XYZ display\n");
}
```

**Unlocking a Mutex**  A mutex is unlocked by calling `k_mutex_unlock()`.

The following code builds on the example above, and unlocks the mutex that was previously locked by the thread.
k_mutex_unlock(&my_mutex);

**Suggested Uses**
Use a mutex to provide exclusive access to a resource, such as a physical device.

**Configuration Options**
Related configuration options:
- CONFIG_PRIORITY_CEILING

**API Reference**

**group** mutex_apis

**Defines**

```c
K_MUTEX_DEFINE(name)
   Statically define and initialize a mutex.
   The mutex can be accessed outside the module where it is defined using:

   extern struct k_mutex <name>;
```

**Parameters**
- **name** – Name of the mutex.

**Functions**

```c
int k_mutex_init(struct k_mutex *mutex)
   Initialize a mutex.
   This routine initializes a mutex object, prior to its first use.
   Upon completion, the mutex is available and does not have an owner.

   **Parameters**
   - **mutex** – Address of the mutex.

   **Return values**
   0 – Mutex object created
```

```c
int k_mutex_lock(struct k_mutex *mutex, k_timeout_t timeout)
   Lock a mutex.
   This routine locks mutex. If the mutex is locked by another thread, the calling thread waits until the mutex becomes available or until a timeout occurs.
   A thread is permitted to lock a mutex it has already locked. The operation completes immediately and the lock count is increased by 1.
   Mutexes may not be locked in ISRs.

   **Parameters**
   - **mutex** – Address of the mutex.
   - **timeout** – Waiting period to lock the mutex, or one of the special values K_NO_WAIT and K_FOREVER.

   **Return values**
```
### int k_mutex_unlock(struct k_mutex *mutex)

Unlock a mutex.

This routine unlocks `mutex`. The mutex must already be locked by the calling thread.

The mutex cannot be claimed by another thread until it has been unlocked by the calling thread as many times as it was previously locked by that thread.

Mutexes may not be unlocked in ISRs, as mutexes must only be manipulated in thread context due to ownership and priority inheritance semantics.

**Parameters**
- `mutex` – Address of the mutex.

**Return values**
- 0 – Mutex unlocked.
- -EPERM – The current thread does not own the mutex
- -EINVAL – The mutex is not locked

```c
#include <kernel.h>

struct k_mutex

Mutex Structure

Public Members

_wait_q_t wait_q
  Mutex wait queue

struct k_thread *owner
  Mutex owner

uint32_t lock_count
  Current lock count

int owner_orig_prio
  Original thread priority
```

**Futex API Reference**

`k_futex` is a lightweight mutual exclusion primitive designed to minimize kernel involvement. Uncontended operation relies only on atomic access to shared memory. `k_futex` are tracked as kernel objects and can live in user memory so that any access bypasses the kernel object permission management mechanism.

**group futexApis**

**Functions**

`int k_futex_wait(struct k_futex *futex, int expected, k_timeout_t timeout)`

Pend the current thread on a futex.

Tests that the supplied futex contains the expected value, and if so, goes to sleep until some other thread calls `k_futex_wake()` on it.
Parameters

- **futex** – Address of the futex.
- **expected** – Expected value of the futex, if it is different the caller will not wait on it.
- **timeout** – Non-negative waiting period on the futex, or one of the special values K_NO_WAIT or K_FOREVER.

Return values

- **-EACCES** – Caller does not have read access to futex address.
- **-EAGAIN** – If the futex value did not match the expected parameter.
- **-EINVAL** – Futex parameter address not recognized by the kernel.
- **-ETIMEDOUT** – Thread woke up due to timeout and not a futex wakeup.
- **0** – if the caller went to sleep and was woken up. The caller should check the futex’s value on wakeup to determine if it needs to block again.

```c
int k_futex_wake(struct k_futex *futex, bool wake_all)
```

Wake up all threads pending on a futex.

Parameters

- **futex** – Futex to wake up pending threads.
- **wake_all** – If true, wake up all pending threads; If false, wakeup the highest priority thread.

Return values

- **-EACCES** – Caller does not have access to the futex address.
- **-EINVAL** – Futex parameter address not recognized by the kernel.
- **Number** – of threads that were woken up.

User Mode Mutex API Reference

sys_mutex behaves almost exactly like k_mutex, with the added advantage that a sys_mutex instance can reside in user memory. When user mode isn’t enabled, sys_mutex behaves like k_mutex.

```c
#define SYS_MUTEX_DEFINE(name)
```

Statically define and initialize a sys_mutex.

The mutex can be accessed outside the module where it is defined using:

```c
extern struct sys_mutex <name>;
```

Route this to memory domains using K_APP_DMEM().

Parameters

- **name** – Name of the mutex.
Functions

```c
static inline void sys_mutex_init(struct sys_mutex *mutex)
{
    Initialize a mutex.
}
```

This routine initializes a mutex object, prior to its first use. Upon completion, the mutex is available and does not have an owner. This routine is only necessary to call when userspace is disabled and the mutex was not created with `SYS_MUTEX_DEFINE()`.

**Parameters**
- `mutex` – Address of the mutex.

```c
static inline int sys_mutex_lock(struct sys_mutex *mutex, k_timeout_t timeout)
{
    Lock a mutex.
}
```

This routine locks `mutex`. If the mutex is locked by another thread, the calling thread waits until the mutex becomes available or until a timeout occurs. A thread is permitted to lock a mutex it has already locked. The operation completes immediately and the lock count is increased by 1.

**Parameters**
- `mutex` – Address of the mutex, which may reside in user memory
- `timeout` – Waiting period to lock the mutex, or one of the special values `K_NO_WAIT` and `K_FOREVER`.

**Return values**
- 0 – Mutex locked.
- -EBUSY – Returned without waiting.
- -EAGAIN – Waiting period timed out.
- -EACCES – Caller has no access to provided mutex address
- -EINVAL – Provided mutex not recognized by the kernel

```c
static inline int sys_mutex_unlock(struct sys_mutex *mutex)
{
    Unlock a mutex.
}
```

This routine unlocks `mutex`. The mutex must already be locked by the calling thread. The mutex cannot be claimed by another thread until it has been unlocked by the calling thread as many times as it was previously locked by that thread.

**Parameters**
- `mutex` – Address of the mutex, which may reside in user memory

**Return values**
- 0 – Mutex unlocked
- -EACCES – Caller has no access to provided mutex address
- -EINVAL – Provided mutex not recognized by the kernel or mutex wasn’t locked
- -EPERM – Caller does not own the mutex

Condition Variables

A *condition variable* is a synchronization primitive that enables threads to wait until a particular condition occurs.
Concepts  Any number of condition variables can be defined (limited only by available RAM). Each condition variable is referenced by its memory address.

To wait for a condition to become true, a thread can make use of a condition variable.

A condition variable is basically a queue of threads that threads can put themselves on when some state of execution (i.e., some condition) is not as desired (by waiting on the condition). The function `k_condvar_wait()` performs atomically the following steps;

1. Releases the last acquired mutex.
2. Puts the current thread in the condition variable queue.

Some other thread, when it changes said state, can then wake one (or more) of those waiting threads and thus allow them to continue by signaling on the condition using `k_condvar_signal()` or `k_condvar_broadcast()` then it:

1. Re-acquires the mutex previously released.
2. Returns from `k_condvar_wait()`.

A condition variable must be initialized before it can be used.

Implementation

Defining a Condition Variable  A condition variable is defined using a variable of type `k_condvar`. It must then be initialized by calling `k_condvar_init()`.

The following code defines a condition variable:

```c
struct k_condvar my_condvar;

k_condvar_init(&my_condvar);
```

Alternatively, a condition variable can be defined and initialized at compile time by calling `K_CONDVAR_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_CONDVAR_DEFINE(my_condvar);
```

Waiting on a Condition Variable  A thread can wait on a condition by calling `k_condvar_wait()`.

The following code waits on the condition variable.
K_MUTEX_DEFINE(mutex);
K_CONDVAR_DEFINE(condvar)

void main(void)
{
    k_mutex_lock(&mutex, K_FOREVER);
    /* block this thread until another thread signals cond. While
       * blocked, the mutex is released, then re-acquired before this
       * thread is woken up and the call returns.
       */
    k_condvar_wait(&condvar, &mutex, K_FOREVER);
    ...
    k_mutex_unlock(&mutex);
}

Signaling a Condition Variable  A condition variable is signaled on by calling `k_condvar_signal()` for one thread or by calling `k_condvar_broadcast()` for multiple threads.

The following code builds on the example above.

void worker_thread(void)
{
    k_mutex_lock(&mutex, K_FOREVER);
    /*
       * Do some work and fullfill the condition
       */
    ...
    ...
    k_condvar_signal(&condvar);
    k_mutex_unlock(&mutex);
}

Suggested Uses  Use condition variables with a mutex to signal changing states (conditions) from one thread to another thread. Condition variables are not the condition itself and they are not events. The condition is contained in the surrounding programming logic.

Mutexes alone are not designed for use as a notification/synchronization mechanism. They are meant to provide mutually exclusive access to a shared resource only.

Configuration Options  Related configuration options:

• None.

API Reference

group condvar_apis

    Defines

    K_CONDVAR_DEFINE(name)
    Statically define and initialize a condition variable.

    The condition variable can be accessed outside the module where it is defined using:
extern struct k_condvar <name>;

Parameters

• name – Name of the condition variable.

Functions

int k_condvar_init(struct k_condvar *condvar)
Initialize a condition variable.

Parameters

• condvar – pointer to a k_condvar structure

Return values 0 – Condition variable created successfully

int k_condvar_signal(struct k_condvar *condvar)
Signals one thread that is pending on the condition variable.

Parameters

• condvar – pointer to a k_condvar structure

Return values 0 – On success

int k_condvar_broadcast(struct k_condvar *condvar)
Unblock all threads that are pending on the condition variable.

Parameters

• condvar – pointer to a k_condvar structure

Returns An integer with number of woken threads on success

int k_condvar_wait(struct k_condvar *condvar, struct k_mutex *mutex, k_timeout_t timeout)
Waits on the condition variable releasing the mutex lock.

Automatically releases the currently owned mutex, blocks the current thread waiting on the condition variable specified by condvar, and finally acquires the mutex again.

The waiting thread unblocks only after another thread calls k_condvar_signal, or k_condvar_broadcast with the same condition variable.

Parameters

• condvar – pointer to a k_condvar structure
• mutex – Address of the mutex.
• timeout – Waiting period for the condition variable or one of the special values K_NO_WAIT and K_FOREVER.

Return values

• 0 – On success
• -EAGAIN – Waiting period timed out.

Events

An event object is a kernel object that implements traditional events.
Concepts Any number of event objects can be defined (limited only by available RAM). Each event object is referenced by its memory address. One or more threads may wait on an event object until the desired set of events has been delivered to the event object. When new events are delivered to the event object, all threads whose wait conditions have been satisfied become ready simultaneously.

An event object has the following key properties:

- A 32-bit value that tracks which events have been delivered to it.

An event object must be initialized before it can be used.

Events may be delivered by a thread or an ISR. When delivering events, the events may either overwrite the existing set of events or add to them in a bitwise fashion. When overwriting the existing set of events, this is referred to as setting. When adding to them in a bitwise fashion, this is referred to as posting. Both posting and setting events have the potential to fulfill match conditions of multiple threads waiting on the event object. All threads whose match conditions have been met are made active at the same time.

Threads may wait on one or more events. They may either wait for all of the requested events, or for any of them. Furthermore, threads making a wait request have the option of resetting the current set of events tracked by the event object prior to waiting. Care must be taken with this option when multiple threads wait on the same event object.

Note: The kernel does allow an ISR to query an event object, however the ISR must not attempt to wait for the events.

Implementation

Defining an Event Object An event object is defined using a variable of type k_event. It must then be initialized by calling k_event_init().

The following code defines an event object.

```c
struct k_event my_event;

k_event_init(&my_event);
```

Alternatively, an event object can be defined and initialized at compile time by calling K_EVENT_DEFINE.

The following code has the same effect as the code segment above.
K_EVENT_DEFINE(my_event);

**Setting Events**  Events in an event object are set by calling `k_event_set()`.

The following code builds on the example above, and sets the events tracked by the event object to 0x001.

```c
void input_available_interrupt_handler(void *arg)
{
    /* notify threads that data is available */
    k_event_set(&my_event, 0x001);
    ...
}
```

**Posting Events**  Events are posted to an event object by calling `k_event_post()`.

The following code builds on the example above, and posts a set of events to the event object.

```c
void input_available_interrupt_handler(void *arg)
{
    /* notify threads that more data is available */
    k_event_post(&my_event, 0x120);
    ...
}
```

**Waiting for Events**  Threads wait for events by calling `k_event_wait()`.

The following code builds on the example above, and waits up to 50 milliseconds for any of the specified events to be posted. A warning is issued if none of the events are posted in time.

```c
void consumer_thread(void)
{
    uint32_t events;

    events = k_event_wait(&my_event, 0xFFF, false, K_MSEC(50));
    if (events == 0) {
        printk("No input devices are available!");
    } else {
        /* Access the desired input device(s) */
        ...
    }
    ...
}
```

Alternatively, the consumer thread may desire to wait for all the events before continuing.

```c
void consumer_thread(void)
{
    uint32_t events;
    (continues on next page)```
events = k_event_wait_all(&my_event, 0x121, false, K_MSEC(50));
if (events == 0) {
    printk("At least one input device is not available!");
} else {
    /* Access the desired input devices */
    ...
    }
    ...
}

**Suggested Uses**  Use events to indicate that a set of conditions have occurred.
Use events to pass small amounts of data to multiple threads at once.

**Configuration Options**  Related configuration options:
- CONFIG_EVENTS

**API Reference**

group event_apis

**Defines**

K_EVENT_DEFINE(name)
  Statically define and initialize an event object.
  The event can be accessed outside the module where it is defined using:

  extern struct k_event <name>;

**Parameters**

- name – Name of the event object.

**Functions**

void k_event_init(struct k_event *event)
  Initialize an event object.
  This routine initializes an event object, prior to its first use.

**Parameters**

- event – Address of the event object.

void k_event_post(struct k_event *event, uint32_t events)
  Post one or more events to an event object.
  This routine posts one or more events to an event object. All tasks waiting on the event object event whose waiting conditions become met by this posting immediately unpend.
  Posting differs from setting in that posted events are merged together with the current set of events tracked by the event object.
Parameters

- `event` – Address of the event object
- `events` – Set of events to post to `event`

```c
void k_event_set(struct k_event *event, uint32_t events)
```

Set the events in an event object.

This routine sets the events stored in event object to the specified value. All tasks waiting on the event object `event` whose waiting conditions become met by this immediately unpend.

Setting differs from posting in that set events replace the current set of events tracked by the event object.

Parameters

- `event` – Address of the event object
- `events` – Set of events to post to `event`

```c
uint32_t k_event_wait(struct k_event *event, uint32_t events, bool reset, k_timeout_t timeout)
```

Wait for any of the specified events.

This routine waits on event object `event` until any of the specified events have been delivered to the event object, or the maximum wait time `timeout` has expired. A thread may wait on up to 32 distinctly numbered events that are expressed as bits in a single 32-bit word.

**Note:** The caller must be careful when resetting if there are multiple threads waiting for the event object `event`.

```c
uint32_t k_event_wait_all(struct k_event *event, uint32_t events, bool reset, k_timeout_t timeout)
```

Wait for any of the specified events.

This routine waits on event object `event` until all of the specified events have been delivered to the event object, or the maximum wait time `timeout` has expired. A thread may wait on up to 32 distinctly numbered events that are expressed as bits in a single 32-bit word.

**Note:** The caller must be careful when resetting if there are multiple threads waiting for the event object `event`.
• **reset** – If true, clear the set of events tracked by the event object before waiting. If false, do not clear the events.

• **timeout** – Waiting period for the desired set of events or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**

• **set** – of matching events upon success

• **0** – if matching events were not received within the specified time

```c
struct k_event
#include <kernel.h> Event Structure
```

## Symmetric Multiprocessing

On multiprocessor architectures, Zephyr supports the use of multiple physical CPUs running Zephyr application code. This support is “symmetric” in the sense that no specific CPU is treated specially by default. Any processor is capable of running any Zephyr thread, with access to all standard Zephyr APIs supported.

No special application code needs to be written to take advantage of this feature. If there are two Zephyr application threads runnable on a supported dual processor device, they will both run simultaneously.

SMP configuration is controlled under the `CONFIG_SMP` kconfig variable. This must be set to “y” to enable SMP features, otherwise a uniprocessor kernel will be built. In general the platform default will have enabled this anywhere it’s supported. When enabled, the number of physical CPUs available is visible at build time as `CONFIG_MP_NUM_CPUS`. Likewise, the default for this will be the number of available CPUs on the platform and it is not expected that typical apps will change it. But it is legal and supported to set this to a smaller (but obviously not larger) number for special purposes (e.g. for testing, or to reserve a physical CPU for running non-Zephyr code).

#### Synchronization

At the application level, core Zephyr IPC and synchronization primitives all behave identically under an SMP kernel. For example semaphores used to implement blocking mutual exclusion continue to be a proper application choice.

At the lowest level, however, Zephyr code has often used the `irq_lock() / irq_unlock()` primitives to implement fine grained critical sections using interrupt masking. These APIs continue to work via an emulation layer (see below), but the masking technique does not: the fact that your CPU will not be interrupted while you are in your critical section says nothing about whether a different CPU will be running simultaneously and be inspecting or modifying the same data!

#### Spinlocks

SMP systems provide a more constrained `k_spin_lock()` primitive that not only masks interrupts locally, as done by `irq_lock()`, but also atomically validates that a shared lock variable has been modified before returning to the caller, “spinning” on the check if needed to wait for the other CPU to exit the lock. The default Zephyr implementation of `k_spin_lock()` and `k_spin_unlock()` is built on top of the pre-existing `atomic_layer` (itself usually implemented using compiler intrinsics), though facilities exist for architectures to define their own for performance reasons.

One important difference between IRQ locks and spinlocks is that the earlier API was naturally recursive: the lock was global, so it was legal to acquire a nested lock inside of a critical section. Spinlocks are separable: you can have many locks for separate subsystems or data structures, preventing CPUs from contending on a single global resource. But that means that spinlocks must not be used recursively. Code that holds a specific lock must not try to re-acquire it or it will deadlock (it is perfectly legal to nest distinct spinlocks, however). A validation layer is available to detect and report bugs like this.

When used on a uniprocessor system, the data component of the spinlock (the atomic lock variable) is unnecessary and elided. Except for the recursive semantics above, spinlocks in single-CPU contexts
produce identical code to legacy IRQ locks. In fact the entirety of the Zephyr core kernel has now been ported to use spinlocks exclusively.

**Legacy irq_lock() emulation** For the benefit of applications written to the uniprocessor locking API, `irq_lock()` and `irq_unlock()` continue to work compatibly on SMP systems with identical semantics to their legacy versions. They are implemented as a single global spinlock, with a nesting count and the ability to be atomically reacquired on context switch into locked threads. The kernel will ensure that only one thread across all CPUs can hold the lock at any time, that it is released on context switch, and that it is re-acquired when necessary to restore the lock state when a thread is switched in. Other CPUs will spin waiting for the release to happen.

The overhead involved in this process has measurable performance impact, however. Unlike uniprocessor apps, SMP apps using `irq_lock()` are not simply invoking a very short (often ~1 instruction) interrupt masking operation. That, and the fact that the IRQ lock is global, means that code expecting to be run in an SMP context should be using the spinlock API wherever possible.

**CPU Mask** It is often desirable for real time applications to deliberately partition work across physical CPUs instead of relying solely on the kernel scheduler to decide on which threads to execute. Zephyr provides an API, controlled by the `CONFIG_SCHED_CPU_MASK` kconfig variable, which can associate a specific set of CPUs with each thread, indicating on which CPUs it can run.

By default, new threads can run on any CPU. Calling `k_thread_cpu_mask_disable()` with a particular CPU ID will prevent that thread from running on that CPU in the future. Likewise `k_thread_cpu_mask_enable()` will re-enable execution. There are also `k_thread_cpu_mask_clear()` and `k_thread_cpu_mask_enable_all()` APIs available for convenience. For obvious reasons, these APIs are illegal if called on a runnable thread. The thread must be blocked or suspended, otherwise an `-EINVAL` will be returned.

Note that when this feature is enabled, the scheduler algorithm involved in doing the per-CPU mask test requires that the list be traversed in full. The kernel does not keep a per-CPU run queue. That means that the performance benefits from the `CONFIG_SCHED_SCALABLE` and `CONFIG_SCHED_MULTIQ` scheduler backends cannot be realized. CPU mask processing is available only when `CONFIG_SCHED_DUMB` is the selected backend. This requirement is enforced in the configuration layer.

**SMP Boot Process** A Zephyr SMP kernel begins boot identically to a uniprocessor kernel. Auxiliary CPUs begin in a disabled state in the architecture layer. All standard kernel initialization, including device initialization, happens on a single CPU before other CPUs are brought online.

Just before entering the application `main()` function, the kernel calls `z_smp_init()` to launch the SMP initialization process. This enumerates over the configured CPUs, calling into the architecture layer using `arch_start_cpu()` for each one. This function is passed a memory region to use as a stack on the foreign CPU (in practice it uses the area that will become that CPU's interrupt stack), the address of a local `smp_init_top()` callback function to run on that CPU, and a pointer to a “start flag” address which will be used as an atomic signal.

The local SMP initialization (`smp_init_top()` on each CPU is then invoked by the architecture layer. Note that interrupts are still masked at this point. This routine is responsible for calling `smp_timer_init()` to set up any needed stat in the timer driver. On many architectures the timer is a per-CPU device and needs to be configured specially on auxiliary CPUs. Then it waits (spinning) for the atomic “start flag” to be released in the main thread, to guarantee that all SMP initialization is complete before any Zephyr application code runs, and finally calls `z_swap()` to transfer control to the appropriate runnable thread via the standard scheduler API.

**Interprocessor Interrupts** When running in multiprocessor environments, it is occasionally the case that state modified on the local CPU needs to be synchronously handled on a different processor.
Fig. 7.2: Example SMP initialization process, showing a configuration with two CPUs and two app threads which begin operating simultaneously.
One example is the Zephyr \texttt{k\_thread\_abort()} API, which cannot return until the thread that had been aborted is no longer runnable. If it is currently running on another CPU, that becomes difficult to implement.

Another is low power idle. It is a firm requirement on many devices that system idle be implemented using a low-power mode with as many interrupts (including periodic timer interrupts) disabled or deferred as is possible. If a CPU is in such a state, and on another CPU a thread becomes runnable, the idle CPU has no way to “wake up” to handle the newly-runnable load.

So where possible, Zephyr SMP architectures should implement an interprocessor interrupt. The current framework is very simple: the architecture provides a \texttt{arch\_sched\_ipi()} call, which when invoked will flag an interrupt on all CPUs (except the current one, though that is allowed behavior) which will then invoke the \texttt{z\_sched\_ipi()} function implemented in the scheduler. The expectation is that these APIs will evolve over time to encompass more functionality (e.g. cross-CPU calls), and that the scheduler-specific calls here will be implemented in terms of a more general framework.

Note that not all SMP architectures will have a usable IPI mechanism (either missing, or just undocumented/unimplemented). In those cases Zephyr provides fallback behavior that is correct, but perhaps suboptimal.

Using this, \texttt{k\_thread\_abort()} becomes only slightly more complicated in SMP: for the case where a thread is actually running on another CPU (we can detect this atomically inside the scheduler), we broadcast an IPI and spin, waiting for the thread to either become “DEAD” or for it to re-enter the queue (in which case we terminate it the same way we would have in uniprocessor mode). Note that the “aborted” check happens on any interrupt exit, so there is no special handling needed in the IPI per se. This allows us to implement a reasonable fallback when IPI is not available: we can simply spin, waiting until the foreign CPU receives any interrupt, though this may be a much longer time!

Likewise idle wakeups are trivially implementable with an empty IPI handler. If a thread is added to an empty run queue (i.e. there may have been idle CPUs), we broadcast an IPI. A foreign CPU will then be able to see the new thread when exiting from the interrupt and will switch to it if available.

Without an IPI, however, a low power idle that requires an interrupt will not work to synchronously run new threads. The workaround in that case is more invasive: Zephyr will not enter the system idle handler and will instead spin in its idle loop, testing the scheduler state at high frequency (not spinning on it though, as that would involve severe lock contention) for new threads. The expectation is that power constrained SMP applications are always going to provide an IPI, and this code will only be used for testing purposes or on systems without power consumption requirements.

### SMP Kernel Internals

In general, Zephyr kernel code is SMP-agnostic and, like application code, will work correctly regardless of the number of CPUs available. But in a few areas there are notable changes in structure or behavior.

#### Per-CPU data

Many elements of the core kernel data need to be implemented for each CPU in SMP mode. For example, the \texttt{\_current} thread pointer obviously needs to reflect what is running locally, there are many threads running concurrently. Likewise a kernel-provided interrupt stack needs to be created and assigned for each physical CPU, as does the interrupt nesting count used to detect ISR state.

These fields are now moved into a separate struct \texttt{\_cpu} instance within the \texttt{\_kernel} struct, which has a \texttt{cpus[]} array indexed by ID. Compatibility fields are provided for legacy uniprocessor code trying to access the fields of \texttt{cpus[0]} using the older syntax and assembly offsets.

Note that an important requirement on the architecture layer is that the pointer to this CPU struct be available rapidly when in kernel context. The expectation is that \texttt{arch\_curr\_cpu()} will be implemented using a CPU-provided register or addressing mode that can store this value across arbitrary context switches or interrupts and make it available to any kernel-mode code.

Similarly, where on a uniprocessor system Zephyr could simply create a global “idle thread” at the lowest priority, in SMP we may need one for each CPU. This makes the internal predicate test for “\texttt{\_is\_idle()}” in the scheduler, which is a hot path performance environment, more complicated than simply testing the
thread pointer for equality with a known static variable. In SMP mode, idle threads are distinguished by a separate field in the thread struct.

**Switch-based context switching**  The traditional Zephyr context switch primitive has been `z_swap()`. Unfortunately, this function takes no argument specifying a thread to switch to. The expectation has always been that the scheduler has already made its preemption decision when its state was last modified and cached the resulting “next thread” pointer in a location where architecture context switch primitives can find it via a simple struct offset. That technique will not work in SMP, because the other CPU may have modified scheduler state since the current CPU last exited the scheduler (for example: it might already be running that cached thread!).

Instead, the SMP “switch to” decision needs to be made synchronously with the swap call, and as we don’t want per-architecture assembly code to be handling scheduler internal state, Zephyr requires a somewhat lower-level context switch primitives for SMP systems: `arch_switch()` is always called with interrupts masked, and takes exactly two arguments. The first is an opaque (architecture defined) handle to the context to which it should switch, and the second is a pointer to such a handle into which it should store the handle resulting from the thread that is being switched out.

The kernel then implements a portable `z_swap()` implementation on top of this primitive which includes the relevant scheduler logic in a location where the architecture doesn’t need to understand it. Similarly, on interrupt exit, switch-based architectures are expected to call `z_get_next_switch_handle()` to retrieve the next thread to run from the scheduler, passing in an “interrupted” handle reflecting the same opaque type used by switch, which the kernel will then save in the interrupted thread struct.

Note that while SMP requires `CONFIG_USE_SWITCH`, the reverse is not true. A uniprocessor architecture built with `CONFIG_SMP` set to No might still decide to implement its context switching using `arch_switch()`.

**API Reference**

`group spinlock_apis`
Spinlock APIs.

**Typedefs**

```c
typedef struct z_spinlock_key k_spinlock_key_t
Spinlock key type.
```

This type defines a “key” value used by a spinlock implementation to store the system interrupt state at the time of a call to `k_spin_lock()`. It is expected to be passed to a matching `k_spin_unlock()`.

This type is opaque and should not be inspected by application code.

**Functions**

```c
ALWAYS_INLINE static k_spinlock_key_t k_spin_lock(struct k_spinlock *l)
Lock a spinlock.
```

This routine locks the specified spinlock, returning a key handle representing interrupt state needed at unlock time. Upon returning, the calling thread is guaranteed not to be suspended or interrupted on its current CPU until it calls `k_spin_unlock()`. The implementation guarantees mutual exclusion: exactly one thread on one CPU will return from `k_spin_lock()` at a time. Other CPUs trying to acquire a lock already held by another CPU will enter an implementation-defined busy loop (“spinning”) until the lock is released.
Separate spin locks may be nested. It is legal to lock an (unlocked) spin lock while holding a different lock. Spin locks are not recursive, however: an attempt to acquire a spin lock that the CPU already holds will deadlock.

In circumstances where only one CPU exists, the behavior of `k_spin_lock()` remains as specified above, though obviously no spinning will take place. Implementations may be free to optimize in uniprocessor contexts such that the locking reduces to an interrupt mask operation.

**Parameters**

- `l` – A pointer to the spinlock to lock

**Returns** A key value that must be passed to `k_spin_unlock()` when the lock is released.

```
 ALWAYS_INLINE static void k_spin_unlock(struct k_spinlock *l, k_spinlock_key_t key)
 Unlock a spin lock.
```

This releases a lock acquired by `k_spin_lock()`. After this function is called, any CPU will be able to acquire the lock. If other CPUs are currently spinning inside `k_spin_lock()` waiting for this lock, exactly one of them will return synchronously with the lock held.

Spin locks must be properly nested. A call to `k_spin_unlock()` must be made on the lock object most recently locked using `k_spin_lock()`, using the key value that it returned. Attempts to unlock mis-nested locks, or to unlock locks that are not held, or to passing a key parameter other than the one returned from `k_spin_lock()`, are illegal. When CONFIG_SPIN_VALIDATE is set, some of these errors can be detected by the framework.

**Parameters**

- `l` – A pointer to the spinlock to release
- `key` – The value returned from `k_spin_lock()` when this lock was acquired

```
 ALWAYS_INLINE static void k_spin_release(struct k_spinlock *l)
```

```
struct k_spinlock
 #include <spinlock.h> Kernel Spin Lock.
```

This struct defines a spin lock record on which CPUs can wait with `k_spin_lock()`. Any number of spinlocks may be defined in application code.

### 7.14.2 Data Passing

These pages cover kernel objects which can be used to pass data between threads and ISRs.

The following table summarizes their high-level features.
Queues

A Queue in Zephyr is a kernel object that implements a traditional queue, allowing threads and ISRs to add and remove data items of any size. The queue is similar to a FIFO and serves as the underlying implementation for both `k_fifo` and `k_lifo`. For more information on usage see `k_fifo`.

Configuration Options

- None

API Reference

group queue_apis

Defines

\[ \text{K_QUEUE_DEFINE(name)} \]

Statically define and initialize a queue.

The queue can be accessed outside the module where it is defined using:

\[
\text{extern struct k_queue <name>;}\]

Parameters

- name – Name of the queue.
Functions

void k_queue_init(struct k_queue *queue)
Initialize a queue.

This routine initializes a queue object, prior to its first use.

Parameters
• queue – Address of the queue.

void k_queue_cancel_wait(struct k_queue *queue)
Cancel waiting on a queue.

This routine causes first thread pending on queue, if any, to return from k_queue_get() call with NULL value (as if timeout expired). If the queue is being waited on by k_poll(), it will return with -EINTR and K_POLL_STATE_CANCELLED state (and per above, subsequent k_queue_get() will return NULL).

Function properties (list may not be complete) isr-ok

Parameters
• queue – Address of the queue.

void k_queue_append(struct k_queue *queue, void *data)
Append an element to the end of a queue.

This routine appends a data item to queue. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel’s use.

Function properties (list may not be complete) isr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

int32_t k_queue_alloc_append(struct k_queue *queue, void *data)
Append an element to a queue.

This routine appends a data item to queue. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread’s resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete) isr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

Return values
• 0 – on success
• -ENOMEM – if there isn’t sufficient RAM in the caller’s resource pool
void k_queue_prepend(struct k_queue *queue, void *data)
    Prepend an element to a queue.

This routine prepends a data item to queue. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel’s use.

**Function properties (list may not be complete) isr-ok**

**Parameters**
- `queue` – Address of the queue.
- `data` – Address of the data item.

int32_t k_queue_alloc_prepend(struct k_queue *queue, void *data)
    Prepend an element to a queue.

This routine prepends a data item to queue. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread’s resource pool, which is automatically freed when the item is removed. The data itself is not copied.

**Function properties (list may not be complete) isr-ok**

**Parameters**
- `queue` – Address of the queue.
- `data` – Address of the data item.

**Return values**
- 0 – on success
- -ENOMEM – if there isn’t sufficient RAM in the caller’s resource pool

void k_queue_insert(struct k_queue *queue, void *prev, void *data)
    Inserts an element to a queue.

This routine inserts a data item to queue after previous item. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel’s use.

**Function properties (list may not be complete) isr-ok**

**Parameters**
- `queue` – Address of the queue.
- `prev` – Address of the previous data item.
- `data` – Address of the data item.

int k_queue_append_list(struct k_queue *queue, void *head, void *tail)
    Atomically append a list of elements to a queue.

This routine adds a list of data items to queue in one operation. The data items must be in a singly-linked list, with the first word in each data item pointing to the next data item; the list must be NULL-terminated.

**Function properties (list may not be complete) isr-ok**

**Parameters**
- queue – Address of the queue.
- head – Pointer to first node in singly-linked list.
- tail – Pointer to last node in singly-linked list.

**Return values**
- 0 – on success
- -EINVAL – on invalid supplied data

```c
int k_queue_merge_slist(struct k_queue *queue, sys_slist_t *list)
```

Atomically add a list of elements to a queue.

This routine adds a list of data items to `queue` in one operation. The data items must be in a singly-linked list implemented using a `sys_slist_t` object. Upon completion, the original list is empty.

**Function properties (list may not be complete) isr-ok**

**Parameters**
- `queue` – Address of the queue.
- `list` – Pointer to `sys_slist_t` object.

**Return values**
- 0 – on success
- -EINVAL – on invalid data

```c
void *k_queue_get(struct k_queue *queue, k_timeout_t timeout)
```

Get an element from a queue.

This routine removes first data item from `queue`. The first word of the data item is reserved for the kernel's use.

**Function properties (list may not be complete) isr-ok**

**Note:** `timeout` must be set to `K_NO_WAIT` if called from ISR.

**Parameters**
- `queue` – Address of the queue.
- `timeout` – Non-negative waiting period to obtain a data item or one of the special values `K_NO_WAIT` and `K_FOREVER`.

**Returns** Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

```c
bool k_queue_remove(struct k_queue *queue, void *data)
```

Remove an element from a queue.

This routine removes data item from `queue`. The first word of the data item is reserved for the kernel's use. Removing elements from `k_queue` rely on `sys_slist_find_and_remove` which is not a constant time operation.

**Function properties (list may not be complete) isr-ok**
**Note:** `timeout` must be set to `K_NO_WAIT` if called from ISR.

### Parameters
- `queue` – Address of the queue.
- `data` – Address of the data item.

### Returns
- `true` if data item was removed

```c
bool k_queue_unique_append(struct k_queue *queue, void *data)
```

Append an element to a queue only if it's not present already.

This routine appends data item to `queue`. The first word of the data item is reserved for the kernel's use. Appending elements to `k_queue` relies on `sys_slist_is_node_in_list` which is not a constant time operation.

**Function properties (list may not be complete)** `isr-ok`

### Parameters
- `queue` – Address of the queue.
- `data` – Address of the data item.

### Returns
- `true` if data item was added, `false` if not

```c
int k_queue_is_empty(struct k_queue *queue)
```

Query a queue to see if it has data available.

Note that the data might be already gone by the time this function returns if other threads are also trying to read from the queue.

**Function properties (list may not be complete)** `isr-ok`

### Parameters
- `queue` – Address of the queue.

### Returns
- Non-zero if the queue is empty.
- `0` if data is available.

```c
void *k_queue_peek_head(struct k_queue *queue)
```

Peek element at the head of queue.

Return element from the head of queue without removing it.

### Parameters
- `queue` – Address of the queue.

### Returns
- `Head element, or NULL if queue is empty.`

```c
void *k_queue_peek_tail(struct k_queue *queue)
```

Peek element at the tail of queue.

Return element from the tail of queue without removing it.

### Parameters
- `queue` – Address of the queue.

### Returns
- `Tail element, or NULL if queue is empty.`
FIFOs

A FIFO is a kernel object that implements a traditional first in, first out (FIFO) queue, allowing threads and ISRs to add and remove data items of any size.

Concepts

Any number of FIFOs can be defined (limited only by available RAM). Each FIFO is referenced by its memory address.

A FIFO has the following key properties:

- A queue of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A FIFO must be initialized before it can be used. This sets its queue to empty.

FIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_fifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread's resource pool.

A data item may be added to a FIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the FIFO's queue. There is no limit to the number of items that may be queued.

A data item may be removed from a FIFO by a thread. If the FIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty FIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note: The kernel does allow an ISR to remove an item from a FIFO, however the ISR must not attempt to wait if the FIFO is empty.

If desired, multiple data items can be added to a FIFO in a single operation if they are chained together into a singly-linked list. This capability can be useful if multiple writers are adding sets of related data items to the FIFO, as it ensures the data items in each set are not interleaved with other data items. Adding multiple data items to a FIFO is also more efficient than adding them one at a time, and can be used to guarantee that anyone who removes the first data item in a set will be able to remove the remaining data items without waiting.

Implementation

Defining a FIFO

A FIFO is defined using a variable of type `k_fifo`. It must then be initialized by calling `k_fifo_init()`. 
The following code defines and initializes an empty FIFO.

```c
struct k_fifo my_fifo;
k_fifo_init(&my_fifo);
```

Alternatively, an empty FIFO can be defined and initialized at compile time by calling `K_FIFO_DEFINE`. The following code has the same effect as the code segment above.

```c
K_FIFO_DEFINE(my_fifo);
```

**Writing to a FIFO**  A data item is added to a FIFO by calling `k_fifo_put()`.

The following code builds on the example above, and uses the FIFO to send data to one or more consumer threads.

```c
struct data_item_t {
    void *fifo_reserved;  /* 1st word reserved for use by FIFO */
    ...
};
struct data_item_t tx_data;

does producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...

        /* send data to consumers */
        k_fifo_put(&my_fifo, &tx_data);

        ...
    }
}
```

Additionally, a singly-linked list of data items can be added to a FIFO by calling `k_fifo_put_list()` or `k_fifo_put_slist()`.

Finally, a data item can be added to a FIFO with `k_fifo_alloc_put()`. With this API, there is no need to reserve space for the kernel’s use in the data item, instead additional memory will be allocated from the calling thread’s resource pool until the item is read.

**Reading from a FIFO**  A data item is removed from a FIFO by calling `k_fifo_get()`.

The following code builds on the example above, and uses the FIFO to obtain data items from a producer thread, which are then processed in some manner.

```c
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t *rx_data;

    while (1) {
        rx_data = k_fifo_get(&my_fifo, K_FOREVER);

        /* process FIFO data item */
        ...
    }
}
```
Suggested Uses  Use a FIFO to asynchronously transfer data items of arbitrary size in a “first in, first out” manner.

Configuration Options  Related configuration options:
  • None

API Reference

**group fifo_apis**

**Defines**

k_fifo_init(fifo)
   Initialize a FIFO queue.
   This routine initializes a FIFO queue, prior to its first use.
   **Parameters**
   • fifo – Address of the FIFO queue.

k_fifo_cancel_wait(fifo)
   Cancel waiting on a FIFO queue.
   This routine causes first thread pending on fifo, if any, to return from k_fifo_get() call with NULL value (as if timeout expired).
   **Function properties (list may not be complete)**  isr-ok
   **Parameters**
   • fifo – Address of the FIFO queue.

k_fifo_put(fifo, data)
   Add an element to a FIFO queue.
   This routine adds a data item to fifo. A FIFO data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.
   **Function properties (list may not be complete)**  isr-ok
   **Parameters**
   • fifo – Address of the FIFO.
   • data – Address of the data item.

k_fifo_alloc_put(fifo, data)
   Add an element to a FIFO queue.
   This routine adds a data item to fifo. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.
Function properties (list may not be complete) \textit{isr-ok}

Parameters
- \textit{fifo} – Address of the FIFO.
- \textit{data} – Address of the data item.

Return values
- \textit{0} – on success
- \texttt{-ENOMEM} – if there isn’t sufficient RAM in the caller’s resource pool

\texttt{k_fifo_put_list(fifo, head, tail)}
Atomically add a list of elements to a FIFO.
This routine adds a list of data items to \textit{fifo} in one operation. The data items must be in a singly-linked list, with the first word of each data item pointing to the next data item; the list must be NULL-terminated.

Function properties (list may not be complete) \textit{isr-ok}

Parameters
- \textit{fifo} – Address of the FIFO queue.
- \textit{head} – Pointer to first node in singly-linked list.
- \textit{tail} – Pointer to last node in singly-linked list.

\texttt{k_fifo_put_slist(fifo, list)}
Atomically add a list of elements to a FIFO queue.
This routine adds a list of data items to \textit{fifo} in one operation. The data items must be in a singly-linked list implemented using a \texttt{sys_slist_t} object. Upon completion, the \texttt{sys_slist_t} object is invalid and must be re-initialized via \texttt{sys_slist_init()}.

Function properties (list may not be complete) \textit{isr-ok}

Parameters
- \textit{fifo} – Address of the FIFO queue.
- \textit{list} – Pointer to \texttt{sys_slist_t} object.

\texttt{k_fifo_get(fifo, timeout)}
Get an element from a FIFO queue.
This routine removes a data item from \textit{fifo} in a “first in, first out” manner. The first word of the data item is reserved for the kernel’s use.

Function properties (list may not be complete) \textit{isr-ok}

\underline{Note:} \textit{timeout} must be set to \texttt{K_NO_WAIT} if called from ISR.

Parameters
- \textit{fifo} – Address of the FIFO queue.
• timeout – Waiting period to obtain a data item, or one of the special values K_NO_WAIT and K_FOREVER.

Returns Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

k_fifo_is_empty(fifo)
Query a FIFO queue to see if it has data available.
Note that the data might be already gone by the time this function returns if other threads is also trying to read from the FIFO.

Function properties (list may not be complete) isr-ok

Parameters
• fifo – Address of the FIFO queue.

Returns Non-zero if the FIFO queue is empty.

Returns 0 if data is available.

k_fifo_peek_head(fifo)
Peek element at the head of a FIFO queue.
Return element from the head of FIFO queue without removing it. A usecase for this is if elements of the FIFO object are themselves containers. Then on each iteration of processing, a head container will be peeked, and some data processed out of it, and only if the container is empty, it will be completely remove from the FIFO queue.

Parameters
• fifo – Address of the FIFO queue.

Returns Head element, or NULL if the FIFO queue is empty.

k_fifo_peek_tail(fifo)
Peek element at the tail of FIFO queue.
Return element from the tail of FIFO queue (without removing it). A usecase for this is if elements of the FIFO queue are themselves containers. Then it may be useful to add more data to the last container in a FIFO queue.

Parameters
• fifo – Address of the FIFO queue.

Returns Tail element, or NULL if a FIFO queue is empty.

K_FIFO_DEFINE(name)
Statically define and initialize a FIFO queue.
The FIFO queue can be accessed outside the module where it is defined using:

extern struct k_fifo <name>;

Parameters
• name – Name of the FIFO queue.
LIFOs

A LIFO is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove data items of any size.

Concepts

Any number of LIFOs can be defined (limited only by available RAM). Each LIFO is referenced by its memory address.

A LIFO has the following key properties:

- A queue of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A LIFO must be initialized before it can be used. This sets its queue to empty.

LIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_lifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread's resource pool.

A data item may be added to a LIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the LIFO's queue. There is no limit to the number of items that may be queued.

A data item may be removed from a LIFO by a thread. If the LIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty LIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note: The kernel does allow an ISR to remove an item from a LIFO, however the ISR must not attempt to wait if the LIFO is empty.

Implementation

Defining a LIFO

A LIFO is defined using a variable of type `k_lifo`. It must then be initialized by calling `k_lifo_init()`.

The following defines and initializes an empty LIFO.

```c
struct k_lifo my_lifo;

k_lifo_init(&my_lifo);
```
Alternatively, an empty LIFO can be defined and initialized at compile time by calling \texttt{K\_LIFO\_DEFINE}.
The following code has the same effect as the code segment above.

\texttt{K\_LIFO\_DEFINE(my\_lifo);}

\paragraph{Writing to a LIFO} A data item is added to a LIFO by calling \texttt{k\_lifo\_put()}. The following code builds on the example above, and uses the LIFO to send data to one or more consumer threads.

\begin{verbatim}
struct data_item_t {
    void *LIFO\_reserved; /* 1st word reserved for use by LIFO */
    ...
};
struct data_item_t tx\_data;

void producer\_thread(int unused1, int unused2, int unused3) {
    while (1) {
        /* create data item to send */
        tx\_data = ...;
        /* send data to consumers */
        k\_lifo\_put(&my\_lifo, &tx\_data);
        ...
    }
}
\end{verbatim}

A data item can be added to a LIFO with \texttt{k\_lifo\_alloc\_put()}. With this API, there is no need to reserve space for the kernel’s use in the data item, instead additional memory will be allocated from the calling thread’s resource pool until the item is read.

\paragraph{Reading from a LIFO} A data item is removed from a LIFO by calling \texttt{k\_lifo\_get()}. The following code builds on the example above, and uses the LIFO to obtain data items from a producer thread, which are then processed in some manner.

\begin{verbatim}
void consumer\_thread(int unused1, int unused2, int unused3) {
    struct data\_item\_t *rx\_data;
    while (1) {
        rx\_data = k\_lifo\_get(&my\_lifo, K\_FOREVER);
        /* process LIFO data item */
        ...
    }
}
\end{verbatim}

\paragraph{Suggested Uses} Use a LIFO to asynchronously transfer data items of arbitrary size in a “last in, first out” manner.

**Configuration Options**

**API Reference**

*group lifo_apis*

**Defines**

- **k_lifo_init(lifo)**  
  Initialize a LIFO queue.  
  This routine initializes a LIFO queue object, prior to its first use.  
  **Parameters**  
  - lifo – Address of the LIFO queue.

- **k_lifo_put(lifo, data)**  
  Add an element to a LIFO queue.  
  This routine adds a data item to lifo. A LIFO queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

  **Function properties (list may not be complete)**  
  * isr-ok*  
  **Parameters**  
  - lifo – Address of the LIFO queue.
  - data – Address of the data item.

- **k_lifo_alloc_put(lifo, data)**  
  Add an element to a LIFO queue.  
  This routine adds a data item to lifo. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

  **Function properties (list may not be complete)**  
  * isr-ok*  
  **Parameters**  
  - lifo – Address of the LIFO.
  - data – Address of the data item.

  **Return values**  
  - 0 – on success
  - -ENOMEM – if there isn't sufficient RAM in the caller's resource pool

- **k_lifo_get(lifo, timeout)**  
  Get an element from a LIFO queue.  
  This routine removes a data item from LIFO in a "last in, first out" manner. The first word of the data item is reserved for the kernel's use.

  **Function properties (list may not be complete)**  
  * isr-ok*
Note: `timeout` must be set to K_NO_WAIT if called from ISR.

Parameters

- `lifo` – Address of the LIFO queue.
- `timeout` – Waiting period to obtain a data item, or one of the special values K_NO_WAIT and K_FOREVER.

Returns Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

```
K_LIFO_DEFINE(name)
Statically define and initialize a LIFO queue.
```

The LIFO queue can be accessed outside the module where it is defined using:

```
extern struct k_lifo <name>;
```

Parameters

- `name` – Name of the fifo.

Stacks

A stack is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove a limited number of integer data values.

- Concepts
- Implementation
  - Defining a Stack
  - Pushing to a Stack
  - Popping from a Stack
- Suggested Uses
- Configuration Options
- API Reference

Concepts Any number of stacks can be defined (limited only by available RAM). Each stack is referenced by its memory address.

A stack has the following key properties:

- A queue of integer data values that have been added but not yet removed. The queue is implemented using an array of `stack_data_t` values and must be aligned on a native word boundary. The `stack_data_t` type corresponds to the native word size i.e. 32 bits or 64 bits depending on the CPU architecture and compilation mode.

- A maximum quantity of data values that can be queued in the array.

A stack must be initialized before it can be used. This sets its queue to empty.

A data value can be added to a stack by a thread or an ISR. The value is given directly to a waiting thread, if one exists; otherwise the value is added to the LIFO’s queue.
Note: If CONFIG_NO_RUNTIME_CHECKS is enabled, the kernel will not detect and prevent attempts to add a data value to a stack that has already reached its maximum quantity of queued values. Adding a data value to a stack that is already full will result in array overflow, and lead to unpredictable behavior.

A data value may be removed from a stack by a thread. If the stack's queue is empty a thread may choose to wait for it to be given. Any number of threads may wait on an empty stack simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note: The kernel does allow an ISR to remove an item from a stack, however the ISR must not attempt to wait if the stack is empty.

Implementation

Defining a Stack  A stack is defined using a variable of type k_stack. It must then be initialized by calling k_stack_init() or k_stack_alloc_init(). In the latter case, a buffer is not provided and it is instead allocated from the calling thread’s resource pool.

The following code defines and initializes an empty stack capable of holding up to ten word-sized data values.

```
#define MAX_ITEMS 10

stack_data_t my_stack_array[MAX_ITEMS];
struct k_stack my_stack;

k_stack_init(&my_stack, my_stack_array, MAX_ITEMS);
```

Alternatively, a stack can be defined and initialized at compile time by calling K_STACK_DEFINE.

The following code has the same effect as the code segment above. Observe that the macro defines both the stack and its array of data values.

```
K_STACK_DEFINE(my_stack, MAX_ITEMS);
```

Pushing to a Stack  A data item is added to a stack by calling k_stack_push().

The following code builds on the example above, and shows how a thread can create a pool of data structures by saving their memory addresses in a stack.

```
/* define array of data structures */
struct my_buffer_type {
    int field1;
    ...
};
struct my_buffer_type my_buffers[MAX_ITEMS];

/* save address of each data structure in a stack */
for (int i = 0; i < MAX_ITEMS; i++) {
    k_stack_push(&my_stack, (stack_data_t)&my_buffers[i]);
}
```

Popping from a Stack  A data item is taken from a stack by calling k_stack_pop().
The following code builds on the example above, and shows how a thread can dynamically allocate an unused data structure. When the data structure is no longer required, the thread must push its address back on the stack to allow the data structure to be reused.

```c
struct my_buffer_type *new_buffer;

k_stack_pop(&buffer_stack, (stack_data_t *)&new_buffer, K_FOREVER);
new_buffer->field1 = ...
```

**Suggested Uses** Use a stack to store and retrieve integer data values in a “last in, first out” manner, when the maximum number of stored items is known.

**Configuration Options** Related configuration options:
- None.

**API Reference**

```plaintext
group stack_apis

Defines

K_STACK_DEFINE(name, stack_num_entries)
Statically define and initialize a stack.

The stack can be accessed outside the module where it is defined using:

```c
extern struct k_stack <name>;
```

**Parameters**
- name – Name of the stack.
- stack_num_entries – Maximum number of values that can be stacked.

**Functions**

```c
void k_stack_init(struct k_stack *stack, stack_data_t *buffer, uint32_t num_entries)
Initialize a stack.
```

This routine initializes a stack object, prior to its first use.

**Parameters**
- stack – Address of the stack.
- buffer – Address of array used to hold stacked values.
- num_entries – Maximum number of values that can be stacked.

```c
int32_t k_stack_alloc_init(struct k_stack *stack, uint32_t num_entries)
Initialize a stack.
```

This routine initializes a stack object, prior to its first use. Internal buffers will be allocated from the calling thread's resource pool. This memory will be released if `k_stack_cleanup()` is called, or userspace is enabled and the stack object loses all references to it.

**Parameters**
• stack – Address of the stack.
• num_entries – Maximum number of values that can be stacked.

**Returns** -ENOMEM if memory couldn’t be allocated

```c
int k_stack_cleanup(struct k_stack *stack)
```

Release a stack’s allocated buffer.

If a stack object was given a dynamically allocated buffer via `k_stack_alloc_init()`, this will free it. This function does nothing if the buffer wasn’t dynamically allocated.

**Parameters**
• stack – Address of the stack.

**Return values**
• 0 – on success
• -EFAULT – when object is still in use

```c
int k_stack_push(struct k_stack *stack, stack_data_t data)
```

Push an element onto a stack.

This routine adds a `stack_data_t` value `data` to `stack`.

**Function properties (list may not be complete)** *isr-ok*

**Parameters**
• stack – Address of the stack.
• data – Value to push onto the stack.

**Return values**
• 0 – on success
• -ENOMEM – if stack is full

```c
int k_stack_pop(struct k_stack *stack, stack_data_t *data, k_timeout_t timeout)
```

Pop an element from a stack.

This routine removes a `stack_data_t` value from `stack` in a “last in, first out” manner and stores the value in `data`.

**Function properties (list may not be complete)** *isr-ok*

**Note:** `timeout` must be set to `K_NO_WAIT` if called from ISR.

**Parameters**
• stack – Address of the stack.
• data – Address of area to hold the value popped from the stack.
• timeout – Waiting period to obtain a value, or one of the special values `K_NO_WAIT` and `K_FOREVER`.

**Return values**
• 0 – Element popped from stack.
• -EBUSY – Returned without waiting.
• -EAGAIN – Waiting period timed out.

Message Queues

A message queue is a kernel object that implements a simple message queue, allowing threads and ISRs to asynchronously send and receive fixed-size data items.

Concepts

Any number of message queues can be defined (limited only by available RAM). Each message queue is referenced by its memory address.

A message queue has the following key properties:

• A ring buffer of data items that have been sent but not yet received.
• A data item size, measured in bytes.
• A maximum quantity of data items that can be queued in the ring buffer.

The message queue’s ring buffer must be aligned to an N-byte boundary, where N is a power of 2 (i.e. 1, 2, 4, 8, …). To ensure that the messages stored in the ring buffer are similarly aligned to this boundary, the data item size must also be a multiple of N.

A message queue must be initialized before it can be used. This sets its ring buffer to empty.

A data item can be sent to a message queue by a thread or an ISR. The data item pointed at by the sending thread is copied to a waiting thread, if one exists; otherwise the item is copied to the message queue’s ring buffer, if space is available. In either case, the size of the data area being sent must equal the message queue’s data item size.

If a thread attempts to send a data item when the ring buffer is full, the sending thread may choose to wait for space to become available. Any number of sending threads may wait simultaneously when the ring buffer is full; when space becomes available it is given to the highest priority sending thread that has waited the longest.

A data item can be received from a message queue by a thread. The data item is copied to the area specified by the receiving thread; the size of the receiving area must equal the message queue’s data item size.

If a thread attempts to receive a data item when the ring buffer is empty, the receiving thread may choose to wait for a data item to be sent. Any number of receiving threads may wait simultaneously when the ring buffer is empty; when a data item becomes available it is given to the highest priority receiving thread that has waited the longest.

A thread can also peek at the message on the head of a message queue without removing it from the queue. The data item is copied to the area specified by the receiving thread; the size of the receiving area must equal the message queue’s data item size.
Note: The kernel does allow an ISR to receive an item from a message queue, however the ISR must not attempt to wait if the message queue is empty.

Implementation

Defining a Message Queue  A message queue is defined using a variable of type `k_msgq`. It must then be initialized by calling `k_msgq_init()`.

The following code defines and initializes an empty message queue that is capable of holding 10 items, each of which is 12 bytes long.

```c
struct data_item_type {
    uint32_t field1;
    uint32_t field2;
    uint32_t field3;
};

char __aligned(4) my_msgq_buffer[10 * sizeof(struct data_item_type)];
struct k_msgq my_msgq;

k_msgq_init(&my_msgq, my_msgq_buffer, sizeof(struct data_item_type), 10);
```

Alternatively, a message queue can be defined and initialized at compile time by calling `K_MSGQ_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the message queue and its buffer.

```
K_MSGQ_DEFINE(my_msgq, sizeof(struct data_item_type), 10, 4);
```

The following code demonstrates an alignment implementation for the structure defined in the previous example code. `aligned` means each `data_item_type` will begin on the specified byte boundary. `aligned(4)` means that the structure is aligned to an address that is divisible by 4.

```c
typedef struct {
    uint32_t field1;
    uint32_t field2;
    uint32_t field3;
} __attribute__((aligned(4))) data_item_type;
```

Writing to a Message Queue  A data item is added to a message queue by calling `k_msgq_put()`.

The following code builds on the example above, and uses the message queue to pass data items from a producing thread to one or more consuming threads. If the message queue fills up because the consumers can't keep up, the producing thread throws away all existing data so the newer data can be saved.

```c
void producer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* create data item to send (e.g. measurement, timestamp, ...) */
        data = ...

        /* send data to consumers */
        while (k_msgq_put(&my_msgq, &data, K_NO_WAIT) != 0) {
```
Reading from a Message Queue  A data item is taken from a message queue by calling \texttt{k\_msgq\_get()}. The following code builds on the example above, and uses the message queue to process data items generated by one or more producing threads. Note that the return value of \texttt{k\_msgq\_get()} should be tested as \texttt{-ENOMSG} can be returned due to \texttt{k\_msgq\_purge()}. 

```c
void consumer_thread(void)
{
    struct data_item_type data;
    while (1) {
        /* get a data item */
        k_msgq_get(&my_msgq, &data, K_FOREVER);
        /* process data item */
        ...
    }
}
```

Peeking into a Message Queue  A data item is read from a message queue by calling \texttt{k\_msgq\_peek()}. The following code peeks into the message queue to read the data item at the head of the queue that is generated by one or more producing threads.

```c
void consumer_thread(void)
{
    struct data_item_type data;
    while (1) {
        /* read a data item by peeking into the queue */
        k_msgq_peek(&my_msgq, &data);
        /* process data item */
        ...
    }
}
```

Suggested Uses  Use a message queue to transfer small data items between threads in an asynchronous manner.

\textbf{Note:} A message queue can be used to transfer large data items, if desired. However, this can increase interrupt latency as interrupts are locked while a data item is written or read. The time to write or read a data item increases linearly with its size since the item is copied in its entirety to or from the buffer in memory. For this reason, it is usually preferable to transfer large data items by exchanging a pointer to the data item, rather than the data item itself.
A synchronous transfer can be achieved by using the kernel's mailbox object type.

**Configuration Options**  Related configuration options:
- None.

**API Reference**

`group msgq_apis`

**Defines**

```c
K_MSGQ_FLAG_ALLOC

K_MSGQ_DEFINE(q_name, q_msg_size, q_max_msgs, q_align)
```

Statically define and initialize a message queue.

The message queue's ring buffer contains space for `q_max_msgs` messages, each of which is `q_msg_size` bytes long. The buffer is aligned to a `q_align`-byte boundary, which must be a power of 2. To ensure that each message is similarly aligned to this boundary, `q_msg_size` must also be a multiple of `q_align`.

The message queue can be accessed outside the module where it is defined using:

```c
extern struct k_msgq <name>;
```

**Parameters**
- `q_name` – Name of the message queue.
- `q_msg_size` – Message size (in bytes).
- `q_max_msgs` – Maximum number of messages that can be queued.
- `q_align` – Alignment of the message queue’s ring buffer.

**Functions**

```c
void k_msgq_init(struct k_msgq *msgq, char *buffer, size_t msg_size, uint32_t max_msgs)
```

Initialize a message queue.

This routine initializes a message queue object, prior to its first use.

The message queue's ring buffer must contain space for `max_msgs` messages, each of which is `msg_size` bytes long. The buffer must be aligned to an N-byte boundary, where N is a power of 2 (i.e. 1, 2, 4, ...). To ensure that each message is similarly aligned to this boundary, `q_msg_size` must also be a multiple of N.

**Parameters**
- `msgq` – Address of the message queue.
- `buffer` – Pointer to ring buffer that holds queued messages.
- `msg_size` – Message size (in bytes).
- `max_msgs` – Maximum number of messages that can be queued.
int k_msgq_alloc_init(struct k_msgq *msgq, size_t msg_size, uint32_t max_msgs)
    Initialize a message queue.

This routine initializes a message queue object, prior to its first use, allocating its internal ring buffer from the calling thread’s resource pool.

Memory allocated for the ring buffer can be released by calling k_msgq_cleanup(), or if userspace is enabled and the msgq object loses all of its references.

**Parameters**

- `msgq` – Address of the message queue.
- `msg_size` – Message size (in bytes).
- `max_msgs` – Maximum number of messages that can be queued.

**Returns**

- 0 on success,
- -ENOMEM if there was insufficient memory in the thread’s resource pool,
- -EINVAL if the size parameters cause an integer overflow.

int k_msgq_cleanup(struct k_msgq *msgq)
    Release allocated buffer for a queue.

Releases memory allocated for the ring buffer.

**Parameters**

- `msgq` – message queue to cleanup

**Return values**

- 0 – on success
- -EBUSY – Queue not empty

int k_msgq_put(struct k_msgq *msgq, const void *data, k_timeout_t timeout)
    Send a message to a message queue.

This routine sends a message to message queue `q`.

**Function properties (list may not be complete) isr-ok**

**Note:** The message content is copied from `data` into `msgq` and the `data` pointer is not retained, so the message content will not be modified by this function.

**Parameters**

- `msgq` – Address of the message queue.
- `data` – Pointer to the message.
- `timeout` – Non-negative waiting period to add the message, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**

- 0 – Message sent.
- -ENOMSG – Returned without waiting or queue purged.
- -EAGAIN – Waiting period timed out.

int k_msgq_get(struct k_msgq *msgq, void *data, k_timeout_t timeout)
    Receive a message from a message queue.

This routine receives a message from message queue `q` in a “first in, first out” manner.
Function properties (list may not be complete) **isr-ok**

---

**Note:** `timeout` must be set to K_NO_WAIT if called from ISR.

---

**Parameters**

- `msgq` – Address of the message queue.
- `data` – Address of area to hold the received message.
- `timeout` – Waiting period to receive the message, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**

- 0 – Message received.
- -ENOMSG – Returned without waiting.
- -EAGAIN – Waiting period timed out.

```c
int k_msgq_peek(struct k_msgq *msgq, void *data)
```

Peek/read a message from a message queue.

This routine reads a message from message queue `q` in a “first in, first out” manner and leaves the message in the queue.

---

Function properties (list may not be complete) **isr-ok**

---

**Parameters**

- `msgq` – Address of the message queue.
- `data` – Address of area to hold the message read from the queue.

**Return values**

- 0 – Message read.
- -ENOMSG – Returned when the queue has no message.

```c
void k_msgq_purge(struct k_msgq *msgq)
```

Purge a message queue.

This routine discards all unreceived messages in a message queue's ring buffer. Any threads that are blocked waiting to send a message to the message queue are unblocked and see an -ENOMSG error code.

---

```c
uint32_t k_msgq_num_free_get(struct k_msgq *msgq)
```

Get the amount of free space in a message queue.

This routine returns the number of unused entries in a message queue's ring buffer.

---

**Parameters**

- `msgq` – Address of the message queue.

**Returns** Number of unused ring buffer entries.
void k_msgq_get_attrs(struct k_msgq *msgq, struct k_msgq_attrs *attrs)
    Get basic attributes of a message queue.

    This routine fetches basic attributes of message queue into attrs argument.

    **Parameters**
    - `msgq` – Address of the message queue.
    - `attrs` – pointer to message queue attribute structure.

uint32_t k_msgq_num_used_get(struct k_msgq *msgq)
    Get the number of messages in a message queue.

    This routine returns the number of messages in a message queue's ring buffer.

    **Parameters**
    - `msgq` – Address of the message queue.

    **Returns**
    Number of messages.

struct k_msgq
    #include <kernel.h> Message Queue Structure.

Mailboxes

A \textit{mailbox} is a kernel object that provides enhanced message queue capabilities that go beyond the capabilities of a message queue object. A mailbox allows threads to send and receive messages of any size synchronously or asynchronously.

- **Concepts**
  - Message Format
  - Message Lifecycle
  - Thread Compatibility
  - Message Flow Control
- **Implementation**
  - Defining a Mailbox
  - Message Descriptors
  - Sending a Message
  - Receiving a Message
- **Suggested Uses**
- **Configuration Options**
- **API Reference**

\textbf{Concepts} Any number of mailboxes can be defined (limited only by available RAM). Each mailbox is referenced by its memory address.

A mailbox has the following key properties:

- A \texttt{send queue} of messages that have been sent but not yet received.
- A \texttt{receive queue} of threads that are waiting to receive a message.

A mailbox must be initialized before it can be used. This sets both of its queues to empty.

A mailbox allows threads, but not ISRs, to exchange messages. A thread that sends a message is known as the \texttt{sending thread}, while a thread that receives the message is known as the \texttt{receiving thread}. Each message may be received by only one thread (i.e. point-to-multipoint and broadcast messaging is not supported).

Messages exchanged using a mailbox are handled non-anonymously, allowing both threads participating in an exchange to know (and even specify) the identity of the other thread.
A message descriptor is a data structure that specifies where a message's data is located, and how the message is to be handled by the mailbox. Both the sending thread and the receiving thread supply a message descriptor when accessing a mailbox. The mailbox uses the message descriptors to perform a message exchange between compatible sending and receiving threads. The mailbox also updates certain message descriptor fields during the exchange, allowing both threads to know what has occurred.

A mailbox message contains zero or more bytes of message data. The size and format of the message data is application-defined, and can vary from one message to the next. There are two forms of message data:

- A message buffer is an area of memory provided by the thread that sends or receives the message. An array or structure variable can often be used for this purpose.
- A message block is an area of memory allocated from a memory pool.

A message may not have both a message buffer and a message block. A message that has neither form of message data is called an empty message.

Note: A message whose message buffer or memory block exists, but contains zero bytes of actual data, is not an empty message.

Message Lifecycle The life cycle of a message is straightforward. A message is created when it is given to a mailbox by the sending thread. The message is then owned by the mailbox until it is given to a receiving thread. The receiving thread may retrieve the message data when it receives the message from the mailbox, or it may perform data retrieval during a second, subsequent mailbox operation. Only when data retrieval has occurred is the message deleted by the mailbox.

Thread Compatibility A sending thread can specify the address of the thread to which the message is sent, or send it to any thread by specifying K_ANY. Likewise, a receiving thread can specify the address of the thread from which it wishes to receive a message, or it can receive a message from any thread by specifying K_ANY. A message is exchanged only when the requirements of both the sending thread and receiving thread are satisfied; such threads are said to be compatible.

For example, if thread A sends a message to thread B (and only thread B) it will be received by thread B if thread B tries to receive a message from thread A or if thread B tries to receive from any thread. The exchange will not occur if thread B tries to receive a message from thread C. The message can never be received by thread C, even if it tries to receive a message from thread A (or from any thread).

Message Flow Control Mailbox messages can be exchanged synchronously or asynchronously. In a synchronous exchange, the sending thread blocks until the message has been fully processed by the receiving thread. In an asynchronous exchange, the sending thread does not wait until the message has been received by another thread before continuing; this allows the sending thread to do other work (such as gather data that will be used in the next message) before the message is given to a receiving thread and fully processed. The technique used for a given message exchange is determined by the sending thread.

The synchronous exchange technique provides an implicit form of flow control, preventing a sending thread from generating messages faster than they can be consumed by receiving threads. The asynchronous exchange technique provides an explicit form of flow control, which allows a sending thread to determine if a previously sent message still exists before sending a subsequent message.

Implementation
Defining a Mailbox  A mailbox is defined using a variable of type `k_mbox`. It must then be initialized by calling `k_mbox_init()`.

The following code defines and initializes an empty mailbox.

```c
struct k_mbox my_mailbox;
k_mbox_init(&my_mailbox);
```

Alternatively, a mailbox can be defined and initialized at compile time by calling `K_MBOX_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_MBOX_DEFINE(my_mailbox);
```

Message Descriptors  A message descriptor is a structure of type `k_mbox_msg`. Only the fields listed below should be used; any other fields are for internal mailbox use only.

- **info**  A 32-bit value that is exchanged by the message sender and receiver, and whose meaning is defined by the application. This exchange is bi-directional, allowing the sender to pass a value to the receiver during any message exchange, and allowing the receiver to pass a value to the sender during a synchronous message exchange.

- **size**  The message data size, in bytes. Set it to zero when sending an empty message, or when sending a message buffer or message block with no actual data. When receiving a message, set it to the maximum amount of data desired, or to zero if the message data is not wanted. The mailbox updates this field with the actual number of data bytes exchanged once the message is received.

- **tx_data**  A pointer to the sending thread's message buffer. Set it to `NULL` when sending a memory block, or when sending an empty message. Leave this field uninitialized when receiving a message.

- **tx_block**  The descriptor for the sending thread's memory block. Set `tx_block.data` to `NULL` when sending an empty message. Leave this field uninitialized when sending a message buffer, or when receiving a message.

- **tx_target_thread**  The address of the desired receiving thread. Set it to `K_ANY` to allow any thread to receive the message. Leave this field uninitialized when receiving a message. The mailbox updates this field with the actual receiver's address once the message is received.

- **rx_source_thread**  The address of the desired sending thread. Set it to `K_ANY` to receive a message sent by any thread. Leave this field uninitialized when sending a message. The mailbox updates this field with the actual sender's address when the message is put into the mailbox.

Sending a Message  A thread sends a message by first creating its message data, if any. A message buffer is typically used when the data volume is small, and the cost of copying the data is less than the cost of allocating and freeing a message block.

Next, the sending thread creates a message descriptor that characterizes the message to be sent, as described in the previous section.

Finally, the sending thread calls a mailbox send API to initiate the message exchange. The message is immediately given to a compatible receiving thread, if one is currently waiting. Otherwise, the message is added to the mailbox's send queue.

Any number of messages may exist simultaneously on a send queue. The messages in the send queue are sorted according to the priority of the sending thread. Messages of equal priority are sorted so that the oldest message can be received first.

For a synchronous send operation, the operation normally completes when a receiving thread has both received the message and retrieved the message data. If the message is not received before the waiting period specified by the sending thread is reached, the message is removed from the mailbox's send queue and the send operation fails. When a send operation completes successfully the sending thread
can examine the message descriptor to determine which thread received the message, how much data was exchanged, and the application-defined info value supplied by the receiving thread.

**Note:** A synchronous send operation may block the sending thread indefinitely, even when the thread specifies a maximum waiting period. The waiting period only limits how long the mailbox waits before the message is received by another thread. Once a message is received there is no limit to the time the receiving thread may take to retrieve the message data and unblock the sending thread.

For an asynchronous send operation, the operation always completes immediately. This allows the sending thread to continue processing regardless of whether the message is given to a receiving thread immediately or added to the send queue. The sending thread may optionally specify a semaphore that the mailbox gives when the message is deleted by the mailbox, for example, when the message has been received and its data retrieved by a receiving thread. The use of a semaphore allows the sending thread to easily implement a flow control mechanism that ensures that the mailbox holds no more than an application-specified number of messages from a sending thread (or set of sending threads) at any point in time.

**Note:** A thread that sends a message asynchronously has no way to determine which thread received the message, how much data was exchanged, or the application-defined info value supplied by the receiving thread.

### Sending an Empty Message

This code uses a mailbox to synchronously pass 4 byte random values to any consuming thread that wants one. The message “info” field is large enough to carry the information being exchanged, so the data portion of the message isn’t used.

```c
void producer_thread(void)
{
    struct k_mbox_msg send_msg;

    while (1) {
        /* generate random value to send */
        uint32_t random_value = sys_rand32_get();

        /* prepare to send empty message */
        send_msg.info = random_value;
        send_msg.size = 0;
        send_msg.tx_data = NULL;
        send_msg.tx_block.data = NULL;
        send_msg.tx_target_thread = K_ANY;

        /* send message and wait until a consumer receives it */
        k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);
    }
}
```

### Sending Data Using a Message Buffer

This code uses a mailbox to synchronously pass variable-sized requests from a producing thread to any consuming thread that wants it. The message “info” field is used to exchange information about the maximum size message buffer that each thread can handle.

```c
void producer_thread(void)
{
    char buffer[100];
```

(continues on next page)
int buffer_bytes_used;

struct k_mbox_msg send_msg;

while (1) {
    /* generate data to send */
    ...
    buffer_bytes_used = ... ;
    memcpy(buffer, source, buffer_bytes_used);

    /* prepare to send message */
    send_msg.info = buffer_bytes_used;
    send_msg.size = buffer_bytes_used;
    send_msg.tx_data = buffer;
    send_msg.tx_block.data = NULL;
    send_msg.tx_target_thread = K_ANY;

    /* send message and wait until a consumer receives it */
    k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);

    /* info, size, and tx_target_thread fields have been updated */

    /* verify that message data was fully received */
    if (send_msg.size < buffer_bytes_used) {
        printf("some message data dropped during transfer!");
        printf("receiver only had room for %d bytes", send_msg.info);
    }
}

Sending Data Using a Message Block  This code uses a mailbox to send asynchronous messages. A semaphore is used to hold off the sending of a new message until the previous message has been consumed, so that a backlog of messages doesn't build up when the consuming thread is unable to keep up.

The message data is stored in a memory block obtained from a memory pool, thereby eliminating unneeded data copying when exchanging large messages. The memory pool contains only two blocks: one block gets filled with data while the previously sent block is being processed

/* define a semaphore, indicating that no message has been sent */
K_SEM_DEFINE(my_sem, 1, 1);

/* define a memory pool containing 2 blocks of 4096 bytes */
K_MEM_POOL_DEFINE(my_pool, 4096, 4096, 2, 4);

void producer_thread(void)
{
    struct k_mbox_msg send_msg;

    volatile char *hw_buffer;

    while (1) {
        /* allocate a memory block to hold the message data */
        k_mem_pool_alloc(&my_pool, &send_msg.tx_block, 4096, K_FOREVER);

(continues on next page)
/* keep overwriting the hardware-generated data in the block */
/* until the previous message has been received by the consumer */
do {
    memcpy(send_msg.tx_block.data, hw_buffer, 4096);
} while (k_sem_take(&my_sem, K_NO_WAIT) != 0);

/* finish preparing to send message */
send_msg.size = 4096;
send_msg.tx_target_thread = K_ANY;

/* send message containing most current data and loop around */
k_mbox_async_put(&my_mailbox, &send_msg, &my_sem);

Receiving a Message  A thread receives a message by first creating a message descriptor that characterizes the message it wants to receive. It then calls one of the mailbox receive APIs. The mailbox searches its send queue and takes the message from the first compatible thread it finds. If no compatible thread exists, the receiving thread may choose to wait for one. If no compatible thread appears before the waiting period specified by the receiving thread is reached, the receive operation fails. Once a receive operation completes successfully the receiving thread can examine the message descriptor to determine which thread sent the message, how much data was exchanged, and the application-defined info value supplied by the sending thread.

Any number of receiving threads may wait simultaneously on a mailboxes' receive queue. The threads are sorted according to their priority; threads of equal priority are sorted so that the one that started waiting first can receive a message first.

Note: Receiving threads do not always receive messages in a first in, first out (FIFO) order, due to the thread compatibility constraints specified by the message descriptors. For example, if thread A waits to receive a message only from thread X and then thread B waits to receive a message from thread Y, an incoming message from thread Y to any thread will be given to thread B and thread A will continue to wait.

The receiving thread controls both the quantity of data it retrieves from an incoming message and where the data ends up. The thread may choose to take all of the data in the message, to take only the initial part of the data, or to take no data at all. Similarly, the thread may choose to have the data copied into a message buffer of its choice or to have it placed in a message block. A message buffer is typically used when the volume of data involved is small, and the cost of copying the data is less than the cost of allocating and freeing a memory pool block.

The following sections outline various approaches a receiving thread may use when retrieving message data.

Retrieving Data at Receive Time  The most straightforward way for a thread to retrieve message data is to specify a message buffer when the message is received. The thread indicates both the location of the message buffer (which must not be NULL) and its size.

The mailbox copies the message's data to the message buffer as part of the receive operation. If the message buffer is not big enough to contain all of the message's data, any uncopied data is lost. If the message is not big enough to fill all of the buffer with data, the unused portion of the message buffer is left unchanged. In all cases the mailbox updates the receiving thread's message descriptor to indicate how many data bytes were copied (if any).

The immediate data retrieval technique is best suited for small messages where the maximum size of a message is known in advance.
Note: This technique can be used when the message data is actually located in a memory block supplied by the sending thread. The mailbox copies the data into the message buffer specified by the receiving thread, then frees the message block back to its memory pool. This allows a receiving thread to retrieve message data without having to know whether the data was sent using a message buffer or a message block.

The following code uses a mailbox to process variable-sized requests from any producing thread, using the immediate data retrieval technique. The message "info" field is used to exchange information about the maximum size message buffer that each thread can handle.

```c
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[100];

    int i;
    int total;

    while (1) {
        /* prepare to receive message */
        recv_msg.info = 100;
        recv_msg.size = 100;
        recv_msg.rx_source_thread = K_ANY;

        /* get a data item, waiting as long as needed */
        k_mbox_get(&my_mailbox, &recv_msg, buffer, K_FOREVER);

        /* info, size, and rx_source_thread fields have been updated */

        /* verify that message data was fully received */
        if (recv_msg.info != recv_msg.size) {
            printf("some message data dropped during transfer!
"

        } /* compute sum of all message bytes (from 0 to 100 of them) */
        total = 0;
        for (i = 0; i < recv_msg.size; i++) {
            total += buffer[i];
        }
    }
}
```

Retrieving Data Later Using a Message Buffer A receiving thread may choose to defer message data retrieval at the time the message is received, so that it can retrieve the data into a message buffer at a later time. The thread does this by specifying a message buffer location of NULL and a size indicating the maximum amount of data it is willing to retrieve later.

The mailbox does not copy any message data as part of the receive operation. However, the mailbox still updates the receiving thread’s message descriptor to indicate how many data bytes are available for retrieval.

The receiving thread must then respond as follows:

- If the message descriptor size is zero, then either the sender’s message contained no data or the receiving thread did not want to receive any data. The receiving thread does not need to take any further action, since the mailbox has already completed data retrieval and deleted the message.
• If the message descriptor size is non-zero and the receiving thread still wants to retrieve the data, the thread must call `k_mbox_data_get()` and supply a message buffer large enough to hold the data. The mailbox copies the data into the message buffer and deletes the message.

• If the message descriptor size is non-zero and the receiving thread does not want to retrieve the data, the thread must call `k_mbox_data_get()` and specify a message buffer of NULL. The mailbox deletes the message without copying the data.

The subsequent data retrieval technique is suitable for applications where immediate retrieval of message data is undesirable. For example, it can be used when memory limitations make it impractical for the receiving thread to always supply a message buffer capable of holding the largest possible incoming message.

**Note:** This technique can be used when the message data is actually located in a memory block supplied by the sending thread. The mailbox copies the data into the message buffer specified by the receiving thread, then frees the message block back to its memory pool. This allows a receiving thread to retrieve message data without having to know whether the data was sent using a message buffer or a message block.

The following code uses a mailbox’s deferred data retrieval mechanism to get message data from a producing thread only if the message meets certain criteria, thereby eliminating unneeded data copying. The message “info” field supplied by the sender is used to classify the message.

```c
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[10000];

    while (1) {
        /* prepare to receive message */
        recv_msg.size = 10000;
        recv_msg.rx_source_thread = K_ANY;

        /* get message, but not its data */
        k_mbox_get(&my_mailbox, &recv_msg, NULL, K_FOREVER);

        /* get message data for only certain types of messages */
        if (is_message_type_ok(recv_msg.info)) {
            /* retrieve message data and delete the message */
            k_mbox_data_get(&recv_msg, buffer);
            /* process data in "buffer" */
            ...
        } else {
            /* ignore message data and delete the message */
            k_mbox_data_get(&recv_msg, NULL);
        }
    }
}
```

**Retrieving Data Later Using a Message Block** A receiving thread may choose to retrieve message data into a memory block, rather than a message buffer. This is done in much the same way as retrieving data subsequently into a message buffer — the receiving thread first receives the message without its data, then retrieves the data by calling `k_mbox_data_block_get()`. The mailbox fills in the block descriptor supplied by the receiving thread, allowing the thread to access the data. The mailbox also deletes the received message, since data retrieval has been completed. The receiving thread is then responsible for freeing the message block back to the memory pool when the data is no longer needed.
This technique is best suited for applications where the message data has been sent using a memory block.

**Note:** This technique can be used when the message data is located in a message buffer supplied by the sending thread. The mailbox automatically allocates a memory block and copies the message data into it. However, this is much less efficient than simply retrieving the data into a message buffer supplied by the receiving thread. In addition, the receiving thread must be designed to handle cases where the data retrieval operation fails because the mailbox cannot allocate a suitable message block from the memory pool. If such cases are possible, the receiving thread must either try retrieving the data at a later time or instruct the mailbox to delete the message without retrieving the data.

The following code uses a mailbox to receive messages sent using a memory block, thereby eliminating unneeded data copying when processing a large message. (The messages may be sent synchronously or asynchronously.)

```c
/* define a memory pool containing 1 block of 10000 bytes */
K_MEM_POOL_DEFINE(my_pool, 10000, 10000, 1, 4);

void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    struct k_mem_block recv_block;

    int total;
    char *data_ptr;
    int i;

    while (1) {
        /* prepare to receive message */
        recv_msg.size = 10000;
        recv_msg.rx_source_thread = K_ANY;

        /* get message, but not its data */
        k_mbox_get(&my_mailbox, &recv_msg, NULL, K_FOREVER);

        /* get message data as a memory block and discard message */
        k_mbox_data_block_get(&recv_msg, &my_pool, &recv_block, K_FOREVER);

        /* compute sum of all message bytes in memory block */
        total = 0;
        data_ptr = (char *)(recv_block.data);
        for (i = 0; i < recv_msg.size; i++) {
            total += data_ptr++;
        }

        /* release memory block containing data */
        k_mem_pool_free(&recv_block);
    }
}
```

**Note:** An incoming message that was sent using a message buffer is also processed correctly by this algorithm, since the mailbox automatically allocates a memory block from the memory pool and fills it with the message data. However, the performance benefit of using the memory block approach is lost.
**Suggested Uses**  Use a mailbox to transfer data items between threads whenever the capabilities of a message queue are insufficient.

**Configuration Options**  Related configuration options:
- `CONFIG_NUM_MBOX_ASYNC_MSGS`

**API Reference**

`group mailbox_apis`

**Defines**

`K_MBOX_DEFINE(name)`

Statically define and initialize a mailbox.

The mailbox is to be accessed outside the module where it is defined using:

```c
extern struct k_mbox <name>;
```

**Parameters**

- `name` – Name of the mailbox.

**Functions**

`void k_mbox_init(struct k_mbox *mbox)`

Initialize a mailbox.

This routine initializes a mailbox object, prior to its first use.

**Parameters**

- `mbox` – Address of the mailbox.

`int k_mbox_put(struct k_mbox *mbox, struct k_mbox_msg *tx_msg, k_timeout_t timeout)`

Send a mailbox message in a synchronous manner.

This routine sends a message to `mbox` and waits for a receiver to both receive and process it. The message data may be in a buffer, in a memory pool block, or non-existent (i.e. an empty message).

**Parameters**

- `mbox` – Address of the mailbox.
- `tx_msg` – Address of the transmit message descriptor.
- `timeout` – Waiting period for the message to be received, or one of the special values `K_NO_WAIT` and `K_FOREVER`. Once the message has been received, this routine waits as long as necessary for the message to be completely processed.

**Return values**

- `0` – Message sent.
- `-ENOMEM` – Returned without waiting.
- `-EAGAIN` – Waiting period timed out.
void k_mbox_async_put(struct k_mbox *mbox, struct k_mbox_msg *tx_msg, struct k_sem *sem)

Send a mailbox message in an asynchronous manner.

This routine sends a message to `mbox` without waiting for a receiver to process it. The message data may be in a buffer, in a memory pool block, or non-existent (i.e. an empty message). Optionally, the semaphore `sem` will be given when the message has been both received and completely processed by the receiver.

**Parameters**

- `mbox` – Address of the mailbox.
- `tx_msg` – Address of the transmit message descriptor.
- `sem` – Address of a semaphore, or NULL if none is needed.

int k_mbox_get(struct k_mbox *mbox, struct k_mbox_msg *rx_msg, void *buffer, k_timeout_t timeout)

Receive a mailbox message.

This routine receives a message from `mbox`, then optionally retrieves its data and disposes of the message.

**Parameters**

- `mbox` – Address of the mailbox.
- `rx_msg` – Address of the receive message descriptor.
- `buffer` – Address of the buffer to receive data, or NULL to defer data retrieval and message disposal until later.
- `timeout` – Waiting period for a message to be received, or one of the special values `K_NO_WAIT` and `K_FOREVER`.

**Return values**

- `0` – Message received.
- `-ENOMSG` – Returned without waiting.
- `-EAGAIN` – Waiting period timed out.

void k_mbox_data_get(struct k_mbox_msg *rx_msg, void *buffer)

Retrieve mailbox message data into a buffer.

This routine completes the processing of a received message by retrieving its data into a buffer, then disposing of the message.

Alternatively, this routine can be used to dispose of a received message without retrieving its data.

**Parameters**

- `rx_msg` – Address of the receive message descriptor.
- `buffer` – Address of the buffer to receive data, or NULL to discard the data.

struct k_mbox_msg

`#include <kernel.h>` Mailbox Message Structure.

**Public Members**

- `size` size

  Receive message queue

## Pipes

A pipe is a kernel object that allows a thread to send a byte stream to another thread. Pipes can be used to synchronously transfer chunks of data in whole or in part.

- **Concepts**
- **Implementation**
  - Writing to a Pipe
  - Reading from a Pipe
  - Flushing a Pipe's Buffer
  - Flushing a Pipe
- **Suggested uses**
- **Configuration Options**
- **API Reference**

### Concepts

The pipe can be configured with a ring buffer which holds data that has been sent but not yet received; alternatively, the pipe may have no ring buffer.

Any number of pipes can be defined (limited only by available RAM). Each pipe is referenced by its memory address.

A pipe has the following key property:
• A **size** that indicates the size of the pipe's ring buffer. Note that a size of zero defines a pipe with no ring buffer.

A pipe must be initialized before it can be used. The pipe is initially empty.

Data is synchronously **sent** either in whole or in part to a pipe by a thread. If the specified minimum number of bytes can not be immediately satisfied, then the operation will either fail immediately or attempt to send as many bytes as possible and then pend in the hope that the send can be completed later. Accepted data is either copied to the pipe's ring buffer or directly to the waiting reader(s).

Data is synchronously **received** from a pipe by a thread. If the specified minimum number of bytes can not be immediately satisfied, then the operation will either fail immediately or attempt to receive as many bytes as possible and then pend in the hope that the receive can be completed later. Accepted data is either copied from the pipe's ring buffer or directly from the waiting sender(s).

Data may also be **flushed** from a pipe by a thread. Flushing can be performed either on the entire pipe or on only its ring buffer. Flushing the entire pipe is equivalent to reading all the information in the ring buffer and waiting to be written into a giant temporary buffer which is then discarded. Flushing the ring buffer is equivalent to reading only the data in the ring buffer into a temporary buffer which is then discarded. Flushing the ring buffer does not guarantee that the ring buffer will stay empty; flushing it may allow a pended writer to fill the ring buffer.

**Note:** Flushing does not in practice allocate or use additional buffers.

**Note:** The kernel does NOT allow for an ISR to send or receive data to/from a pipe or flush even if it does not attempt to wait for space/data.

**Implementation** A pipe is defined using a variable of type `k_pipe` and an optional character buffer of type `unsigned char`. It must then be initialized by calling `k_pipe_init()`.

The following code defines and initializes an empty pipe that has a ring buffer capable of holding 100 bytes and is aligned to a 4-byte boundary.

```c
unsigned char __aligned(4) my_ring_buffer[100];
struct k_pipe my_pipe;

k_pipe_init(&my_pipe, my_ring_buffer, sizeof(my_ring_buffer));
```

Alternatively, a pipe can be defined and initialized at compile time by calling `K_PIPE_DEFINE`.

The following code has the same effect as the code segment above. Observe that that macro defines both the pipe and its ring buffer.

```c
K_PIPE_DEFINE(my_pipe, 100, 4);
```

**Writing to a Pipe** Data is added to a pipe by calling `k_pipe_put()`.

The following code builds on the example above, and uses the pipe to pass data from a producing thread to one or more consuming threads. If the pipe's ring buffer fills up because the consumers can't keep up, the producing thread waits for a specified amount of time.

```c
struct message_header {
  ...
};

void producer_thread(void)
```
Reading from a Pipe  Data is read from the pipe by calling \texttt{k.pipe.get()}. The following code builds on the example above, and uses the pipe to process data items generated by one or more producing threads.

\begin{verbatim}
void consumer_thread(void)
{
    unsigned char buffer[120];
    size_t bytes_read;
    struct message_header  *header = (struct message_header *)buffer;

    while (1) {
        rc = k_pipe_get(&my_pipe, buffer, sizeof(buffer), &bytes_read,
                          sizeof(header), K_MSEC(100));

        if ((rc < 0) || (bytes_read < sizeof (header))) {
            /* Incomplete message header received */
            ...
        } else if (header->num_data_bytes + sizeof(header) > bytes_read) {
            /* Only some data was received */
            ...
        } else {
            /* All data was received */
            ...
        }
    }
}
\end{verbatim}
Use a pipe to send streams of data between threads.

**Note:** A pipe can be used to transfer long streams of data if desired. However it is often preferable to send pointers to large data items to avoid copying the data.

**Flushing a Pipe’s Buffer** Data is flushed from the pipe’s ring buffer by calling `k_pipe_buffer_flush()`.

The following code builds on the examples above, and flushes the pipe’s buffer.

```c
void monitor_thread(void)
{
    while (1) {
        /* Pipe buffer contains stale data. Flush it. */
        k_pipe_buffer_flush(&my_pipe);
        ...
    }
}
```

**Flushing a Pipe** All data in the pipe is flushed by calling `k_pipe_flush()`.

The following code builds on the examples above, and flushes all the data in the pipe.

**Suggested uses**

```c
void monitor_thread(void)
{
    while (1) {
        ...
        /* Critical error detected. Flush the entire pipe to reset it. */
        k_pipe_flush(&my_pipe);
        ...
    }
}
```

**Configuration Options** Related configuration options:

- None.

**API Reference**

`group pipe.Apis`

**Defines**

```c
K_PIPE_DEFINE(name, pipe_buffer_size, pipe_align)
```

Statically define and initialize a pipe.

The pipe can be accessed outside the module where it is defined using:

```c
extern struct k_pipe <name>;
```
Parameters

- **name** – Name of the pipe.
- **pipe_buffer_size** – Size of the pipe’s ring buffer (in bytes), or zero if no ring buffer is used.
- **pipe_align** – Alignment of the pipe’s ring buffer (power of 2).

Functions

```c
void k_pipe_init(struct k_pipe *pipe, unsigned char *buffer, size_t size)
```
Initialize a pipe.
This routine initializes a pipe object, prior to its first use.

**Parameters**

- **pipe** – Address of the pipe.
- **buffer** – Address of the pipe’s ring buffer, or NULL if no ring buffer is used.
- **size** – Size of the pipe’s ring buffer (in bytes), or zero if no ring buffer is used.

```c
int k_pipe_cleanup(struct k_pipe *pipe)
```
Release a pipe’s allocated buffer.
If a pipe object was given a dynamically allocated buffer via `k_pipe_alloc_init()`, this will free it. This function does nothing if the buffer wasn’t dynamically allocated.

**Parameters**

- **pipe** – Address of the pipe.

**Return values**

- **0** – on success
- **-EAGAIN** – nothing to cleanup

```c
int k_pipe_alloc_init(struct k_pipe *pipe, size_t size)
```
Initialize a pipe and allocate a buffer for it.
Storage for the buffer region will be allocated from the calling thread’s resource pool. This memory will be released if `k_pipe_cleanup()` is called, or userspace is enabled and the pipe object loses all references to it.

This function should only be called on uninitialized pipe objects.

**Parameters**

- **pipe** – Address of the pipe.
- **size** – Size of the pipe’s ring buffer (in bytes), or zero if no ring buffer is used.

**Return values**

- **0** – on success
- **-ENOMEM** – if memory couldn’t be allocated

```c
int k_pipe_put(struct k_pipe *pipe, void *data, size_t bytes_to_write, size_t *bytes_written, size_t min_xfer, k_timeout_t timeout)
```
Write data to a pipe.
This routine writes up to `bytes_to_write` bytes of data to `pipe`.

**Parameters**

- **pipe** – Address of the pipe.
- **data** – Address of data to write.
• bytes_to_write – Size of data (in bytes).
• bytes_written – Address of area to hold the number of bytes written.
• min_xfer – Minimum number of bytes to write.
• timeout – Waiting period to wait for the data to be written, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

• 0 – At least min_xfer bytes of data were written.
• -EINVAL – Invalid parameters supplied.
• -EIO – Returned without waiting; zero data bytes were written.
• -EAGAIN – Waiting period timed out; between zero and min_xfer minus one data bytes were written.

int k_pipe_get(struct k_pipe *pipe, void *data, size_t bytes_to_read, size_t *bytes_read, size_t min_xfer, k_timeout_t timeout)

Read data from a pipe.

This routine reads up to bytes_to_read bytes of data from pipe.

Parameters

• pipe – Address of the pipe.
• data – Address to place the data read from pipe.
• bytes_to_read – Maximum number of data bytes to read.
• bytes_read – Address of area to hold the number of bytes read.
• min_xfer – Minimum number of data bytes to read.
• timeout – Waiting period to wait for the data to be read, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

• 0 – At least min_xfer bytes of data were read.
• -EINVAL – Invalid parameters supplied.
• -EIO – Returned without waiting; zero data bytes were read.
• -EAGAIN – Waiting period timed out; between zero and min_xfer minus one data bytes were read.

size_t k_pipe_read_avail(struct k_pipe *pipe)

Query the number of bytes that may be read from pipe.

Parameters

• pipe – Address of the pipe.

Return values a – number n such that 0 <= n <= k_pipe::size; the result is zero for unbuffered pipes.

size_t k_pipe_write_avail(struct k_pipe *pipe)

Query the number of bytes that may be written to pipe.

Parameters

• pipe – Address of the pipe.

Return values a – number n such that 0 <= n <= k_pipe::size; the result is zero for unbuffered pipes.
void k_pipe_flush(struct k_pipe *pipe)
    Flush the pipe of write data.

This routine flushes the pipe. Flushing the pipe is equivalent to reading both all the data in the pipe's buffer and all the data waiting to go into that pipe into a large temporary buffer and discarding the buffer. Any writers that were previously pended become unpended.

**Parameters**
- `pipe` – Address of the pipe.

void k_pipe_buffer_flush(struct k_pipe *pipe)
    Flush the pipe's internal buffer.

This routine flushes the pipe's internal buffer. This is equivalent to reading up to N bytes from the pipe (where N is the size of the pipe's buffer) into a temporary buffer and then discarding that buffer. If there were writers previously pending, then some may unpend as they try to fill up the pipe's emptied buffer.

**Parameters**
- `pipe` – Address of the pipe.

struct k_pipe
    #include <kernel.h> Pipe Structure

**Public Members**

unsigned char *buffer
    Pipe buffer: may be NULL

size_t size
    Buffer size

size_t bytes_used

size_t read_index
    Where in buffer to read from

size_t write_index
    Where in buffer to write

struct k_spinlock lock
    Synchronization lock

_wait_q_t readers
    Reader wait queue

_wait_q_t writers
    Writer wait queue
7.14.3 Memory Management

These pages cover memory allocation and management services.

Memory Heaps

Zephyr provides a collection of utilities that allow threads to dynamically allocate memory.

Synchronized Heap Allocator

Creating a Heap  The simplest way to define a heap is statically, with the K_HEAP_DEFINE macro. This creates a static k_heap variable with a given name that manages a memory region of the specified size. Heaps can also be created to manage arbitrary regions of application-controlled memory using k_heap_init().

Allocating Memory  Memory can be allocated from a heap using k_heap_alloc(), passing it the address of the heap object and the number of bytes desired. This functions similarly to standard C malloc(), returning a NULL pointer on an allocation failure.

The heap supports blocking operation, allowing threads to go to sleep until memory is available. The final argument is a k_timeout_t timeout value indicating how long the thread may sleep before returning, or else one of the constant timeout values K_NO_WAIT or K_FOREVER.

Releasing Memory  Memory allocated with k_heap_alloc() must be released using k_heap_free(). Similar to standard C free(), the pointer provided must be either a NULL value or a pointer previously returned by k_heap_alloc() for the same heap. Freeing a NULL value is defined to have no effect.

Low Level Heap Allocator  The underlying implementation of the k_heap abstraction is provided a data structure named sys_heap. This implements exactly the same allocation semantics, but provides no kernel synchronization tools. It is available for applications that want to manage their own blocks of memory in contexts (for example, userspace) where synchronization is unavailable or more complicated. Unlike k_heap, all calls to any sys_heap functions on a single heap must be serialized by the caller. Simultaneous use from separate threads is disallowed.

Implementation  Internally, the sys_heap memory block is partitioned into “chunks” of 8 bytes. All allocations are made out of a contiguous region of chunks. The first chunk of every allocation or unused block is prefixed by a chunk header that stores the length of the chunk, the length of the next lower (“left”) chunk in physical memory, a bit indicating whether the chunk is in use, and chunk-indexed link pointers to the previous and next chunk in a “free list” to which unused chunks are added.

The heap code takes reasonable care to avoid fragmentation. Free block lists are stored in “buckets” by their size, each bucket storing blocks within one power of two (i.e. a bucket for blocks of 3-4 chunks, another for 5-8, 9-16, etc...) this allows new allocations to be made from the smallest/most-fragmented...
blocks available. Also, as allocations are freed and added to the heap, they are automatically combined with adjacent free blocks to prevent fragmentation.

All metadata is stored at the beginning of the contiguous block of heap memory, including the variable-length list of bucket list heads (which depend on heap size). The only external memory required is the sys_heap structure itself.

The sys_heap functions are unsynchronized. Care must be taken by any users to prevent concurrent access. Only one context may be inside one of the API functions at a time.

The heap code takes care to present high performance and reliable latency. All sys_heap API functions are guaranteed to complete within constant time. On typical architectures, they will all complete within 1-200 cycles. One complexity is that the search of the minimum bucket size for an allocation (the set of free blocks that “might fit”) has a compile-time upper bound of iterations to prevent unbounded list searches, at the expense of some fragmentation resistance. This CONFIG_SYS_HEAP_ALLOC_LOOPS value may be chosen by the user at build time, and defaults to a value of 3.

Multi-Heap Wrapper Utility The sys_heap utility requires that all managed memory be in a single contiguous block. It is common for complicated microcontroller applications to have more complicated memory setups that they still want to manage dynamically as a “heap”. For example, the memory might exist as separate discontiguous regions, different areas may have different cache, performance or power behavior, peripheral devices may only be able to perform DMA to certain regions, etc…

For those situations, Zephyr provides a sys_multi_heap utility. Effectively this is a simple wrapper around a set of one or more sys_heap objects. It should be initialized after its child heaps via sys_multi_heap_init(), after which each heap can be added to the managed set via sys_multi_heap_add_heap(). No destruction utility is provided; just as for sys_heap, applications that want to destroy a multi heap should simply ensure all allocated blocks are freed (or at least will never be used again) and repurpose the underlying memory for another usage.

It has a single pair of allocation entry points, sys_multi_heap_alloc() and sys_multi_heap_aligned_alloc(). These behave identically to the sys_heap functions with similar names, except that they also accept an opaque “configuration” parameter. This pointer is uninspected by the multi heap code itself; instead it is passed to a callback function provided at initialization time. This application-provided callback is responsible for doing the underlying allocation from one of the managed heaps, and may use the configuration parameter in any way it likes to make that decision.

When unused, a multi heap may be freed via sys_multi_heap_free(). The application does not need to pass a configuration parameter. Memory allocated from any of the managed sys_heap objects may be freed with in the same way.

System Heap The system heap is a predefined memory allocator that allows threads to dynamically allocate memory from a common memory region in a malloc()-like manner.

Only a single system heap is defined. Unlike other heaps or memory pools, the system heap cannot be directly referenced using its memory address.

The size of the system heap is configurable to arbitrary sizes, subject to space availability.

A thread can dynamically allocate a chunk of heap memory by calling k_malloc(). The address of the allocated chunk is guaranteed to be aligned on a multiple of pointer sizes. If a suitable chunk of heap memory cannot be found NULL is returned.

When the thread is finished with a chunk of heap memory it can release the chunk back to the system heap by calling k_free().

Defining the Heap Memory Pool The size of the heap memory pool is specified using the CONFIG_HEAP_MEM_POOL_SIZE configuration option.
By default, the heap memory pool size is zero bytes. This value instructs the kernel not to define the heap memory pool object. The maximum size is limited by the amount of available memory in the system. The project build will fail in the link stage if the size specified can not be supported.

**Allocating Memory**  A chunk of heap memory is allocated by calling `k_malloc()`.
The following code allocates a 200 byte chunk of heap memory, then fills it with zeros. A warning is issued if a suitable chunk is not obtained.

```c
char *mem_ptr;
mem_ptr = k_malloc(200);
if (mem_ptr != NULL)) {
    memset(mem_ptr, 0, 200);
    ...
} else {
    printf("Memory not allocated");
}
```

**Releasing Memory**  A chunk of heap memory is released by calling `k_free()`.
The following code allocates a 75 byte chunk of memory, then releases it once it is no longer needed.

```c
char *mem_ptr;
mem_ptr = k_malloc(75);
... /* use memory block */
k_free(mem_ptr);
```

**Suggested Uses**  Use the heap memory pool to dynamically allocate memory in a `malloc()`-like manner.

**Configuration Options**  Related configuration options:

- `CONFIG_HEAP_MEM_POOL_SIZE`

**API Reference**

`group heap_apis`

**Defines**

`K_HEAP_DEFINE(name, bytes)`

Define a static `k_heap`.

This macro defines and initializes a static memory region and `k_heap` of the requested size. After kernel start, `&name` can be used as if `k_heap_init()` had been called.

Note that this macro enforces a minimum size on the memory region to accommodate metadata requirements. Very small heaps will be padded to fit.

**Parameters**

- `name` – Symbol name for the struct `k_heap` object
- `bytes` – Size of memory region, in bytes
K_HEAP_DEFINE_NOCACHE(name, bytes)
Define a static \textit{k_heap} in uncached memory.

This macro defines and initializes a static memory region and \textit{k_heap} of the requested size in uncache memory. After kernel start, \&name can be used as if \textit{k_heap_init()} had been called.

Note that this macro enforces a minimum size on the memory region to accommodate meta-data requirements. Very small heaps will be padded to fit.

\textbf{Parameters}
- \textit{name} – Symbol name for the struct \textit{k_heap} object
- \textit{bytes} – Size of memory region, in bytes

\textbf{Functions}

void \textit{k_heap_init} (struct \textit{k_heap} \*h, void \*mem, size_t \textit{bytes})
Initialize a \textit{k_heap}.

This constructs a synchronized \textit{k_heap} object over a memory region specified by the user. Note that while any alignment and size can be passed as valid parameters, internal alignment restrictions inside the inner sys_heap mean that not all bytes may be usable as allocated memory.

\textbf{Parameters}
- \textit{h} – Heap struct to initialize
- \textit{mem} – Pointer to memory.
- \textit{bytes} – Size of memory region, in bytes

void \*\textit{k_heap_aligned_alloc} (struct \textit{k_heap} \*h, size_t \textit{align}, size_t \textit{bytes}, \textit{k_timeout_t} \textit{timeout})
Allocate aligned memory from a \textit{k_heap}.

Behaves in all ways like \textit{k_heap_alloc()}, except that the returned memory (if available) will have a starting address in memory which is a multiple of the specified power-of-two alignment value in bytes. The resulting memory can be returned to the heap using \textit{k_heap_free()}.

\textbf{Function properties (list may not be complete) isr-ok}

\textbf{Note}: \textit{timeout} must be set to K_NO_WAIT if called from ISR.

\textbf{Note}: When CONFIG_MULTITHREADING=n any \textit{timeout} is treated as K_NO_WAIT.

\textbf{Parameters}
- \textit{h} – Heap from which to allocate
- \textit{align} – Alignment in bytes, must be a power of two
- \textit{bytes} – Number of bytes requested
- \textit{timeout} – How long to wait, or K_NO_WAIT

\textbf{Returns} Pointer to memory the caller can now use

void \*\textit{k_heap_alloc} (struct \textit{k_heap} \*h, size_t \textit{bytes}, \textit{k_timeout_t} \textit{timeout})
Allocate memory from a \textit{k_heap}.
Allocates and returns a memory buffer from the memory region owned by the heap. If no memory is available immediately, the call will block for the specified timeout (constructed via the standard timeout API, or K_NO_WAIT or K_FOREVER) waiting for memory to be freed. If the allocation cannot be performed by the expiration of the timeout, NULL will be returned.

**Function properties (list may not be complete)** *isr-ok*

**Note:** `timeout` must be set to K_NO_WAIT if called from ISR.

**Note:** When CONFIG_MULTITHREADING=n any `timeout` is treated as K_NO_WAIT.

**Parameters**
- `h` – Heap from which to allocate
- `bytes` – Desired size of block to allocate
- `timeout` – How long to wait, or K_NO_WAIT

**Returns** A pointer to valid heap memory, or NULL.

```c
void k_heap_free(struct k_heap *h, void *mem)
```

Free memory allocated by `k_heap_alloc()`

Returns the specified memory block, which must have been returned from `k_heap_alloc()`, to the heap for use by other callers. Passing a NULL block is legal, and has no effect.

**Parameters**
- `h` – Heap to which to return the memory
- `mem` – A valid memory block, or NULL

```c
void *k_aligned_alloc(size_t align, size_t size)
```

Allocate memory from the heap with a specified alignment.

This routine provides semantics similar to aligned_alloc(); memory is allocated from the heap with a specified alignment. However, one minor difference is that `k_aligned_alloc()` accepts any non-zero `size`, whereas aligned_alloc() only accepts a `size` that is an integral multiple of `align`.

Above, aligned_alloc() refers to: C11 standard (ISO/IEC 9899:2011): 7.22.3.1 The aligned_alloc function (p: 347-348)

**Parameters**
- `align` – Alignment of memory requested (in bytes).
- `size` – Amount of memory requested (in bytes).

**Returns** Address of the allocated memory if successful; otherwise NULL.

```c
void *k_malloc(size_t size)
```

Allocate memory from the heap.

This routine provides traditional malloc() semantics. Memory is allocated from the heap memory pool.

**Parameters**
- `size` – Amount of memory requested (in bytes).

**Returns** Address of the allocated memory if successful; otherwise NULL.
void k_free(void *ptr)
    Free memory allocated from heap.

    This routine provides traditional free() semantics. The memory being returned must have
    been allocated from the heap memory pool or k_mem_pool_malloc().

    If ptr is NULL, no operation is performed.

Parameters
    • ptr – Pointer to previously allocated memory.

void *k_calloc(size_t nmemb, size_t size)
Allocate memory from heap, array style.

    This routine provides traditional calloc() semantics. Memory is allocated from the heap mem-
    ory pool and zeroed.

Parameters
    • nmemb – Number of elements in the requested array
    • size – Size of each array element (in bytes).

Returns Address of the allocated memory if successful; otherwise NULL.

struct k_heap
#include <kernel.h>

Heap listener
group heap_listener_apis

Defines

HEAP_ID_FROM_POINTER(heap_pointer)
    Construct heap identifier from heap pointer.

    Construct a heap identifier from a pointer to the heap object, such as sys_heap.

Parameters
    • heap_pointer – Pointer to the heap object

HEAP_ID_LIBC
    Libc heap identifier.

    Identifier of the global libc heap.

HEAP_LISTENER_ALLOC_DEFINE(name, _heap_id, _alloc_cb)
    Define heap event listener node for allocation event.

    Sample usage:

    void on_heap_alloc(uintptr_t heap_id, void *mem, size_t bytes)
    {
        LOG_INF("Memory allocated at %p, size %ld", heap_id, mem, bytes);
    }

    HEAP_LISTENER_ALLOC_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_alloc);

Parameters
    • name – Name of the heap event listener object
- **_heap_id** – Identifier of the heap to be listened
- **_alloc_cb** – Function to be called for allocation event

```c
HEAP_LISTENER_FREE_DEFINE(name, _heap_id, _free_cb)
Define heap event listener node for free event.
```

Sample usage:
```c
void on_heap_free(uintptr_t heap_id, void *mem, size_t bytes)
{
    LOG_INF("Memory freed at %p, size %ld", heap_id, mem, bytes);
}
HEAP_LISTENER_FREE_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_free);
```

**Parameters**
- **name** – Name of the heap event listener object
- **_heap_id** – Identifier of the heap to be listened
- **_free_cb** – Function to be called for free event

```c
HEAP_LISTENER_RESIZE_DEFINE(name, _heap_id, _resize_cb)
Define heap event listener node for resize event.
```

Sample usage:
```c
void on_heap_resized(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)
{
    LOG_INF("Libc heap end moved from %p to %p", old_heap_end, new_heap_end);
}
HEAP_LISTENER_RESIZE_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_resized);
```

**Parameters**
- **name** – Name of the heap event listener object
- **_heap_id** – Identifier of the heap to be listened
- **_resize_cb** – Function to be called when the listened heap is resized

**Typedefs**
```c
typedef void (*heap_listener_resize_cb_t)(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)
Callback used when heap is resized.
```

**Note:** Minimal C library does not emit this event.

**Param heap_id**  Identifier of heap being resized
**Param old_heap_end**  Pointer to end of heap before resize
**Param new_heap_end**  Pointer to end of heap after resize
typedef void (*heap_listener_alloc_cb_t)(uintptr_t heap_id, void *mem, size_t bytes)
Callback used when there is heap allocation.

**Note:** Heaps managed by libraries outside of code in Zephyr main code repository may not emit this event.

**Note:** The number of bytes allocated may not match exactly to the request to the allocation function. Internal mechanism of the heap may allocate more than requested.

**Param heap_id**  Heap identifier

**Param mem**  Pointer to the allocated memory

**Param bytes**  Size of allocated memory

typedef void (*heap_listener_free_cb_t)(uintptr_t heap_id, void *mem, size_t bytes)
Callback used when memory is freed from heap.

**Note:** Heaps managed by libraries outside of code in Zephyr main code repository may not emit this event.

**Note:** The number of bytes freed may not match exactly to the request to the allocation function. Internal mechanism of the heap dictates how memory is allocated or freed.

**Param heap_id**  Heap identifier

**Param mem**  Pointer to the freed memory

**Param bytes**  Size of freed memory

**Enums**

enum heap_event_types
Values:

enumerator HEAP_EVT_UNKNOWN = 0

enumerator HEAP_RESIZE

enumerator HEAP_ALLOC

enumerator HEAP_FREE

enumerator HEAP_REALLOC
enumerator HEAP_MAX_EVENTS

Functions

void heap_listener_register(struct heap_listener *listener)

Register heap event listener.
Add the listener to the global list of heap listeners that can be notified by different heap implementations upon certain events related to the heap usage.

Parameters

• listener – Pointer to the heap_listener object

void heap_listener_unregister(struct heap_listener *listener)

Unregister heap event listener.
Remove the listener from the global list of heap listeners that can be notified by different heap implementations upon certain events related to the heap usage.

Parameters

• listener – Pointer to the heap_listener object

void heap_listener_notify_alloc(uintptr_t heap_id, void *mem, size_t bytes)

Notify listeners of heap allocation event.
Notify registered heap event listeners with matching heap identifier that an allocation has been done on heap

Parameters

• heap_id – Heap identifier
• mem – Pointer to the allocated memory
• bytes – Size of allocated memory

void heap_listener_notify_free(uintptr_t heap_id, void *mem, size_t bytes)

Notify listeners of heap free event.
Notify registered heap event listeners with matching heap identifier that memory is freed on heap

Parameters

• heap_id – Heap identifier
• mem – Pointer to the freed memory
• bytes – Size of freed memory

void heap_listener_notify_resize(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)

Notify listeners of heap resize event.
Notify registered heap event listeners with matching heap identifier that the heap has been resized.

Parameters

• heap_id – Heap identifier
• old_heap_end – Address of the heap end before the change
• new_heap_end – Address of the heap end after the change
struct heap_listener
   #include <heap_listener.h>

Public Members

sys_snode_t node
   Singly linked list node

uintptr_t heap_id
   Identifier of the heap whose events are listened.
   It can be a heap pointer, if the heap is represented as an object, or 0 in the case of the
global libc heap.

enum heap_event_types event
   The heap event to be notified.

Memory Slabs

A memory slab is a kernel object that allows memory blocks to be dynamically allocated from a designated
memory region. All memory blocks in a memory slab have a single fixed size, allowing them to be
allocated and released efficiently and avoiding memory fragmentation concerns.

- Concepts
  - Internal Operation
- Implementation
  - Defining a Memory Slab
  - Allocating a Memory Block
  - Releasing a Memory Block
- Suggested Uses
- Configuration Options
- API Reference

Concepts Any number of memory slabs can be defined (limited only by available RAM). Each memory
slab is referenced by its memory address.

A memory slab has the following key properties:

- The block size of each block, measured in bytes. It must be at least 4N bytes long, where N is
greater than 0.
- The number of blocks available for allocation. It must be greater than zero.
- A buffer that provides the memory for the memory slab's blocks. It must be at least “block size”
times “number of blocks” bytes long.

The memory slab's buffer must be aligned to an N-byte boundary, where N is a power of 2 larger than 2
(i.e. 4, 8, 16, . . . ). To ensure that all memory blocks in the buffer are similarly aligned to this boundary,
the block size must also be a multiple of N.

A memory slab must be initialized before it can be used. This marks all of its blocks as unused.
A thread that needs to use a memory block simply allocates it from a memory slab. When the thread finishes with a memory block, it must release the block back to the memory slab so the block can be reused.

If all the blocks are currently in use, a thread can optionally wait for one to become available. Any number of threads may wait on an empty memory slab simultaneously; when a memory block becomes available, it is given to the highest-priority thread that has waited the longest.

Unlike a heap, more than one memory slab can be defined, if needed. This allows for a memory slab with smaller blocks and others with larger-sized blocks. Alternatively, a memory pool object may be used.

**Internal Operation**  A memory slab’s buffer is an array of fixed-size blocks, with no wasted space between the blocks.

The memory slab keeps track of unallocated blocks using a linked list; the first 4 bytes of each unused block provide the necessary linkage.

**Implementation**

**Defining a Memory Slab**  A memory slab is defined using a variable of type `k_mem_slab`. It must then be initialized by calling `k_mem_slab_init()`.

The following code defines and initializes a memory slab that has 6 blocks that are 400 bytes long, each of which is aligned to a 4-byte boundary.

```c
struct k_mem_slab my_slab;
char __aligned(4) my_slab_buffer[6 * 400];
k_mem_slab_init(&my_slab, my_slab_buffer, 400, 6);
```

Alternatively, a memory slab can be defined and initialized at compile time by calling `K_MEM_SLAB_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the memory slab and its buffer.

```c
K_MEM_SLAB_DEFINE(my_slab, 400, 6, 4);
```

Similarly, you can define a memory slab in private scope:

```c
K_MEM_SLAB_DEFINE_STATIC(my_slab, 400, 6, 4);
```

**Allocating a Memory Block**  A memory block is allocated by calling `k_mem_slab_alloc()`.

The following code builds on the example above, and waits up to 100 milliseconds for a memory block to become available, then fills it with zeroes. A warning is printed if a suitable block is not obtained.

```c
char *block_ptr;

if (k_mem_slab_alloc(&my_slab, &block_ptr, 100) == 0)) {
    memset(block_ptr, 0, 400);
}
else {
    printf("Memory allocation time-out");
}
```
Releasing a Memory Block  A memory block is released by calling \texttt{k_mem_slab_free()}.  

The following code builds on the example above, and allocates a memory block, then releases it once it is no longer needed.

```c
char *block_ptr;

k_mem_slab_alloc(&my_slab, &block_ptr, K_FOREVER);
...
/* use memory block pointed at by block_ptr */
k_mem_slab_free(&my_slab, &block_ptr);
```

Suggested Uses  Use a memory slab to allocate and free memory in fixed-size blocks.  

Use memory slab blocks when sending large amounts of data from one thread to another, to avoid unnecessary copying of the data.

Configuration Options  Related configuration options:

- \texttt{CONFIG_MEM_SLAB_TRACE_MAX_UTILIZATION}

API Reference

group mem_slab.Apis

Defines

\texttt{K_MEM_SLAB_DEFINE(name, slab_block_size, slab_num_blocks, slab_align)}  
Statically define and initialize a memory slab in a public (non-static) scope.

The memory slab's buffer contains \texttt{slab_num_blocks} memory blocks that are \texttt{slab_block_size} bytes long. The buffer is aligned to a \texttt{slab_align}-byte boundary. To ensure that each memory block is similarly aligned to this boundary, \texttt{slab_block_size} must also be a multiple of \texttt{slab_align}.

The memory slab can be accessed outside the module where it is defined using:

```c
extern struct k_mem_slab <name>;
```

Note:  This macro cannot be used together with a static keyword. If such a use-case is desired, use \texttt{K_MEM_SLAB_DEFINE_STATIC} instead.

Parameters

- \texttt{name} – Name of the memory slab.
- \texttt{slab_block_size} – Size of each memory block (in bytes).
- \texttt{slab_num_blocks} – Number memory blocks.
- \texttt{slab_align} – Alignment of the memory slab's buffer (power of 2).

\texttt{K_MEM_SLAB_DEFINE_STATIC(name, slab_block_size, slab_num_blocks, slab_align)}  
Statically define and initialize a memory slab in a private (static) scope.

The memory slab's buffer contains \texttt{slab_num_blocks} memory blocks that are \texttt{slab_block_size} bytes long. The buffer is aligned to a \texttt{slab_align}-byte boundary. To ensure that each memory block is similarly aligned to this boundary, \texttt{slab_block_size} must also be a multiple of \texttt{slab_align}.
Parameters

- **name** – Name of the memory slab.
- **slab_block_size** – Size of each memory block (in bytes).
- **slab_num_blocks** – Number of memory blocks.
- **slab_align** – Alignment of the memory slab's buffer (power of 2).

Functions

```c
int k_mem_slab_init(struct k_mem_slab *slab, void *buffer, size_t block_size, uint32_t num_blocks)
```

Initializes a memory slab.

Initializes a memory slab, prior to its first use.

The memory slab's buffer contains `slab_num_blocks` memory blocks that are `slab_block_size` bytes long. The buffer must be aligned to an N-byte boundary matching a word boundary, where N is a power of 2 (i.e., 4 on 32-bit systems, 8, 16, ...). To ensure that each memory block is similarly aligned to this boundary, `slab_block_size` must also be a multiple of N.

Parameters

- **slab** – Address of the memory slab.
- **buffer** – Pointer to buffer used for the memory blocks.
- **block_size** – Size of each memory block (in bytes).
- **num_blocks** – Number of memory blocks.

Return values

- **0** – on success
- **EINVAL** – invalid data supplied

```c
int k_mem_slab_alloc(struct k_mem_slab *slab, void **mem, k_timeout_t timeout)
```

Allocates memory from a memory slab.

This routine allocates a memory block from a memory slab.

Function properties (list may not be complete) **ISR-ok**

**Note:** `timeout` must be set to K_NO_WAIT if called from ISR.

**Note:** When CONFIG_MULTITHREADING=n any `timeout` is treated as K_NO_WAIT.

Parameters

- **slab** – Address of the memory slab.
- **mem** – Pointer to block address area.
- **timeout** – Non-negative waiting period to wait for operation to complete. Use K_NO_WAIT to return without waiting, or K_FOREVER to wait as long as necessary.

Return values

- **0** – Memory allocated. The block address area pointed at by `mem` is set to the starting address of the memory block.
-ENOMEM – Returned without waiting.
-ENOMSG – Waiting period timed out.
-EINVAL – Invalid data supplied

void k_mem_slab_free(struct k_mem_slab *slab, void **mem)
Free memory allocated from a memory slab.

This routine releases a previously allocated memory block back to its associated memory slab.

Parameters
- slab – Address of the memory slab.
- mem – Pointer to block address area (as set by k_mem_slab_alloc()).

static inline uint32_t k_mem_slab_num_used_get(struct k_mem_slab *slab)
Get the number of used blocks in a memory slab.

This routine gets the number of memory blocks that are currently allocated in slab.

Parameters
- slab – Address of the memory slab.

Returns Number of allocated memory blocks.

static inline uint32_t k_mem_slab_max_used_get(struct k_mem_slab *slab)
Get the number of maximum used blocks so far in a memory slab.

This routine gets the maximum number of memory blocks that were allocated in slab.

Parameters
- slab – Address of the memory slab.

Returns Maximum number of allocated memory blocks.

static inline uint32_t k_mem_slab_num_free_get(struct k_mem_slab *slab)
Get the number of unused blocks in a memory slab.

This routine gets the number of memory blocks that are currently unallocated in slab.

Parameters
- slab – Address of the memory slab.

Returns Number of unallocated memory blocks.

7.14.4 Timing

These pages cover timing related services.

Kernel Timing

Zephyr provides a robust and scalable timing framework to enable reporting and tracking of timed events from hardware timing sources of arbitrary precision.

Time Units  Kernel time is tracked in several units which are used for different purposes.

Real time values, typically specified in milliseconds or microseconds, are the default presentation of time to application code. They have the advantages of being universally portable and pervasively understood, though they may not match the precision of the underlying hardware perfectly.

The kernel presents a “cycle” count via the k_cycle_get_32() and k_cycle_get_64() APIs. The intent is that this counter represents the fastest cycle counter that the operating system is able to present
to the user (for example, a CPU cycle counter) and that the read operation is very fast. The expectation is that very sensitive application code might use this in a polling manner to achieve maximal precision. The frequency of this counter is required to be steady over time, and is available from sys_clock_hw_cycles_per_sec() (which on almost all platforms is a runtime constant that evaluates to CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC).

For asynchronous timekeeping, the kernel defines a “ticks” concept. A “tick” is the internal count in which the kernel does all its internal uptime and timeout bookkeeping. Interrupts are expected to be delivered on tick boundaries to the extent practical, and no fractional ticks are tracked. The choice of tick rate is configurable via CONFIG_SYS_CLOCK_TICKS_PER_SEC. Defaults on most hardware platforms (ones that support setting arbitrary interrupt timeouts) are expected to be in the range of 10 kHz, with software emulation platforms and legacy drivers using a more traditional 100 Hz value.

Conversion Zephyr provides an extensively enumerated conversion library with rounding control for all time units. Any unit of “ms” (milliseconds), “us” (microseconds), “tick”, or “cyc” can be converted to any other. Control of rounding is provided, and each conversion is available in “floor” (round down to nearest output unit), “ceil” (round up) and “near” (round to nearest). Finally the output precision can be specified as either 32 or 64 bits.

For example: k_ms_to_ticks_ceil32() will convert a millisecond input value to the next higher number of ticks, returning a result truncated to 32 bits of precision; and k_cyc_to_us_floor64() will convert a measured cycle count to an elapsed number of microseconds in a full 64 bits of precision. See the reference documentation for the full enumeration of conversion routines.

On most platforms, where the various counter rates are integral multiples of each other and where the output fits within a single word, these conversions expand to a 2-4 operation sequence, requiring full precision only where actually required and requested.

Uptime The kernel tracks a system uptime count on behalf of the application. This is available at all times via k_uptime_get(), which provides an uptime value in milliseconds since system boot. This is expected to be the utility used by most portable application code.

The internal tracking, however, is as a 64 bit integer count of ticks. Apps with precise timing requirements (that are willing to do their own conversions to portable real time units) may access this with k_uptime_ticks().

Timeouts The Zephyr kernel provides many APIs with a “timeout” parameter. Conceptually, this indicates the time at which an event will occur. For example:

• Kernel blocking operations like k_sem_take() or k_queue_get() may provide a timeout after which the routine will return with an error code if no data is available.

• Kernel k_timer objects must specify delays for their duration and period.

• The kernel k_work_delayable API provides a timeout parameter indicating when a work queue item will be added to the system queue.

All these values are specified using a k_timeout_t value. This is an opaque struct type that must be initialized using one of a family of kernel timeout macros. The most common, K_MSEC, defines a time in milliseconds after the current time (strictly: the time at which the kernel receives the timeout value).

Other options for timeout initialization follow the unit conventions described above: K_NSEC(), K_USEC, K_TICKS and K_CYC() specify timeout values that will expire after specified numbers of nanoseconds, microseconds, ticks and cycles, respectively.

Precision of k_timeout_t values is configurable, with the default being 32 bits. Large uptime counts in non-tick units will experience complicated rollover semantics, so it is expected that timing-sensitive applications with long uptimes will be configured to use a 64 bit timeout type.
Finally, it is possible to specify timeouts as absolute times since system boot. A timeout initialized with `K_TIMEOUT_ABS_MS` indicates a timeout that will expire after the system uptime reaches the specified value. There are likewise nanosecond, microsecond, cycles and ticks variants of this API.

### Timing Internals

#### Timeout Queue
All Zephyr `k_timeout_t` events specified using the API above are managed in a single, global queue of events. Each event is stored in a double-linked list, with an attendant delta count in ticks from the previous event. The action to take on an event is specified as a callback function pointer provided by the subsystem requesting the event, along with a `_timeout` tracking struct that is expected to be embedded within subsystem-defined data structures (for example: a `wait_q` struct, or a `k_tid_t` thread struct).

Note that all variant units passed via a `k_timeout_t` are converted to ticks once on insertion into the list. There no multiple-conversion steps internal to the kernel, so precision is guaranteed at the tick level no matter how many events exist or how long a timeout might be.

Note that the list structure means that the CPU work involved in managing large numbers of timeouts is quadratic in the number of active timeouts. The API design of the timeout queue was intended to permit a more scalable backend data structure, but no such implementation exists currently.

#### Timer Drivers
Kernel timing at the tick level is driven by a timer driver with a comparatively simple API.

- The driver is expected to be able to “announce” new ticks to the kernel via the `sys_clock_announce()` call, which passes an integer number of ticks that have elapsed since the last announce call (or system boot). These calls can occur at any time, but the driver is expected to attempt to ensure (to the extent practical given interrupt latency interactions) that they occur near tick boundaries (i.e. not “halfway through” a tick), and most importantly that they be correct over time and subject to minimal skew vs. other counters and real world time.

- The driver is expected to provide a `sys_clock_set_timeout()` call to the kernel which indicates how many ticks may elapse before the kernel must receive an announce call to trigger registered timeouts. It is legal to announce new ticks before that moment (though they must be correct) but delay after that will cause events to be missed. Note that the timeout value passed here is in a delta from current time, but that does not absolve the driver of the requirement to provide ticks at a steady rate over time. Naive implementations of this function are subject to bugs where the fractional tick gets “reset” incorrectly and causes clock skew.

- The driver is expected to provide a `sys_clock_elapsed()` call which provides a current indication of how many ticks have elapsed (as compared to a real world clock) since the last call to `sys_clock_announce()`, which the kernel needs to test newly arriving timeouts for expiration.

Note that a natural implementation of this API results in a “tickless” kernel, which receives and processes timer interrupts only for registered events, relying on programmable hardware counters to provide irregular interrupts. But a traditional, “ticked” or “dumb” counter driver can be trivially implemented also:

- The driver can receive interrupts at a regular rate corresponding to the OS tick rate, calling `sys_clock_announce()` with an argument of one each time.

- The driver can ignore calls to `sys_clock_set_timeout()`, as every tick will be announced regardless of timeout status.

- The driver can return zero for every call to `sys_clock_elapsed()` as no more than one tick can be detected as having elapsed (because otherwise an interrupt would have been received).

#### SMP Details
In general, the timer API described above does not change when run in a multiprocessor context. The kernel will internally synchronize all access appropriately, and ensure that all critical sections are small and minimal. But some notes are important to detail:
• Zephyr is agnostic about which CPU services timer interrupts. It is not illegal (though probably undesirable in some circumstances) to have every timer interrupt handled on a single processor. Existing SMP architectures implement symmetric timer drivers.

• The `sys_clock_announce()` call is expected to be globally synchronized at the driver level. The kernel does not do any per-CPU tracking, and expects that if two timer interrupts fire simultaneously, that only one will provide the current tick count to the timing subsystem. The other may legally provide a tick count of zero if no ticks have elapsed. It should not “skip” the announce call because of timeslicing requirements (see below).

• Some SMP hardware uses a single, global timer device, others use a per-CPU counter. The complexity here (for example: ensuring counter synchronization between CPUs) is expected to be managed by the driver, not the kernel.

• The next timeout value passed back to the driver via `sys_clock_set_timeout()` is done identically for every CPU. So by default, every CPU will see simultaneous timer interrupts for every event, even though by definition only one of them should see a non-zero ticks argument to `sys_clock_announce()`. This is probably a correct default for timing sensitive applications (because it minimizes the chance that an errant ISR or interrupt lock will delay a timeout), but may be a performance problem in some cases. The current design expects that any such optimization is the responsibility of the timer driver.

**Time Slicing** An auxiliary job of the timing subsystem is to provide tick counters to the scheduler that allow implementation of time slicing of threads. A thread time-slice cannot be a timeout value, as it does not reflect a global expiration but instead a per-CPU value that needs to be tracked independently on each CPU in an SMP context.

Because there may be no other hardware available to drive timeslicing, Zephyr multiplexes the existing timer driver. This means that the value passed to `sys_clock_set_timeout()` may be clamped to a smaller value than the current next timeout when a time sliced thread is currently scheduled.

**Subsystems that keep millisecond APIs** In general, code like this will port just like applications code will. Millisecond values from the user may be treated any way the subsystem likes, and then converted into kernel timeouts using `K_MSEC()` at the point where they are presented to the kernel.

Obviously this comes at the cost of not being able to use new features, like the higher precision timeout constructors or absolute timeouts. But for many subsystems with simple needs, this may be acceptable.

One complexity is `K_FOREVER`. Subsystems that might have been able to accept this value to their millisecond API in the past no longer can, because it is no longer an integral type. Such code will need to use a different, integer-valued token to represent “forever”. `K_NO_WAIT` has the same typesafety concern too, of course, but as it is (and has always been) simply a numerical zero, it has a natural porting path.

**Subsystems using k_timeout_t** Ideally, code that takes a “timeout” parameter specifying a time to wait should be using the kernel native abstraction where possible. But `k_timeout_t` is opaque, and needs to be converted before it can be inspected by an application.

Some conversions are simple. Code that needs to test for `K_FOREVER` can simply use the `K_TIMEOUT_EQ()` macro to test the opaque struct for equality and take special action.

The more complicated case is when the subsystem needs to take a timeout and loop, waiting for it to finish while doing some processing that may require multiple blocking operations on underlying kernel code. For example, consider this design:

```c
void my_wait_for_event(struct my_subsys *obj, int32_t timeout_in_ms)
{
    while (true) {
        uint32_t start = k_uptime_get_32();

        // The rest of your loop...
    }
}
```
if (is_event_complete(obj)) {
    return;
}

/* Wait for notification of state change */
k_sem_take(obj->sem, timeout_in_ms);

/* Subtract elapsed time */
timeout_in_ms -= (k_uptime_get_32() - start);
}
}

This code requires that the timeout value be inspected, which is no longer possible. For situations like this, the new API provides an internal `sys_clock_timeout_end_calc()` routine that converts an arbitrary timeout to the uptime value in ticks at which it will expire. So such a loop might look like:

```c
void my_wait_for_event(struct my_subsys *obj, k_timeout_t timeout_in_ms)
{
    /* Compute the end time from the timeout */
    uint64_t end = sys_clock_timeout_end_calc(timeout_in_ms);

    while (end > k_uptime_ticks()) {
        if (is_event_complete(obj)) {
            return;
        }

        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout_in_ms);
    }
}
```

Note that `sys_clock_timeout_end_calc()` returns values in units of ticks, to prevent conversion aliasing, is always presented at 64 bit uptime precision to prevent rollover bugs, handles special `K_FOREVER` naturally (as `UINT64_MAX`), and works identically for absolute timeouts as well as conventional ones.

But some care is still required for subsystems that use it. Note that delta timeouts need to be interpreted relative to a “current time”, and obviously that time is the time of the call to `sys_clock_timeout_end_calc()`. But the user expects that the time is the time they passed the timeout to you. Care must be taken to call this function just once, as synchronously as possible to the timeout creation in user code. It should not be used on a “stored” timeout value, and should never be called iteratively in a loop.

**API Reference**

**group clock_apis**

Clock APIs.

**Defines**

```
K_NO_WAIT
    Generate null timeout delay.
```

This macro generates a timeout delay that instructs a kernel API not to wait if the requested operation cannot be performed immediately.

**Returns** Timeout delay value.
K\_NSEC(t)
    Generate timeout delay from nanoseconds.
    This macro generates a timeout delay that instructs a kernel API to wait up to \(t\) nanoseconds to perform the requested operation. Note that timer precision is limited to the tick rate, not the requested value.
    
    Parameters
    • \(t\) – Duration in nanoseconds.
    
    Returns Timeout delay value.

K\_USEC(t)
    Generate timeout delay from microseconds.
    This macro generates a timeout delay that instructs a kernel API to wait up to \(t\) microseconds to perform the requested operation. Note that timer precision is limited to the tick rate, not the requested value.
    
    Parameters
    • \(t\) – Duration in microseconds.
    
    Returns Timeout delay value.

K\_CYC(t)
    Generate timeout delay from cycles.
    This macro generates a timeout delay that instructs a kernel API to wait up to \(t\) cycles to perform the requested operation.
    
    Parameters
    • \(t\) – Duration in cycles.
    
    Returns Timeout delay value.

K\_TICKS(t)
    Generate timeout delay from system ticks.
    This macro generates a timeout delay that instructs a kernel API to wait up to \(t\) ticks to perform the requested operation.
    
    Parameters
    • \(t\) – Duration in system ticks.
    
    Returns Timeout delay value.

K\_MSEC(ms)
    Generate timeout delay from milliseconds.
    This macro generates a timeout delay that instructs a kernel API to wait up to \(ms\) milliseconds to perform the requested operation.
    
    Parameters
    • \(ms\) – Duration in milliseconds.
    
    Returns Timeout delay value.

K\_SECONDS(s)
    Generate timeout delay from seconds.
    This macro generates a timeout delay that instructs a kernel API to wait up to \(s\) seconds to perform the requested operation.
    
    Parameters
    • \(s\) – Duration in seconds.
    
    Returns Timeout delay value.
K_MINUTES(m)
Generate timeout delay from minutes.
This macro generates a timeout delay that instructs a kernel API to wait up to \( m \) minutes to perform the requested operation.

**Parameters**
- \( m \) – Duration in minutes.

**Returns** Timeout delay value.

K_HOURS(h)
Generate timeout delay from hours.
This macro generates a timeout delay that instructs a kernel API to wait up to \( h \) hours to perform the requested operation.

**Parameters**
- \( h \) – Duration in hours.

**Returns** Timeout delay value.

K_FOREVER
Generate infinite timeout delay.
This macro generates a timeout delay that instructs a kernel API to wait as long as necessary to perform the requested operation.

**Returns** Timeout delay value.

K_TICKS_FOREVER

K_TIMEOUT_EQ(a, b)
Compare timeouts for equality.
The \( k\_timeout\_t \) object is an opaque struct that should not be inspected by application code. This macro exists so that users can test timeout objects for equality with known constants (e.g. K_NO_WAIT and K_FOREVER) when implementing their own APIs in terms of Zephyr timeout constants.

**Returns** True if the timeout objects are identical

**Typedefs**

typedef uint32_t k_ticks_t
Tick precision used in timeout APIs.
This type defines the word size of the timeout values used in \( k\_timeout\_t \) objects, and thus defines an upper bound on maximum timeout length (or equivalently minimum tick duration). Note that this does not affect the size of the system uptime counter, which is always a 64 bit count of ticks.

**Functions**

void sys_clock_set_timeout(int32_t ticks, bool idle)
Set system clock timeout.
Informs the system clock driver that the next needed call to \( \text{sys\_clock\_announce}() \) will not be until the specified number of ticks from the current time have elapsed. Note that spurious calls to \( \text{sys\_clock\_announce}() \) are allowed (i.e. it's legal to announce every tick and implement
this function as a noop), the requirement is that one tick announcement should occur within one tick BEFORE the specified expiration (that is, passing ticks=−1 means “announce the next tick”, this convention was chosen to match legacy usage). Similarly a ticks value of zero (or even negative) is legal and treated identically: it simply indicates the kernel would like the next tick announcement as soon as possible.

Note that ticks can also be passed the special value K_TICKS_FOREVER, indicating that no future timer interrupts are expected or required and that the system is permitted to enter an indefinite sleep even if this could cause rollover of the internal counter (i.e. the system uptime counter is allowed to be wrong).

Note also that it is conventional for the kernel to pass INT_MAX for ticks if it wants to preserve the uptime tick count but doesn't have a specific event to await. The intent here is that the driver will schedule any needed timeout as far into the future as possible. For the specific case of INT_MAX, the next call to sys_clock_announce() may occur at any point in the future, not just at INT_MAX ticks. But the correspondence between the announced ticks and real-world time must be correct.

A final note about SMP: note that the call to sys_clock_set_timeout() is made on any CPU, and reflects the next timeout desired globally. The resulting calls(s) to sys_clock_announce() must be properly serialized by the driver such that a given tick is announced exactly once across the system. The kernel does not (cannot, really) attempt to serialize things by “assigning” timeouts to specific CPUs.

Parameters

• ticks – Timeout in tick units
• idle – Hint to the driver that the system is about to enter the idle state immediately after setting the timeout

void sys_clock_idle_exit(void)
Timer idle exit notification.

This notifies the timer driver that the system is exiting the idle and allows it to do whatever bookkeeping is needed to restore timer operation and compute elapsed ticks.

Note: Legacy timer drivers also use this opportunity to call back into sys_clock_announce() to notify the kernel of expired ticks. This is allowed for compatibility, but not recommended. The kernel will figure that out on its own.

void sys_clock_announce(int32_t ticks)
Announce time progress to the kernel.

Informs the kernel that the specified number of ticks have elapsed since the last call to sys_clock_announce() (or system startup for the first call). The timer driver is expected to deliver these announcements as close as practical (subject to hardware and latency limitations) to tick boundaries.

Parameters

• ticks – Elapsed time, in ticks

uint32_t sys_clock_elapsed(void)
Ticks elapsed since last sys_clock_announce() call.

Queries the clock driver for the current time elapsed since the last call to sys_clock_announce() was made. The kernel will call this with appropriate locking, the driver needs only provide an instantaneous answer.

void sys_clock_disable(void)
Disable system timer.

This function is a no-op if the system timer does not have the capability of being disabled.
N64_t k_uptime_ticks(void)
Get system uptime, in system ticks.

This routine returns the elapsed time since the system booted, in ticks (c.f. CONFIG_SYS_CLOCK_TICKS_PER_SEC), which is the fundamental unit of resolution of kernel timekeeping.

**Returns** Current uptime in ticks.

static inline int64_t k_uptime_get(void)
Get system uptime.

This routine returns the elapsed time since the system booted, in milliseconds.

**Note:** While this function returns time in milliseconds, it does not mean it has millisecond resolution. The actual resolution depends on CONFIG_SYS_CLOCK_TICKS_PER_SEC config option.

**Returns** Current uptime in milliseconds.

static inline uint32_t k_uptime_get_32(void)
Get system uptime (32-bit version).

This routine returns the lower 32 bits of the system uptime in milliseconds.

Because correct conversion requires full precision of the system clock there is no benefit to using this over k_uptime_get() unless you know the application will never run long enough for the system clock to approach $2^{32}$ ticks. Calls to this function may involve interrupt blocking and 64-bit math.

**Note:** While this function returns time in milliseconds, it does not mean it has millisecond resolution. The actual resolution depends on CONFIG_SYS_CLOCK_TICKS_PER_SEC config option.

**Returns** The low 32 bits of the current uptime, in milliseconds.

static inline int64_t k_uptime_delta(int64_t *reftime)
Get elapsed time.

This routine computes the elapsed time between the current system uptime and an earlier reference time, in milliseconds.

**Parameters**
- *reftime* - Pointer to a reference time, which is updated to the current uptime upon return.

**Returns** Elapsed time.

static inline uint32_t k_cycle_get_32(void)
Read the hardware clock.

This routine returns the current time, as measured by the system's hardware clock.

**Returns** Current hardware clock up-counter (in cycles).

static inline uint64_t k_cycle_get_64(void)
Read the 64-bit hardware clock.

This routine returns the current time in 64-bits, as measured by the system's hardware clock, if available.
See also:
CONFIG_TIMER_HAS_64BIT_CYCLE_COUNTER

**Returns** Current hardware clock up-counter (in cycles).

```c
struct k_timeout_t
#include <sys_clock.h> Kernel timeout type.
```

Timeout arguments presented to kernel APIs are stored in this opaque type, which is capable of representing times in various formats and units. It should be constructed from application data using one of the macros defined for this purpose (e.g. `K_MSEC()`, `K_TIMEOUT_ABS_TICKS()`, etc...), or be one of the two constants `K_NO_WAIT` or `K_FOREVER`. Applications should not inspect the internal data once constructed. Timeout values may be compared for equality with the `K_TIMEOUT_EQ()` macro.

**Timers**

A *timer* is a kernel object that measures the passage of time using the kernel's system clock. When a timer's specified time limit is reached it can perform an application-defined action, or it can simply record the expiration and wait for the application to read its status.

- **Concepts**
- **Implementation**
  - Defining a Timer
  - Using a Timer Expiry Function
  - Reading Timer Status
  - Using Timer Status Synchronization
- **Suggested Uses**
- **Configuration Options**
- **API Reference**

**Concepts** Any number of timers can be defined (limited only by available RAM). Each timer is referenced by its memory address.

A timer has the following key properties:

- A *duration* specifying the time interval before the timer expires for the first time. This is a `k_timeout_t` value that may be initialized via different units.
- A *period* specifying the time interval between all timer expirations after the first one, also a `k_timeout_t`. It must be non-negative. A period of `K_NO_WAIT` (i.e. zero) or `K_FOREVER` means that the timer is a one shot timer that stops after a single expiration. (For example then, if a timer is started with a duration of 200 and a period of 75, it will first expire after 200ms and then every 75ms after that.)
- An *expiry function* that is executed each time the timer expires. The function is executed by the system clock interrupt handler. If no expiry function is required a `NULL` function can be specified.
- A *stop function* that is executed if the timer is stopped prematurely while running. The function is executed by the thread that stops the timer. If no stop function is required a `NULL` function can be specified.
A timer must be initialized before it can be used. This specifies its expiry function and stop function values, sets the timer's status to zero, and puts the timer into the stopped state.

A timer is started by specifying a duration and a period. The timer's status is reset to zero, then the timer enters the running state and begins counting down towards expiry.

Note that the timer's duration and period parameters specify minimum delays that will elapse. Because of internal system timer precision (and potentially runtime interactions like interrupt delay) it is possible that more time may have passed as measured by reads from the relevant system time APIs. But at least this much time is guaranteed to have elapsed.

When a running timer expires its status is incremented and the timer executes its expiry function, if one exists; If a thread is waiting on the timer, it is unblocked. If the timer's period is zero the timer enters the stopped state; otherwise the timer restarts with a new duration equal to its period.

A running timer can be stopped in mid-countdown, if desired. The timer's status is left unchanged, then the timer enters the stopped state and executes its stop function, if one exists. If a thread is waiting on the timer, it is unblocked. Attempting to stop a non-running timer is permitted, but has no effect on the timer since it is already stopped.

A running timer can be restarted in mid-countdown, if desired. The timer's status is reset to zero, then the timer begins counting down using the new duration and period values specified by the caller. If a thread is waiting on the timer, it continues waiting.

A timer's status can be read directly at any time to determine how many times the timer has expired since its status was last read. Reading a timer's status resets its value to zero. The amount of time remaining before the timer expires can also be read; a value of zero indicates that the timer is stopped.

A thread may read a timer's status indirectly by synchronizing with the timer. This blocks the thread until the timer's status is non-zero (indicating that it has expired at least once) or the timer is stopped; if the timer status is already non-zero or the timer is already stopped the thread continues without waiting. The synchronization operation returns the timer's status and resets it to zero.

Note: Only a single user should examine the status of any given timer, since reading the status (directly or indirectly) changes its value. Similarly, only a single thread at a time should synchronize with a given timer. ISRs are not permitted to synchronize with timers, since ISRs are not allowed to block.

Implementation

Defining a Timer A timer is defined using a variable of type k_timer. It must then be initialized by calling k_timer_init().

The following code defines and initializes a timer.

```c
struct k_timer my_timer;
extern void my_expiry_function(struct k_timer *timer_id);
k_timer_init(&my_timer, my_expiry_function, NULL);
```

Alternatively, a timer can be defined and initialized at compile time by calling K_TIMER_DEFINE.

The following code has the same effect as the code segment above.

```c
K_TIMER_DEFINE(my_timer, my_expiry_function, NULL);
```
Using a Timer Expiry Function  The following code uses a timer to perform a non-trivial action on a periodic basis. Since the required work cannot be done at interrupt level, the timer's expiry function submits a work item to the system workqueue, whose thread performs the work.

```c
void my_work_handler(struct k_work *work) {
   /* do the processing that needs to be done periodically */
   ...
}
K_WORK_DEFINE(my_work, my_work_handler);

void my_timer_handler(struct k_timer *dummy) {
   k_work_submit(&my_work);
}
K_TIMER_DEFINE(my_timer, my_timer_handler, NULL);
...

/* start periodic timer that expires once every second */
k_timer_start(&my_timer, K_SECONDS(1), K_SECONDS(1));
```

Reading Timer Status  The following code reads a timer's status directly to determine if the timer has expired on not.

```c
K_TIMER_DEFINE(my_status_timer, NULL, NULL);
...

/* start one shot timer that expires after 200 ms */
k_timer_start(&my_status_timer, K_MSEC(200), K_NO_WAIT);

/* do work */
...

/* check timer status */
if (k_timer_status_get(&my_status_timer) > 0) {
   /* timer has expired */
} else if (k_timer_remaining_get(&my_status_timer) == 0) {
   /* timer was stopped (by someone else) before expiring */
} else {
   /* timer is still running */
}
```

Using Timer Status Synchronization  The following code performs timer status synchronization to allow a thread to do useful work while ensuring that a pair of protocol operations are separated by the specified time interval.

```c
K_TIMER_DEFINE(my_sync_timer, NULL, NULL);
...

/* do first protocol operation */
...
```
/* start one shot timer that expires after 500 ms */
k_timer_start(&my_sync_timer, K_MSEC(500), K_NO_WAIT);

/* do other work */
...

/* ensure timer has expired (waiting for expiry, if necessary) */
k_timer_status_sync(&my_sync_timer);

/* do second protocol operation */
...

**Note:** If the thread had no other work to do it could simply sleep between the two protocol operations, without using a timer.

**Suggested Uses** Use a timer to initiate an asynchronous operation after a specified amount of time.

Use a timer to determine whether or not a specified amount of time has elapsed. In particular, timers should be used when higher precision and/or unit control is required than that afforded by the simpler `k_sleep()` and `k_usleep()` calls.

Use a timer to perform other work while carrying out operations involving time limits.

**Note:** If a thread needs to measure the time required to perform an operation it can read the *system clock or the hardware clock* directly, rather than using a timer.

**Configuration Options** Related configuration options:

- None

**API Reference**

*group* timer_apis

**Defines**

```
K_TIMER_DEFINE(name, expiry_fn, stop_fn)
```
Statically define and initialize a timer.

The timer can be accessed outside the module where it is defined using:

```
extern struct k_timer <name>;
```

**Parameters**

- `name` – Name of the timer variable.
- `expiry_fn` – Function to invoke each time the timer expires.
- `stop_fn` – Function to invoke if the timer is stopped while running.
Typedefs

typedef void (*k_timer_expiry_t)(struct k_timer *timer)
Timer expiry function type.
A timer's expiry function is executed by the system clock interrupt handler each time the timer expires. The expiry function is optional, and is only invoked if the timer has been initialized with one.

    Param timer Address of timer.

typedef void (*k_timer_stop_t)(struct k_timer *timer)
Timer stop function type.
A timer's stop function is executed if the timer is stopped prematurely. The function runs in the context of call that stops the timer. As k_timer_stop() can be invoked from an ISR, the stop function must be callable from interrupt context (isr-ok).
The stop function is optional, and is only invoked if the timer has been initialized with one.

    Param timer Address of timer.

Functions

void k_timer_init(struct k_timer *timer, k_timer_expiry_t expiry_fn, k_timer_stop_t stop_fn)
Initialize a timer.
This routine initializes a timer, prior to its first use.

    Parameters
    • timer – Address of timer.
    • expiry_fn – Function to invoke each time the timer expires.
    • stop_fn – Function to invoke if the timer is stopped while running.

void k_timer_start(struct k_timer *timer, k_timeout_t duration, k_timeout_t period)
Start a timer.
This routine starts a timer, and resets its status to zero. The timer begins counting down using the specified duration and period values.
Attempting to start a timer that is already running is permitted. The timer's status is reset to zero and the timer begins counting down using the new duration and period values.

    Parameters
    • timer – Address of timer.
    • duration – Initial timer duration.
    • period – Timer period.

void k_timer_stop(struct k_timer *timer)
Stop a timer.
This routine stops a running timer prematurely. The timer's stop function, if one exists, is invoked by the caller.
Attempting to stop a timer that is not running is permitted, but has no effect on the timer.

Function properties (list may not be complete) isr-ok
Note: The stop handler has to be callable from ISRs if `k_timer_stop` is to be called from ISRs.

### Parameters
- **timer** – Address of timer.

#### `uint32_t k_timer_status_get(struct k_timer *timer)`
Read timer status.

This routine reads the timer's status, which indicates the number of times it has expired since its status was last read.

Calling this routine resets the timer's status to zero.

#### Parameters
- **timer** – Address of timer.

#### Returns
Timer status.

#### `uint32_t k_timer_status_sync(struct k_timer *timer)`
Synchronize thread to timer expiration.

This routine blocks the calling thread until the timer's status is non-zero (indicating that it has expired at least once since it was last examined) or the timer is stopped. If the timer status is already non-zero, or the timer is already stopped, the caller continues without waiting.

Calling this routine resets the timer's status to zero.

This routine must not be used by interrupt handlers, since they are not allowed to block.

#### Parameters
- **timer** – Address of timer.

#### Returns
Timer status.

#### `k_ticks_t k_timer_expires_ticks(const struct k_timer *timer)`
Get next expiration time of a timer, in system ticks.

This routine returns the future system uptime reached at the next time of expiration of the timer, in units of system ticks. If the timer is not running, current system time is returned.

#### Parameters
- **timer** – The timer object

#### Returns
Uptime of expiration, in ticks

#### `k_ticks_t k_timer_remaining_ticks(const struct k_timer *timer)`
Get time remaining before a timer next expires, in system ticks.

This routine computes the time remaining before a running timer next expires, in units of system ticks. If the timer is not running, it returns zero.

#### Parameters
- **timer** – Address of timer.

#### Returns
Remaining time (in milliseconds).
void k_timer_user_data_set(struct k_timer *timer, void *user_data)

Associate user-specific data with a timer.

This routine records the user_data with the timer, to be retrieved later.

It can be used e.g. in a timer handler shared across multiple subsystems to retrieve data specific to the subsystem this timer is associated with.

Parameters

• timer – Address of timer.
• user_data – User data to associate with the timer.

void *k_timer_user_data_get(const struct k_timer *timer)

Retrieve the user-specific data from a timer.

Parameters

• timer – Address of timer.

Returns The user data.

CPU Idling

Although normally reserved for the idle thread, in certain special applications, a thread might want to make the CPU idle.

• Concepts
• Implementation
  – Making the CPU idle
  – Making the CPU idle in an atomic fashion
• Suggested Uses
• API Reference

Concepts Making the CPU idle causes the kernel to pause all operations until an event, normally an interrupt, wakes up the CPU. In a regular system, the idle thread is responsible for this. However, in some constrained systems, it is possible that another thread takes this duty.

Implementation

Making the CPU idle Making the CPU idle is simple: call the k_cpu_idle() API. The CPU will stop executing instructions until an event occurs. Most likely, the function will be called within a loop. Note that in certain architectures, upon return, k_cpu_idle() unconditionally unmasks interrupts.

```c
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}
```

(continues on next page)
Making the CPU idle in an atomic fashion  It is possible that there is a need to do some work atomically before making the CPU idle. In such a case, k_cpu_atomic_idle() should be used instead.

In fact, there is a race condition in the previous example: the interrupt could occur between the time the semaphore is taken, finding out it is not available and making the CPU idle again. In some systems, this can cause the CPU to idle until another interrupt occurs, which might be never, thus hanging the system completely. To prevent this, k_cpu_atomic_idle() should have been used, like in this example.

```c
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}

void main(void)
{
    k_sem_init(&my_sem, 0, 1);
    for (;;) {
        unsigned int key = irq_lock();
        /* Wait for semaphore from ISR; if acquired, do related work, then 
        * go to next loop iteration (the semaphore might have been given 
        * again); else, make the CPU idle. 
        */
        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {
            irq_unlock(key);
            /* ... do processing */
        }
    }
}
```
} else {
    /* put CPU to sleep to save power */
    k_cpu_atomic_idle(key);
}
}

**Suggested Uses**  Use `k_cpu_atomic_idle()` when a thread has to do some real work in addition to idling
the CPU to wait for an event. See example above.

Use `k_cpu_idle()` only when a thread is only responsible for idling the CPU, i.e. not doing any real work,
like in this example below.

```c
void main(void)
{
    /* ... do some system/application initialization */

    /* thread is only used for CPU idling from this point on */
    for (;;) {
        k_cpu_idle();
    }
}
```

**Note:**  Do not use these APIs unless absolutely necessary. In a normal system, the idle thread takes
care of power management, including CPU idling.

**API Reference**

group cpu_idle_apis

**Functions**

- **static inline void** `k_cpu_idle(void)`
  Make the CPU idle.

  This function makes the CPU idle until an event wakes it up.

  In a regular system, the idle thread should be the only thread responsible for making the
  CPU idle and triggering any type of power management. However, in some more constrained
  systems, such as a single-threaded system, the only thread would be responsible for this if
  needed.

  **Note:**  In some architectures, before returning, the function unmarks interrupts unconditionally.

- **static inline void** `k_cpu_atomic_idle(unsigned int key)`
  Make the CPU idle in an atomic fashion.

  Similar to `k_cpu_idle()`, but must be called with interrupts locked.
Enabling interrupts and entering a low-power mode will be atomic, i.e. there will be no period of time where interrupts are enabled before the processor enters a low-power mode.

After waking up from the low-power mode, the interrupt lockout state will be restored as if by \texttt{irq_unlock(key)}.

**Parameters**

- \texttt{key} – Interrupt locking key obtained from \texttt{irq_lock()}.

**Atomic Services**

An **atomic variable** is one that can be read and modified by threads and ISRs in an uninterruptible manner. It is 32-bit on 32-bit machines and 64-bit on 64-bit machines.

- **Concepts**
- **Implementation**
  - Defining an Atomic Variable
  - Manipulating an Atomic Variable
  - Manipulating an Array of Atomic Variables
- **Suggested Uses**
- **Configuration Options**
- **API Reference**

**Concepts** Any number of atomic variables can be defined (limited only by available RAM). Using the kernel's atomic APIs to manipulate an atomic variable guarantees that the desired operation occurs correctly, even if higher priority contexts also manipulate the same variable.

The kernel also supports the atomic manipulation of a single bit in an array of atomic variables.

**Implementation**

**Defining an Atomic Variable** An atomic variable is defined using a variable of type \texttt{atomic_t}.

By default an atomic variable is initialized to zero. However, it can be given a different value using \texttt{ATOMIC_INIT}:

\begin{verbatim}
atomic_t flags = ATOMIC_INIT(0xFF);
\end{verbatim}

**Manipulating an Atomic Variable** An atomic variable is manipulated using the APIs listed at the end of this section.

The following code shows how an atomic variable can be used to keep track of the number of times a function has been invoked. Since the count is incremented atomically, there is no risk that it will become corrupted in mid-increment if a thread calling the function is interrupted if by a higher priority context that also calls the routine.

\begin{verbatim}
atomic_t call_count;

int call_counting_routine(void)
{
    (continues on next page)
\end{verbatim}
/* increment invocation counter */
atomic_inc(&call_count);

/* do rest of routine's processing */
...
}

Manipulating an Array of Atomic Variables  An array of 32-bit atomic variables can be defined in the conventional manner. However, you can also define an N-bit array of atomic variables using ATOMIC_DEFINE.

A single bit in array of atomic variables can be manipulated using the APIs listed at the end of this section that end with _bit().

The following code shows how a set of 200 flag bits can be implemented using an array of atomic variables.

```c
#define NUM_FLAG_BITS 200
ATOMIC_DEFINE(flag_bits, NUM_FLAG_BITS);

/* set specified flag bit & return its previous value */
int set_flag_bit(int bit_position)
{
    return (int)atomic_set_bit(flag_bits, bit_position);
}
```

Suggested Uses  Use an atomic variable to implement critical section processing that only requires the manipulation of a single 32-bit value.

Use multiple atomic variables to implement critical section processing on a set of flag bits in a bit array longer than 32 bits.

Note: Using atomic variables is typically far more efficient than using other techniques to implement critical sections such as using a mutex or locking interrupts.

Configuration Options  Related configuration options:

- CONFIG_ATOMIC_OPERATIONS_BUILTIN
- CONFIG_ATOMIC_OPERATIONS_ARCH
- CONFIG_ATOMIC_OPERATIONS_C

API Reference  Important: All atomic services APIs can be used by both threads and ISRs.

group atomic_apis

Defines

ATOMIC_INIT(i)
    Initialize an atomic variable.
This macro can be used to initialize an atomic variable. For example,

```c
atomic_t my_var = ATOMIC_INIT(75);
```

**Parameters**
- `i` – Value to assign to atomic variable.

**ATOMIC_PTR_INIT(p)**
Initialize an atomic pointer variable.

This macro can be used to initialize an atomic pointer variable. For example,

```c
atomic_ptr_t my_ptr = ATOMIC_PTR_INIT(&data);
```

**Parameters**
- `p` – Pointer value to assign to atomic pointer variable.

**ATOMIC_BITMAP_SIZE(num_bits)**
This macro computes the number of atomic variables necessary to represent a bitmap with `num_bits`.

**Parameters**
- `num_bits` – Number of bits.

**ATOMIC_DEFINE(name, num_bits)**
Define an array of atomic variables.

This macro defines an array of atomic variables containing at least `num_bits` bits.

**Note:** If used from file scope, the bits of the array are initialized to zero; if used from within a function, the bits are left uninitialized.

**Parameters**
- `name` – Name of array of atomic variables.
- `num_bits` – Number of bits needed.

**Functions**

**static inline bool atomic_test_bit(const atomic_t *target, int bit)**
Atomically test a bit.

This routine tests whether bit number `bit` of `target` is set or not. The target may be a single atomic variable or an array of them.

**Parameters**
- `target` – Address of atomic variable or array.
- `bit` – Bit number (starting from 0).

**Returns** true if the bit was set, false if it wasn't.

**static inline bool atomic_test_and_clear_bit(atomic_t *target, int bit)**
Atomically test and clear a bit.

Atomically clear bit number `bit` of `target` and return its old value. The target may be a single atomic variable or an array of them.

**Parameters**
• target – Address of atomic variable or array.
• bit – Bit number (starting from 0).

**Returns** true if the bit was set, false if it wasn’t.

static inline bool atomic_test_and_set_bit(atomic_t *target, int bit)
Atomically set a bit.

Atomically set bit number bit of target and return its old value. The target may be a single atomic variable or an array of them.

**Parameters**
• target – Address of atomic variable or array.
• bit – Bit number (starting from 0).

**Returns** true if the bit was set, false if it wasn’t.

static inline void atomic_clear_bit(atomic_t *target, int bit)
Atomically clear a bit.

Atomically clear bit number bit of target. The target may be a single atomic variable or an array of them.

**Parameters**
• target – Address of atomic variable or array.
• bit – Bit number (starting from 0).

static inline void atomic_set_bit(atomic_t *target, int bit)
Atomically set a bit.

Atomically set bit number bit of target. The target may be a single atomic variable or an array of them.

**Parameters**
• target – Address of atomic variable or array.
• bit – Bit number (starting from 0).

static inline void atomic_set_bit_to(atomic_t *target, int bit, bool val)
Atomically set a bit to a given value.

Atomically set bit number bit of target to value val. The target may be a single atomic variable or an array of them.

**Parameters**
• target – Address of atomic variable or array.
• bit – Bit number (starting from 0).
• val – true for 1, false for 0.

static inline bool atomic_cas(atomic_t *target, atomic_val_t old_value, atomic_val_t new_value)
Atomic compare-and-set.

This routine performs an atomic compare-and-set on target. If the current value of target equals old_value, target is set to new_value. If the current value of target does not equal old_value, target is left unchanged.

**Parameters**
• target – Address of atomic variable.
• old_value – Original value to compare against.
• new_value – New value to store.

**Returns** true if new_value is written, false otherwise.
static inline bool atomic_ptr_cas(atomic_ptr_t *target, atomic_ptr_val_t old_value, atomic_ptr_val_t new_value)

Atomic compare-and-set with pointer values.

This routine performs an atomic compare-and-set on target. If the current value of target equals old_value, target is set to new_value. If the current value of target does not equal old_value, target is left unchanged.

Parameters

• target – Address of atomic variable.
• old_value – Original value to compare against.
• new_value – New value to store.

Returns true if new_value is written, false otherwise.

static inline atomic_val_t atomic_add(atomic_t *target, atomic_val_t value)

Atomic addition.

This routine performs an atomic addition on target.

Parameters

• target – Address of atomic variable.
• value – Value to add.

Returns Previous value of target.

static inline atomic_val_t atomic_sub(atomic_t *target, atomic_val_t value)

Atomic subtraction.

This routine performs an atomic subtraction on target.

Parameters

• target – Address of atomic variable.
• value – Value to subtract.

Returns Previous value of target.

static inline atomic_val_t atomic_inc(atomic_t *target)

Atomic increment.

This routine performs an atomic increment by 1 on target.

Parameters

• target – Address of atomic variable.

Returns Previous value of target.

static inline atomic_val_t atomic_dec(atomic_t *target)

Atomic decrement.

This routine performs an atomic decrement by 1 on target.

Parameters

• target – Address of atomic variable.

Returns Previous value of target.

static inline atomic_val_t atomic_get(const atomic_t *target)

Atomic get.

This routine performs an atomic read on target.

Parameters

• target – Address of atomic variable.
**Returns** Value of `target`.

static inline atomic_ptr_val_t atomic_ptr_get(const atomic_ptr_t *target)

Atomic get a pointer value.

This routine performs an atomic read on `target`.

**Parameters**

- `target` – Address of pointer variable.

**Returns** Value of `target`.

static inline atomic_val_t atomic_set(atomic_t *target, atomic_val_t value)

Atomic get-and-set.

This routine atomically sets `target` to `value` and returns the previous value of `target`.

**Parameters**

- `target` – Address of atomic variable.
- `value` – Value to write to `target`.

**Returns** Previous value of `target`.

static inline atomic_ptr_val_t atomic_ptr_set(atomic_ptr_t *target, atomic_ptr_val_t value)

Atomic get-and-set for pointer values.

This routine atomically sets `target` to `value` and returns the previous value of `target`.

**Parameters**

- `target` – Address of atomic variable.
- `value` – Value to write to `target`.

**Returns** Previous value of `target`.

static inline atomic_val_t atomic_clear(atomic_t *target)

Atomic clear.

This routine atomically sets `target` to zero and returns its previous value. (Hence, it is equivalent to `atomic_set(target, 0)`.)

**Parameters**

- `target` – Address of atomic variable.

**Returns** Previous value of `target`.

static inline atomic_ptr_val_t atomic_ptr_clear(atomic_ptr_t *target)

Atomic clear of a pointer value.

This routine atomically sets `target` to zero and returns its previous value. (Hence, it is equivalent to `atomic_set(target, 0)`.)

**Parameters**

- `target` – Address of atomic variable.

**Returns** Previous value of `target`.

static inline atomic_val_t atomic_or(atomic_t *target, atomic_val_t value)

Atomic bitwise inclusive OR.

This routine atomically sets `target` to the bitwise inclusive OR of `target` and `value`.

**Parameters**

- `target` – Address of atomic variable.
- `value` – Value to OR.

**Returns** Previous value of `target`.
static inline atomic_val_t atomic_xor(atomic_t *target, atomic_val_t value)
    Atomic bitwise exclusive OR (XOR).
    This routine atomically sets target to the bitwise exclusive OR (XOR) of target and value.

    Parameters
    • target – Address of atomic variable.
    • value – Value to XOR

    Returns Previous value of target.

static inline atomic_val_t atomic_and(atomic_t *target, atomic_val_t value)
    Atomic bitwise AND.
    This routine atomically sets target to the bitwise AND of target and value.

    Parameters
    • target – Address of atomic variable.
    • value – Value to AND.

    Returns Previous value of target.

static inline atomic_val_t atomic_nand(atomic_t *target, atomic_val_t value)
    Atomic bitwise NAND.
    This routine atomically sets target to the bitwise NAND of target and value. (This operation is equivalent to target = ~(target & value).)

    Parameters
    • target – Address of atomic variable.
    • value – Value to NAND.

    Returns Previous value of target.

Floating Point Services

The kernel allows threads to use floating point registers on board configurations that support these registers.

Note: Floating point services are currently available only for boards based on ARM Cortex-M SoCs supporting the Floating Point Extension, the Intel x86 architecture, the SPARC architecture and ARCv2 SoCs supporting the Floating Point Extension. The services provided are architecture specific. The kernel does not support the use of floating point registers by ISRs.
The kernel can be configured to provide only the floating point services required by an application. Three modes of operation are supported, which are described below. In addition, the kernel's support for the SSE registers can be included or omitted, as desired.

**No FP registers mode**  This mode is used when the application has no threads that use floating point registers. It is the kernel's default floating point services mode.

If a thread uses any floating point register, the kernel generates a fatal error condition and aborts the thread.

**Unshared FP registers mode**  This mode is used when the application has only a single thread that uses floating point registers.

On x86 platforms, the kernel initializes the floating point registers so they can be used by any thread (initialization is skipped on ARM Cortex-M platforms and ARCv2 platforms). The floating point registers are left unchanged whenever a context switch occurs.

**Note:** The behavior is undefined, if two or more threads attempt to use the floating point registers, as the kernel does not attempt to detect (or prevent) multiple threads from using these registers.

**Shared FP registers mode**  This mode is used when the application has two or more threads that use floating point registers. Depending upon the underlying CPU architecture, the kernel supports one or more of the following thread sub-classes:

- non-user: A thread that cannot use any floating point registers
- FPU user: A thread that can use the standard floating point registers
- SSE user: A thread that can use both the standard floating point registers and SSE registers

The kernel initializes and enables access to the floating point registers, so they can be used by any thread, then saves and restores these registers during context switches to ensure the computations performed by each FPU user or SSE user are not impacted by the computations performed by the other users.

**Note:** The Shared FP registers mode is the default Floating Point Services mode in ARM Cortex-M.

On the ARM Cortex-M architecture with the Floating Point Extension, the kernel treats all threads as FPU users when shared FP registers mode is enabled. This means that any thread is allowed to access the floating point registers. The ARM kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them.

Pretag a thread that intends to use the FP registers by using one of the techniques listed below:

- A statically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `k_thread_create()`.

Pretagging a thread with the `K_FP_REGS` option instructs the MPU-based stack protection mechanism to properly configure the size of the thread's guard region to always guarantee stack overflow detection, and enable lazy stacking for the given thread upon thread creation.
During thread context switching the ARM kernel saves the **callee-saved** floating point registers, if the switched-out thread has been using them. Additionally, the **caller-saved** floating point registers are saved on the thread’s stack. If the switched-in thread has been using the floating point registers, the kernel restores the **callee-saved** FP registers of the switched-in thread and the **caller-saved** FP context is restored from the thread’s stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers.

Each thread that intends to use the floating point registers must provide an extra 72 bytes of stack space where the callee-saved FP context can be saved.

**Lazy Stacking** is currently enabled in Zephyr applications on ARM Cortex-M architecture, minimizing interrupt latency, when the floating point context is active.

When the MPU-based stack protection mechanism is not enabled, lazy stacking is always active in the Zephyr application. When the MPU-based stack protection is enabled, the following rules apply with respect to lazy stacking:

- Lazy stacking is activated by default on threads that are pretagged with `K_FP_REGS`
- Lazy stacking is activated dynamically on threads that are not pretagged with `K_FP_REGS`, as soon as the kernel detects that they are using the floating point registers.

If an ARM thread does not require use of the floating point registers any more, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching.

**ARM64 architecture**

**Note:** The Shared FP registers mode is the default Floating Point Services mode on ARM64. The compiler is free to optimize code using FP/SIMD registers, and library functions such as `memcpy` are known to make use of them.

On the ARM64 (Aarch64) architecture the kernel treats each thread as a FPU user on a case-by-case basis. A “lazy save” algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are *not* saved when switching from an FPU user to a non-user thread, and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don’t have a persistent register context, there are no provision for saving an ISR’s FPU context either, hence the IRQ disabling.

Each thread object becomes 512 bytes larger when Shared FP registers mode is enabled.

**ARCv2 architecture**  
On the Arcv2 architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques.

- A statically-created ARC thread can be tagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created ARC thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

If an ARC thread does not require use of the floating point registers any more, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching.

During thread context switching the ARC kernel saves the **callee-saved** floating point registers, if the switched-out thread has been using them. Additionally, the **caller-saved** floating point registers are saved on the thread’s stack. If the switched-in thread has been using the floating point registers, the kernel restores the **callee-saved** FP registers of the switched-in thread and the **caller-saved** FP context is restored from the thread’s stack. Thus, the kernel does not save or restore the FP context of threads that are not
using the FP registers. An extra 16 bytes (single floating point hardware) or 32 bytes (double floating point hardware) of stack space is required to load and store floating point registers.

RISC-V architecture  On the RISC-V architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques:

- A statically-created RISC-V thread can be tagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created RISC-V thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.
- A running RISC-V thread can be tagged by calling `k_float_enable()`. This function can only be called from the thread itself.

If a RISC-V thread no longer requires the use of the floating point registers, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching. This function can only be called from the thread itself.

During thread context switching the RISC-V kernel saves the callee-saved floating point registers, if the switched-out thread is tagged with `K_FP_REGS`. Additionally, the caller-saved floating point registers are saved on the thread's stack. If the switched-in thread has been tagged with `K_FP_REGS`, then the kernel restores the callee-saved FP registers of the switched-in thread and the caller-saved FP context is restored from the thread's stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers. An extra 84 bytes (single floating point hardware) or 164 bytes (double floating point hardware) of stack space is required to load and store floating point registers.

SPARC architecture  On the SPARC architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques:

- A statically-created thread can be tagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

During thread context switch at exit from interrupt handler, the SPARC kernel saves all floating point registers, if the FPU was enabled in the switched-out thread. Floating point registers are saved on the thread's stack. Floating point registers are restored when a thread context is restored iff they were saved at the context save. Saving and restoring of the floating point registers is synchronous and thus not lazy. The FPU is always disabled when an ISR is called (independent of `CONFIG_FPU_SHARING`).

Floating point disabling with `k_float_disable()` is not implemented.

When `CONFIG_FPU_SHARING` is used, then 136 bytes of stack space is required for each FPU user thread to load and store floating point registers. No extra stack is required if `CONFIG_FPU_SHARING` is not used.

x86 architecture  On the x86 architecture the kernel treats each thread as a non-user, FPU user or SSE user on a case-by-case basis. A “lazy save” algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are not saved when switching from an FPU user to a non-user thread, and then back to the original FPU user. The following table indicates the amount of additional stack space a thread must provide so the registers can be saved properly.

<table>
<thead>
<tr>
<th>Thread type</th>
<th>FP register use</th>
<th>Extra stack space required</th>
</tr>
</thead>
<tbody>
<tr>
<td>cooperative</td>
<td>any</td>
<td>0 bytes</td>
</tr>
<tr>
<td>preemptive</td>
<td>none</td>
<td>0 bytes</td>
</tr>
<tr>
<td>preemptive</td>
<td>FPU</td>
<td>108 bytes</td>
</tr>
<tr>
<td>preemptive</td>
<td>SSE</td>
<td>464 bytes</td>
</tr>
</tbody>
</table>

The x86 kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them. The thread is tagged as an SSE user if the kernel has been configured to
support the SSE registers, or as an FPU user if the SSE registers are not supported. If this would result in a thread that is an FPU user being tagged as an SSE user, or if the application wants to avoid the exception handling overhead involved in auto-tagging threads, it is possible to pretag a thread using one of the techniques listed below.

- A statically-created x86 thread can be pretagged by passing the \texttt{K_FP_REGS} or \texttt{K_SSE_REGS} option to \texttt{K_THREAD_DEFINE}.
- A dynamically-created x86 thread can be pretagged by passing the \texttt{K_FP_REGS} or \texttt{K_SSE_REGS} option to \texttt{k_thread_create()}.  
- An already-created x86 thread can pretag itself once it has started by passing the \texttt{K_FP_REGS} or \texttt{K_SSE_REGS} option to \texttt{k_float_enable()}.  

If an x86 thread uses the floating point registers infrequently it can call \texttt{k_float_disable()} to remove its tagging as an FPU user or SSE user. This eliminates the need for the kernel to take steps to preserve the contents of the floating point registers during context switches when there is no need to do so. When the thread again needs to use the floating point registers it can re-tag itself as an FPU user or SSE user by calling \texttt{k_float_enable()}.  

\section*{Implementation}

\textbf{Performing Floating Point Arithmetic}  
No special coding is required for a thread to use floating point arithmetic if the kernel is properly configured.

The following code shows how a routine can use floating point arithmetic to avoid overflow issues when computing the average of a series of integer values.

\begin{verbatim}
int average(int *values, int num_values)
{
    double sum;
    int i;

    sum = 0.0;

    for (i = 0; i < num_values; i++) {
        sum += *values;
        values++;
    }

    return (int)((sum / num_values) + 0.5);
}
\end{verbatim}

\textbf{Suggested Uses}  
Use the kernel floating point services when an application needs to perform floating point operations.

\textbf{Configuration Options}  
To configure unshared FP registers mode, enable the \texttt{CONFIG_FPU} configuration option and leave the \texttt{CONFIG_FPU_SHARING} configuration option disabled.

To configure shared FP registers mode, enable both the \texttt{CONFIG_FPU} configuration option and the \texttt{CONFIG_FPU_SHARING} configuration option. Also, ensure that any thread that uses the floating point registers has sufficient added stack space for saving floating point register values during context switches, as described above.

For x86, use the \texttt{CONFIG_X86_SSE} configuration option to enable support for SSEx instructions.
C++ Support for Applications

The kernel supports applications written in both C and C++. However, to use C++ in an application you must configure the kernel to include C++ support and the build system must select the correct compiler. The build system selects the C++ compiler based on the suffix of the files. Files identified with either a `.cxx` or a `.cpp` suffix are compiled using the C++ compiler. For example, `myCplusplusApp.cpp` is compiled using C++.

The kernel currently provides only a subset of C++ functionality. The following features are not supported:

- Dynamic object management with the `new` and `delete` operators
- RTTI (runtime type information)
- Static global object destruction

While not an exhaustive list, support for the following functionality is included:

- Inheritance
- Virtual functions
- Virtual tables
- Static global object constructors
- Exceptions

Static global object constructors are initialized after the drivers are initialized but before the application `main()` function. Therefore, use of C++ is restricted to application code.

Note: Do not use C++ for kernel, driver, or system initialization code.

Version

Kernel version handling and APIs related to kernel version being used.

API Reference

```c
uint32_t sys_kernel_version_get(void)

    Return the kernel version of the present build.
    The kernel version is a four-byte value, whose format is described in the file “kernel_version.h”.

    Returns  kernel version
SYS_KERNEL_VER_MAJOR(ver)
SYS_KERNEL_VER_MINOR(ver)
SYS_KERNEL_VER_PATCHLEVEL(ver)
```
Fatal Errors

Software Errors Triggered in Source Code  Zephyr provides several methods for inducing fatal error conditions through either build-time checks, conditionally compiled assertions, or deliberately invoked panic or oops conditions.

Runtime Assertions  Zephyr provides some macros to perform runtime assertions which may be conditionally compiled. Their definitions may be found in include/sys/__assert.h.

Assertions are enabled by setting the `__ASSERT_ON` preprocessor symbol to a non-zero value. There are two ways to do this:

- Use the CONFIG_ASSERT and CONFIG_ASSERT_LEVEL kconfig options.
- Add `-D__ASSERT_ON=<level>` to the project’s CFLAGS, either on the build command line or in a CMakeLists.txt.

The `__ASSERT_ON` method takes precedence over the kconfig option if both are used.

Specifying an assertion level of 1 causes the compiler to issue warnings that the kernel contains debug-type `__ASSERT()` statements; this reminder is issued since assertion code is not normally present in a final product. Specifying assertion level 2 suppresses these warnings.

Assertions are enabled by default when running Zephyr test cases, as configured by the CONFIG_TEST option.

The policy for what to do when encountering a failed assertion is controlled by the implementation of assert_post_action(). Zephyr provides a default implementation with weak linkage which invokes a kernel oops if the thread that failed the assertion was running in user mode, and a kernel panic otherwise.

`__ASSERT()` The `__ASSERT()` macro can be used inside kernel and application code to perform optional runtime checks which will induce a fatal error if the check does not pass. The macro takes a string message which will be printed to provide context to the assertion. In addition, the kernel will print a text representation of the expression code that was evaluated, and the file and line number where the assertion can be found.

For example:

```
__ASSERT(foo == 0xF0CACC1A, "Invalid value of foo, got 0x%x", foo);
```

If at runtime `foo` had some unexpected value, the error produced may look like the following:

```
ASSERTION FAIL [foo == 0xF0CACC1A] @ ZEPHYR_BASE/tests/kernel/fatal/src/main.c:367
    Invalid value of foo, got 0xdeadbeef
    [00:00:00.000,000] <err> os: r0/a1: 0x00000004 r1/a2: 0x0000001f r2/a3: 0x00000000
    [00:00:00.000,000] <err> os: r3/a4: 0x00000000 r12/ip: 0x00000a6d r14/lr: 0x00000a6d
    [00:00:00.000,000] <err> os: xpsr: 0x61000000
    [00:00:00.000,000] <err> os: Faulting instruction address (r15/pc): 0x000000fe
    [00:00:00.000,000] <err> os: >>> ZEPHYR FATAL ERROR 4: Kernel panic
    [00:00:00.000,000] <err> os: Current thread: 0x20000414 (main)
    [00:00:00.000,000] <err> os: Halting system
```

`__ASSERT_EVAL()` The `__ASSERT_EVAL()` macro can also be used inside kernel and application code, with special semantics for the evaluation of its arguments.

It makes use of the `__ASSERT()` macro, but has some extra flexibility. It allows the developer to specify different actions depending whether the `__ASSERT()` macro is enabled or not. This can be particularly useful to prevent the compiler from generating comments (errors, warnings or remarks) about variables
that are only used with __ASSERT() being assigned a value, but otherwise unused when the __ASSERT() macro is disabled.

Consider the following example:

```c
int x;
int x = foo();
__ASSERT(x != 0, "foo() returned zero!");
```

If __ASSERT() is disabled, then ‘x’ is assigned a value, but never used. This type of situation can be resolved using the __ASSERT_EVAL() macro.

```c
__ASSERT_EVAL ((void) foo(),
    int x = foo(),
    x != 0,
    "foo() returned zero!");
```

The first parameter tells __ASSERT_EVAL() what to do if __ASSERT() is disabled. The second parameter tells __ASSERT_EVAL() what to do if __ASSERT() is enabled. The third and fourth parameters are the parameters it passes to __ASSERT().

__ASSERT_NO_MSG() The __ASSERT_NO_MSG() macro can be used to perform an assertion that reports the failed test and its location, but lacks additional debugging information provided to assist the user in diagnosing the problem; its use is discouraged.

Build Assertions  Zephyr provides two macros for performing build-time assertion checks. These are evaluated completely at compile-time, and are always checked.

BUILD_ASSERT() This has the same semantics as C's __Static_assert or C++'s static_assert. If the evaluation fails, a build error will be generated by the compiler. If the compiler supports it, the provided message will be printed to provide further context.

Unlike __ASSERT(), the message must be a static string, without printf()-like format codes or extra arguments.

For example, suppose this check fails:

```c
BUILD_ASSERT(FOO == 2000, "Invalid value of FOO");
```

With GCC, the output resembles:

```c
error: static assertion failed: "Invalid value of FOO"
```

Kernel Oops  A kernel oops is a software triggered fatal error invoked by k_oops(). This should be used to indicate an unrecoverable condition in application logic.

The fatal error reason code generated will be K_ERR_KERNEL_OOPS.
**Kernel Panic**  A kernel error is a software triggered fatal error invoked by `k_panic()`. This should be used to indicate that the Zephyr kernel is in an unrecoverable state. Implementations of `k_sys_fatal_error_handler()` should not return if the kernel encounters a panic condition, as the entire system needs to be reset.

Threads running in user mode are not permitted to invoke `k_panic()`, and doing so will generate a kernel oops instead. Otherwise, the fatal error reason code generated will be `K_ERR_KERNEL_PANIC`.

**Exceptions**

**Spurious Interrupts**  If the CPU receives a hardware interrupt on an interrupt line that has not had a handler installed with `IRQ_CONNECT()` or `irq_connect_dynamic()`, then the kernel will generate a fatal error with the reason code `K_ERR_SPURIOUS_IRQ()`.

**Stack Overflows**  In the event that a thread pushes more data onto its execution stack than its stack buffer provides, the kernel may be able to detect this situation and generate a fatal error with a reason code of `K_ERR_STACK_CHK_FAIL`.

If a thread is running in user mode, then stack overflows are always caught, as the thread will simply not have permission to write to adjacent memory addresses outside of the stack buffer. Because this is enforced by the memory protection hardware, there is no risk of data corruption to memory that the thread would not otherwise be able to write to.

If a thread is running in supervisor mode, or if `CONFIG_USERSPACE` is not enabled, depending on configuration stack overflows may or may not be caught. `CONFIG_HW_STACK_PROTECTION` is supported on some architectures and will catch stack overflows in supervisor mode, including when handling a system call on behalf of a user thread. Typically this is implemented via dedicated CPU features, or read-only MMU/MPU guard regions placed immediately adjacent to the stack buffer. Stack overflows caught in this way can detect the overflow, but cannot guarantee against data corruption and should be treated as a very serious condition impacting the health of the entire system.

If a platform lacks memory management hardware support, `CONFIG_STACK_SENTINEL` is a software-only stack overflow detection feature which periodically checks if a sentinel value at the end of the stack buffer has been corrupted. It does not require hardware support, but provides no protection against data corruption. Since the checks are typically done at interrupt exit, the overflow may be detected a nontrivial amount of time after the stack actually overflowed.

Finally, Zephyr supports GCC compiler stack canaries via `CONFIG_STACK_CANARIES`. If enabled, the compiler will insert a canary value randomly generated at boot into function stack frames, checking that the canary has not been overwritten at function exit. If the check fails, the compiler invokes `__stack_chk_fail()`, whose Zephyr implementation invokes a fatal stack overflow error. An error in this case does not indicate that the entire stack buffer has overflowed, but instead that the current function stack frame has been corrupted. See the compiler documentation for more details.

**Other Exceptions**  Any other type of unhandled CPU exception will generate an error code of `K_ERR_CPU_EXCEPTION`.

**Fatal Error Handling**  The policy for what to do when encountering a fatal error is determined by the implementation of the `k_sys_fatal_error_handler()` function. This function has a default implementation with weak linkage that calls `LOG_PANIC()` to dump all pending logging messages and then unconditionally halts the system with `k_fatal_halt()`.

Applications are free to implement their own error handling policy by overriding the implementation of `k_sys_fatal_error_handler()`. If the implementation returns, the faulting thread will be aborted and the system will otherwise continue to function. See the documentation for this function for additional details and constraints.

*group* fatal_apis

** Enums **

enum *k_fatal_error_reason*

*Values:*

enumerator *K_ERR_CPU_EXCEPTION*
  Generic CPU exception, not covered by other codes

enumerator *K_ERR_SPURIOUS_IRQ*
  Unhandled hardware interrupt

enumerator *K_ERR_STACK_CHK_FAIL*
  Faulting context overflowed its stack buffer

enumerator *K_ERR_KERNEL_OOPS*
  Moderate severity software error

enumerator *K_ERR_KERNEL_PANIC*
  High severity software error

** Functions **

FUNC NORETURN void *k_fatal_halt(unsigned int reason)*

Halt the system on a fatal error.

Invokes architecture-specific code to power off or halt the system in a low power state. Lacking that, lock interrupts and sit in an idle loop.

*Parameters*

- *reason* – Fatal exception reason code

void *k_sys_fatal_error_handler(unsigned int reason, const z_arch_esf_t *esf)*

Fatal error policy handler.

This function is not invoked by application code, but is declared as a weak symbol so that applications may introduce their own policy.

The default implementation of this function halts the system unconditionally. Depending on architecture support, this may be a simple infinite loop, power off the hardware, or exit an emulator.

If this function returns, then the currently executing thread will be aborted.

A few notes for custom implementations:

- If the error is determined to be unrecoverable, `LOG_PANIC()` should be invoked to flush any pending logging buffers.
- `K_ERR_KERNEL_PANIC` indicates a severe unrecoverable error in the kernel itself, and should not be considered recoverable. There is an assertion in `z_fatal_error()` to enforce this.
• Even outside of a kernel panic, unless the fault occurred in user mode, the kernel itself may be in an inconsistent state, with API calls to kernel objects possibly exhibiting undefined behavior or triggering another exception.

Parameters

• reason – The reason for the fatal error
• esf – Exception context, with details and partial or full register state when the error occurred. May in some cases be NULL.

Thread Local Storage (TLS)

Thread Local Storage (TLS) allows variables to be allocated on a per-thread basis. These variables are stored in the thread stack which means every thread has its own copy of these variables.

Zephyr currently requires toolchain support for TLS.

Configuration

To enable thread local storage in Zephyr, CONFIG_THREAD_LOCAL_STORAGE needs to be enabled. Note that this option may not be available if the architecture or the SoC does not have the hidden option CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE enabled, which means the architecture or the SoC does not have the necessary code to support thread local storage and/or the toolchain does not support TLS.

CONFIG_ERRNO_IN_TLS can be enabled together with CONFIG_ERRNO to let the variable errno be a thread local variable. This allows user threads to access the value of errno without making a system call.

Declaring and Using Thread Local Variables

The keyword __thread can be used to declare thread local variables.

For example, to declare a thread local variable in header files:

```c
extern __thread int i;
```

And to declare the actual variable in source files:

```c
__thread int i;
```

Keyword static can also be used to limit the variable within a source file:

```c
static __thread int j;
```

Using the thread local variable is the same as using other variable, for example:

```c
void testing(void) {
    i = 10;
}
```

7.15 C standard library

- API Reference
  - Error numbers
The C standard library is an integral part of any C program, and Zephyr provides two implementations for the application to choose from.

The first one, named “minimal libc” is part of the Zephyr code base and provides the minimal subset of the standard C library required to meet the needs of Zephyr and its subsystems and features, primarily in the areas of string manipulation and display. It is very low footprint and is suitable for projects that do not rely on less frequently used portions of the ISO C standard library. Its implementation can be found in lib/libc/minimal in the main zephyr tree.

The second one is newlib, a complete C library implementation written for embedded systems. Newlib is separate open source project and is not included in source code form with Zephyr. Instead, the Install the Zephyr Software Development Kit (SDK) comes with a precompiled library for each supported architecture (libc.a and libm.a). Other 3rd-party toolchains, such as GNU Arm Embedded, also bundle newlib as a precompiled library. Newlib can be enabled by selecting the CONFIG_NEWLIB_LIBC in the application configuration file. Part of the support for newlib is a set of hooks available under lib/libc/newlib/libc-hooks.c which integrates the C standard library with basic kernel services.

7.15.1 API Reference

Error numbers

Error numbers are used throughout Zephyr APIs to signal error conditions as return values from functions. They are typically returned as the negative value of the integer literals defined in this section, and are defined in the errno.h header file. A subset of the error numbers are defined in the POSIX errno.h specification, and others have been added to it from other sources.

A conscious effort is made in Zephyr to keep the values of system error numbers consistent between the different implementations of the C standard library. The version of errno.h that is in the main zephyr tree, errno.h, is checked against newlib’s own list to ensure that the error numbers are kept aligned.

Below is a list of the error number definitions. For the actual numeric values please refer to errno.h.

**group system_errno**

System error numbers Error codes returned by functions. Includes a list of those defined by IEEE Std 1003.1-2017.

**Defines**

errno

EPERM
Not owner

ENOENT
No such file or directory

ESRCH
No such context

EINTR
Interrupted system call

EIO
I/O error
ENXIO
   No such device or address

E2BIG
   Arg list too long

ENOEXEC
   Exec format error

EBADF
   Bad file number

ECHILD
   No children

EAGAIN
   No more contexts

ENOMEM
   Not enough core

EACCES
   Permission denied

EFAULT
   Bad address

ENOTBLK
   Block device required

EBUSY
   Mount device busy

EXEXIST
   File exists

EXDEV
   Cross-device link

ENODEV
   No such device

ENOTDIR
   Not a directory

EISDIR
   Is a directory

EINVAL
   Invalid argument

ENFILE
   File table overflow
EMFILE
   Too many open files

ENOTTY
   Not a typewriter

ETXTBSY
   Text file busy

EFBIG
   File too large

ENOSPC
   No space left on device

ESPIPE
   Illegal seek

ERofs
   Read-only file system

EMLINK
   Too many links

EPIPE
   Broken pipe

EDOM
   Argument too large

ERANGE
   Result too large

ENOMSG
   Unexpected message type

EDEADLK
   Resource deadlock avoided

ENOLCK
   No locks available

ENOSTR
   STREAMS device required

ENODATA
   Missing expected message data

ETIME
   STREAMS timeout occurred

ENOSR
   Insufficient memory
EPROTO
  Generic STREAMS error

EBADMSG
  Invalid STREAMS message

ENOSYS
  Function not implemented

ENOTEMPTY
  Directory not empty

ENAMETOOLONG
  File name too long

ELOOP
  Too many levels of symbolic links

EOPNOTSUPP
  Operation not supported on socket

EPFNOSUPPORT
  Protocol family not supported

ECONNRESET
  Connection reset by peer

ENOBUFFS
  No buffer space available

EAFNOSUPPORT
  Addr family not supported

EPROTOTYPE
  Protocol wrong type for socket

ENOTSOCK
  Socket operation on non-socket

ENOPROTOOPT
  Protocol not available

ESHUTDOWN
  Can't send after socket shutdown

ECONNREFUSED
  Connection refused

EADDRINUSE
  Address already in use

ECONNABORTED
  Software caused connection abort
ENETUNREACH
Network is unreachable

ENETDOWN
Network is down

ETIMEDOUT
Connection timed out

EHOSTDOWN
Host is down

EHOSTUNREACH
No route to host

EINPROGRESS
Operation now in progress

EALREADY
Operation already in progress

EDESTADDRREQ
Destination address required

EMSGSIZE
Message size

EPROTONOSUPPORT
Protocol not supported

ESOCKTNOSUPPORT
Socket type not supported

EADDRNOTAVAIL
Can't assign requested address

ENETRESET
Network dropped connection on reset

EISCONN
Socket is already connected

ENOTCONN
Socket is not connected

ETOOMANYREFS
Too many references: can't splice

ENOTSUP
Unsupported value

EILSEQ
Illegal byte sequence
7.16 Logging

- Global Kconfig Options
- Usage
  - Logging in a module
  - Logging in a module instance
  - Controlling the logging
- Logging panic
- Architecture
  - Default Frontend
  - Custom Frontend
  - Logging strings
  - Logging backends
  - Dictionary-based Logging
- Limitations and recommendations
  - Logging v1
  - Logging v2
- Benchmark
- Stack usage
- API Reference
  - Logger API
  - Logger control
  - Log message
  - Logger backend interface
  - Logger output formatting

The logging API provides a common interface to process messages issued by developers. Messages are passed through a frontend and are then processed by active backends. Custom frontend and backends can be used if needed. Default configuration uses built-in frontend and UART backend.

Summary of the logging features:
- Deferred logging reduces the time needed to log a message by shifting time consuming operations to a known context instead of processing and sending the log message when called.
• Multiple backends supported (up to 9 backends).
• Custom frontend supported.
• Compile time filtering on module level.
• Run time filtering independent for each backend.
• Additional run time filtering on module instance level.
• Timestamping with user provided function.
• Dedicated API for dumping data.
• Dedicated API for handling transient strings.
• Panic support - in panic mode logging switches to blocking, synchronous processing.
• Printk support - printk message can be redirected to the logging.
• Design ready for multi-domain/multi-processor system.

Logging v2 introduces following changes:
• Option to use 64 bit timestamp
• Support for logging floating point variables
• Support for logging variables extending size of a machine word (64 bit values on 32 bit architectures)
• Remove the need for special treatment of `%s` format specifier
• Extend API for dumping data to accept formatted string
• Improve memory utilization. More log messages fit in the logging buffer in deferred mode.
• Log message is no longer fragmented. It is self-contained block of memory which simplifies out of domain handling (e.g. offline processing)
• Improved performance when logging from user space
• Improved performance when logging to full buffer and message are dropped.
• Slightly degrade performance in normal circumstances due to the fact that allocation from ring buffer is more complex than from memslab.
• No change in logging API
• Logging backend API extended with function for processing v2 messages.

Note: Logging v1 is deprecated! Version 2 supports same set of features with extensions listed above. However, logging backend API is different. All backends in the tree support version 2 API. Any custom backend must be adapted to version 2. Version 1 support will be removed after 3.1 release.

Logging API is highly configurable at compile time as well as at run time. Using Kconfig options (see Global Kconfig Options) logs can be gradually removed from compilation to reduce image size and execution time when logs are not needed. During compilation logs can be filtered out on module basis and severity level.

Logs can also be compiled in but filtered on run time using dedicate API. Run time filtering is independent for each backend and each source of log messages. Source of log messages can be a module or specific instance of the module.

There are four severity levels available in the system: error, warning, info and debug. For each severity level the logging API (include/logging/log.h) has set of dedicated macros. Logger API also has macros for logging data.

For each level following set of macros are available:
• `LOG_X` for standard printf-like messages, e.g. `LOG_ERR`.
• LOG_HEXDUMP_X for dumping data, e.g. LOG_HEXDUMP_WRN.
• LOG_INST_X for standard printf-like message associated with the particular instance, e.g. LOG_INST_INF.
• LOG_INST_HEXDUMP_X for dumping data associated with the particular instance, e.g. LOG_HEXDUMP_INST_DBG

There are two configuration categories: configurations per module and global configuration. When logging is enabled globally, it works for modules. However, modules can disable logging locally. Every module can specify its own logging level. The module must define the LOG_LEVEL macro before using the API. Unless a global override is set, the module logging level will be honored. The global override can only increase the logging level. It cannot be used to lower module logging levels that were previously set higher. It is also possible to globally limit logs by providing maximal severity level present in the system, where maximal means lowest severity (e.g. if maximal level in the system is set to info, it means that errors, warnings and info levels are present but debug messages are excluded).

Each module which is using the logging must specify its unique name and register itself to the logging. If module consists of more than one file, registration is performed in one file but each file must define a module name.

Logger’s default frontend is designed to be thread safe and minimizes time needed to log the message. Time consuming operations like string formatting or access to the transport are not performed by default when logging API is called. When logging API is called a message is created and added to the list. Dedicated, configurable buffer for pool of log messages is used. There are 2 types of messages: standard and hexdump. Each message contain source ID (module or instance ID and domain ID which might be used for multiprocessor systems), timestamp and severity level. Standard message contains pointer to the string and arguments. Hexdump message contains copied data and string.

7.16.1 Global Kconfig Options

These options can be found in the following path subsys/logging/Kconfig.

CONFIG_LOG: Global switch, turns on/off the logging.
Mode of operations:
CONFIG_LOG_MODE_DEFERRED: Deferred mode.
CONFIG_LOG_MODE_IMMEDIATE: Immediate (synchronous) mode.
CONFIG_LOG_MODE_MINIMAL: Minimal footprint mode.
CONFIG_LOG1: Use deprecated version of logging.
Filtering options:
CONFIG_LOG_RUNTIME_FILTERING: Enables runtime reconfiguration of the filtering.
CONFIG_LOG_DEFAULT_LEVEL: Default level, sets the logging level used by modules that are not setting their own logging level.
CONFIG_LOG_OVERRIDE_LEVEL: It overrides module logging level when it is not set or set lower than the override value.
CONFIG_LOG_MAX_LEVEL: Maximal (lowest severity) level which is compiled in.
Processing options:
CONFIG_LOG_MODE_OVERFLOW: When new message cannot be allocated, oldest one are discarded.
CONFIG_LOG_BLOCK_IN_THREAD: If enabled and new log message cannot be allocated thread context will block for up to CONFIG_LOG_BLOCK_IN_THREAD_TIMEOUT_MS or until log message is allocated.
CONFIG_LOG_PRINTK: Redirect printk calls to the logging.
CONFIG_LOG_PRINTK_MAX_STRING_LENGTH: Maximal string length that can be processed by printk. Longer strings are trimmed.
CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD: When number of buffered log messages reaches the threshold dedicated thread (see log_thread_set()) is waken up. If CONFIG_LOG_PROCESS_THREAD is enabled then this threshold is used by the internal thread.

CONFIG_LOG_PROCESS_THREAD: When enabled, logging thread is created which handles log processing.

CONFIG_LOG_PROCESS_THREAD_STARTUP_DELAY_MS: Delay in milliseconds after which logging thread is started.

CONFIG_LOG_BUFFER_SIZE: Number of bytes dedicated for the message pool. Single message capable of storing standard log with up to 3 arguments or hexdump message with 12 bytes of data take 32 bytes. In v2 it indicates buffer size dedicated for circular packet buffer.

CONFIG_LOG_DETECT_MISSED_STRDUP: Enable detection of missed transient strings handling.

CONFIG_LOG_STRDUP_MAX_STRING: Longest string that can be duplicated using log_strdup().

CONFIG_LOG_STRDUP_BUF_COUNT: Number of buffers in the pool used by log_strdup().

CONFIG_LOG_DOMAIN_ID: Domain ID. Valid in multi-domain systems.

CONFIG_LOG_FRONTEND: Redirect logs to a custom frontend.

CONFIG_LOG_TIMESTAMP_64BIT: 64 bit timestamp.

Formatting options:

CONFIG_LOG_FUNC_NAME_PREFIX_ERR: Prepend standard ERROR log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_WRN: Prepend standard WARNING log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_INF: Prepend standard INFO log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_DBG: Prepend standard DEBUG log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_BACKEND_SHOW_COLOR: Enables coloring of errors (red) and warnings (yellow).

CONFIG_LOG_BACKEND_FORMAT_TIMESTAMP: If enabled timestamp is formatted to hh:mm:ss:mmm,uuu. Otherwise is printed in raw format.

Backend options:

CONFIG_LOG_BACKEND_UART: Enabled build-in UART backend.

### 7.16.2 Usage

#### Logging in a module

In order to use logging in the module, a unique name of a module must be specified and module must be registered using LOG_MODULE_REGISTER. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if custom log level is not provided.

```c
#include <logging/log.h>
LOG_MODULE_REGISTER(foo, CONFIG_FOO_LOG_LEVEL);
```

If the module consists of multiple files, then LOG_MODULE_REGISTER() should appear in exactly one of them. Each other file should use LOG_MODULE_DECLARE to declare its membership in the module. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if custom log level is not provided.
# include <logging/log.h>
/* In all files comprising the module but one */
LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);

In order to use logging API in a function implemented in a header file \texttt{LOG_MODULE_DECLARE} macro must be used in the function body before logging API is called. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (\texttt{CONFIG\_LOG\_DEFAULT\_LEVEL}) is used if custom log level is not provided.

```c
#include <logging/log.h>

static inline void foo(void)
{
    LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);
    LOG_INF("foo");
}
```

Dedicated \texttt{Kconfig} template (\texttt{subsys/logging/Kconfig.template.log_config}) can be used to create local log level configuration.

Example below presents usage of the template. As a result \texttt{CONFIG\_FOO\_LOG\_LEVEL} will be generated:

```c
cmake
module = FOO
module-str = foo
source "subsys/logging/Kconfig.template.log_config"
```

### Logging in a module instance

In case of modules which are multi-instance and instances are widely used across the system enabling logs will lead to flooding. Logger provide the tools which can be used to provide filtering on instance level rather than module level. In that case logging can be enabled for particular instance.

In order to use instance level filtering following steps must be performed:

- a pointer to specific logging structure is declared in instance structure. \texttt{LOG\_INSTANCE\_PTR\_DECLARE} is used for that.

```c
#include <logging/log_instance.h>

struct foo_object {
    LOG_INSTANCE_PTR_DECLARE(log);
    uint32_t id;
}
```

- module must provide macro for instantiation. In that macro, logging instance is registered and log instance pointer is initialized in the object structure.

```c
#define FOO\_OBJECT\_DEFINE(_name) \{| LOG_INSTANCE_REGISTER(foo, _name, CONFIG_FOO\_LOG\_LEVEL) \| struct foo_object _name = { \| LOG\_INSTANCE\_PTR\_INIT(log, foo, _name) \| }
```

Note that when logging is disabled logging instance and pointer to that instance are not created.

In order to use the instance logging API in a source file, a compile-time log level must be set using \texttt{LOG\_LEVEL\_SET}.
In order to use the instance logging API in a header file, a compile-time log level must be set using `LOG_LEVEL_SET`.

```c
static inline void foo_init(foo_object *f)
{
    LOG_LEVEL_SET(CONFIG_FOO_LOG_LEVEL);
    LOG_INST_INF(f->log, "Initialized.");
}
```

Controlling the logging

Logging can be controlled using API defined in `include/logging/log_ctrl.h`. Logger must be initialized before it can be used. Optionally, user can provide function which returns timestamp value. If not provided, `k_cycle_get_32` is used for timestamping. `log_process()` function is used to trigger processing of one log message (if pending). Function returns true if there is more messages pending.

Following snippet shows how logging can be processed in simple forever loop.

```c
#include <log_ctrl.h>

void main(void)
{
    log_init();
    while (1) {
        if (log_process() == false) {
            /* sleep */
        }
    }
}
```

If logs are processed from a thread then it is possible to enable a feature which will wake up processing thread when certain amount of log messages are buffered (see `CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD`). It is also possible to enable internal logging thread (see `CONFIG_LOG_PROCESS_THREAD`). In that case, logging thread is initialized and log messages are processed implicitly.

### 7.16.3 Logging panic

In case of error condition system usually can no longer rely on scheduler or interrupts. In that situation deferred log message processing is not an option. Logger controlling API provides a function for entering into panic mode (`log_panic()`), which should be called in such situation.

When `log_panic()` is called, `_panic_` notification is sent to all active backends. Once all backends are notified, all buffered messages are flushed. Since that moment all logs are processed in a blocking way.
7.16.4 Architecture

Logging consists of 3 main parts:

- Frontend
- Core
- Backends

Log message is generated by a source of logging which can be a module or instance of a module.

Default Frontend

Default frontend is engaged when logging API is called in a source of logging (e.g. `LOG_INF`) and is responsible for filtering a message (compile and run time), allocating buffer for the message, creating the message and committing that message. Since logging API can be called in an interrupt, frontend is optimized to log the message as fast as possible.

**Log message v1** Each log message consists of one or more fixed size chunks allocated from the pool of fixed size buffers (Memory Slabs). Message head chunk contains log entry details like: source ID, timestamp, severity level and the data (string pointer and arguments or raw data). Message contains also a reference counter which indicates how many users still uses this message. It is used to return message to the pool once last user indicates that it can be freed. If more than 3 arguments or 12 bytes of raw data is used in the log then log message is formed from multiple chunks which are linked together. When message body is filled it is put into the list. When log processing is triggered, a message is removed from the list of pending messages. If runtime filtering is disabled, the message is passed to all active backends, otherwise the message is passed to only those backends that have requested messages from that particular source (based on the source ID in the message), and severity level. Once all backends are iterated, the message is considered processed, but the message may still be in use by a backend. Because message is allocated from a pool, it is not mandatory to sequentially free messages. Processing by the backends is asynchronous and memory is freed when last user indicates that message can be freed. It also means that improper backend implementation may lead to pool drought.

**Log message v2** Log message v2 contains message descriptor (source, domain and level), timestamp, formatted string details (see Cbprintf Packaging) and optional data. Log messages v2 are stored in a continuous block of memory (contrary to v1). Memory is allocated from a circular packet buffer (Multi Producer Single Consumer Packet Buffer). It has few consequences:

- Each message is self-contained, continuous block of memory thus it is suited for copying the message (e.g. for offline processing).
- Memory is better utilized because fixed size chunks are not used.
- Messages must be sequentially freed. Backend processing is synchronous. Backend can make a copy for deferred processing.

Log message has following format:
Log message allocation  It may happen that frontend cannot allocate a message. It happens if system is generating more log messages than it can process in certain time frame. There are two strategies to handle that case:

- No overflow - new log is dropped if space for a message cannot be allocated.
- Overflow - oldest pending messages are freed, until new message can be allocated. Enabled by `CONFIG_LOG_MODE_OVERFLOW`. Note that it degrades performance thus it is recommended to adjust buffer size and amount of enabled logs to limit dropping.

Run-time filtering  If run-time filtering is enabled, then for each source of logging a filter structure in RAM is declared. Such filter is using 32 bits divided into ten 3 bit slots. Except slot 0, each slot stores current filter for one backend in the system. Slot 0 (bits 0-2) is used to aggregate maximal filter setting for given source of logging. Aggregate slot determines if log message is created for given entry since it indicates if there is at least one backend expecting that log entry. Backend slots are examined when message is processed by the core to determine if message is accepted by the given backend. Contrary to compile time filtering, binary footprint is increased because logs are compiled in.

In the example below backend 1 is set to receive errors (slot 1) and backend 2 up to info level (slot 2). Slots 3-9 are not used. Aggregated filter (slot 0) is set to info level and up to this level message from that particular source will be buffered.

```
<table>
<thead>
<tr>
<th>slot 0</th>
<th>slot 1</th>
<th>slot 2</th>
<th>slot 3</th>
<th>...</th>
<th>slot 9</th>
</tr>
</thead>
<tbody>
<tr>
<td>INF</td>
<td>ERR</td>
<td>INF</td>
<td>OFF</td>
<td>...</td>
<td>OFF</td>
</tr>
</tbody>
</table>
```

Custom Frontend

Custom frontend is enabled using `CONFIG_LOG_FRONTEND`. Logs are redirected to functions declared in `include/logging/log_frontend.h`. This may be required in very time-sensitive cases, but most of the logging features cannot be used then, which includes default frontend, core and all backends features.

\[1\] Depending on the platform and the timestamp size fields may be swapped.

\[2\] It may be required for `cbprintf` package alignment.
Log strings

Logging v1 Since log message contains only the value of the argument, when `%s` is used only the address of a string is stored. Because a string variable argument could be transient, allocated on the stack, or modifiable, logger provides a mechanism and a dedicated buffer pool to hold copies of strings. The buffer size and count is configurable (see `CONFIG_LOG_STRDUP_MAX_STRING` and `CONFIG_LOG_STRDUP_BUF_COUNT`).

If a string argument is transient, the user must call `log_strdup()` to duplicate the passed string into a buffer from the pool. See the examples below. If a strdup buffer cannot be allocated, a warning message is logged and an error code returned indicating `CONFIG_LOG_STRDUP_BUF_COUNT` should be increased.

Buffers are freed together with the log message.

```c
char local_str[] = "abc";
LOG_INF("logging transient string: %s", log_strdup(local_str));
local_str[0] = '\0'; /* String can be modified, logger will use duplicate."
```

When `CONFIG_LOG_DETECT_MISSED_STRDUP` is enabled logger will scan each log message and report if string format specifier is found and string address is not in read only memory section or does not belong to memory pool dedicated to string duplicates. It indicates that `log_strdup()` is missing in a call to log a message, such as `LOG_INF`.

Logging v2 String arguments are handled by `Cprintf Packaging` thus no special action is required.

Log backends

Logging backends are registered using `LOG_BACKEND_DEFINE`. The macro creates an instance in the dedicated memory section. Backends can be dynamically enabled (`log_backend_enable()`) and disabled. When `Run-time filtering` is enabled, `log_filter_set()` can be used to dynamically change filtering of a module logs for given backend. Module is identified by source ID and domain ID. Source ID can be retrieved if source name is known by iterating through all registered sources.

Logging supports up to 9 concurrent backends. Log message is passed to the each backend in processing phase. Additionally, backend is notified when logging enter panic mode with `log_backend_panic()`. On that call backend should switch to synchronous, interrupt-less operation or shut down itself if that is not supported. Occasionally, logging may inform backend about number of dropped messages with `log_backend_dropped()`. Message processing API is version specific.

Logging v1 Logging backend interface contains following functions for processing:

- `log_backend_put()` - backend gets log message in deferred mode.
- `log_backend_put_sync_string()` - backend gets log message with formatted string message in the immediate mode.
- `log_backend_put_sync_hexdump()` - backend gets log message with hexdump message in the immediate mode.

The log message contains a reference counter tracking how many backends are processing the message. On receiving a message backend must claim it by calling `log_msg_get()` on that message which increments a reference counter. Once message is processed, backend puts back the message (`log_msg_put()`) decrementing a reference counter. On last `log_msg_put()`, when reference counter reaches 0, message is returned to the pool. It is up to the backend how message is processed.

**Note:** The message pool can be starved if a backend does not call `log_msg_put()` when it is done processing a message. The logging core has no means to force messages back to the pool if they're still
marked as in use (with a non-zero reference counter).

```c
#include <log_backend.h>

void put(const struct log_backend *const backend, 
          struct log_msg *msg)
{
    log_msg_get(msg);
    /* message processing */
    log_msg_put(msg);
}
```

**Logging v2**  `log_backend_msg2_process()` is used for processing message. It is common for standard and hexdump messages because log message v2 hold string with arguments and data. It is also common for deferred and immediate logging.

**Message formatting**  Logging provides set of function that can be used by the backend to format a message. Helper functions are available in `include/logging/log_output.h`.

Example message formatted using `log_output_msg_process()` or `log_output_msg2_process()`.

```
[00:00:00.000,274] <info> sample_instance.inst1: logging message
```

**Dictionary-based Logging**

Dictionary-based logging, instead of human readable texts, outputs the log messages in binary format. This binary format encodes arguments to formatted strings in their native storage formats which can be more compact than their text equivalents. For statically defined strings (including the format strings and any string arguments), references to the ELF file are encoded instead of the whole strings. A dictionary created at build time contains the mappings between these references and the actual strings. This allows the offline parser to obtain the strings from the dictionary to parse the log messages. This binary format allows a more compact representation of log messages in certain scenarios. However, this requires the use of an offline parser and is not as intuitive to use as text-based log messages.

Note that `long double` is not supported by Python’s `struct` module. Therefore, log messages with `long double` will not display the correct values.

**Configuration**  Here are kconfig options related to dictionary-based logging:

- `CONFIG_LOG_DICTIONARY_SUPPORT` enables dictionary-based logging support. This should be selected by the backends which require it.
- The UART backend can be used for dictionary-based logging. These are additional config for the UART backend:
  - `CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX` tells the UART backend to output hexadecimal characters for dictionary based logging. This is useful when the log data needs to be captured manually via terminals and consoles.
  - `CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_BIN` tells the UART backend to output binary data.
**Usage**
When dictionary-based logging is enabled via enabling related logging backends, a JSON database file, named `log_dictionary.json`, will be created in the build directory. This database file contains information for the parser to correctly parse the log data. Note that this database file only works with the same build, and cannot be used for any other builds.

To use the log parser:

```
./scripts/logging/dictionary/log_parser.py <build dir>/log_dictionary.json <log data file>
```

The parser takes two required arguments, where the first one is the full path to the JSON database file, and the second part is the file containing log data. Add an optional argument `--hex` to the end if the log data file contains hexadecimal characters (e.g. when `CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX=y`). This tells the parser to convert the hexadecimal characters to binary before parsing.

Please refer to `logging_dictionary_sample` on how to use the log parser.

### 7.16.5 Limitations and recommendations

**Logging v1**

The are following limitations:

- Strings as arguments (`%s`) require special treatment (see *Logging strings*).
- Logging double and float variables is not possible because arguments are word size.
- Variables larger than word size cannot be logged.
- Number of arguments in the string is limited to 15.

**Logging v2**

Solves major limitations of v1. However, in order to get most of the logging capabilities following recommendations shall be followed:

- Enable `CONFIG_LOG_SPEED` to slightly speed up deferred logging at the cost of slight increase in memory footprint.
- Compiler with C11 `_Generic` keyword support is recommended. Logging performance is significantly degraded without it. See *Cbprintf Packaging*.
- When `_Generic` is supported, during compilation it is determined which packaging method shall be used: static or runtime. It is done by searching for any string pointers in the argument list. If string pointer is used with format specifier other than string, e.g. `%p`, it is recommended to cast it to `void *`.

```c
LOG_WRN("%s", str);
LOG_WRN("%p", (void *)str);
```

### 7.16.6 Benchmark

Benchmark numbers from `tests/subsys/logging/log_benchmark` performed on qemu_x86. It is a rough comparison to give general overview. Overall, logging v2 improves in most a the areas with the biggest improvement in logging from userspace. It is at the cost of larger memory footprint for a log message.
### Benchmark details

#### 7.16.7 Stack usage

When logging is enabled it impacts stack usage of the context that uses logging API. If stack is optimized it may lead to stack overflow. Stack usage depends on mode and optimization. It also significantly varies between platforms. In general, when `CONFIG_LOG_MODE_DEFERRED` is used stack usage is smaller since logging is limited to creating and storing log message. When `CONFIG_LOG_MODE_IMMEDIATE` is used then log message is processed by the backend which includes string formatting. In case of that mode, stack usage will depend on which backends are used.

The `tests/subsys/logging/log_stack` test is used to characterize stack usage depending on mode, optimization and platform used. Test is using only the default backend.

Some of the platforms characterization for log message with two integer arguments listed below:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Deferred</th>
<th>Deferred (no optimization)</th>
<th>Immediate</th>
<th>Immediate (no optimization)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARM Cortex-M3</td>
<td>40</td>
<td>152</td>
<td>412</td>
<td>783</td>

#### 7.16.8 API Reference

**Logger API**

`group log_api`

`Logger API.`

**Defines**

```c
LOG_ERR(...)  // Writes an ERROR level message to the log.

It's meant to report severe errors, such as those from which it's not possible to recover.
```

---

3 `CONFIG_LOG_SPEED` enabled.
4 Number of log messages with various number of arguments that fits in 2048 bytes dedicated for logging.
5 Logging subsystem memory footprint in `tests/subsys/logging/log_benchmark` where filtering and formatting features are not used.
6 Logging subsystem memory footprint in `samples/subsys/logging/logger`.
7 Average size of a log message (excluding string) with 2 arguments on Cortex M3.
Parameters

- \ldots – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

**LOG_WRN(...)**

Writes a WARNING level message to the log.

It’s meant to register messages related to unusual situations that are not necessarily errors.

**Parameters**

- \ldots – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

**LOG_INF(...)**

Writes an INFO level message to the log.

It’s meant to write generic user oriented messages.

**Parameters**

- \ldots – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

**LOG_DBG(...)**

 Writes a DEBUG level message to the log.

It’s meant to write developer oriented information.

**Parameters**

- \ldots – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

**LOG_PRINTK(...)**

Unconditionally print raw log message.

The result is same as if printk was used but it goes through logging infrastructure thus utilizes logging mode, e.g. deferred mode.

**Parameters**

- \ldots – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

**LOG_INST_ERR(_log_inst, ...)**

Writes an ERROR level message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It’s meant to report severe errors, such as those from which it’s not possible to recover.

**Parameters**

- \_log\_inst – Pointer to the log structure associated with the instance.
- \ldots – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

**LOG_INST_WRN(_log_inst, ...)**

Writes a WARNING level message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It’s meant to register messages related to unusual situations that are not necessarily errors.

**Parameters**
• _log_inst – Pointer to the log structure associated with the instance.
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_INF(_log_inst, ...)
Writes an INFO level message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to write generic user oriented messages.

Parameters
• _log_inst – Pointer to the log structure associated with the instance.
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_DBG(_log_inst, ...)
Writes a DEBUG level message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to write developer oriented information.

Parameters
• _log_inst – Pointer to the log structure associated with the instance.
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_HEXDUMP_ERR(_data, _length, _str)
Writes an ERROR level hexdump message to the log.

It's meant to report severe errors, such as those from which it's not possible to recover.

Parameters
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_HEXDUMP_WRN(_data, _length, _str)
Writes a WARNING level message to the log.

It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_HEXDUMP_INF(_data, _length, _str)
Writes an INFO level message to the log.

It's meant to write generic user oriented messages.

Parameters
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.
LOG_HEXDUMP_DBG(_data, _length, _str)
Writes a DEBUG level message to the log.

It’s meant to write developer oriented information.

Parameters

• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_INST_HEXDUMP_ERR(_log_inst, _data, _length, _str)
Writes an ERROR hexdump message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It’s meant to report severe errors, such as those from which it’s not possible to recover.

Parameters

• _log_inst – Pointer to the log structure associated with the instance.
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_INST_HEXDUMP_WRN(_log_inst, _data, _length, _str)
Writes a WARNING level hexdump message associated with the instance to the log.

It’s meant to register messages related to unusual situations that are not necessarily errors.

Parameters

• _log_inst – Pointer to the log structure associated with the instance.
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_INST_HEXDUMP_INF(_log_inst, _data, _length, _str)
Writes an INFO level hexdump message associated with the instance to the log.

It’s meant to write generic user oriented messages.

Parameters

• _log_inst – Pointer to the log structure associated with the instance.
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_INST_HEXDUMP_DBG(_log_inst, _data, _length, _str)
Writes a DEBUG level hexdump message associated with the instance to the log.

It’s meant to write developer oriented information.

Parameters

• _log_inst – Pointer to the log structure associated with the instance.
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.
LOG_MODULE_REGISTER(…)
Create module-specific state and register the module with Logger.

This macro normally must be used after including <logging/log.h> to complete the initialization of the module.

Module registration can be skipped in two cases:

- The module consists of more than one file, and another file invokes this macro. (LOG_MODULE_DECLARE() should be used instead in all of the module’s other files.)
- Instance logging is used and there is no need to create module entry. In that case LOG_LEVEL_SET() should be used to set log level used within the file.

Macro accepts one or two parameters:

- module name
- optional log level. If not provided then default log level is used in the file.

Example usage:

- LOG_MODULE_REGISTER(foo, CONFIG_FOO_LOG_LEVEL)
- LOG_MODULE_REGISTER(foo)

See also:
LOG_MODULE_DECLARE

Note: The module’s state is defined, and the module is registered, only if LOG_LEVEL for the current source file is non-zero or it is not defined and CONFIG_LOG_DEFAULT_LEVEL is non-zero. In other cases, this macro has no effect.

LOG_MODULE_DECLARE(…)
Macro for declaring a log module (not registering it).

Modules which are split up over multiple files must have exactly one file use LOG_MODULE_REGISTER() to create module-specific state and register the module with the logger core.

The other files in the module should use this macro instead to declare that same state. (Otherwise, LOG_INF() etc. will not be able to refer to module-specific state variables.)

Macro accepts one or two parameters:

- module name
- optional log level. If not provided then default log level is used in the file.

Example usage:

- LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL)
- LOG_MODULE_DECLARE(foo)

See also:
LOG_MODULE_REGISTER
Note: The module's state is declared only if LOG_LEVEL for the current source file is non-zero or it is not defined and CONFIG_LOG_DEFAULT_LEVEL is non-zero. In other cases, this macro has no effect.

LOG_LEVEL_SET(level)
Macro for setting log level in the file or function where instance logging API is used.

Parameters

- level – Level used in file or in function.

Functions

static inline char *log_strdup(const char *str)

Logger control

group log_ctrl
Logger control API.

Defines

LOG_CORE_INIT()

LOG_INIT()

LOG_PANIC()

LOG_PROCESS()

Typedefs

typedef log_timestamp_t (*log_timestamp_get_t)(void)

Functions

void log_core_init(void)
Function system initialization of the logger.
Function is called during start up to allow logging before user can explicitly initialize the logger.

void log_init(void)
Function for user initialization of the logger.

void log_thread_set(k_tid_t process_tid)
Function for providing thread which is processing logs.
See CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD.
Parameters

- `process_tid` – Process thread id. Used to wake up the thread.

```c
int log_set_timestamp_func(log_timestamp_get_t timestamp_getter, uint32_t freq)
```

Function for providing timestamp function.

Parameters

- `timestamp_getter` – Timestamp function.
- `freq` – Timestamping frequency.

Returns 0 on success or error.

```c
void log_panic(void)
```

Switch the logger subsystem to the panic mode.

Returns immediately if the logger is already in the panic mode.

On panic the logger subsystem informs all backends about panic mode. Backends must switch to blocking mode or halt. All pending logs are flushed after switching to panic mode. In panic mode, all log messages must be processed in the context of the call.

```c
bool log_process(bool bypass)
```

Process one pending log message.

Parameters

- `bypass` – If true message is released without being processed.

Return values

- `true` – There is more messages pending to be processed.
- `false` – No messages pending.

```c
uint32_t log_buffered_cnt(void)
```

Return number of buffered log messages.

Returns Number of currently buffered log messages.

```c
uint32_t log_src_cnt_get(uint32_t domain_id)
```

Get number of independent logger sources (modules and instances)

Parameters

- `domain_id` – Domain ID.

Returns Number of sources.

```c
const char *log_source_name_get(uint32_t domain_id, uint32_t source_id)
```

Get name of the source (module or instance).

Parameters

- `domain_id` – Domain ID.
- `source_id` – Source ID.

Returns Source name or NULL if invalid arguments.

```c
const char *log_domain_name_get(uint32_t domain_id)
```

Get name of the domain.

Parameters

- `domain_id` – Domain ID.
Returns Domain name.
uint32_t log_filter_get(struct log_backend const *const backend, uint32_t domain_id, int16_t source_id, bool runtime)
Get source filter for the provided backend.

Parameters
• backend – Backend instance.
• domain_id – ID of the domain.
• source_id – Source (module or instance) ID.
• runtime – True for runtime filter or false for compiled in.

Returns Severity level.
uint32_t log_filter_set(struct log_backend const *const backend, uint32_t domain_id, int16_t source_id, uint32_t level)
Set filter on given source for the provided backend.

Parameters
• backend – Backend instance. NULL for all backends.
• domain_id – ID of the domain.
• source_id – Source (module or instance) ID.
• level – Severity level.

Returns Actual level set which may be limited by compiled level. If filter was set for all backends then maximal level that was set is returned.

void log_backend_enable(struct log_backend const *const backend, void *ctx, uint32_t level)
Enable backend with initial maximum filtering level.

Parameters
• backend – Backend instance.
• ctx – User context.
• level – Severity level.

void log_backend_disable(struct log_backend const *const backend)
Disable backend.

Parameters
• backend – Backend instance.

const struct log_backend *log_backend_get_by_name(const char *backend_name)
Get backend by name.

Parameters
• backend_name – [in] Name of the backend as defined by the
  LOG_BACKEND_DEFINE.

Return values Pointer – to the backend instance if found, NULL if backend is not found.

const struct log_backend *log_format_set_all_active_backends(size_t log_type)
Sets logging format for all active backends.

Parameters
• log_type – Log format.

Return values Pointer – to the last backend that failed, NULL for success.
uint32_t log_get_strdup_pool_current_utilization(void)
    Get current number of allocated buffers for string duplicates.

uint32_t log_get_strdup_pool_utilization(void)
    Get maximal number of simultaneously allocated buffers for string duplicates.
    Value can be used to determine pool size.

uint32_t log_get_strdup_longest_string(void)
    Get length of the longest string duplicated.
    Value can be used to determine buffer size in the string duplicates pool.

static inline bool log_data_pending(void)
    Check if there is pending data to be processed by the logging subsystem.
    Function can be used to determine if all logs have been flushed. Function returns false when deferred mode is not enabled.

    Return values
    • true – There is pending data.
    • false – No pending data to process.

int log_set_tag(const char *tag)
    Configure tag used to prefix each message.

    Parameters
    • tag – Tag.

    Return values
    • 0 – on successful operation.
    • -ENOMEM – if string is longer than the buffer capacity. Tag will be trimmed.

int log_mem_get_usage(uint32_t *buf_size, uint32_t *usage)
    Get current memory usage.

    Parameters
    • buf_size – [out] Capacity of the buffer used for storing log messages.
    • usage – [out] Number of bytes currently containing pending log messages.

    Return values
    • -EINVAL – if logging mode does not use the buffer.
    • 0 – successfully collected usage data.

int log_mem_get_max_usage(uint32_t *max)
    Get maximum memory usage.

    Requires CONFIG_LOG_MEM_UTILIZATION option.

    Parameters
    • max – [out] Maximum number of bytes used for pending log messages.

    Return values
    • -EINVAL – if logging mode does not use the buffer.
    • -ENOMEM – if feature is disabled.
    • -ENOаблиц – if instrumentation is not enabled. not been enabled.
    • 0 – successfully collected usage data.
Log message

#define log_msg

Log message API.

Defines

#define LOG_MAX_NARGS
Maximum number of arguments in the standard log entry.

It is limited by 4 bit nargs field in the log message.

#define LOG_MSG_NARGS_SINGLE_CHUNK
Number of arguments in the log entry which fits in one chunk.

#define LOG_MSG_NARGS_HEAD_CHUNK
Number of arguments in the head of extended standard log message.

#define LOG_MSG_HEXDUMP_BYTES_SINGLE_CHUNK
Maximal amount of bytes in the hexdump entry which fits in one chunk.

#define LOG_MSG_HEXDUMP_BYTES_HEAD_CHUNK
Number of bytes in the first chunk of hexdump message if message consists of more than one chunk.

#define HEXDUMP_BYTES_CONT MSG
Number of bytes that can be stored in chunks following head chunk in hexdump log message.

#define ARGS_CONT_MSG

#define LOG_MSG_TYPE_STD
Flag indicating standard log message.

#define LOG_MSG_TYPE_HEXDUMP
Flag indicating hexdump log message.

#define COMMON_PARAM_HDR()
Common part of log message header.

#define LOG_MSG_HEXDUMP_LENGTH_BITS
Number of bits used for storing length of hexdump log message.

#define LOG_MSG_HEXDUMP_MAX_LENGTH
Maximum length of log hexdump message.

typedef unsigned long log_arg_t
Log argument type.

Should preferably be equivalent to a native word size.
Functions

```c
void log_msg_pool_init(void)
    /* Function for initialization of the log message pool. */
```

```c
void log_msg_get(struct log_msg *msg)
    /* Function for indicating that message is in use. */
    /* Message can be used (read) by multiple users. Internal reference counter is atomically increased. See log_msg_put. */

    Parameters
    • msg – Message.
```

```c
void log_msg_put(struct log_msg *msg)
    /* Function for indicating that message is no longer in use. */
    /* Internal reference counter is atomically decreased. If reference counter equals 0 message is freed. */

    Parameters
    • msg – Message.
```

```c
static inline uint32_t log_msg_domain_id_get(struct log_msg *msg)
    /* Get domain ID of the message. */

    Parameters
    • msg – Message

    Returns Domain ID.
```

```c
static inline uint32_t log_msg_source_id_get(struct log_msg *msg)
    /* Get source ID (module or instance) of the message. */

    Parameters
    • msg – Message

    Returns Source ID.
```

```c
static inline uint32_t log_msg_level_get(struct log_msg *msg)
    /* Get severity level of the message. */

    Parameters
    • msg – Message

    Returns Severity message.
```

```c
static inline uint32_t log_msg_timestamp_get(struct log_msg *msg)
    /* Get timestamp of the message. */

    Parameters
    • msg – Message

    Returns Timestamp value.
```

```c
static inline bool log_msg_is_std(struct log_msg *msg)
    /* Check if message is of standard type. */

    Parameters
    • msg – Message

    Return values
    • true – Standard message.
    • false – Hexdump message.
```
uint32_t log_msg_nargs_get(struct log_msg *msg)
    Returns number of arguments in standard log message.

Parameters
• msg – Standard log message.

Returns Number of arguments.

log_arg_t log_msg_arg_get(struct log_msg *msg, uint32_t arg_idx)
    Gets argument from standard log message.

Parameters
• msg – Standard log message.
• arg_idx – Argument index.

Returns Argument value or 0 if arg_idx exceeds number of arguments in the message.

const char *log_msg_str_get(struct log_msg *msg)
    Gets pointer to the unformatted string from standard log message.

Parameters
• msg – Standard log message.

Returns Pointer to the string.

struct log_msg *log_msg_hexdump_create(const char *str, const uint8_t *data, uint32_t length)
    Allocates chunks for hexdump message and copies the data.
    Function resets header and sets following fields:
• message type
• length

Note: Allocation and partial filling is combined for performance reasons.

Parameters
• str – String.
• data – Data.
• length – Data length.

Returns Pointer to allocated head of the message or NULL

void log_msg_hexdump_data_put(struct log_msg *msg, uint8_t *data, size_t *length, size_t offset)
    Put data into hexdump log message.

Parameters
• data – [in] Data to be copied.

void log_msg_hexdump_data_get(struct log_msg *msg, uint8_t *data, size_t *length, size_t offset)
    Get data from hexdump log message.

Parameters
• data – [in] Buffer for data.

union log_msg_chunk *log_msg_no_space_handle(void)

union log_msg_chunk *log_msg_chunk_alloc(void)

Allocate single chunk from the pool.

Returns Pointer to the allocated chunk or NULL if failed to allocate.

static inline struct log_msg *log_msg_create_0(const char *str)

Create standard log message with no arguments.

Function resets header and sets following fields:
• message type
• string pointer

Returns Pointer to allocated head of the message or NULL.

static inline struct log_msg *log_msg_create_1(const char *str, log_arg_t arg1)

Create standard log message with one argument.

Function resets header and sets following fields:
• message type
• string pointer
• number of arguments
• argument

Parameters
• str – String.
• arg1 – Argument.

Returns Pointer to allocated head of the message or NULL.

static inline struct log_msg *log_msg_create_2(const char *str, log_arg_t arg1, log_arg_t arg2)

Create standard log message with two arguments.

Function resets header and sets following fields:
• message type
• string pointer
• number of arguments
• arguments

Parameters
• str – String.
• arg1 – Argument 1.
• arg2 – Argument 2.

Returns Pointer to allocated head of the message or NULL.
static inline struct log_msg *log_msg_create_3(const char *str, log_arg_t arg1, log_arg_t arg2, log_arg_t arg3)

Create standard log message with three arguments.

Function resets header and sets following fields:

- message type
- string pointer
- number of arguments
- arguments

**Parameters**

- **str** – String.
- **arg1** – Argument 1.
- **arg2** – Argument 2.
- **arg3** – Argument 3.

**Returns** Pointer to allocated head of the message or NULL.

struct log_msg *log_msg_create_n(const char *str, log_arg_t *args, uint32_t nargs)

Create standard log message with variable number of arguments.

Function resets header and sets following fields:

- message type
- string pointer
- number of arguments
- arguments

**Parameters**

- **str** – String.
- **args** – Array with arguments.
- **nargs** – Number of arguments.

**Returns** Pointer to allocated head of the message or NULL.

uint32_t log_msg_mem_get_free(void)

Get number of free blocks from the log mem pool.

uint32_t log_msg_mem_get_used(void)

Get number of used blocks from the log mem pool.

uint32_t log_msg_mem_get_max_used(void)

Get max used blocks from the log mem pool.

size_t log_msg_get_slab_size(void)

Get slab size.

**Returns** Size of a slab used in slab pool for log messages.

struct log_msg_ids

*include <log_msg.h>* Part of log message header identifying source and level.
Public Members

uint16_t level
Severity.

uint16_t domain_id
Originating domain.

uint16_t source_id
Source ID.

struct log_msg_generic_hdr
#include <log_msg.h> Part of log message header common to standard and hexdump log message.

struct log_msg_std_hdr
#include <log_msg.h> Part of log message header specific to standard log message.

struct log_msg_hexdump_hdr
#include <log_msg.h> Part of log message header specific to hexdump log message.

struct log_msg_hdr
#include <log_msg.h> Log message header structure

Public Members

atomic_t ref_cnt
Reference counter for tracking message users.

struct log_msg_ids ids
Identification part of the message.

uint32_t timestamp
Timestamp.

union log_msg_hdr_params
#include <log_msg.h>

Public Members

struct log_msg_generic_hdr generic

struct log_msg_std_hdr std

struct log_msg_hexdump_hdr hexdump

uint16_t raw
union log_msg_head_data
    #include <log_msg.h> Data part of log message.

Public Members

log_arg_t args[3U]

union8_t bytes[(3U * sizeof(log_arg_t))]

struct log_msg_ext_head_data
    #include <log_msg.h> Data part of extended log message.

union log_msg_ext_head_data_data
    #include <log_msg.h>

Logger backend interface

group log_backend
Logger backend interface.

Defines

LOG_BACKEND_DEFINE(_name, _api, _autostart, ...)
Macro for creating a logger backend instance.

Parameters

• _name – Name of the backend instance.
• _api – Logger backend API.
• _autostart – If true backend is initialized and activated together with the logger subsystem.
• ... – Optional context.
Functions

static inline void log_backend_put(const struct log_backend *const backend, struct log_msg *msg)
Put message with log entry to the backend.

Warning: DEPRECATED. Use logging v2.

Parameters
• backend – [in] Pointer to the backend instance.
• msg – [in] Pointer to message with log entry.

static inline void log_backend_msg2_process(const struct log_backend *const backend, union log_msg2_generic *msg)
Process message.
Function is used in deferred and immediate mode. On return, message content is processed by the backend and memory can be freed.

Parameters
• backend – [in] Pointer to the backend instance.
• msg – [in] Pointer to message with log entry.

static inline void log_backend_put_sync_string(const struct log_backend *const backend, struct log_msg_ids src_level, uint32_t timestamp, const char *fmt, va_list ap)
Synchronously process log message.

Warning: DEPRECATED. Use logging v2.

Parameters
• backend – [in] Pointer to the backend instance.
• timestamp – [in] Timestamp.
• fmt – [in] Log string.
• ap – [in] Log string arguments.

static inline void log_backend_put_sync_hexdump(const struct log_backend *const backend, struct log_msg_ids src_level, uint32_t timestamp, const char *metadata, const uint8_t *data, uint32_t len)
Synchronously process log hexdump_message.

Warning: DEPRECATED. Use logging v2.

Parameters
• backend – [in] Pointer to the backend instance.
• timestamp – [in] Timestamp.
• metadata – [in] Raw string associated with the data.
• len – [in] Data length.

static inline void log_backend_dropped(const struct log_backend *const backend, uint32_t cnt)
    Notify backend about dropped log messages.

    Function is optional.

    Parameters
    • backend – [in] Pointer to the backend instance.
    • cnt – [in] Number of dropped logs since last notification.

static inline void log_backend_panic(const struct log_backend *const backend)
    Reconfigure backend to panic mode.

    Parameters
    • backend – [in] Pointer to the backend instance.

static inline void log_backend_id_set(const struct log_backend *const backend, uint8_t id)
    Set backend id.

    Note: It is used internally by the logger.

    Parameters
    • backend – Pointer to the backend instance.
    • id – ID.

static inline uint8_t log_backend_id_get(const struct log_backend *const backend)
    Get backend id.

    Note: It is used internally by the logger.

    Parameters
    • backend – [in] Pointer to the backend instance.

static inline const struct log_backend *log_backend_get(uint32_t idx)
    Get backend.

    Parameters
    • idx – [in] Pointer to the backend instance.

    Returns Id.

static inline int log_backend_count_get(void)
    Get number of backends.

    Returns Number of backends.

static inline void log_backend_activate(const struct log_backend *const backend, void *ctx)
    Activate backend.

    Parameters
    • backend – [in] Pointer to the backend instance.
static inline void log_backend_deactivate(const struct log_backend *const backend)
  Deactivate backend.

Parameters
  • backend – [in] Pointer to the backend instance.

static inline bool log_backend_is_active(const struct log_backend *const backend)
  Check state of the backend.

Parameters
  • backend – [in] Pointer to the backend instance.

Returns True if backend is active, false otherwise.

static inline int log_backend_format_set(const struct log_backend *backend, uint32_t log_type)
  Set logging format.

Parameters
  • backend – Pointer to the backend instance.
  • log_type – Log format.

Return values
  • -ENOTSUP – If the backend does not support changing format types.
  • -EINVAL – If the input is invalid.
  • 0 – for success.

struct log_backend_api
  #include <log_backend.h> Logger backend API.

struct log_backend_control_block
  #include <log_backend.h> Logger backend control block.

struct log_backend
  #include <log_backend.h> Logger backend structure.

Logger output formatting

group log_output
  Log output API.

Defines

LOG_OUTPUT_FLAG_COLORS
  Flag forcing ANSI escape code colors, red (errors), yellow (warnings).

LOG_OUTPUT_FLAG_TIMESTAMP
  Flag forcing timestamp.

LOG_OUTPUT_FLAG_FORMAT_TIMESTAMP
  Flag forcing timestamp formatting.
LOG_OUTPUT_FLAG_LEVEL
Flag forcing severity level prefix.

LOG_OUTPUT_FLAG_CRLF_NONE
Flag preventing the logger from adding CR and LF characters.

LOG_OUTPUT_FLAG_CRLF_LFONLY
Flag forcing a single LF character for line breaks.

LOG_OUTPUT_FLAG_FORMAT_SYSLOG
Flag forcing syslog format specified in RFC 5424.

LOG_OUTPUT_FLAG_FORMAT_SYST
Flag forcing syslog format specified in mipi sys-t. This flag is deprecated and can only be used when CONFIG_LOG1 is enabled.

LOG_OUTPUT_TEXT
Supported backend logging format types for use with log_format_set() API to switch log format at runtime.

LOG_OUTPUT_SYST

LOG_OUTPUT_DICT

LOG_OUTPUT_DEFINE(name, _func, _buf, _size)
Create log_output instance.

Parameters
• _name – Instance name.
• _func – Function for processing output data.
• _buf – Pointer to the output buffer.
• _size – Size of the output buffer.

Typedefs

typedef int (*log_output_func_t)(uint8_t *buf, size_t size, void *ctx)
Prototype of the function processing output data.

Note: If the log output function cannot process all of the data, it is its responsibility to mark them as dropped or discarded by returning the corresponding number of bytes dropped or discarded to the caller.

Param buf The buffer data.
Param size The buffer size.
Param ctx User context.
Return Number of bytes processed, dropped or discarded.
typedef void (*log_format_func_t)(const struct log_output *output, struct log_msg2 *msg2, uint32_t flags)

Typedef of the function pointer table “format_table”.

- **Param output**  Pointer to log_output struct.
- **Param msg2**  Pointer to log_msg2 struct.
- **Param flags**  Flags used for text formatting options.
- **Return**  Function pointer based on Kconfigs defined for backends.

**Functions**

- **log_format_func_t log_format_func_t_get(uint32_t log_type)**
  Declaration of the get routine for function pointer table format_table.

- **void log_output_msg_process(const struct log_output *output, struct log_msg *msg, uint32_t flags)**
  Process log messages to readable strings.
  Function is using provided context with the buffer and output function to process formatted string and output the data.

  - **Parameters**
    - output – Pointer to the log output instance.
    - msg – Log message.
    - flags – Optional flags.

- **void log_output_msg2_process(const struct log_output *log_output, struct log_msg2 *msg, uint32_t flags)**
  Process log messages v2 to readable strings.
  Function is using provided context with the buffer and output function to process formatted string and output the data.

  - **Parameters**
    - log_output – Pointer to the log output instance.
    - msg – Log message.
    - flags – Optional flags.

- **void log_output_msg2_syst_process(const struct log_output *log_output, struct log_msg2 *msg, uint32_t flag)**
  Process log messages v2 to SYS-T format.
  Function is using provided context with the buffer and output function to process formatted string and output the data in sys-t log output format.

  - **Parameters**
    - log_output – Pointer to the log output instance.
    - msg – Log message.
    - flag – Optional flags.

- **void log_output_string(const struct log_output *output, struct log_msg_ids src_level, uint32_t timestamp, const char *fmt, va_list ap, uint32_t flags)**
  Process log string.
  Function is formatting provided string adding optional prefixes and postixes.

  - **Parameters**
void log_output_hexdump(const struct log_output *output, struct log_msg_ids src_level, uint32_t timestamp, const char *metadata, const uint8_t *data, uint32_t length, uint32_t flags)

Process log hexdump.

Function is formatting provided hexdump adding optional prefixes and postfixes.

Parameters

- **output** – Pointer to log_output instance.
- **src_level** – Log source and level structure.
- **timestamp** – Timestamp.
- **metadata** – String.
- **data** – Data.
- **length** – Data length.
- **flags** – Optional flags.

void log_output_dropped_process(const struct log_output *output, uint32_t cnt)

Process dropped messages indication.

Function prints error message indicating lost log messages.

Parameters

- **output** – Pointer to the log output instance.
- **cnt** – Number of dropped messages.

void log_output_flush(const struct log_output *output)

Flush output buffer.

Parameters

- **output** – Pointer to the log output instance.

static inline void log_output_ctx_set(const struct log_output *output, void *ctx)

Function for setting user context passed to the output function.

Parameters

- **output** – Pointer to the log output instance.
- **ctx** – User context.

static inline void log_output_hostname_set(const struct log_output *output, const char *hostname)

Function for setting hostname of this device.

Parameters

- **output** – Pointer to the log output instance.
- **hostname** – Hostname of this device

void log_output_timestamp_freq_set(uint32_t freq)

Set timestamp frequency.
Parameters

- freq – Frequency in Hz.

```c
uint64_t log_output_timestamp_to_us(uint32_t timestamp)
```

Convert timestamp of the message to us.

**Parameters**

- timestamp – Message timestamp

**Returns** Timestamp value in us.

```c
struct log_output_control_block
#include <log_output.h>
```

```c
struct log_output
#include <log_output.h> Log_output instance structure.
```

## 7.17 Memory Management

The following contains various topics regarding memory management.

### 7.17.1 Demand Paging

Demand paging provides a mechanism where data is only brought into physical memory as required by current execution context. The physical memory is conceptually divided in page-sized page frames as regions to hold data.

- When the processor tries to access data and the data page exists in one of the page frames, the execution continues without any interruptions.

- When the processor tries to access the data page that does not exist in any page frames, a page fault occurs. The paging code then brings in the corresponding data page from backing store into physical memory if there is a free page frame. If there is no more free page frames, the eviction algorithm is invoked to select a data page to be paged out, thus freeing up a page frame for new data to be paged in. If this data page has been modified after it is first paged in, the data will be written back into the backing store. If no modifications is done or after written back into backing store, the data page is now considered paged out and the corresponding page frame is now free. The paging code then invokes the backing store to page in the data page corresponding to the location of the requested data. The backing store copies that data page into the free page frame. Now the data page is in physical memory and execution can continue.

There are functions where paging in and out can be invoked manually using `k_mem_page_in()` and `k_mem_page_out()`. `k_mem_page_in()` can be used to page in data pages in anticipation that they are required in the near future. This is used to minimize number of page faults as these data pages are already in physical memory, and thus minimizing latency. `k_mem_page_out()` can be used to page out data pages where they are not going to be accessed for a considerable amount of time. This frees up page frames so that the next page in can be executed faster as the paging code does not need to invoke the eviction algorithm.

### Terminology

**Data Page** A data page is a page-sized region of data. It may exist in a page frame, or be paged out to some backing store. Its location can always be looked up in the CPU's page tables (or equivalent) by virtual address. The data type will always be `void *` or in some cases `uint8_t *` when doing pointer arithmetic.
**Page Frame** A page frame is a page-sized physical memory region in RAM. It is a container where a data page may be placed. It is always referred to by physical address. Zephyr has a convention of using `uintptr_t` for physical addresses. For every page frame, a `struct z_page_frame` is instantiated to store metadata. Flags for each page frame:

- `Z_PAGE_FRAME_PINNED` indicates a page frame is pinned in memory and should never be paged out.
- `Z_PAGE_FRAME_RESERVED` indicates a physical page reserved by hardware and should not be used at all.
- `Z_PAGE_FRAME_MAPPED` is set when a physical page is mapped to virtual memory address.
- `Z_PAGE_FRAME_BUSY` indicates a page frame is currently involved in a page-in/out operation.
- `Z_PAGE_FRAME_BACKED` indicates a page frame has a clean copy in the backing store.

**Z_SCRATCH_PAGE** The virtual address of a special page provided to the backing store to:

- Copy a data page from `Z_SCRATCH_PAGE` to the specified location; or,
- Copy a data page from the provided location to `Z_SCRATCH_PAGE`. This is used as an intermediate page for page in/out operations. This scratch needs to be mapped read/write for backing store code to access. However the data page itself may only be mapped as read-only in virtual address space. If this page is provided as-is to backing store, the data page must be re-mapped as read/write which has security implications as the data page is no longer read-only to other parts of the application.

**Paging Statistics**

Paging statistics can be obtained via various function calls when `CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS` is enabled:

- Overall statistics via `k_mem_paging_stats_get()`
- Per-thread statistics via `k_mem_paging_thread_stats_get()` if `CONFIG_DEMAND_PAGING_THREAD_STATS` is enabled
- Execution time histogram can be obtained when `CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM` is enabled, and `CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS` is defined. Note that the timing is highly dependent on the architecture, SoC or board. It is highly recommended that `k_mem_paging_eviction_histogram_bounds[]` and `k_mem_paging_backing_store_histogram_bounds[]` be defined for a particular application.
  - Execution time histogram of eviction algorithm via `k_mem_paging_histogram_eviction_get()`
  - Execution time histogram of backing store doing page-in via `k_mem_paging_histogram_backing_store_page_in_get()`
  - Execution time histogram of backing store doing page-out via `k_mem_paging_histogram_backing_store_page_out_get()`

**Eviction Algorithm**

The eviction algorithm is used to determine which data page and its corresponding page frame can be paged out to free up a page frame for the next page in operation. There are two functions which are called from the kernel paging code:

- `k_mem_paging_eviction_init()` is called to initialize the eviction algorithm. This is called at `POST_KERNEL`.
- `k_mem_paging_eviction_select()` is called to select a data page to evict. A function argument `dirty` is written to signal the caller whether the selected data page has been modified since it is first paged in. If the `dirty` bit is returned as set, the paging code signals to the backing store to write the data page back into storage (thus updating its content). The function returns a pointer to the page frame corresponding to the selected data page.
Currently, a NRU (Not-Recently-Used) eviction algorithm has been implemented as a sample. This is a very simple algorithm which ranks each data page on whether they have been accessed and modified. The selection is based on this ranking.

To implement a new eviction algorithm, the two functions mentioned above must be implemented.

**Backing Store**

Backling store is responsible for paging in/out data page between their corresponding page frames and storage. These are the functions which must be implemented:

- `k_mem_paging_backing_store_init()` is called to initialized the backing store at `POST_KERNEL`.
- `k_mem_paging_backing_store_location_get()` is called to reserve a backing store location so a data page can be paged out. This location token is passed to `k_mem_paging_backing_store_page_out()` to perform actual page out operation.
- `k_mem_paging_backing_store_location_free()` is called to free a backing store location (the location token) which can then be used for subsequent page out operation.
- `k_mem_paging_backing_store_page_in()` copies a data page from the backing store location associated with the provided location token to the page pointed by `Z_SCRATCH_PAGE`.
- `k_mem_paging_backing_store_page_out()` copies a data page from `Z_SCRATCH_PAGE` to the backing store location associated with the provided location token.
- `k_mem_paging_backing_store_page_finalize()` is invoked after `k_mem_paging_backing_store_page_in()` so that the page frame struct may be updated for internal accounting. This can be a no-op.

To implement a new backing store, the functions mentioned above must be implemented. `k_mem_paging_backing_store_page_finalize()` can be an empty function if so desired.

**API Reference**

`group mem-demand-paging`

**Functions**

`int k_mem_page_out(void *addr, size_t size)`

Evict a page-aligned virtual memory region to the backing store

Useful if it is known that a memory region will not be used for some time. All the data pages within the specified region will be evicted to the backing store if they weren’t already, with their associated page frames marked as available for mappings or page-ins.

None of the associated page frames mapped to the provided region should be pinned.

Note that there are no guarantees how long these pages will be evicted, they could take page faults immediately.

If `CONFIG_DEMAND_PAGING_ALLOW_IRQ` is enabled, this function may not be called by ISRs as the backing store may be in-use.

**Parameters**

- `addr` – Base page-aligned virtual address
- `size` – Page-aligned data region size

**Return values**

- `0` – Success
• -ENOMEM – Insufficient space in backing store to satisfy request. The region may be partially paged out.

```c
void k_mem_page_in(void *addr, size_t size)
Load a virtual data region into memory
```

After the function completes, all the page frames associated with this function will be paged in. However, they are not guaranteed to stay there. This is useful if the region is known to be used soon.

If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by ISRs as the backing store may be in-use.

**Parameters**

- `addr` – Base page-aligned virtual address
- `size` – Page-aligned data region size

```c
void k_mem_pin(void *addr, size_t size)
Pin an aligned virtual data region, paging in as necessary
```

After the function completes, all the page frames associated with this region will be resident in memory and pinned such that they stay that way. This is a stronger version of `z_mem_page_in()`.

If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by ISRs as the backing store may be in-use.

**Parameters**

- `addr` – Base page-aligned virtual address
- `size` – Page-aligned data region size

```c
void k_mem_unpin(void *addr, size_t size)
Un-pin an aligned virtual data region
```

After the function completes, all the page frames associated with this region will be no longer marked as pinned. This does not evict the region, follow this with `z_mem_page_out()` if you need that.

**Parameters**

- `addr` – Base page-aligned virtual address
- `size` – Page-aligned data region size

```c
void k_mem_paging_stats_get(struct k_mem_paging_stats_t *stats)
Get the paging statistics since system startup
```

This populates the paging statistics struct being passed in as argument.

**Parameters**

- `stats` – [inout] Paging statistics struct to be filled.

```c
void k_mem_paging_thread_stats_get(struct k_thread *thread, struct k_mem_paging_stats_t *stats)
Get the paging statistics since system startup for a thread
```

This populates the paging statistics struct being passed in as argument for a particular thread.

**Parameters**

- `thread` – [in] Thread
- `stats` – [inout] Paging statistics struct to be filled.
void k_mem_paging_histogram_eviction_get(struct k_mem_paging_histogram_t *hist)
Get the eviction timing histogram
This populates the timing histogram struct being passed in as argument.

Parameters
- hist – [inout] Timing histogram struct to be filled.

void k_mem_paging_histogram_backing_store_page_in_get(struct
  k_mem_paging_histogram_t *hist)
Get the backing store page-in timing histogram
This populates the timing histogram struct being passed in as argument.

Parameters
- hist – [inout] Timing histogram struct to be filled.

void k_mem_paging_histogram_backing_store_page_out_get(struct
  k_mem_paging_histogram_t *hist)
Get the backing store page-out timing histogram
This populates the timing histogram struct being passed in as argument.

Parameters
- hist – [inout] Timing histogram struct to be filled.

Eviction Algorithm APIs

group mem-demand-paging-eviction
Eviction algorithm APIs

Functions

struct z_page_frame *k_mem_paging_eviction_select(bool *dirty)
Select a page frame for eviction
The kernel will invoke this to choose a page frame to evict if there are no free page frames.
This function will never be called before the initial k_mem_paging_eviction_init().
This function is invoked with interrupts locked.

Parameters
- dirty – [out] Whether the page to evict is dirty

Returns The page frame to evict

void k_mem_paging_eviction_init(void)
Initialization function
Called at POST_KERNEL to perform any necessary initialization tasks for the eviction algorithm. k_mem_paging_eviction_select() is guaranteed to never be called until this has returned, and this will only be called once.

Backing Store APIs

group mem-demand-paging-backing-store
Backing store APIs
Functions

```c
int k_mem_paging_backing_store_location_get(struct z_page_frame *pf, uintptr_t *location, bool page_fault)
```

Reserve or fetch a storage location for a data page loaded into a page frame

The returned location token must be unique to the mapped virtual address. This location will be used in the backing store to page out data page contents for later retrieval. The location value must be page-aligned.

This function may be called multiple times on the same data page. If its page frame has its Z_PAGE_FRAME_BACKED bit set, it is expected to return the previous backing store location for the data page containing a cached clean copy. This clean copy may be updated on page-out, or used to discard clean pages without needing to write out their contents.

If the backing store is full, some other backing store location which caches a loaded data page may be selected, in which case its associated page frame will have the Z_PAGE_FRAME_BACKED bit cleared (as it is no longer cached).

pf->addr will indicate the virtual address the page is currently mapped to. Large, sparse backing stores which can contain the entire address space may simply generate location tokens purely as a function of pf->addr with no other management necessary.

This function distinguishes whether it was called on behalf of a page fault. A free backing store location must always be reserved in order for page faults to succeed. If the page_fault parameter is not set, this function should return -ENOMEM even if one location is available.

This function is invoked with interrupts locked.

**Parameters**

- pf – Virtual address to obtain a storage location
- location – [out] storage location token
- page_fault – Whether this request was for a page fault

**Returns**

0 Success

-ENOMEM Backing store is full

```c
void k_mem_paging_backing_store_location_free(uintptr_t location)
```

Free a backing store location

Any stored data may be discarded, and the location token associated with this address may be re-used for some other data page.

This function is invoked with interrupts locked.

**Parameters**

- location – Location token to free

```c
void k_mem_paging_backing_store_page_out(uintptr_t location)
```

Copy a data page from Z_SCRATCH_PAGE to the specified location

Immediately before this is called, Z_SCRATCH_PAGE will be mapped read-write to the intended source page frame for the calling context.

Calls to this and `k_mem_paging_backing_store_page_in()` will always be serialized, but interrupts may be enabled.

**Parameters**

- location – Location token for the data page, for later retrieval

```c
void k_mem_paging_backing_store_page_in(uintptr_t location)
```

Copy a data page from the provided location to Z_SCRATCH_PAGE.
Immediately before this is called, Z_SCRATCH_PAGE will be mapped read-write to the intended destination page frame for the calling context.

Calls to this and \texttt{k_mem_paging_backing_store_page_out()} will always be serialized, but interrupts may be enabled.

**Parameters**

- \texttt{location} – Location token for the data page

\begin{verbatim}
void k_mem_paging_backing_store_page_finalize(struct z_page_frame *pf, uintptr_t location)
\end{verbatim}

Update internal accounting after a page-in

This is invoked after \texttt{k_mem_paging_backing_store_page_in()} and interrupts have been re-locked, making it safe to access the z_page_frame data. The location value will be the same passed to \texttt{k_mem_paging_backing_store_page_in()}.

The primary use-case for this is to update custom fields for the backing store in the page frame, to reflect where the data should be evicted to if it is paged out again. This may be a no-op in some implementations.

If the backing store caches paged-in data pages, this is the appropriate time to set the Z_PAGE_FRAME_BACKED bit. The kernel only skips paging out clean data pages if they are noted as clean in the page tables and the Z_PAGE_FRAME_BACKED bit is set in their associated page frame.

**Parameters**

- \texttt{pf} – Page frame that was loaded in
- \texttt{location} – Location of where the loaded data page was retrieved

\begin{verbatim}
void k_mem_paging_backing_store_init(void)
\end{verbatim}

Backing store initialization function.

The implementation may expect to receive page in/out calls as soon as this returns, but not before that. Called at POST_KERNEL.

This function is expected to do two things:

- Initialize any internal data structures and accounting for the backing store.
- If the backing store already contains all or some loaded kernel data pages at boot time, Z_PAGE_FRAME_BACKED should be appropriately set for their associated page frames, and any internal accounting set up appropriately.

### 7.17.2 Shared Multi Heap

The shared multi-heap memory pool manager uses the multi-heap allocator to manage a set of reserved memory regions with different capabilities / attributes (cacheable, non-cacheable, etc...) defined in the DT.

The user can request allocation from the shared pool specifying the capability / attribute of interest for the memory (cacheable / non-cacheable memory, etc...).

The different heaps with their attributes available in the shared pool are defined into the DT file leveraging the reserved-memory nodes.

This is a DT example declaring three different memory regions with different cacheability attributes:

```c
/ {
    reserved-memory {
        compatible = "reserved-memory";
        #address-cells = <1>;
    }
}
```

(continues on next page)
Zephyr Project Documentation, Release 3.0.99

(continued from previous page)

```c
#size-cells = <1>;

res0: reserved@42000000 {
    compatible = "shared-multi-heap";
    reg = <0x42000000 0x1000>;
    capability = "cacheable";
    label = "res0";
};

res1: reserved@43000000 {
    compatible = "shared-multi-heap";
    reg = <0x43000000 0x2000>;
    capability = "non-cacheable";
    label = "res1";
};

res2: reserved2@44000000 {
    compatible = "shared-multi-heap";
    reg = <0x44000000 0x3000>;
    capability = "cacheable";
    label = "res2";
};
```

The user can then request 4K from heap memory cacheable or non-cacheable using the provided APIs:

```c
// Allocate 4K from cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_CACHEABLE, 0x1000);

// Allocate 4K from non-cacheable
shared_multi_heap_alloc(SMH_REG_ATTR_NON_CACHEABLE, 0x1000);
```

The backend implementation will allocate the memory region from the heap with the correct attribute and using the region able to accommodate the required size.

### Special handling for MMU/MPU

For MMU/MPU enabled platform sometimes it is required to setup and configure the memory regions before these are added to the managed pool. This is done at init time using the `shared_multi_heap_pool_init()` function that is accepting a `smh_init_reg_fn_t` callback function. This callback will be called for each memory region at init time and it can be used to correctly map the region before this is considered valid and accessible.

### Adding new attributes

Currently only two memory attributes are supported: cacheable and non-cacheable. To add a new attribute:

1. Add the new `enum` for the attribute in the `smh_reg_attr` group.
2. Add the corresponding attribute name in `shared-multi-heap.yaml`.

```yaml
group shared_multi_heap
    Shared multi-heap interface.
```
The shared multi-heap manager uses the multi-heap allocator to manage a set of reserved memory regions with different capabilities / attributes (cacheable, non-cacheable, etc...) defined in the DT.

The user can request allocation from the shared pool specifying the capability / attribute of interest for the memory (cacheable / non-cacheable memory, etc...)

**Typedefs**

typedef bool (*smh_init_reg_fn_t)(struct shared_multi_heap_region *reg, uint8_t **v_addr, size_t *size)

  Region init function.

  This is a user-provided function whose responsibility is to setup or initialize the memory region passed in input before this is added to the heap pool by the shared multi-heap manager. This function can be used by architectures using MMU / MPU that must correctly map the region before this is considered valid and accessible.

  **Param reg** Pointer to the SMH region structure.

  **Param v_addr** Virtual address obtained after mapping. For non-MMU architectures this value is the physical address of the region.

  **Param size** Size of the region after mapping.

  **Return** True if the region is ready to be added to the heap pool. False if the region must be skipped.

**Enums**

enum smh_reg_attr

  Memory region attributes / capabilities.

  **This list needs to be kept in sync with shared-multi-heap.yaml**

  **Values:**

  enumerator SMH_REG_ATTR_CACHEABLE cacheable

  enumerator SMH_REG_ATTR_NON_CACHEABLE non-cacheable

  enumerator SMH_REG_ATTR_NUM must be the last item

**Functions**

int shared_multi_heap_pool_init(smh_init_reg_fn_t smh_init_reg_fn)

  Init the pool.

  Initialize the shared multi-heap pool and hook-up the region init function.

  **Parameters**

  • smh_init_reg_fn – The function pointer to the region init function. Can be NULL for non-MPU / non-MMU architectures.
void *shared_multi_heap Alloc(enum smh_reg_attr attr, size_t bytes)
Allocate memory from the memory shared multi-heap pool.
Allocate a block of memory of the specified size in bytes and with a specified capability / attribute.

Parameters
• attr – Capability / attribute requested for the memory block.
• bytes – Requested size of the allocation in bytes.

Returns A valid pointer to heap memory or NULL if no memory is available.

void shared_multi_heap_free(void *block)
Free memory from the shared multi-heap pool.
Free the passed block of memory.

Parameters
• block – Block to free.

struct shared_multi_heap_region
#include <shared_multi_heap.h> SMH region struct.
This struct is carrying information about the memory region to be added in the multi-heap pool. This is filled by the manager with the information coming from the reserved memory children nodes in the DT.

7.17.3 Memory Blocks Allocator

The Memory Blocks Allocator allows memory blocks to be dynamically allocated from a designated memory region, where:
• All memory blocks have a single fixed size.
• Multiple blocks can be allocated or freed at the same time.
• A group of blocks allocated together may not be contiguous. This is useful for operations such as scatter-gather DMA transfers.
• Bookkeeping of allocated blocks is done outside of the associated buffer (unlike memory slab). This allows the buffer to reside in memory regions where these can be powered down to conserve energy.

• Concepts
  – Internal Operation
• Memory Blocks Allocator
• Multi Memory Blocks Allocator Group
• Usage
  – Defining a Memory Blocks Allocator
  – Allocating Memory Blocks
  – Releasing a Memory Block
  – Using Multi Memory Blocks Allocator Group
• API Reference
Concepts

Any number of Memory Blocks Allocator can be defined (limited only by available RAM). Each allocator is referenced by its memory address.

A memory blocks allocator has the following key properties:

- The block size of each block, measured in bytes. It must be at least 4N bytes long, where N is greater than 0.
- The number of blocks available for allocation. It must be greater than zero.
- A buffer that provides the memory for the memory slab's blocks. It must be at least “block size” times “number of blocks” bytes long.
- A blocks bitmap to keep track of which block has been allocated.

The buffer must be aligned to an N-byte boundary, where N is a power of 2 larger than 2 (i.e. 4, 8, 16, ...). To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of N.

Due to the use of internal bookkeeping structures and their creation, each memory blocks allocator must be declared and defined at compile time.

Internal Operation  Each buffer associated with an allocator is an array of fixed-size blocks, with no wasted space between the blocks.

The memory blocks allocator keeps track of unallocated blocks using a bitmap.

Memory Blocks Allocator

Internally, the memory blocks allocator uses a bitmap to keep track of which blocks have been allocated. Each allocator, utilizing the sys_bitarray interface, gets memory blocks one by one from the backing buffer up to the requested number of blocks. All the metadata about an allocator is stored outside of the backing buffer. This allows the memory region of the backing buffer to be powered down to conserve energy, as the allocator code never touches the content of the buffer.

Multi Memory Blocks Allocator Group

The Multi Memory Blocks Allocator Group utility functions provide a convenient to manage a group of allocators. A custom allocator choosing function is used to choose which allocator to use among this group.

An allocator group should be initialized at runtime via sys_multi_mem_blocks_init(). Each allocator can then be added via sys_multi_mem_blocks_add_allocator().

To allocate memory blocks from group, sys_multi_mem_blocks_alloc() is called with an opaque “configuration” parameter. This parameter is passed directly to the allocator choosing function so that an appropriate allocator can be chosen. After an allocator is chosen, memory blocks are allocated via sys_mem_blocks_alloc().

Allocated memory blocks can be freed via sys_multi_mem_blocks_free(). The caller does not need to pass a configuration parameter. The allocator code matches the passed in memory addresses to find the correct allocator and then memory blocks are freed via sys_mem_blocks_free().

Usage

Defining a Memory Blocks Allocator  A memory blocks allocator is defined using a variable of type sys_mem_blocks_t. It needs to be defined and initialized at compile time by calling SYS_MEM_BLOCKS_DEFINE.
The following code defines and initializes a memory blocks allocator which has 4 blocks that are 64 bytes long, each of which is aligned to a 4-byte boundary:

```c
SYS_MEM_BLOCKS_DEFINE(allocator, 64, 4, 4);
```

Similarly, you can define a memory slab in private scope:

```c
SYS_MEM_BLOCKS_DEFINE_STATIC(static_allocator, 64, 4, 4);
```

A pre-defined buffer can also be provided to the allocator where the buffer can be placed separately. Note that the alignment of the buffer needs to be done at its definition.

```c
uint8_t __aligned(4) backing_buffer[64 * 4];
SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(allocator, 64, 4, backing_buffer);
```

### Allocating Memory Blocks

Memory blocks can be allocated by calling `sys_mem_blocks_alloc()`.

```c
int ret;
uintptr_t blocks[2];
ret = sys_mem_blocks_alloc(allocator, 2, blocks);
```

If `ret == 0`, the array `blocks` will contain an array of memory addresses pointing to the allocated blocks.

### Releasing a Memory Block

Memory blocks are released by calling `sys_mem_blocks_free()`.

The following code builds on the example above which allocates 2 memory blocks, then releases them once they are no longer needed.

```c
int ret;
uintptr_t blocks[2];
ret = sys_mem_blocks_alloc(allocator, 2, blocks);
... /* perform some operations on the allocated memory blocks */
ret = sys_mem_blocks_free(allocator, 2, blocks);
```

### Using Multi Memory Blocks Allocator Group

The following code demonstrates how to initialize an allocator group:

```c
sys_mem_blocks_t *choice_fn(struct sys_multi_mem_blocks *group, void *cfg)
{
   ...
}
SYS_MEM_BLOCKS_DEFINE(allocator0, 64, 4, 4);
SYS_MEM_BLOCKS_DEFINE(allocator1, 64, 4, 4);
static sys_multi_mem_blocks_t alloc_group;
sys_multi_mem_blocks_init(&alloc_group, choice_fn);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator0);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator1);
```

To allocate and free memory blocks from the group:
```c
int ret;
uintptr_t blocks[1];
sizet blk_size;

ret = sys_multi_mem_blocks_alloc(&alloc_group, UINT_TO_POINTER(0),
                                1, blocks, &blk_size);
ret = sys_multi_mem_blocks_free(&alloc_group, 1, blocks);
```

**API Reference**

`group mem_blocks_apis`

**Defines**

`SYS_MEM_BLOCKS_DEFINE(name, blk_sz, num_blks, buf_align)`
Create a memory block object with a new backing buffer.

**Parameters**

- `name` – Name of the memory block object.
- `blk_sz` – Size of each memory block (in bytes).
- `num_blks` – Total number of memory blocks.
- `buf_align` – Alignment of the memory block buffer (power of 2).

`SYS_MEM_BLOCKS_DEFINE_STATIC(name, blk_sz, num_blks, buf_align)`
Create a static memory block object with a new backing buffer.

**Parameters**

- `name` – Name of the memory block object.
- `blk_sz` – Size of each memory block (in bytes).
- `num_blks` – Total number of memory blocks.
- `buf_align` – Alignment of the memory block buffer (power of 2).

`SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(name, blk_sz, num_blks, buf)`
Create a memory block object with a providing backing buffer.

**Parameters**

- `name` – Name of the memory block object.
- `blk_sz` – Size of each memory block (in bytes).
- `num_blks` – Total number of memory blocks.
- `buf` – Backing buffer of type `uint8_t`.

`SYS_MEM_BLOCKS_DEFINE_STATIC_WITH_EXT_BUF(name, blk_sz, num_blks, buf)`
Create a static memory block object with a providing backing buffer.

**Parameters**

- `name` – Name of the memory block object.
- `blk_sz` – Size of each memory block (in bytes).
- `num_blks` – Total number of memory blocks.
- `buf` – Backing buffer of type `uint8_t`. 
**Typedefs**

typedef struct sys_mem_blocks sys_mem_blocks_t
   Memory Blocks Allocator.

typedef struct sys_multi_mem_blocks sys_multi_mem_blocks_t
   Multi Memory Blocks Allocator.

typedef sys_mem_blocks_t *(*sys_multi_mem_blocks_choice_fn_t)(struct
sys_multi_mem_blocks *group, void *cfg)
   Multi memory blocks allocator choice function.

This is a user-provided functions whose responsibility is selecting a specific memory blocks
allocator based on the opaque cfg value, which is specified by the user as an argument to
sys_multi_mem_blocks_alloc(). The callback returns a pointer to the chosen allocator where
the allocation is performed.

NULL may be returned, which will cause the allocation to fail and a -EINVAL reported to the
calling code.

**Param group** Multi memory blocks allocator structure.

**Param cfg** An opaque user-provided value. It may be interpreted in any way by the
application.

**Return** A pointer to the chosen allocator, or NULL if none is chosen.

**Functions**

int sys_mem_blocks_alloc(sys_mem_blocks_t *mem_block, size_t count, void **out_blocks)
   Allocate multiple memory blocks.
   Allocate multiple memory blocks, and place their pointers into the output array.

**Parameters**

- mem_block – Pointer to memory block object.
- count – [in] Number of blocks to allocate.
- out_blocks – [out] Output array to be populated by pointers to the memory
  blocks. It must have at least count elements.

**Return values**

- 0 – Successful
- -EINVAL – Invalid argument supplied.
- -ENOMEM – Not enough blocks for allocation.

int sys_mem_blocks_free(sys_mem_blocks_t *mem_block, size_t count, void **in_blocks)
   Free multiple memory blocks.
   Free multiple memory blocks according to the array of memory block pointers.

**Parameters**

- mem_block – Pointer to memory block object.
- count – [in] Number of blocks to free.

**Return values**

- 0 – Successful
-EINVAL – Invalid argument supplied.
-EFAULT – Invalid pointers supplied.

```c
void sys_multi_mem_blocks_init(sys_multi_mem_blocks_t *group,
        sys_multi_mem_blocks_choice_fn_t choice_fn)
```

Initialize multi memory blocks allocator group.

Initialize a `sys_multi_mem_blocks_t` struct with the specified choice function. Note that individual allocator must be added later with `sys_multi_mem_blocks_add_allocator`.

**Parameters**
- `group` – Multi memory blocks allocator structure.
- `choice_fn` – A `sys_multi_mem_blocks_choice_fn_t` callback used to select the allocator to be used at allocation time.

```c
void sys_multi_mem_blocks_add_allocator(sys_multi_mem_blocks_t *group,
        sys_mem_blocks_t *alloc)
```

Add an allocator to an allocator group.

This adds a known allocator to an existing multi memory blocks allocator group.

**Parameters**
- `group` – Multi memory blocks allocator structure.
- `alloc` – Allocator to add

```c
int sys_multi_mem_blocks_alloc(sys_multi_mem_blocks_t *group,
        void *cfg, size_t count, void **out_blocks,
        size_t *blk_size)
```

Allocate memory from multi memory blocks allocator group.

Just as for `sys_mem_blocks_alloc()`, allocates multiple blocks of memory. Takes an opaque configuration pointer passed to the choice function, which is used by integration code to choose an allocator.

**Parameters**
- `cfg` – [in] Opaque configuration parameter, as for `sys_multi_mem_blocks_choice_fn_t`
- `count` – [in] Number of blocks to allocate
- `out_blocks` – [out] Output array to be populated by pointers to the memory blocks. It must have at least `count` elements.
- `blk_size` – [out] If not NULL, output the block size of the chosen allocator.

**Return values**
- 0 – Successful
- -EINVAL – Invalid argument supplied, or no allocator chosen.
- -ENOMEM – Not enough blocks for allocation.

```c
int sys_multi_mem_blocks_free(sys_multi_mem_blocks_t *group,
        size_t count, void **in_blocks)
```

Free memory allocated from multi memory blocks allocator group.

Free previous allocated memory blocks from `sys_multi_mem_blocks_alloc()`.

Note that all blocks in `in_blocks` must be from the same allocator.

**Parameters**
- `count` – [in] Number of blocks to free.
• in_blocks – [in] Input array of pointers to the memory blocks.

Return values
• 0 – Successful
• -EINVAL – Invalid argument supplied, or no allocator chosen.
• -EFAULT – Invalid pointer(s) supplied.

7.18 Miscellaneous

7.18.1 Checksum APIs

**CRC**

*group crc*

**Functions**

`uint16_t crc16(uint16_t poly, uint16_t seed, const uint8_t *src, size_t len)`

Generic function for computing a CRC-16 without input or output reflection.

Compute CRC-16 by passing in the address of the input, the input length and polynomial used in addition to the initial value. This is O(n*8) where n is the length of the buffer provided. No reflection is performed.

**Note:** If you are planning to use a CRC based on poly 0x1012 the functions `crc16_itu_t()` is faster and thus recommended over this one.

**Parameters**

• poly – The polynomial to use omitting the leading x^16 coefficient
• seed – Initial value for the CRC computation
• src – Input bytes for the computation
• len – Length of the input in bytes

**Returns** The computed CRC16 value (without any XOR applied to it)

`uint16_t crc16_reflect(uint16_t poly, uint16_t seed, const uint8_t *src, size_t len)`

Generic function for computing a CRC-16 with input and output reflection.

Compute CRC-16 by passing in the address of the input, the input length and polynomial used in addition to the initial value. This is O(n*8) where n is the length of the buffer provided. Both input and output are reflected.

The following checksums can, among others, be calculated by this function, depending on the value provided for the initial seed and the value the final calculated CRC is XORed with:

- CRC-16/ANSI, CRC-16/MODBUS, CRC-16/USB, CRC-16/IBM [http://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-modbus](http://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-modbus) poly: 0x8005 (0xA001) initial seed: 0xffff, xor output: 0x0000
Note: If you are planning to use a CRC based on poly 0x1012 the function `crc16_ccitt()` is faster and thus recommended over this one.

### Parameters
- **poly** – The polynomial to use omitting the leading x^16 coefficient. Important: please reflect the poly. For example, use 0xA001 instead of 0x8005 for CRC-16-MODBUS.
- **seed** – Initial value for the CRC computation
- **src** – Input bytes for the computation
- **len** – Length of the input in bytes

### Returns
The computed CRC16 value (without any XOR applied to it)

```c
uint8_t crc8(const uint8_t *src, size_t len, uint8_t polynomial, uint8_t initial_value, bool reversed)
```

Generic function for computing CRC 8.

Compute CRC 8 by passing in the address of the input, the input length and polynomial used in addition to the initial value.

### Parameters
- **src** – Input bytes for the computation
- **len** – Length of the input in bytes
- **polynomial** – The polynomial to use omitting the leading x^8 coefficient
- **initial_value** – Initial value for the CRC computation
- **reversed** – Should we use reflected/reversed values or not

### Returns
The computed CRC8 value

```c
uint16_t crc16_ccitt(uint16_t seed, const uint8_t *src, size_t len)
```

Compute the checksum of a buffer with polynomial 0x1021, reflecting input and output.

This function is able to calculate any CRC that uses 0x1021 as its polynomial and requires reflecting both the input and the output. It is a fast variant that runs in O(n) time, where n is the length of the input buffer.

The following checksums can, among others, be calculated by this function, depending on the value provided for the initial seed and the value the final calculated CRC is XORed with:

- **CRC-16/CCITT, CRC-16/CCITT-TRUE, CRC-16/KERMIT**
  [https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-kermit](https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-kermit) initial seed: 0x0000, xor output: 0x0000

- **CRC-16/X-25, CRC-16/IBM-SDLC, CRC-16/ISO-HDLC**

Note: To calculate the CRC across non-contiguous blocks use the return value from block N-1 as the seed for block N.

### Parameters
- **seed** – Value to seed the CRC with
• src – Input bytes for the computation
• len – Length of the input in bytes

Returns The computed CRC16 value (without any XOR applied to it)

```c
uint16_t crc16_itu_t(uint16_t seed, const uint8_t *src, size_t len)
```

Compute the checksum of a buffer with polynomial 0x1021, no reflection of input or output.

This function is able to calculate any CRC that uses 0x1021 as it polynomial and requires no reflection on both the input and the output. It is a fast variant that runs in O(n) time, where n is the length of the input buffer.

The following checksums can, among others, be calculated by this function, depending on the value provided for the initial seed and the value the final calculated CRC is XORed with:

- CRC-16/XMODEM, CRC-16/ACORN, CRC-16/LTE [https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-xmodem initial seed: 0x0000, xor output: 0x0000]
- CRC16/CCITT-FALSE, CRC-16/IBM-3740, CRC-16/AUTOSAR [https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-ibm-3740 initial seed: 0xffff, xor output: 0x0000]
- CRC-16/GSM [https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-gsm initial seed: 0x0000, xor output: 0xffff]

Note: To calculate the CRC across non-contiguous blocks use the return value from block N-1 as the seed for block N.

Parameters
• seed – Value to seed the CRC with
• src – Input bytes for the computation
• len – Length of the input in bytes

Returns The computed CRC16 value (without any XOR applied to it)

```c
static inline uint16_t crc16_ansi(const uint8_t *src, size_t len)
```

Compute the ANSI (or Modbus) variant of CRC-16.

The ANSI variant of CRC-16 uses 0x8005 (0xA001 reflected) as its polynomial with the initial * value set to 0xffff.

Parameters
• src – Input bytes for the computation
• len – Length of the input in bytes

Returns The computed CRC16 value

```c
uint32_t crc32_ieee(const uint8_t *data, size_t len)
```

Generate IEEE conform CRC32 checksum.

Parameters
• *data – Pointer to data on which the CRC should be calculated.
• len – Data length.

Returns CRC32 value.
The Zephyr Project Documentation, Release 3.0.99

uint32_t crc32_ieee_update(uint32_t crc, const uint8_t *data, size_t len)
Update an IEEE conforming CRC32 checksum.

Parameters
• crc – CRC32 checksum that needs to be updated.
• *data – Pointer to data on which the CRC should be calculated.
• len – Data length.

Returns CRC32 value.

uint32_t crc32_c(uint32_t crc, const uint8_t *data, size_t len, bool first_pkt, bool last_pkt)
Calculate CRC32C (Castagnoli) checksum.

Parameters
• crc – CRC32C checksum that needs to be updated.
• *data – Pointer to data on which the CRC should be calculated.
• len – Data length.
• first_pkt – Whether this is the first packet in the stream.
• last_pkt – Whether this is the last packet in the stream.

Returns CRC32 value.

uint8_t crc8_ccitt(uint8_t initial_value, const void *buf, size_t len)
Compute CCITT variant of CRC 8.

Normal CCITT variant of CRC 8 is using 0x07.

Parameters
• initial_value – Initial value for the CRC computation
• buf – Input bytes for the computation
• len – Length of the input in bytes

Returns The computed CRC8 value

uint8_t crc7_be(uint8_t seed, const uint8_t *src, size_t len)
Compute the CRC-7 checksum of a buffer.

See JESD84-A441. Used by the MMC protocol. Uses 0x09 as the polynomial with no reflection. The CRC is left justified, so bit 7 of the result is bit 6 of the CRC.

Parameters
• seed – Value to seed the CRC with
• src – Input bytes for the computation
• len – Length of the input in bytes

Returns The computed CRC7 value

7.18.2 Structured Data APIs

JSON

group json
Defines

JSON_OBJ_DESCR_PRIM(struct_, field_name_, type_)
Helper macro to declare a descriptor for supported primitive values.

Here's an example of use:

```c
struct foo {
    int some_int;
};
struct json_obj_descr foo[] = {
    JSON_OBJ_DESCR_PRIM(struct foo, some_int, JSON_TOK_NUMBER),
};
```

Parameters
- struct_ – Struct packing the values
- field_name_ – Field name in the struct
- type_ – Token type for JSON value corresponding to a primitive type. Must be one of: JSON_TOK_STRING for strings, JSON_TOK_NUMBER for numbers, JSON_TOK_TRUE (or JSON_TOK_FALSE) for booleans.

JSON_OBJ_DESCR_OBJECT(struct_, field_name_, sub_descr_)
Helper macro to declare a descriptor for an object value.

Here's an example of use:

```c
struct nested {
    int foo;
    struct {
        int baz;
    } bar;
};
struct json_obj_descr nested_bar[] = {
    { ... declare bar.baz descriptor ... },
};
struct json_obj_descr nested[] = {
    { ... declare foo descriptor ... },
    JSON_OBJ_DESCR_OBJECT(struct nested, bar, nested_bar),
};
```

Parameters
- struct_ – Struct packing the values
- field_name_ – Field name in the struct
- sub_descr_ – Array of json_obj_descr describing the subobject

JSON_OBJ_DESCR_ARRAY(struct_, field_name_, max_len_, len_field_, elem_type_)
Helper macro to declare a descriptor for an array of primitives.

Here's an example of use:
struct example {
    int foo[10];
    size_t foo_len;
};

struct json_obj_descr array[] = {
    JSON_OBJ_DESCR_ARRAY(struct example, foo, 10, foo_len,
                         JSON_TOK_NUMBER)
};

Parameters

• struct_ – Struct packing the values
• field_name_ – Field name in the struct
• max_len_ – Maximum number of elements in array
• len_field_ – Field name in the struct for the number of elements in the array
• elem_type_ – Element type, must be a primitive type

JSON_OBJ_DESCR_OBJ_ARRAY(struct_, field_name_, max_len_, len_field_, elem_descr_,
                           elem_descr_len_)
Helper macro to declare a descriptor for an array of objects.

Here’s an example of use:

struct person_height {
    const char *name;
    int height;
};

struct people_heights {
    struct person_height heights[10];
    size_t heights_len;
};

struct json_obj_descr person_height_descr[] = {
    JSON_OBJ_DESCR_PRIM(struct person_height, name, JSON_TOK_STRING),
    JSON_OBJ_DESCR_PRIM(struct person_height, height, JSON_TOK_NUMBER),
};

struct json_obj_descr array[] = {
    JSON_OBJ_DESCR_OBJ_ARRAY(struct people_heights, heights, 10,
                               heights_len, person_height descr,
                               ARRAY_SIZE(person_height descr)),
};

Parameters

• struct_ – Struct packing the values
• field_name_ – Field name in the struct containing the array
• max_len_ – Maximum number of elements in the array
• len_field_ – Field name in the struct for the number of elements in the array
• elem_descr_ – Element descriptor, pointer to a descriptor array
• \texttt{elem descr\_len\_} – Number of elements in \texttt{elem descr\_}

\texttt{JSON\_OBJ\_DESCR\_ARRAY\_ARRAY} (\texttt{struct\_, field name\_, max\_len\_, len field\_, elem descr\_,
\texttt{elem descr\_len\_})

Helper macro to declare a descriptor for an array of array.

Here’s an example of use:

```c
struct person_height {
    const char *name;
    int height;
};

struct person_heights_array {
    struct person_height heights;
}

struct people_heights {
    struct person_heights_array heights[10];
    size_t heights\_len;
};

struct json\_obj\_descr person\_height\_descr[] = {
    JSON\_OBJ\_DESCR\_PRIM(struct person\_height, name, JSON\_TOK\_STRING),
    JSON\_OBJ\_DESCR\_PRIM(struct person\_height, height, JSON\_TOK\_NUMBER),
};

struct json\_obj\_descr person\_height\_array\_descr[] = {
    JSON\_OBJ\_DESCR\_OBJECT(struct person\_heights\_array,
        heights, person\_height\_descr),
};

struct json\_obj\_descr array\_array[] = {
    JSON\_OBJ\_DESCR\_ARRAY\_ARRAY(struct people\_height\_s\_array, heights, 10,
        heights\_len, person\_height\_array\_descr,
        ARRAY\_SIZE(person\_height\_array\_descr)),
};
```

**Parameters**

- \texttt{struct\_} – Struct packing the values
- \texttt{field name\_} – Field name in the struct containing the array
- \texttt{max\_len\_} – Maximum number of elements in the array
- \texttt{len field\_} – Field name in the struct for the number of elements in the array
- \texttt{elem descr\_} – Element descriptor, pointer to a descriptor array
- \texttt{elem descr\_len\_} – Number of elements in \texttt{elem descr\_}

\texttt{JSON\_OBJ\_DESCR\_PRIM\_NAMED} (\texttt{struct\_, json field name\_, struct field name\_, type\_})

Variant of \texttt{JSON\_OBJ\_DESCR\_PRIM\_NAMED} that can be used when the structure and JSON field names differ.

This is useful when the JSON field is not a valid C identifier.
See also:

`JSON_OBJ_DESCR_PRIM`

**Parameters**

- `struct_` – Struct packing the values.
- `json_field_name_` – String, field name in JSON strings
- `struct_field_name_` – Field name in the struct
- `type_` – Token type for JSON value corresponding to a primitive type.

`JSON_OBJ_DESCR_OBJECT_NAMED(struct_, json_field_name_, struct_field_name_, sub_descr_)`

Variant of `JSON_OBJ_DESCR_OBJECT` that can be used when the structure and JSON field names differ.

This is useful when the JSON field is not a valid C identifier.

See also:

`JSON_OBJ_DESCR_OBJECT`

**Parameters**

- `struct_` – Struct packing the values
- `json_field_name_` – String, field name in JSON strings
- `struct_field_name_` – Field name in the struct
- `sub_descr_` – Array of `json_obj_descr` describing the subobject

`JSON_OBJ_DESCR_ARRAY_NAMED(struct_, json_field_name_, struct_field_name_, max_len_, len_field_, elem_type_)`

Variant of `JSON_OBJ_DESCR_ARRAY` that can be used when the structure and JSON field names differ.

This is useful when the JSON field is not a valid C identifier.

See also:

`JSON_OBJ_DESCR_ARRAY`

**Parameters**

- `struct_` – Struct packing the values
- `json_field_name_` – String, field name in JSON strings
- `struct_field_name_` – Field name in the struct
- `max_len_` – Maximum number of elements in array
- `len_field_` – Field name in the struct for the number of elements in the array
- `elem_type_` – Element type, must be a primitive type

`JSON_OBJ_DESCR_OBJ_ARRAY_NAMED(struct_, json_field_name_, struct_field_name_, max_len_, len_field_, elem_descr_, elem_descr_len_)`

Variant of `JSON_OBJ_DESCR_OBJ_ARRAY` that can be used when the structure and JSON field names differ.

This is useful when the JSON field is not a valid C identifier.
Here's an example of use:

```c
struct person_height {
    const char *name;
    int height;
};

struct people_heights {
    struct person_height heights[10];
    size_t heights_len;
};

struct json_obj_descr person_height_descr[] = {
    JSON_OBJ_DESCR_PRIM(struct person_height, name, JSON_TOK_STRING),
    JSON_OBJ_DESCR_PRIM(struct person_height, height, JSON_TOK_NUMBER),
};

struct json_obj_descr array[] = {
    JSON_OBJ_DESCR_OBJ_ARRAY_NAMED(struct people_heights, "people-heights", heights,
                                    10, heights_len,
                                    person_height_descr,
                                    ARRAY_SIZE(person_height_descr)),
};
```

**Parameters**

- `struct_` - Struct packing the values
- `json_field_name_` - String, field name of the array in JSON strings
- `struct_field_name_` - Field name in the struct containing the array
- `max_len_` - Maximum number of elements in the array
- `len_field_` - Field name in the struct for the number of elements in the array
- `elem_descr_` - Element descriptor, pointer to a descriptor array
- `elem_descr_len_` - Number of elements in `elem_descr_`

**Typedefs**

```c
typedef int (*json_append_bytes_t)(const char *bytes, size_t len, void *data)
```

Function pointer type to append bytes to a buffer while encoding JSON data.

**Param bytes** Contents to write to the output

**Param len** Number of bytes to append to output

**Param data** User-provided pointer

**Return** This callback function should return a negative number on error (which will be propagated to the return value of `json_obj_encode()`), or 0 on success.

**Enums**

```c
enum json_tokens
```

**Values:**
Functions

```c
int json_obj_parse(char *json, size_t len, const struct json_obj_descr *descr, size_t descr_len, void *val)
```

Parses the JSON-encoded object pointed to by `json`, with size `len`, according to the descriptor
pointed to by descr. Values are stored in a struct pointed to by val. Set up the descriptor like this:

```c
struct s { int foo; char *bar; } struct json_obj_descr descr[] = { JSON_OBJ_DESCR_PRIM(struct s, foo, JSON_TOK_NUMBER), JSON_OBJ_DESCR_PRIM(struct s, bar, JSON_TOK_STRING), }; 
```

Since this parser is designed for machine-to-machine communications, some liberties were taken to simplify the design: (1) strings are not unescaped (but only valid escape sequences are accepted); (2) no UTF-8 validation is performed; and (3) only integer numbers are supported (no strdup() in the minimal libc).

**Parameters**

- **json** – Pointer to JSON-encoded value to be parsed
- **len** – Length of JSON-encoded value
- **descr** – Pointer to the descriptor array
- **descr_len** – Number of elements in the descriptor array. Must be less than 31 due to implementation detail reasons (if more fields are necessary, use two descriptors)
- **val** – Pointer to the struct to hold the decoded values

**Returns**

< 0 if error, bitmap of decoded fields on success (bit 0 is set if first field in the descriptor has been properly decoded, etc).

```c
int json_arr_parse(char *json, size_t len, const struct json_obj_descr *descr, void *val)
```

Parses the JSON-encoded array pointed to by json, with size len, according to the descriptor pointed to by descr. Values are stored in a struct pointed to by val. Set up the descriptor like this:

```c
struct s { int foo; char *bar; } struct json_obj_descr descr[] = { JSON_OBJ_DESCR_PRIM(struct s, foo, JSON_TOK_NUMBER), JSON_OBJ_DESCR_PRIM(struct s, bar, JSON_TOK_STRING), }; struct a { struct s baz[10]; size_t count; } struct json_obj_descr array[] = { JSON_OBJ_DESCR_OBJ_ARRAY(struct a, baz, 10, count, descr, ARRAY_SIZE(descr)), }; 
```

Since this parser is designed for machine-to-machine communications, some liberties were taken to simplify the design: (1) strings are not unescaped (but only valid escape sequences are accepted); (2) no UTF-8 validation is performed; and (3) only integer numbers are supported (no strdup() in the minimal libc).

**Parameters**

- **json** – Pointer to JSON-encoded array to be parsed
- **len** – Length of JSON-encoded array
- **descr** – Pointer to the descriptor array
- **val** – Pointer to the struct to hold the decoded values

**Returns**

0 if array has been successfully parsed. A negative value indicates an error (as defined on errno.h).

```c
ssize_t json_escape(char *str, size_t *len, size_t buf_size)
```

Escapes the string so it can be used to encode JSON objects.

**Parameters**

- **str** – The string to escape; the escape string is stored the buffer pointed to by this parameter
- **len** – Points to a size_t containing the size before and after the escaping process
- **buf_size** – The size of buffer str points to

**Returns**

0 if string has been escaped properly, or -ENOMEM if there was not enough space to escape the buffer

---

7.18. Miscellaneous 891
size_t json_calc_escaped_len(const char *str, size_t len)
Calculates the JSON-escaped string length.

Parameters
• str – The string to analyze
• len – String size

Returns The length str would have if it were escaped

size_t json_calc_encoded_len(const struct json_obj_descr *descr, size_t descr_len, const void *val)
Calculates the string length to fully encode an object.

Parameters
• descr – Pointer to the descriptor array
• descr_len – Number of elements in the descriptor array
• val – Struct holding the values

Returns Number of bytes necessary to encode the values if >0, an error code is returned.

int json_obj_encode_buf(const struct json_obj_descr *descr, size_t descr_len, const void *val, char *buffer, size_t buf_size)
Encodes an object in a contiguous memory location.

Parameters
• descr – Pointer to the descriptor array
• descr_len – Number of elements in the descriptor array
• val – Struct holding the values
• buffer – Buffer to store the JSON data
• buf_size – Size of buffer, in bytes, with space for the terminating NUL character

Returns 0 if object has been successfully encoded. A negative value indicates an error (as defined on errno.h).

int json_arr_encode_buf(const struct json_obj_descr *descr, const void *val, char *buffer, size_t buf_size)
Encodes an array in a contiguous memory location.

Parameters
• descr – Pointer to the descriptor array
• val – Struct holding the values
• buffer – Buffer to store the JSON data
• buf_size – Size of buffer, in bytes, with space for the terminating NUL character

Returns 0 if object has been successfully encoded. A negative value indicates an error (as defined on errno.h).

int json_obj_encode(const struct json_obj_descr *descr, size_t descr_len, const void *val, json_append_bytes_t append_bytes, void *data)
Encodes an object using an arbitrary writer function.

Parameters
• descr – Pointer to the descriptor array
• descr_len – Number of elements in the descriptor array
• val – Struct holding the values
• append_bytes – Function to append bytes to the output
• data – Data pointer to be passed to the append_bytes callback function.

**Returns** 0 if object has been successfully encoded. A negative value indicates an error.

```c
int json_arr_encode(const struct json_obj_descr *descr, const void *val,
                    json_append_bytes_t append_bytes, void *data)
```

Encodes an array using an arbitrary writer function.

**Parameters**

• descr – Pointer to the descriptor array
• val – Struct holding the values
• append_bytes – Function to append bytes to the output
• data – Data pointer to be passed to the append_bytes callback function.

**Returns** 0 if object has been successfully encoded. A negative value indicates an error.

```c
struct json_obj descr
#include <json.h>
```

**JWT**

JSON Web Tokens (JWT) are an open, industry standard [RFC 7519](https://tools.ietf.org/html/rfc7519) method for representing claims securely between two parties. Although JWT is fairly flexible, this API is limited to creating the simplistic tokens needed to authenticate with the Google Core IoT infrastructure.

**group jwt**

JSON Web Token (JWT)

**Functions**

```c
int jwt_init_builder(struct jwt_builder *builder, char *buffer, size_t buffer_size)
```

Initialize the JWT builder.

Initialize the given JWT builder for the creation of a fresh token. The buffer size should at least be as long as JWT_BUILDER_MAX_SIZE returns.

**Parameters**

• builder – The builder to initialize.
• buffer – The buffer to write the token to.
• buffer_size – The size of this buffer. The token will be NULL terminated, which needs to be allowed for in this size.

**Return values**

• 0 – Success
• -ENOSPC – Buffer is insufficient to initialize

```c
int jwt_add_payload(struct jwt_builder *builder, int32_t exp, int32_t iat, const char *aud)
```

add JWT primary payload.
int jwt_sign(struct jwt_builder *builder, const char *der_key, size_t der_key_len)
Sign the JWT token.

static inline size_t jwt_payload_len(struct jwt_builder *builder)

struct jwt_builder
#include <jwt.h> JWT data tracking.

JSON Web Tokens contain several sections, each encoded in base-64. This structure tracks the token as it is being built, including limits on the amount of available space. It should be initialized with jwt_init().

Public Members

char *base
The base of the buffer we are writing to.

char *buf
The place in this buffer where we are currently writing.

size_t len
The length remaining to write.

bool overflowed
Flag that is set if we try to write past the end of the buffer. If set, the token is not valid.

7.19 Data Structures

Zephyr provides a library of common general purpose data structures used within the kernel, but useful by application code in general. These include list and balanced tree structures for storing ordered data, and a ring buffer for managing “byte stream” data in a clean way.

Note that in general, the collections are implemented as “intrusive” data structures. The “node” data is the only struct used by the library code, and it does not store a pointer or other metadata to indicate what user data is “owned” by that node. Instead, the expectation is that the node will be itself embedded within a user-defined struct. Macros are provided to retrieve a user struct address from the embedded node pointer in a clean way. The purpose behind this design is to allow the collections to be used in contexts where dynamic allocation is disallowed (i.e. there is no need to allocate node objects because the memory is provided by the user).

Note also that these libraries are uniformly unsynchronized; access to them is not threadsafe by default. These are data structures, not synchronization primitives. The expectation is that any locking needed will be provided by the user.

7.19.1 Single-linked List

Zephyr provides a sys_slist_t type for storing simple singly-linked list data (i.e. data where each list element stores a pointer to the next element, but not the previous one). This supports constant-time access to the first (head) and last (tail) elements of the list, insertion before the head and after the tail of the list and constant time removal of the head. Removal of subsequent nodes requires access to the “previous” pointer and thus can only be performed in linear time by searching the list.
The `sys_slist_t` struct may be instantiated by the user in any accessible memory. It should be initialized with either `sys_slist_init()` or by static assignment from `SYS_SLIST_STATIC_INIT` before use. Its interior fields are opaque and should not be accessed by user code.

The end nodes of a list may be retrieved with `sys_slist_peek_head()` and `sys_slist_peek_tail()`, which will return NULL if the list is empty, otherwise a pointer to a `sys_snode_t` struct.

The `sys_snode_t` struct represents the data to be inserted. In general, it is expected to be allocated/controlled by the user, usually embedded within a struct which is to be added to the list. The container struct pointer may be retrieved from a list node using `SYS_SLIST_CONTAINER`, passing it the struct name of the containing struct and the field name of the node. Internally, the `sys_snode_t` struct contains only a next pointer, which may be accessed with `sys_slist_peek_next()`.

Lists may be modified by adding a single node at the head or tail with `sys_slist_prepend()` and `sys_slist_append()`. They may also have a node added to an interior point with `sys_slist_insert()`, which inserts a new node after an existing one. Similarly `sys_slist_remove()` will remove a node given a pointer to its predecessor. These operations are all constant time.

Convenience routines exist for more complicated modifications to a list. `sys_slist_merge_slist()` will append an entire list to an existing one. `sys_slist_append_list()` will append a bounded subset of an existing list in constant time. And `sys_slist_find_and_remove()` will search a list (in linear time) for a given node and remove it if present.

Finally the slist implementation provides a set of “for each” macros that allows for iterating over a list in a natural way without needing to manually traverse the next pointers. `SYS_SLIST_FOR_EACH_NODE` will enumerate every node in a list given a local variable to store the node pointer. `SYS_SLIST_FOR_EACH_NODE_SAFE` behaves similarly, but has a more complicated implementation that requires an extra scratch variable for storage and allows the user to delete the iterated node during the iteration. Each of those macros also exists in a “container” variant (`SYS_SLIST_FOR_EACH_CONTAINER` and `SYS_SLIST_FOR_EACH_CONTAINER_SAFE`) which assigns a local variable of a type that matches the user’s container struct and not the node struct, performing the required offsets internally. And `SYS_SLIST_ITERATE_FROM_NODE` exists to allow for enumerating a node and all its successors only, without inspecting the earlier part of the list.

**Single-linked List Internals**

The slist code is designed to be minimal and conventional. Internally, a `sys_slist_t` struct is nothing more than a pair of “head” and “tail” pointer fields. And a `sys_snode_t` stores only a single “next” pointer.

The specific implementation of the list code, however, is done with an internal “Z_GENLIST” template API which allows for extracting those fields from arbitrary structures and emits an arbitrarily named set of functions. This allows for implementing more complicated single-linked list variants using the same basic primitives. The genlist implementor is responsible for a custom implementation of the primitive operations only: an “init” step for each struct, and a “get” and “set” primitives for each of head, tail and next pointers on their relevant structs. These inline functions are passed as parameters to the genlist macro expansion.

Only one such variant, sflist, exists in Zephyr at the moment.
Flagged List

The `sys_sflist_t` is implemented using the described genlist template API. With the exception of symbol naming ("sflist" instead of "slist") and the additional API described next, it operates in all ways identically to the slist API.

It adds the ability to associate exactly two bits of user defined “flags” with each list node. These can be accessed and modified with `sys_sfnode_flags_get()` and `sys_sfnode_flags_set()`. Internally, the flags are stored unioned with the bottom bits of the next pointer and incur no SRAM storage overhead when compared with the simpler slist code.

Single-linked List API Reference

group single-linked-list_apis

Defines

```c
SYS_SLIST_FOR_EACH_NODE(__sl, __sn)
Provide the primitive to iterate on a list Note: the loop is unsafe and thus __sn should not be removed.
User MUST add the loop statement curly braces enclosing its own code:
```
```c
SYS_SLIST_FOR_EACH_NODE(1, n) {
    <user code>
}
```

This and other SYS_SLIST_*() macros are not thread safe.

Parameters

- `__sl` – A pointer on a sys_slist_t to iterate on
- `__sn` – A sys_snode_t pointer to peek each node of the list

```c
SYS_SLIST_ITERATE_FROM_NODE(__sl, __sn)
Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __sn should not be removed.
User MUST add the loop statement curly braces enclosing its own code:
```
```c
SYS_SLIST_ITERATE_FROM_NODE(1, n) {
    <user code>
}
```

Like `SYS_SLIST_FOR_EACH_NODE()`, but __dn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.
This and other SYS_SLIST_*() macros are not thread safe.

**Parameters**
- __sl – A pointer on a sys_slist_t to iterate on
- __sn – A sys_snode_t pointer to peek each node of the list it contains the starting node, or NULL to start from the head

SYS_SLIST_FOR_EACH_NODE_SAFE(__sl, __sn, __sns)

Provide the primitive to safely iterate on a list Note: __sn can be removed, it will not break the loop.

User **MUST** add the loop statement curly braces enclosing its own code:

```c
SYS_SLIST_FOR_EACH_NODE_SAFE(l, n, s) {
    <user code>
}
```

This and other SYS_SLIST_*() macros are not thread safe.

**Parameters**
- __sl – A pointer on a sys_slist_t to iterate on
- __sn – A sys_snode_t pointer to peek each node of the list
- __sns – A sys_snode_t pointer for the loop to run safely

SYS_SLIST_CONTAINER(__ln, __cn, __n)

SYS_SLIST_PEEK_HEAD_CONTAINER(__sl, __cn, __n)

SYS_SLIST_PEEK_TAIL_CONTAINER(__sl, __cn, __n)

SYS_SLIST_PEEK_NEXT_CONTAINER(__cn, __n)

SYS_SLIST_FOR_EACH_CONTAINER(__sl, __cn, __n)

Provide the primitive to iterate on a list under a container Note: the loop is unsafe and thus __cn should not be detached.

User **MUST** add the loop statement curly braces enclosing its own code:

```c
SYS_SLIST_FOR_EACH_CONTAINER(l, c, n) {
    <user code>
}
```

**Parameters**
- __sl – A pointer on a sys_slist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __n – The field name of sys_node_t within the container struct

SYS_SLIST_FOR_EACH_CONTAINER_SAFE(__sl, __cn, __cns, __n)

Provide the primitive to safely iterate on a list under a container Note: __cn can be detached, it will not break the loop.

User **MUST** add the loop statement curly braces enclosing its own code:
SYS_SLIST_FOR_EACH_NODE_SAFE(l, c, cn, n) {
    <user code>
}

Parameters

- __sl – A pointer on a sys_slist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __cns – A pointer for the loop to run safely
- __n – The field name of sys_node_t within the container struct

SYS_SLIST_STATIC_INIT(ptr_to_list)

Functions

static inline void sys_slist_init(sys_slist_t *list)
Initialize a list.

Parameters

- list – A pointer on the list to initialize

static inline sys_snode_t *sys_slist.peek_head(sys_slist_t *list)
Peek the first node from the list.

Parameters

- list – A point on the list to peek the first node from

Returns

A pointer on the first node of the list (or NULL if none)

static inline sys_snode_t *sys_slist.peek_tail(sys_slist_t *list)
Peek the last node from the list.

Parameters

- list – A point on the list to peek the last node from

Returns

A pointer on the last node of the list (or NULL if none)

static inline bool sys_slist.is_empty(sys_slist_t *list)
Test if the given list is empty.

Parameters

- list – A pointer on the list to test

Returns

a boolean, true if it's empty, false otherwise

static inline sys_snode_t *sys_slist.peek_next_no_check(sys_snode_t *node)
Peek the next node from current node, node is not NULL.

Faster then sys_slist.peek_next() if node is known not to be NULL.

Parameters

- node – A pointer on the node where to peek the next node

Returns

a pointer on the next node (or NULL if none)

static inline sys_snode_t *sys_slist.peek_next(sys_snode_t *node)
Peek the next node from current node.

Parameters
• node – A pointer on the node where to peek the next node

**Returns** a pointer on the next node (or NULL if none)

```c
static inline void sys_slist_prepend(sys_slist_t *list, sys_snode_t *node)
Prepend a node to the given list.
```

This and other `sys_slist_*()` functions are not thread safe.

**Parameters**

- `list` – A pointer on the list to affect
- `node` – A pointer on the node to prepend

```c
static inline void sys_slist_append(sys_slist_t *list, sys_snode_t *node)
Append a node to the given list.
```

This and other `sys_slist_*()` functions are not thread safe.

**Parameters**

- `list` – A pointer on the list to affect
- `node` – A pointer on the node to append

```c
static inline void sys_slist_append_list(sys_slist_t *list, void *head, void *tail)
Append a singly-linked, NULL-terminated list consisting of nodes containing the pointer to the
next node as the first element of a node, to `list`. This and other `sys_slist_*()` functions are not
thread safe.
```

FIXME: Why are the element parameters void *?

**Parameters**

- `list` – A pointer on the list to affect
- `head` – A pointer to the first element of the list to append
- `tail` – A pointer to the last element of the list to append

```c
static inline void sys_slist_merge_slist(sys_slist_t *list, sys_slist_t *list_to_append)
merge two slists, appending the second one to the first
```

When the operation is completed, the appending list is empty. This and other `sys_slist_*()` functions are not thread safe.

**Parameters**

- `list` – A pointer on the list to affect
- `list_to_append` – A pointer to the list to append.

```c
static inline void sys_slist_insert(sys_slist_t *list, sys_snode_t *prev, sys_snode_t *node)
Insert a node to the given list.
```

This and other `sys_slist_*()` functions are not thread safe.

**Parameters**

- `list` – A pointer on the list to affect
- `prev` – A pointer on the previous node
- `node` – A pointer on the node to insert

```c
static inline sys_snode_t *sys_slist_get_not_empty(sys_slist_t *list)
Fetch and remove the first node of the given list.
```

List must be known to be non-empty. This and other `sys_slist_*()` functions are not thread safe.
Parameters

- list – A pointer on the list to affect

Returns A pointer to the first node of the list

static inline sys_snodet* sys_list_get(sys_slist_t* list)
Fetch and remove the first node of the given list.
This and other sys_list_*( ) functions are not thread safe.

Parameters

- list – A pointer on the list to affect

Returns A pointer to the first node of the list (or NULL if empty)

static inline void sys_list_remove(sys_slist_t* list, sys_snodet* prev_node, sys_snodet* node)
Remove a node.
This and other sys_list_*( ) functions are not thread safe.

Parameters

- list – A pointer on the list to affect
- prev_node – A pointer on the previous node (can be NULL, which means the node is the list’s head)
- node – A pointer on the node to remove

static inline bool sys_list_find_and_remove(sys_slist_t* list, sys_snodet* node)
Find and remove a node from a list.
This and other sys_list_*( ) functions are not thread safe.

Parameters

- list – A pointer on the list to affect
- node – A pointer on the node to remove from the list

Returns true if node was removed

Flagged List API Reference

Defines

SYS_SFLIST_FOR_EACH_NODE(__sl, __sn)
Provide the primitive to iterate on a list Note: the loop is unsafe and thus __sn should not be removed.
User MUST add the loop statement curly braces enclosing its own code:

SYS_SFLIST_FOR_EACH_NODE(l, n) {
    <user code>
}

This and other SYS_SFLIST_*( ) macros are not thread safe.

Parameters

- __sl – A pointer on a sys_sflist_t to iterate on
• __sn – A sys_sfnode_t pointer to peek each node of the list

SYS_SFLIST_ITERATE_FROM_NODE(__sl, __sn)
Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and
thus __sn should not be removed.
User MUST add the loop statement curly braces enclosing its own code:

SYS_SFLIST_ITERATE_FROM_NODE(1, n) {

• __sn – A sys_sfnode_t pointer to peek each node of the list it contains the
    starting node, or NULL to start from the head

SYS_SFLIST_FOR_EACH_NODE_SAFE(__sl, __sn, __sns)
Provide the primitive to safely iterate on a list Note: __sn can be removed, it will not break
the loop.
User MUST add the loop statement curly braces enclosing its own code:

SYS_SFLIST_FOR_EACH_NODE_SAFE(1, n, s) {
    <user code>
}

This and other SYS_SFLIST_*() macros are not thread safe.

Parameters
• __sl – A pointer on a sys_sflist_t to iterate on
• __sn – A sys_sfnode_t pointer to peek each node of the list
• __sns – A sys_sfnode_t pointer for the loop to run safely

SYS_SFLIST_CONTAINER(__ln, __cn, __n)

SYS_SFLIST_PEEK_HEAD_CONTAINER(__sl, __cn, __n)

SYS_SFLIST_PEEK_TAIL_CONTAINER(__sl, __cn, __n)

SYS_SFLIST_PEEK_NEXT_CONTAINER(__cn, __n)

SYS_SFLIST_FOR_EACH_CONTAINER(__sl, __cn, __n)
Provide the primitive to iterate on a list under a container Note: the loop is unsafe and thus
__cn should not be detached.
User MUST add the loop statement curly braces enclosing its own code:

SYS_SFLIST_FOR_EACH_CONTAINER(1, c, n) {
    <user code>
}

Parameters
• __sl – A pointer on a sys_sflist_t to iterate on
• __cn – A pointer to peek each entry of the list
• __n  – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_FOR_EACH_CONTAINER_SAFE(__sl, __cn, __cns, __n)

Provide the primitive to safely iterate on a list under a container Note: __cn can be detached, it will not break the loop.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_SFLIST_FOR_EACH_NODE_SAFE(l, c, cn, n) {
   <user code>
}
```

Parameters

• __sl – A pointer on a sys_sflist_t to iterate on
• __cn – A pointer to peek each entry of the list
• __cns – A pointer for the loop to run safely
• __n  – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_STATIC_INIT(ptr_to_list)

SYS_SFLIST_FLAGS_MASK

Functions

static inline void sys_sflist_init(sys_sflist_t *list)
   Initialize a list.

   Parameters

   • list – A pointer on the list to initialize

static inline uint8_t sys_sfnode_flags_get(sys_sfnode_t *node)
   Fetch flags value for a particular sfnode.

   Parameters

   • node – A pointer to the node to fetch flags from

   Returns The value of flags, which will be between 0 and 3

static inline sys_sfnode_t *sys_sflist_peek_head(sys_sflist_t *list)
   Peek the first node from the list.

   Parameters

   • list – A point on the list to peek the first node from

   Returns A pointer on the first node of the list (or NULL if none)

static inline sys_sfnode_t *sys_sflist_peek_tail(sys_sflist_t *list)
   Peek the last node from the list.

   Parameters

   • list – A point on the list to peek the last node from

   Returns A pointer on the last node of the list (or NULL if none)
static inline void sys_sfnode_init(sys_sfnode_t *node, uint8_t flags)
    
    Initialize an sflist node.
    Set an initial flags value for this slist node, which can be a value between 0 and 3. These
    flags will persist even if the node is moved around within a list, removed, or transplanted to
    a different slist.
    This is ever so slightly faster than sys_sfnode_flags_set() and should only be used on a node
    that hasn’t been added to any list.

    Parameters
    • node – A pointer to the node to set the flags on
    • flags – A value between 0 and 3 to set the flags value

static inline void sys_sfnode_flags_set(sys_sfnode_t *node, uint8_t flags)
    
    Set flags value for an sflist node.
    Set a flags value for this slist node, which can be a value between 0 and 3. These flags will
    persist even if the node is moved around within a list, removed, or transplanted to a different
    slist.

    Parameters
    • node – A pointer to the node to set the flags on
    • flags – A value between 0 and 3 to set the flags value

static inline bool sys_sflist_is_empty(sys_sflist_t *list)
    
    Test if the given list is empty.

    Parameters
    • list – A pointer on the list to test

    Returns a boolean, true if it's empty, false otherwise

static inline sys_sfnode_t *sys_sflist_peek_next_no_check(sys_sfnode_t *node)
    
    Peek the next node from current node, node is not NULL.
    Faster then sys_sflist_peek_next() if node is known not to be NULL.

    Parameters
    • node – A pointer on the node where to peek the next node

    Returns a pointer on the next node (or NULL if none)

static inline sys_sfnode_t *sys_sflist_peek_next(sys_sfnode_t *node)
    
    Peek the next node from current node.

    Parameters
    • node – A pointer on the node where to peek the next node

    Returns a pointer on the next node (or NULL if none)

static inline void sys_sflist_prepend(sys_sflist_t *list, sys_sfnode_t *node)
    
    Prepend a node to the given list.
    This and other sys_sflist_*() functions are not thread safe.

    Parameters
    • list – A pointer on the list to affect
    • node – A pointer on the node to prepend

static inline void sys_sflist_append(sys_sflist_t *list, sys_sfnode_t *node)
    
    Append a node to the given list.
    This and other sys_sflist_*() functions are not thread safe.
Parameters

- list – A pointer on the list to affect
- node – A pointer on the node to append

static inline void sys_sflist_append_list(sys_sflist_t *list, void *head, void *tail)
Append a list to the given list.

Append a singly-linked, NULL-terminated list consisting of nodes containing the pointer to the
next node as the first element of a node, to list. This and other sys_sflist_*() functions are not
thread safe.

FIXME: Why are the element parameters void *?

Parameters

- list – A pointer on the list to affect
- head – A pointer to the first element of the list to append
- tail – A pointer to the last element of the list to append

static inline void sys_sflist_merge_sflist(sys_sflist_t *list, sys_sflist_t *list_to_append)
merge two sflists, appending the second one to the first

When the operation is completed, the appending list is empty. This and other sys_sflist_*() 
functions are not thread safe.

Parameters

- list – A pointer on the list to affect
- list_to_append – A pointer to the list to append.

static inline void sys_sflist_insert(sys_sflist_t *list, sys_sfnode_t *prev, sys_sfnode_t *node)
Insert a node to the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

- list – A pointer on the list to affect
- prev – A pointer on the previous node
- node – A pointer on the node to insert

static inline sys_sfnode_t *sys_sflist_get_not_empty(sys_sflist_t *list)
Fetch and remove the first node of the given list.

List must be known to be non-empty. This and other sys_sflist_*() functions are not thread 
safe.

Parameters

- list – A pointer on the list to affect

Returns A pointer to the first node of the list

static inline sys_sfnode_t *sys_sflist_get(sys_sflist_t *list)
Fetch and remove the first node of the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

- list – A pointer on the list to affect

Returns A pointer to the first node of the list (or NULL if empty)
static inline void sys_sflist_remove(sys_sflist_t *list, sys_sfnode_t *prev_node, sys_sfnode_t *node)

Remove a node.

This and other sys_sflist_*() functions are not thread safe.

**Parameters**
- `list` – A pointer on the list to affect
- `prev_node` – A pointer on the previous node (can be NULL, which means the node is the list’s head)
- `node` – A pointer on the node to remove

static inline bool sys_sflist_find_and_remove(sys_sflist_t *list, sys_sfnode_t *node)

Find and remove a node from a list.

This and other sys_sflist_*() functions are not thread safe.

**Parameters**
- `list` – A pointer on the list to affect
- `node` – A pointer on the node to remove from the list

**Returns** true if node was removed

### 7.19.2 Double-linked List

Similar to the single-linked list in many respects, Zephyr includes a double-linked implementation. This provides the same algorithmic behavior for all the existing slist operations, but also allows for constant-time removal and insertion (at all points: before or after the head, tail or any internal node). To do this, the list stores two pointers per node, and thus has somewhat higher runtime code and memory space needs.

A `sys_dlist_t` struct may be instantiated by the user in any accessible memory. It must be initialized with `sys_dlist_init()` or `SYS_DLIST_STATIC_INIT` before use. The `sys_dnode_t` struct is expected to be provided by the user for any nodes added to the list (typically embedded within the struct to be tracked, as described above). It must be initialized in zeroed/bss memory or with `sys_dnode_init()` before use.

Primitive operations may retrieve the head/tail of a list and the next/prev pointers of a node with `sys_dlist_peek_head()`, `sys_dlist_peek_tail()`, `sys_dlist_peek_next()` and `sys_dlist_peek_prev()`. These can all return NULL where appropriate (i.e. for empty lists, or nodes at the endpoints of the list).

A dlist can be modified in constant time by removing a node with `sys_dlist_remove()`, by adding a node to the head or tail of a list with `sys_dlist_prepend()` and `sys_dlist_append()`, or by inserting a node before an existing node with `sys_dlist_insert()`.

As for slist, each node in a dlist can be processed in a natural code block style using `SYS_DLIST_FOREACH_NODE`. This macro also exists in a “FROM_NODE” form which allows for iterating from a known starting point, a “SAFE” variant that allows for removing the node being inspected within the code block, a “CONTAINER” style that provides the pointer to a containing struct instead of the raw node, and a “CONTAINER_SAFE” variant that provides both properties.

Convenience utilities provided by dlist include `sys_dlist_insert_at()`, which inserts a node that linearly searches through a list to find the right insertion point, which is provided by the user as a C callback function pointer, and `sys_dnode_is_linked()`, which will affirmatively return whether or not a node is currently linked into a dlist or not (via an implementation that has zero overhead vs. the normal list processing).
Double-linked List Internals

Internally, the dlist implementation is minimal: the `sys_dlist_t` struct contains “head” and “tail” pointer fields, the `sys_dnode_t` contains “prev” and “next” pointers, and no other data is stored. But in practice the two structs are internally identical, and the list struct is inserted as a node into the list itself. This allows for a very clean symmetry of operations:

- An empty list has backpointers to itself in the list struct, which can be trivially detected.
- The head and tail of the list can be detected by comparing the prev/next pointers of a node vs. the list struct address.
- An insertion or deletion never needs to check for the special case of inserting at the head or tail. There are never any NULL pointers within the list to be avoided. Exactly the same operations are run, without tests or branches, for all list modification primitives.

Effectively, a dlist of N nodes can be thought of as a “ring” of “N+1” nodes, where one node represents the list tracking struct.

---

Doubly-linked List API Reference

**group** doubly-linked-list_apis

**Defines**

```c
SYS_DLIST_FOR_EACH_NODE(__dl, __dn)
```

Provide the primitive to iterate on a list Note: the loop is unsafe and thus `__dn` should not be
Zephyr Project Documentation, Release 3.0.99

Fig. 7.7: An empty dlist.

removed.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_DLIST_FOR_EACH_NODE(l, n) {
    <user code>
}
```

This and other SYS_DLIST_*() macros are not thread safe.

**Parameters**
- `__dl` – A pointer on a `sys_dlist_t` to iterate on
- `__dn` – A `sys_dnode_t` pointer to peek each node of the list

```c
SYS_DLIST_ITERATE_FROM_NODE(__dl, __dn)
```

Provide the primitive to iterate on a list, from a node in the list. Note: the loop is unsafe and thus `__dn` should not be removed.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_DLIST_ITERATE_FROM_NODE(l, n) {
    <user code>
}
```

Like `SYS_DLIST_FOR_EACH_NODE()`, but `__dn` already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.

This and other SYS_DLIST_*() macros are not thread safe.

**Parameters**
- `__dl` – A pointer on a `sys_dlist_t` to iterate on
- `__dn` – A `sys_dnode_t` pointer to peek each node of the list; it contains the starting node, or NULL to start from the head

```c
SYS_DLIST_FOR_EACH_NODE_SAFE(__dl, __dn, __dns)
```

Provide the primitive to safely iterate on a list. Note: `__dn` can be removed, it will not break the loop.

7.19. Data Structures 907
User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_DLIST_FOR_EACH_NODE_SAFE(l, n, s) {
  <user code>
}
```

This and other SYS_DLIST_*() macros are not thread safe.

**Parameters**
- `__dl` – A pointer on a sys_dlist_t to iterate on
- `__dn` – A sys_dnode_t pointer to peek each node of the list
- `__dns` – A sys_dnode_t pointer for the loop to run safely

```c
SYS_DLIST_CONTAINER(__dn, __cn, __n)
SYS_DLIST_PEEK_HEAD_CONTAINER(__dl, __cn, __n)
SYS_DLIST_PEEK_NEXT_CONTAINER(__dl, __cn, __n)
SYS_DLIST_FOR_EACH_CONTAINER(__dl, __cn, __n)
```

Provide the primitive to iterate on a list under a container. Note: the loop is unsafe and thus `__cn` should not be detached.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_DLIST_FOR_EACH_CONTAINER(1, c, n) {
  <user code>
}
```

**Parameters**
- `__dl` – A pointer on a sys_dlist_t to iterate on
- `__cn` – A pointer to peek each entry of the list
- `__n` – The field name of sys_dnode_t within the container struct

```c
SYS_DLIST_FOR_EACH_CONTAINER_SAFE(__dl, __cn, __cns, __n)
```

Provide the primitive to safely iterate on a list under a container. Note: `__cn` can be detached, it will not break the loop.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_DLIST_FOR_EACH_CONTAINER_SAFE(1, c, cn, n) {
  <user code>
}
```

**Parameters**
- `__dl` – A pointer on a sys_dlist_t to iterate on
- `__cn` – A pointer to peek each entry of the list
- `__cns` – A pointer for the loop to run safely
- `__n` – The field name of sys_dnode_t within the container struct

```c
SYS_DLIST_STATIC_INIT(ptr_to_list)
```
Typedefs

typedef struct _dnode sys_dlist_t

typedef struct _dnode sys_dnode_t

Functions

static inline void sys_dlist_init(sys_dlist_t *list)
initialize list to its empty state

Parameters
• list – the doubly-linked list

static inline void sys_dnode_init(sys_dnode_t *node)
initialize node to its state when not in a list

Parameters
• node – the node

static inline bool sys_dnode_is_linked(const sys_dnode_t *node)
check if a node is a member of any list

Parameters
• node – the node

Returns true if node is linked into a list, false if it is not

static inline bool sys_dlist_is_head(sys_dlist_t *list, sys_dnode_t *node)
check if a node is the list’s head

Parameters
• list – the doubly-linked list to operate on
• node – the node to check

Returns true if node is the head, false otherwise

static inline bool sys_dlist_is_tail(sys_dlist_t *list, sys_dnode_t *node)
check if a node is the list’s tail

Parameters
• list – the doubly-linked list to operate on
• node – the node to check

Returns true if node is the tail, false otherwise

static inline bool sys_dlist_is_empty(sys_dlist_t *list)
check if the list is empty

Parameters
• list – the doubly-linked list to operate on

Returns true if empty, false otherwise

static inline bool sys_dlist_has_multiple_nodes(sys_dlist_t *list)
check if more than one node present

This and other sys_dlist_*() functions are not thread safe.
static inline sys_dnode_t *sys_dlist_peek_head(sys_dlist_t *list)
get a reference to the head item in the list

Parameters
• list – the doubly-linked list to operate on

Returns true if multiple nodes, false otherwise

static inline sys_dnode_t *sys_dlist_peek_head_not_empty(sys_dlist_t *list)
get a reference to the head item in the list

Parameters
• list – the doubly-linked list to operate on

Returns a pointer to the head element, NULL if list is empty

The list must be known to be non-empty.

Parameters
• list – the doubly-linked list to operate on

static inline sys_dnode_t *sys_dlist_peek_next_no_check(sys_dlist_t *list, sys_dnode_t *node)
get a reference to the next item in the list, node is not NULL.
Faster than sys_dlist_peek_next() if node is known not to be NULL.

Parameters
• list – the doubly-linked list to operate on
• node – the node from which to get the next element in the list

Returns a pointer to the next element from a node, NULL if node is the tail.

static inline sys_dnode_t *sys_dlist_peek_next(sys_dlist_t *list, sys_dnode_t *node)
get a reference to the next item in the list

Parameters
• list – the doubly-linked list to operate on
• node – the node from which to get the next element in the list

Returns a pointer to the next element from a node, NULL if node is the tail or NULL
(when node comes from reading the head of an empty list).

static inline sys_dnode_t *sys_dlist_peek_prev_no_check(sys_dlist_t *list, sys_dnode_t *node)
get a reference to the previous item in the list, node is not NULL.
Faster than sys_dlist_peek_prev() if node is known not to be NULL.

Parameters
• list – the doubly-linked list to operate on
• node – the node from which to get the previous element in the list

Returns a pointer to the previous element from a node, NULL if node is the tail.

static inline sys_dnode_t *sys_dlist_peek_prev(sys_dlist_t *list, sys_dnode_t *node)
get a reference to the previous item in the list

Parameters
• list – the doubly-linked list to operate on
• node – the node from which to get the previous element in the list

Returns a pointer to the previous element from a node, NULL if node is the tail or NULL (when node comes from reading the head of an empty list).
**static inline** `sys_dnode_t *sys_dlist.peek_tail(sys_dlist_t *list)`
get a reference to the tail item in the list

**Parameters**

- `list` – the doubly-linked list to operate on

**Returns**
a pointer to the tail element, NULL if list is empty

**static inline void** `sys_dlist.append(sys_dlist_t *list, sys_dnode_t *node)`
add node to tail of list

This and other `sys_dlist_*()` functions are not thread safe.

**Parameters**

- `list` – the doubly-linked list to operate on
- `node` – the element to append

**static inline void** `sys_dlist.prepend(sys_dlist_t *list, sys_dnode_t *node)`
add node to head of list

This and other `sys_dlist_*()` functions are not thread safe.

**Parameters**

- `list` – the doubly-linked list to operate on
- `node` – the element to append

**static inline void** `sys_dlist.insert(sys_dnode_t *successor, sys_dnode_t *node)`
Insert a node into a list.

Insert a node before a specified node in a dlist.

**Parameters**

- `successor` – the position before which “node” will be inserted
- `node` – the element to insert

**static inline void** `sys_dlist.insert_at(sys_dlist_t *list, sys_dnode_t *node, int (*cond)(sys_dnode_t *node, void *data), void *data)`
insert node at position

Insert a node in a location depending on a external condition. The cond() function checks if
the node is to be inserted before the current node against which it is checked. This and other
`sys_dlist_*()` functions are not thread safe.

**Parameters**

- `list` – the doubly-linked list to operate on
- `node` – the element to insert
- `cond` – a function that determines if the current node is the correct insert point
- `data` – parameter to cond()

**static inline void** `sys_dlist.remove(sys_dnode_t *node)`
remove a specific node from a list

The list is implicit from the node. The node must be part of a list. This and other `sys_dlist_*()`
functions are not thread safe.

**Parameters**

- `node` – the node to remove

**static inline** `sys_dnode_t *sys_dlist.get(sys_dlist_t *list)`
get the first node in a list

This and other `sys_dlist_*()` functions are not thread safe.
Parameters
- list – the doubly-linked list to operate on

Returns the first node in the list, NULL if list is empty

7.19.3 Multi Producer Single Consumer Packet Buffer

A Multi Producer Single Consumer Packet Buffer (MPSC_PBUF) is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that consumes the data. However, it is possible that another context may interfere to flush the data and never come back (panic case). Packet is produced in two steps: first requested amount of data is allocated, producer fills the data and commits it. Consuming a packet is also performed in two steps: consumer claims the packet, gets pointer to it and length and later on packet is freed. This approach reduces memory copying.

A MPSC Packet Buffer has the following key properties:
- Allocate, commit scheme used for packet producing.
- Claim, free scheme used for packet consuming.
- Allocator ensures that continue memory of requested length is allocated.
- Following policies can be applied when requested space cannot be allocated:
  - Overwrite - oldest entries are dropped until requested amount of memory can be allocated. For each dropped packet user callback is called.
  - No overwrite - When requested amount of space cannot be allocated, allocation fails.
- Dedicated, optimized API for storing short packets.
- Allocation with timeout.

Internals

Each packet in the buffer contains MPSC_PBUF specific header which is used for internal management. Header consists of 2 bit flags. In order to optimize memory usage, header can be added on top of the user header using MPSC_PBUF_HDR and remaining bits in the first word can be application specific. Header consists of following flags:
- valid - bit set to one when packet contains valid user packet
- busy - bit set when packet is being consumed (claimed but not free)

Header state:

<table>
<thead>
<tr>
<th>valid</th>
<th>busy</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>space is free</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>valid packet</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>claimed valid packet</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>internal skip packet</td>
</tr>
</tbody>
</table>

Packet buffer space contains free space, valid user packets and internal skip packets. Internal skip packets indicates padding, e.g. at the of the buffer.

Allocation Using pairs for read and write indexes, available space is determined. If space can be allocated, temporary write index is moved and pointer to a space writing buffer is returned. Packet header is reset. If allocation required wrapping of the write index, a skip packet is added to the end of buffer. If space cannot be allocated and overwrite is disabled then NULL pointer is returned or context blocks if allocation was with timeout.
Allocation with overwrite   If overwrite is enabled, oldest packets are dropped until requested amount of space can be allocated. When packets are dropped busy flag is checked in the header to ensure that currently consumed packet is not overwritten. In that case, skip packet is added before busy packet and packets following the busy packet are dropped. When busy packet is being freed, such situation is detected and packet is converted to skip packet to avoid double processing.

Usage

Packet header definition   Packet header details can be found in include/sys/mpsc_packet.h. API functions can be found in include/sys/mpsc_pbuf.h. Headers are split to avoid include spam when declaring the packet.

User header structure must start with internal header:

```c
#include <sys/mpsc_packet.h>

struct foo_header {
    MPSC_PBUF_HDR;
    uint32_t length: 32 - MPSC_PBUF_HDR_BITS;
};
```

Packet buffer configuration   Configuration structure contains buffer details, configuration flags and callbacks. Following callbacks are used by the packet buffer:

- Drop notification - callback called whenever a packet is dropped due to overwrite.
- Get packet length - callback to determine packet length

Packet producing   Standard, two step method:

```c
foo_packet *packet = mpsc_pbuf_alloc(buffer, len, K_NO_WAIT);
fill_data(packet);
mpsc_pbuf_commit(buffer, packet);
```

Performance optimized storing of small packets:

- 32 bit word packet
- 32 bit word with pointer packet

Note that since packets are written by value, they should already contain valid bit set in the header.

```c
mpsc_pbuf_put_word(buffer, data);
mpsc_pbuf_put_word_ext(buffer, data, ptr);
```

Packet consuming   Two step method:

```c
foo_packet *packet = mpsc_pbuf_claim(buffer);
process(packet);
mpsc_pbuf_free(buffer, packet);
```
7.19.4 Balanced Red/Black Tree

For circumstances where sorted containers may become large at runtime, a list becomes problematic due to algorithmic costs of searching it. For these situations, Zephyr provides a balanced tree implementation which has runtimes on search and removal operations bounded at \(O(\log_2(N))\) for a tree of size \(N\). This is implemented using a conventional red/black tree as described by multiple academic sources.

The `rbtree` tracking struct for a rbtree may be initialized anywhere in user accessible memory. It should contain only zero bits before first use. No specific initialization API is needed or required.

Unlike a list, where position is explicit, the ordering of nodes within an rbtree must be provided as a predicate function by the user. A function of type `rb_lessthan_t()` should be assigned to the `lessthan_fn` field of the `:c:struct rbtree` struct before any tree operations are attempted. This function should, as its name suggests, return a boolean True value if the first node argument is “less than” the second in the ordering desired by the tree. Note that “equal” is not allowed, nodes within a tree must have a single fixed order for the algorithm to work correctly.

As with the slist and dlist containers, nodes within an rbtree are represented as an `rbnode` structure which exists in user-managed memory, typically embedded within the data structure being tracked in the tree. Unlike the list code, the data within an rbnode is entirely opaque. It is not possible for the user to extract the binary tree topology and “manually” traverse the tree as it is for a list.

Nodes can be inserted into a tree with `rb_insert()` and removed with `rb_remove()`. Access to the “first” and “last” nodes within a tree (in the sense of the order defined by the comparison function) is provided by `rb_get_min()` and `rb_get_max()`. There is also a predicate, `rb_contains()`, which returns a boolean True if the provided node pointer exists as an element within the tree. As described above, all of these routines are guaranteed to have at most log time complexity in the size of the tree.

There are two mechanisms provided for enumerating all elements in an rbtree. The first, `rb_walk()`, is a simple callback implementation where the caller specifies a C function pointer and an untyped argument to be passed to it, and the tree code calls that function for each node in order. This has the advantage of a very simple implementation, at the cost of a somewhat more cumbersome API for the user (not unlike ISO C’s `bsearch()` routine). It is a recursive implementation, however, and is thus not always available in environments that forbid the use of unbounded stack techniques like recursion.

There is also a `RB_FOR_EACH` iterator provided, which, like the similar APIs for the lists, works to iterate over a list in a more natural way, using a nested code block instead of a callback. It is also nonrecursive, though it requires log-sized space on the stack by default (however, this can be configured to use a fixed/maximally size buffer instead where needed to avoid the dynamic allocation). As with the lists, this is also available in a `RB_FOR_EACH_CONTAINER` variant which enumerates using a pointer to a container field and not the raw node pointer.

Tree Internals

As described, the Zephyr rbtree implementation is a conventional red/black tree as described pervasively in academic sources. Low level details about the algorithm are out of scope for this document, as they match existing conventions. This discussion will be limited to details notable or specific to the Zephyr implementation.

The core invariant guaranteed by the tree is that the path from the root of the tree to any leaf is no more than twice as long as the path to any other leaf. This is achieved by associating one bit of “color” with each node, either red or black, and enforcing a rule that no red child can be a child of another red child (i.e. that the number of black nodes on any path to the root must be the same, and that no more than that number of “extra” red nodes may be present). This rule is enforced by a set of rotation rules used to “fix” trees following modification.

These rotations are conceptually implemented on top of a primitive that “swaps” the position of one node with another in the list. Typical implementations effect this by simply swapping the nodes internal “data” pointers, but because the Zephyr `rbnode` is intrusive, that cannot work. Zephyr must include somewhat more elaborate code to handle the edge cases (for example, one swapped node can be the root, or the two may already be parent/child).
Fig. 7.8: A maximally unbalanced rbtree with a black height of two. No more nodes can be added underneath the rightmost node without rebalancing.
The `rbnode` struct for a Zephyr rbtree contains only two pointers, representing the “left”, and “right” children of a node within the binary tree. Traversal of a tree for rebalancing following modification, however, routinely requires the ability to iterate “upwards” from a node as well. It is very common for red/black trees in the industry to store a third “parent” pointer for this purpose. Zephyr avoids this requirement by building a “stack” of node pointers locally as it traverses downward through the tree and updating it appropriately as modifications are made. So a Zephyr rbtree can be implemented with no more runtime storage overhead than a dlist.

These properties, of a balanced tree data structure that works with only two pointers of data per node and that works without any need for a memory allocation API, are quite rare in the industry and are somewhat unique to Zephyr.

### Red/Black Tree API Reference

#### group rbtree_apis

**Defines**

```c
RB_FOR_EACH(tree, node)
Walk a tree in-order without recursing.

While `rb_walk()` is very simple, recursing on the C stack can be clumsy for some purposes and on some architectures wastes significant memory in stack frames. This macro implements a non-recursive “foreach” loop that can iterate directly on the tree, at a moderate cost in code size.

Note that the resulting loop is not safe against modifications to the tree. Changes to the tree structure during the loop will produce incorrect results, as nodes may be skipped or duplicated. Unlike linked lists, no _SAFE variant exists.

Note also that the macro expands its arguments multiple times, so they should not be expressions with side effects.

**Parameters**

- `tree` – A pointer to a struct rbtree to walk
- `node` – The symbol name of a local struct rbnode* variable to use as the iterator

```c
RB_FOR_EACH_CONTAINER(tree, node, field)
Loop over rbtree with implicit container field logic.

As for `RB_FOR_EACH()`, but “node” can have an arbitrary type containing a struct rbnode.

**Parameters**

- `tree` – A pointer to a struct rbtree to walk
- `node` – The symbol name of a local iterator
- `field` – The field name of a struct rbnode inside node

**Typedefs**

```c
typedef bool (*rb_lessthan_t)(struct rbnode *a, struct rbnode *b)
Red/black tree comparison predicate.

Compares the two nodes and returns true if node A is strictly less than B according to the tree’s sorting criteria, false otherwise.

Note that during insert, the new node being inserted will always be “A”, where “B” is the existing node within the tree against which it is being compared. This trait can be used
typedef void (*rb_visit_t)(struct rbnode *node, void *cookie)

Functions

void rb_insert(struct rbtree *tree, struct rbnode *node)
   Insert node into tree.

void rb_remove(struct rbtree *tree, struct rbnode *node)
   Remove node from tree.

static inline struct rbnode *rb_get_min(struct rbtree *tree)
   Returns the lowest-sorted member of the tree.

static inline struct rbnode *rb_get_max(struct rbtree *tree)
   Returns the highest-sorted member of the tree.

bool rb_contains(struct rbtree *tree, struct rbnode *node)
   Returns true if the given node is part of the tree.
   Note that this does not internally dereference the node pointer (though the tree's lessthan callback might!), it just tests it for equality with items in the tree. So it's feasible to use this to implement a "set" construct by simply testing the pointer value itself.

static inline void rb_walk(struct rbtree *tree, rb_visit_t visit_fn, void *cookie)
   Walk/enumerate a rbtree.
   Very simple recursive enumeration. Low code size, but requiring a separate function can be clumsy for the user and there is no way to break out of the loop early. See RB_FOR_EACH for an iterative implementation.

struct rbtree
    #include <rb.h>

7.19.5 Ring Buffers

A ring buffer is a circular buffer, whose contents are stored in first-in-first-out order.

For circumstances where an application needs to implement asynchronous "streaming" copying of data, Zephyr provides a struct ring_buf abstraction to manage copies of such data in and out of a shared buffer of memory.

Two content data modes are supported:

- **Byte mode**: raw bytes can be enqueued and dequeued.
- **Data item mode**: Multiple 32-bit word data items with metadata can be enqueued and dequeued from the ring buffer in chunks of up to 1020 bytes. Each data item also has two associated metadata values: a type identifier and a 16-bit integer value, both of which are application-specific.

While the underlying data structure is the same, it is not legal to mix these two modes on a single ring buffer instance. A ring buffer initialized with a byte count must be used only with the "bytes" API, one initialized with a word count must use the "items" calls.

- **Concepts**
  - **Byte mode**
Any number of ring buffers can be defined (limited only by available RAM). Each ring buffer is referenced by its memory address.

A ring buffer has the following key properties:

- A **data buffer** of bytes or 32-bit words. The data buffer contains the raw bytes or 32-bit words that have been added to the ring buffer but not yet removed.
- A **data buffer size**, measured in bytes or 32-byte words. This governs the maximum amount of data (including possible metadata values) the ring buffer can hold.

A ring buffer must be initialized before it can be used. This sets its data buffer to empty.

A `struct ring_buf` may be placed anywhere in user-accessible memory, and must be initialized with `ring_buf_init()` or `ring_buf_element_init()` before use. This must be provided a region of user-controlled memory for use as the buffer itself. Note carefully that the units of the size of the buffer passed change (either bytes or words) depending on how the ring buffer will be used later. Macros for combining these steps in a single static declaration exist for convenience. `RING_BUF_DECLARE` will declare and statically initialize a ring buffer with a specified byte count, where `RING_BUF_ITEM_DECLARE` will declare and statically initialize a buffer with a given count of 32 bit words.

“Bytes” data may be copied into the ring buffer using `ring_buf_put()`, passing a data pointer and byte count. These bytes will be copied into the buffer in order, as many as will fit in the allocated buffer. The total number of bytes copied (which may be fewer than provided) will be returned. Likewise `ring_buf_get()` will copy bytes out of the ring buffer in the order that they were written, into a user-provided buffer, returning the number of bytes that were transferred.

To avoid multiply-copied-data situations, a “claim” API exists for byte mode. `ring_buf_put_claim()` takes a byte size value from the user and returns a pointer to memory internal to the ring buffer that can be used to receive those bytes, along with a size of the contiguous internal region (which may be smaller than requested). The user can then copy data into that region at a later time without assembling all the bytes in a single region first. When complete, `ring_buf_put_finish()` can be used to signal the buffer that the transfer is complete, passing the number of bytes actually transferred. At this point a new transfer can be initiated. Similarly, `ring_buf_get_claim()` returns a pointer to internal ring buffer data from which the user can read without making a verbatim copy, and `ring_buf_get_finish()` signals the buffer with how many bytes have been consumed and allows for a new transfer to begin.

“Items” mode works similarly to bytes mode, except that all transfers are in units of 32 bit words and all memory is assumed to be aligned on 32 bit boundaries. The write and read operations are `ring_buf_item_put()` and `ring_buf_item_get()`, and work otherwise identically to the bytes mode APIs. There no “claim” API provided for items mode. One important difference is that unlike `ring_buf_put()`, `ring_buf_item_put()` will not do a partial transfer; it will return an error in the case where the provided data does not fit in its entirety.
The user can manage the capacity of a ring buffer without modifying it using either `ring_buf_space_get()` or `ring_buf_item_space_get()` which returns the number of free bytes or free 32-bit item words respectively, or by testing the `ring_buf_is_empty()` predicate.

Finally, a `ring_buf_reset()` call exists to immediately empty a ring buffer, discarding the tracking of any bytes or items already written to the buffer. It does not modify the memory contents of the buffer itself, however.

**Byte mode** A byte mode ring buffer instance is declared using `RING_BUF_DECLARE()` and accessed using: `ring_buf_put_claim()`, `ring_buf_put_finish()`, `ring_buf_get_claim()`, `ring_buf_get_finish()`, `ring_buf_put()` and `ring_buf_get()`.

Data can be copied into the ring buffer (see `ring_buf_put()`) or ring buffer memory can be used directly by the user. In the latter case, the operation is split into three stages:

1. allocating the buffer (`ring_buf_put_claim()`) when user requests the destination location where data can be written.
2. writing the data by the user (e.g. buffer written by DMA).
3. indicating the amount of data written to the provided buffer (`ring_buf.put_finish()`). The amount can be less than or equal to the allocated amount.

Data can be retrieved from a ring buffer through copying (see `ring_buf.get()`) or accessed directly by address. In the latter case, the operation is split into three stages:

1. retrieving source location with valid data written to a ring buffer (see `ring_buf_get_claim()`).
2. processing data
3. freeing processed data (see `ring_buf_get_finish()`). The amount freed can be less than or equal to the retrieved amount.

**Data item mode** A data item mode ring buffer instance is declared using `RING_BUF_ITEM_DECLARE()` and accessed using `ring_buf_item_put()` and `ring_buf_item_get()`.

A ring buffer data item is an array of 32-bit words from 0 to 1020 bytes in length. When a data item is enqueued (`ring_buf_item_put()`) its contents are copied to the data buffer, along with its associated metadata values (which occupy one additional 32-bit word). If the ring buffer has insufficient space to hold the new data item the enqueue operation fails.

A data items is dequeued (`ring_buf_item_get()`) from a ring buffer by removing the oldest enqueued item. The contents of the dequeued data item, as well as its two metadata values, are copied to areas supplied by the retriever. If the ring buffer is empty, or if the data array supplied by the retriever is not large enough to hold the data item’s data, the dequeue operation fails.

**Concurrency** The ring buffer APIs do not provide any concurrency control. Depending on usage (particularly with respect to number of concurrent readers/writers) applications may need to protect the ring buffer with mutexes and/or use semaphores to notify consumers that there is data to read.

For the trivial case of one producer and one consumer, concurrency control shouldn’t be needed.

**Internal Operation** Data streamed through a ring buffer is always written to the next byte within the buffer, wrapping around to the first element after reaching the end, thus the “ring” structure. Internally, the struct `ring_buf` contains its own buffer pointer and its size, and also a set of “head” and “tail” indices representing where the next read and write operations may occur.

This boundary is invisible to the user using the normal put/get APIs, but becomes a barrier to the “claim” API, because obviously no contiguous region can be returned that crosses the end of the buffer. This can be surprising to application code, and produce performance artifacts when transfers need to happen close to the end of the buffer, as the number of calls to claim/finish needs to double for such transfers.
Implementation

Defining a Ring Buffer A ring buffer is defined using a variable of type `ring_buf`. It must then be initialized by calling `ring_buf_init()` or `c:func:ring_buf_item_init`.

The following code defines and initializes an empty data item mode ring buffer (which is part of a larger data structure). The ring buffer's data buffer is capable of holding 64 words of data and metadata information.

```c
#define MY_RING_BUF_WORDS 64

struct my_struct {
    struct ring_buf rb;
    uint32_t buffer[MY_RING_BUF_WORDS];
    ...
};

struct my_struct ms;

void init_my_struct {
    ring_buf_item_init(&ms.rb, MY_RING_BUF_WORDS, ms.buffer);
    ...
}
```

Alternatively, a ring buffer can be defined and initialized at compile time using one of two macros at file scope. Each macro defines both the ring buffer itself and its data buffer.

The following code defines a data item mode ring buffer:

```c
#define MY_RING_BUF_WORDS 93
RING_BUF_ITEM_DECLARE(my_ring_buf, MY_RING_BUF_WORDS);
```

The following code defines a ring buffer intended to be used for raw bytes:

```c
#define MY_RING_BUF_BYTES 93
RING_BUF_DECLARE(my_ring_buf, MY_RING_BUF_BYTES);
```

Enqueuing Data Bytes are copied to a byte mode ring buffer by calling `ring_buf_put()`.

```c
uint8_t my_data[MY_RING_BUF_BYTES];
uint32_t ret;

ret = ring_buf_put(&ring_buf, my_data, MY_RING_BUF_BYTES);
if (ret != MY_RING_BUF_BYTES) {
    /* not enough room, partial copy. */
    ...
}
```

Data can be added to a byte mode ring buffer by directly accessing the ring buffer's memory. For example:

```c
uint32_t size;
uint32_t rx_size;
uint8_t *data;
int err;

/* Allocate buffer within a ring buffer memory. */
size = ring_buf_put_claim(&ring_buf, &data, MY_RING_BUF_BYTES);
```

(continues on next page)
A data item is added to a ring buffer by calling `ring_buf_item_put()`.  

```c
uint32_t data[MY_DATA_WORDS];
int ret;

ret = ring_buf_item_put(&ring_buf, TYPE_FOO, 0, data, MY_DATA_WORDS);
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}
```

If the data item requires only the type or application-specific integer value (i.e. it has no data array), a size of 0 and data pointer of `NULL` can be specified.  

```c
int ret;

ret = ring_buf_item_put(&ring_buf, TYPE_BAR, 17, NULL, 0);
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}
```

### Retrieving Data

Data bytes are copied out from a `byte mode` ring buffer by calling `ring_buf_get()`.  

For example:

```c
uint8_t my_data[MY_DATA_BYTES];
size_t ret;

ret = ring_buf_get(&ring_buf, my_data, sizeof(my_data));
if (ret != sizeof(my_data)) {
    /* Fewer bytes copied. */
} else {
    /* Requested amount of bytes retrieved. */
}
```

Data can be retrieved from a `byte mode` ring buffer by direct operations on the ring buffer’s memory.  

For example:

```c
uint32_t size;
uint32_t proc_size;
uint8_t *data;
int err;

/* Get buffer within a ring buffer memory. */
size = ring_buf_get_claim(&ring_buf, &data, MY_RING_BUF_BYTES);
```
A data item is removed from a ring buffer by calling `ring_buf_item_get()`.

```c
uint32_t my_data[MY_DATA_WORDS];
uint16_t my_type;
uint8_t my_value;
uint8_t my_size;
int ret;

my_size = MY_DATA_WORDS;
ret = ring_buf_item_get(&ring_buf, &my_type, &my_value, my_data, &my_size);
if (ret == -EMSGSIZE) {
    printk("Buffer is too small, need %d uint32_t\n", my_size);
} else if (ret == -EAGAIN) {
    printk("Ring buffer is empty\n");
} else {
    printk("Got item of type %u value &u of size %u dwords\n", 
            my_type, my_value, my_size);
    ...
}
```

Configuration Options

Related configuration options:

- `CONFIG_RING_BUFFER`: Enable ring buffer.

API Reference

The following ring buffer APIs are provided by include/sys/ring_buffer.h:

```c
group ring_buffer_apis

Defines

RING_BUF_DECLARE(name, size8)
Define and initialize a ring buffer for byte data.
This macro establishes a ring buffer of an arbitrary size. The basic storage unit is a byte.
The ring buffer can be accessed outside the module where it is defined using:
```
extern struct ring_buf <name>;

Parameters

• name – Name of the ring buffer.
• size8 – Size of ring buffer (in bytes).

RING_BUF_ITEM_DECLARE(name, size32)
Define and initialize an “item based” ring buffer.
This macro establishes an “item based” ring buffer. Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.
The ring buffer can be accessed outside the module where it is defined using:

extern struct ring_buf <name>;

Parameters

• name – Name of the ring buffer.
• size32 – Size of ring buffer (in 32-bit words).

RING_BUF_ITEM_DECLARE_SIZE(name, size32)
Define and initialize an “item based” ring buffer.
This exists for backward compatibility reasons. RING_BUF_ITEM_DECLARE should be used instead.

Parameters

• name – Name of the ring buffer.
• size32 – Size of ring buffer (in 32-bit words).

RING_BUF_ITEM_DECLARE_pow2(name, pow)
Define and initialize a power-of-2 sized “item based” ring buffer.
This macro establishes an “item based” ring buffer by specifying its size using a power of 2. This exists mainly for backward compatibility reasons. RING_BUF_ITEM_DECLARE should be used instead.

Parameters

• name – Name of the ring buffer.
• pow – Ring buffer size exponent.

Functions

static inline void ring_buf_init(struct ring_buf *buf, uint32_t size, uint8_t *data)
Initialize a ring buffer for byte data.
This routine initializes a ring buffer, prior to its first use. It is only used for ring buffers not defined using RING_BUF_DECLARE.

Parameters

• buf – Address of ring buffer.
• size – Ring buffer size (in bytes).
• data – Ring buffer data area (uint8_t data[size]).

static inline void ring_buf_item_init(struct ring_buf *buf, uint32_t size, uint32_t *data)
Initialize an “item based” ring buffer.

This routine initializes a ring buffer, prior to its first use. It is only used for ring buffers not
defined using RING_BUF_ITEM_DECLARE.

Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with
a 16-bit type identifier and an 8-bit integer value.

Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with
a 16-bit type identifier and an 8-bit integer value.

Parameters
• buf – Address of ring buffer.
• size – Ring buffer size (in 32-bit words)
• data – Ring buffer data area (uint32_t data[size]).

static inline bool ring_buf_is_empty(struct ring_buf *buf)
Determine if a ring buffer is empty.

Parameters
• buf – Address of ring buffer.

Returns true if the ring buffer is empty, or false if not.

static inline void ring_buf_reset(struct ring_buf *buf)
Reset ring buffer state.

Parameters
• buf – Address of ring buffer.

static inline uint32_t ring_buf_space_get(struct ring_buf *buf)
Determine free space in a ring buffer.

Parameters
• buf – Address of ring buffer.

Returns Ring buffer free space (in bytes).

static inline uint32_t ring_buf_item_space_get(struct ring_buf *buf)
Determine free space in an “item based” ring buffer.

Parameters
• buf – Address of ring buffer.

Returns Ring buffer free space (in 32-bit words).

static inline uint32_t ring_buf_capacity_get(struct ring_buf *buf)
Return ring buffer capacity.

Parameters
• buf – Address of ring buffer.

Returns Ring buffer capacity (in bytes).

static inline uint32_t ring_buf_size_get(struct ring_buf *buf)
Determine used space in a ring buffer.

Parameters
• buf – Address of ring buffer.

Returns Ring buffer space used (in bytes).
uint32_t ring_buf_put_claim(struct ring_buf *buf, uint8_t **data, uint32_t size)
Allocate buffer for writing data to a ring buffer.
With this routine, memory copying can be reduced since internal ring buffer can be used
directly by the user. Once data is written to allocated area number of bytes written must be
confirmed (see ring_buf_put_finish).

Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent
write operations, either by preventing all writers from being preempted or by using a
mutex to govern writes to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item access (calls prefixed
with ring_buf_item_).

Parameters
• data – [out] Pointer to the address. It is set to a location within ring buffer.

Returns Size of allocated buffer which can be smaller than requested if there is not
enough free space or buffer wraps.

int ring_buf_put_finish(struct ring_buf *buf, uint32_t size)
Indicate number of bytes written to allocated buffers.
The number of bytes must be equal to or lower than the sum corresponding to all preceding
ring_buf_put_claim invocations (or even 0). Surplus bytes will be returned to the available
free buffer space.

Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent
write operations, either by preventing all writers from being preempted or by using a
mutex to govern writes to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item access (calls prefixed
with ring_buf_item_).

Parameters
• buf – Address of ring buffer.
• size – Number of valid bytes in the allocated buffers.

Return values
• 0 – Successful operation.
• -EINVAL – Provided size exceeds free space in the ring buffer.

uint32_t ring_buf_put(struct ring_buf *buf, const uint8_t *data, uint32_t size)
Write (copy) data to a ring buffer.
This routine writes data to a ring buffer buf.
Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters
- buf – Address of ring buffer.
- data – Address of data.
- size – Data size (in bytes).

Returns
- Number – of bytes written.

uint32_t ring_buf_get_claim(struct ring_buf *buf, uint8_t **data, uint32_t size)
Get address of a valid data in a ring buffer.

With this routine, memory copying can be reduced since internal ring buffer can be used directly by the user. Once data is processed it must be freed using ring_buf_get_finish.

Warning: Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters
- data – [out] Pointer to the address. It is set to a location within ring buffer.

Returns
- Number of valid bytes in the provided buffer which can be smaller than requested if there is not enough free space or buffer wraps.

int ring_buf_get_finish(struct ring_buf *buf, uint32_t size)
Indicate number of bytes read from claimed buffer.

The number of bytes must be equal or lower than the sum corresponding to all preceding ring_buf_get_claim invocations (or even 0). Surplus bytes will remain available in the buffer.

Warning: Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item mode (calls prefixed with ring_buf_item_).
Parameters
  • `buf` – Address of ring buffer.
  • `size` – Number of bytes that can be freed.

Return values
  • `0` – Successful operation.
  • `-EINVAL` – Provided `size` exceeds valid bytes in the ring buffer.

```
uint32_t ring_buf_get(struct ring_buf *buf, uint8_t *data, uint32_t size)
```

Read data from a ring buffer.

This routine reads data from a ring buffer `buf`.

**Warning:** Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

**Warning:** Ring buffer instance should not mix byte access and item mode (calls prefixed with `ring_buf_item_`).

Parameters
  • `buf` – Address of ring buffer.
  • `data` – Address of the output buffer. Can be NULL to discard data.
  • `size` – Data size (in bytes).

Return values: Number of bytes written to the output buffer.

```
uint32_t ring_buf_peek(struct ring_buf *buf, uint8_t *data, uint32_t size)
```

Peek at data from a ring buffer.

This routine reads data from a ring buffer `buf` without removal.

**Warning:** Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

**Warning:** Ring buffer instance should not mix byte access and item mode (calls prefixed with `ring_buf_item_`).

**Warning:** Multiple calls to peek will result in the same data being ‘peeked’ multiple times. To remove data, use either `ring_buf_get` or `ring_buf_get_claim` followed by `ring_buf_get_finish` with a non-zero `size`.

Parameters
  • `buf` – Address of ring buffer.
  • `data` – Address of the output buffer. Cannot be NULL.
size – Data size (in bytes).

Return values
Number – of bytes written to the output buffer.

int ring_buf_item_put(struct ring_buf *buf, uint16_t type, uint8_t value, uint32_t *data, uint8_t size32)
Write a data item to a ring buffer.

This routine writes a data item to ring buffer buf. The data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Parameters
• buf – Address of ring buffer.
• type – Data item's type identifier (application specific).
• value – Data item's integer value (application specific).
• data – Address of data item.
• size32 – Data item size (number of 32-bit words).

Return values
• 0 – Data item was written.
• -EMSGSIZE – Ring buffer has insufficient free space.

int ring_buf_item_get(struct ring_buf *buf, uint16_t *type, uint8_t *value, uint32_t *data, uint8_t *size32)
Read a data item from a ring buffer.

This routine reads a data item from ring buffer buf. The data item is an array of 32-bit words (up to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

Warning: Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Parameters
• buf – Address of ring buffer.
• type – Area to store the data item’s type identifier.
• value – Area to store the data item’s integer value.
• data – Area to store the data item. Can be NULL to discard data.
• size32 – Size of the data item storage area (number of 32-bit chunks).

Return values
• 0 – Data item was fetched; size32 now contains the number of 32-bit words read into data area data.
• -EAGAIN – Ring buffer is empty.
• -EMSGSIZE – Data area data is too small; size32 now contains the number of 32-bit words needed.

7.20 Modbus

Modbus is an industrial messaging protocol. The protocol is specified for different types of networks or buses. Zephyr OS implementation supports communication over serial line and may be used with different physical interfaces, like RS485 or RS232. TCP support is not implemented directly, but there are helper functions to realize TCP support according to the application’s needs.

Modbus communication is based on client/server model. Only one client may be present on the bus. Client can communicate with several server devices. Server devices themselves are passive and must not send requests or unsolicited responses. Services requested by the client are specified by function codes (FCxx), and can be found in the specification or documentation of the API below.

Zephyr RTOS implementation supports both client and server roles.

More information about Modbus and Modbus RTU can be found on the website [MODBUS Protocol Specifications](#).

7.20.1 Samples

modbus-rtu-server-sample and modbus-rtu-client-sample give the possibility to try out RTU server and RTU client implementation with an evaluation board.

modbus-tcp-server-sample is a simple Modbus TCP server.

modbus-gateway-sample is an example how to build a TCP to serial line gateway with Zephyr OS.

7.20.2 API Reference

```c
#include "modbus.h"

typedef int (*modbus_raw_cb_t)(const int iface, const struct modbus_adu *adu)
ADU raw callback function signature.
```

- **Param iface** Modbus RTU interface index
- **Param adu** Pointer to the RAW ADU struct to send
- **Retval 0** If transfer was successful
Enums

enum modbus_mode
    Modbus interface mode.
    Values:

    enumerator MODBUS_MODE_RTU
        Modbus over serial line RTU mode

    enumerator MODBUS_MODE_ASCII
        Modbus over serial line ASCII mode

    enumerator MODBUS_MODE_RAW
        Modbus raw ADU mode

Functions

int modbus_read_coils(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint8_t *const coil_tbl, const uint16_t num_coils)

Coil read (FC01)

Sends a Modbus message to read the status of coils from a server.

Parameters

• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Coil starting address
• coil_tbl – Pointer to an array of bytes containing the value of the coils read. The format is:

<table>
<thead>
<tr>
<th>MSB</th>
<th>LSB</th>
</tr>
</thead>
<tbody>
<tr>
<td>B7</td>
<td>B0</td>
</tr>
<tr>
<td>B6</td>
<td>#8</td>
</tr>
<tr>
<td>B5</td>
<td>#7</td>
</tr>
<tr>
<td>B4</td>
<td>#1</td>
</tr>
<tr>
<td>B3</td>
<td>#9</td>
</tr>
<tr>
<td>B2</td>
<td>#15</td>
</tr>
<tr>
<td>B1</td>
<td>#8</td>
</tr>
<tr>
<td>B0</td>
<td>#7</td>
</tr>
</tbody>
</table>

Note that the array that will be receiving the coil values must be greater than or equal to: (num_coils - 1) / 8 + 1

• num_coils – Quantity of coils to read

Return values  0 – If the function was successful

int modbus_read_dinputs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint8_t *const di_tbl, const uint16_t num_di)

Read discrete inputs (FC02)

Sends a Modbus message to read the status of discrete inputs from a server.

Parameters

• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Discrete input starting address
• di_tbl – Pointer to an array that will receive the state of the discrete inputs. The format of the array is as follows:

<table>
<thead>
<tr>
<th>MSB</th>
<th>B7</th>
<th>B6</th>
<th>B5</th>
<th>B4</th>
<th>B3</th>
<th>B2</th>
<th>B1</th>
<th>B0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>#8</td>
<td>#7</td>
<td>#1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note that the array that will be receiving the discrete input values must be greater than or equal to: \((\text{num\_di} - 1) / 8 + 1\)

• num_di – Quantity of discrete inputs to read

**Return values** 0 – If the function was successful

```c
int modbus_read_holding_regs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint16_t *const reg_buf, const uint16_t num_regs)
```

Read holding registers (FC03)

Sends a Modbus message to read the value of holding registers from a server.

**Parameters**

- **iface** – Modbus interface index
- **unit_id** – Modbus unit ID of the server
- **start_addr** – Register starting address
- **reg_buf** – Is a pointer to an array that will receive the current values of the holding registers from the server. The array pointed to by ‘reg_buf’ needs to be able to hold at least ‘num_regs’ entries.
- **num_regs** – Quantity of registers to read

**Return values** 0 – If the function was successful

```c
int modbus_read_input_regs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint16_t *const reg_buf, const uint16_t num_regs)
```

Read input registers (FC04)

Sends a Modbus message to read the value of input registers from a server.

**Parameters**

- **iface** – Modbus interface index
- **unit_id** – Modbus unit ID of the server
- **start_addr** – Register starting address
- **reg_buf** – Is a pointer to an array that will receive the current value of the holding registers from the server. The array pointed to by ‘reg_buf’ needs to be able to hold at least ‘num_regs’ entries.
- **num_regs** – Quantity of registers to read

**Return values** 0 – If the function was successful

```c
int modbus_write_coil(const int iface, const uint8_t unit_id, const uint16_t coil_addr, const bool coil_state)
```

Write single coil (FC05)

Sends a Modbus message to write the value of single coil to a server.

**Parameters**
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• coil_addr – Coils starting address
• coil_state – Is the desired state of the coil

Return values  0 – If the function was successful

int modbus_write_holding_reg(const int iface, const uint8_t unit_id, const uint16_t start_addr, const uint16_t reg_val)

Write single holding register (FC06)
Sends a Modbus message to write the value of single holding register to a server unit.

Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Coils starting address
• reg_val – Desired value of the holding register

Return values  0 – If the function was successful

int modbus_request_diagnostic(const int iface, const uint8_t unit_id, const uint16_t sfunc, const uint16_t data, uint16_t *const data_out)

Read diagnostic (FC08)
Sends a Modbus message to perform a diagnostic function of a server unit.

Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• sfunc – Diagnostic sub-function code
• data – Sub-function data
• data_out – Pointer to the data value

Return values  0 – If the function was successful

int modbus_write_coils(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint8_t *const coil_tbl, const uint16_t num_coils)

Write coils (FC15)
Sends a Modbus message to write to coils on a server unit.

Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Coils starting address
• coil_tbl – Pointer to an array of bytes containing the value of the coils to write. The format is:

<table>
<thead>
<tr>
<th>MSB</th>
<th>B7</th>
<th>B6</th>
<th>B5</th>
<th>B4</th>
<th>B3</th>
<th>B2</th>
<th>B1</th>
<th>LSB</th>
</tr>
</thead>
<tbody>
<tr>
<td>coil_tbl[0]</td>
<td>#8</td>
<td>#7</td>
<td>#1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>coil_tbl[1]</td>
<td>#16</td>
<td>#15</td>
<td>#9</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>:</td>
<td>:</td>
<td>:</td>
<td>:</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Zephyr Project Documentation, Release 3.0.99

Note that the array that will be receiving the coil values must be greater than
or equal to: (num_coils - 1) / 8 + 1
• num_coils – Quantity of coils to write
Return values 0 – If the function was successful
int modbus_write_holding_regs(const int iface, const uint8_t unit_id, const uint16_t start_addr,
uint16_t *const reg_buf, const uint16_t num_regs)
Write holding registers (FC16)
Sends a Modbus message to write to integer holding registers to a server unit.
Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Register starting address
• reg_buf – Is a pointer to an array containing the value of the holding registers
to write. Note that the array containing the register values must be greater
than or equal to ‘num_regs’
• num_regs – Quantity of registers to write
Return values 0 – If the function was successful
int modbus_read_holding_regs_fp(const int iface, const uint8_t unit_id, const uint16_t
start_addr, float *const reg_buf, const uint16_t num_regs)
Read floating-point holding registers (FC03)
Sends a Modbus message to read the value of floating-point holding registers from a server
unit.
Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Register starting address
• reg_buf – Is a pointer to an array that will receive the current values of the
holding registers from the server. The array pointed to by ‘reg_buf’ needs to be
able to hold at least ‘num_regs’ entries.
• num_regs – Quantity of registers to read
Return values 0 – If the function was successful
int modbus_write_holding_regs_fp(const int iface, const uint8_t unit_id, const uint16_t
start_addr, float *const reg_buf, const uint16_t num_regs)
Write floating-point holding registers (FC16)
Sends a Modbus message to write to floating-point holding registers to a server unit.
Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Register starting address
• reg_buf – Is a pointer to an array containing the value of the holding registers
to write. Note that the array containing the register values must be greater
than or equal to ‘num_regs’
• num_regs – Quantity of registers to write
Return values 0 – If the function was successful
7.20. Modbus

933


int modbus_iface_get_by_name(const char *iface_name)
Get Modbus interface index according to interface name.
If there is more than one interface, it can be used to clearly identify interfaces in the application.

Parameters
  • iface_name – Modbus interface name

Return values Modbus – interface index or negative error value.

int modbus_init_server(const int iface, struct modbus_iface_param param)
Configure Modbus Interface as raw ADU server.

Parameters
  • iface – Modbus RTU interface index
  • param – Configuration parameter of the server interface

Return values 0 – If the function was successful

int modbus_init_client(const int iface, struct modbus_iface_param param)
Configure Modbus Interface as raw ADU client.

Parameters
  • iface – Modbus RTU interface index
  • param – Configuration parameter of the client interface

Return values 0 – If the function was successful

int modbus_disable(const uint8_t iface)
Disable Modbus Interface.
This function is called to disable Modbus interface.

Parameters
  • iface – Modbus interface index

Return values 0 – If the function was successful

int modbus_raw_submit_rx(const int iface, const struct modbus_adu *adu)
Submit raw ADU.

Parameters
  • iface – Modbus RTU interface index
  • adu – Pointer to the RAW ADU struct that is received

Return values 0 – If transfer was successful

void modbus_raw_put_header(const struct modbus_adu *adu, uint8_t *header)
Put MBAP header into a buffer.

Parameters
  • adu – Pointer to the RAW ADU struct
  • header – Pointer to the buffer in which MBAP header will be placed.

void modbus_raw_get_header(struct modbus_adu *adu, const uint8_t *header)
Get MBAP header from a buffer.

Parameters
  • adu – Pointer to the RAW ADU struct
  • header – Pointer to the buffer containing MBAP header
void modbus_raw_set_server_failure(struct modbus_adu *adu)
    Set Server Device Failure exception.
    This function modifies ADU passed by the pointer.

    **Parameters**
    - adu – Pointer to the RAW ADU struct

int modbus_raw_backend_txn(const int iface, struct modbus_adu *adu)
    Use interface as backend to send and receive ADU.
    This function overwrites ADU passed by the pointer and generates exception responses if backend interface is misconfigured or target device is unreachable.

    **Parameters**
    - iface – Modbus client interface index
    - adu – Pointer to the RAW ADU struct

    **Return values**
    0 – If transfer was successful

struct modbus_adu
    
#include <modbus.h> Frame struct used internally and for raw ADU support.

**Public Members**

uint16_t trans_id
    Transaction Identifier

uint16_t proto_id
    Protocol Identifier

uint16_t length
    Length of the data only (not the length of unit ID + PDU)

uint8_t unit_id
    Unit Identifier

uint8_t fc
    Function Code

uint8_t data[CONFIG_MODBUS_BUFFER_SIZE - 4]
    Transaction Data

uint16_t crc
    RTU CRC

struct modbus_user_callbacks
    #include <modbus.h> Modbus Server User Callback structure

**Public Members**

int (*coil_rd)(uint16_t addr, bool *state)
    Coil read callback
int (*coil_wr)(uint16_t addr, bool state)
    Coil write callback

int (*discrete_input_rd)(uint16_t addr, bool *state)
    Discrete Input read callback

int (*input_reg_rd)(uint16_t addr, uint16_t *reg)
    Input Register read callback

int (*input_reg_rd_fp)(uint16_t addr, float *reg)
    Floating Point Input Register read callback

int (*holding_reg_rd)(uint16_t addr, uint16_t *reg)
    Holding Register read callback

int (*holding_reg_wr)(uint16_t addr, uint16_t reg)
    Holding Register write callback

int (*holding_reg_rd_fp)(uint16_t addr, float *reg)
    Floating Point Holding Register read callback

int (*holding_reg_wr_fp)(uint16_t addr, float reg)
    Floating Point Holding Register write callback

struct modbus_serial_param
    #include <modbus.h> Modbus serial line parameter.

Public Members

uint32_t baud
    Baudrate of the serial line

enum uart_config_parity parity
    parity UART’s parity setting: UART_CFG_PARITY_NONE, UART_CFG_PARITY_EVEN,
    UART_CFG_PARITY_ODD

struct modbus_server_param
    #include <modbus.h> Modbus server parameter.

Public Members

struct modbus_user_callbacks *user_cb
    Pointer to the User Callback structure

uint8_t unit_id
    Modbus unit ID of the server

struct modbus_iface_param
    #include <modbus.h> User parameter structure to configure Modbus interface as client or server.
Public Members

enum _modbus_mode_ mode
    Mode of the interface

uint32_t _rx_timeout_
    Amount of time client will wait for a response from the server.

struct _modbus_serial_param_ serial
    Serial support parameter of the interface

_modbus_raw_cb_t raw_tx_cb
    Pointer to raw ADU callback function

7.21 Networking

7.21.1 Network APIs

BSD Sockets

Overview  Zephyr offers an implementation of a subset of the BSD Sockets API (a part of the POSIX standard). This API allows to reuse existing programming experience and port existing simple networking applications to Zephyr.

Here are the key requirements and concepts which governed BSD Sockets compatible API implementation for Zephyr:

• Has minimal overhead, similar to the requirement for other Zephyr subsystems.

• Is namespaced by default, to avoid name conflicts with well-known names like close(), which may be part of libc or other POSIX compatibility libraries. If enabled by CONFIG_NET_SOCKETS_POSIX_NAMES, it will also expose native POSIX names.

BSD Sockets compatible API is enabled using CONFIG_NET_SOCKETS config option and implements the following operations: socket(), close(), recv(), recvfrom(), send(), sendto(), connect(), bind(), listen(), accept(), fcntl() (to set non-blocking mode), getsockopt(), setsockopt(), poll(), select(), getaddrinfo(), getnameinfo().

Based on the namespacing requirements above, these operations are by default exposed as functions with zsock_ prefix, e.g. zsock_socket() and zsock_close(). If the config option
CONFIG_NET_SOCKETS_POSIX_NAMES is defined, all the functions will be also exposed as aliases without the prefix. This includes the functions like close() and fcntl() (which may conflict with functions in libc or other libraries, for example, with the filesystem libraries).

Another entailment of the design requirements above is that the Zephyr API aggressively employs the short-read/short-write property of the POSIX API whenever possible (to minimize complexity and overheads). POSIX allows for calls like recv() and send() to actually process (receive or send) less data than requested by the user (on SOCK_STREAM type sockets). For example, a call recv(sock, 1000, 0) may return 100, meaning that only 100 bytes were read (short read), and the application needs to retry call(s) to receive the remaining 900 bytes.

The BSD Sockets API uses file descriptors to represent sockets. File descriptors are small integers, consecutively assigned from zero, shared among sockets, files, special devices (like stdin/stdout), etc. Internally, there is a table mapping file descriptors to internal object pointers. The file descriptor table is used by the BSD Sockets API even if the rest of the POSIX subsystem (filesystem, stdin/stdout) is not enabled.

Secure Sockets Zephyr provides an extension of standard POSIX socket API, allowing to create and configure sockets with TLS protocol types, facilitating secure communication. Secure functions for the implementation are provided by mbedTLS library. Secure sockets implementation allows use of both TLS and DTLS protocols with standard socket calls. See net_ip_protocol_secure type for supported secure protocol versions.

To enable secure sockets, set the CONFIG_NET_SOCKETS_SOCKOPT_TLS option. To enable DTLS support, use CONFIG_NET_SOCKETS_ENABLE_DTLS option.

TLS credentials subsystem TLS credentials must be registered in the system before they can be used with secure sockets. See tls_credential_add() for more information.

When a specific TLS credential is registered in the system, it is assigned with numeric value of type sec_tag_t, called a tag. This value can be used later on to reference the credential during secure socket configuration with socket options.

The following TLS credential types can be registered in the system:

- TLS_CREDENTIAL_CA_CERTIFICATE
- TLS_CREDENTIAL_SERVER_CERTIFICATE
- TLS_CREDENTIAL_PRIVATE_KEY
- TLS_CREDENTIAL_PSK
- TLS_CREDENTIAL_PSK_ID

An example registration of CA certificate (provided in ca_certificate array) looks like this:

```c
ret = tls_credential_add(CA_CERTIFICATE_TAG, TLS_CREDENTIAL_CA_CERTIFICATE,
                        ca_certificate, sizeof(ca_certificate));
```

By default certificates in DER format are supported. PEM support can be enabled in mbedTLS settings.

Secure Socket Creation A secure socket can be created by specifying secure protocol type, for instance:

```c
sock = socket(AF_INET, SOCK_STREAM, IPPROTO_TLS_1_2);
```

Once created, it can be configured with socket options. For instance, the CA certificate and hostname can be set:

```c
sec_tag_t sec_tag_opt[] = {
    CA_CERTIFICATE_TAG,
};
```

(continues on next page)
Once configured, socket can be used just like a regular TCP socket.

Several samples in Zephyr use secure sockets for communication. For a sample use see e.g. echo-server sample application or HTTP GET sample application.

### Secure Sockets options

Secure sockets offer the following options for socket management:

#### Defines

- **TLS_SEC_TAG_LIST**
  Socket option to select TLS credentials to use. It accepts and returns an array of sec_tag_t that indicate which TLS credentials should be used with specific socket.

- **TLS_HOSTNAME**
  Write-only socket option to set hostname. It accepts a string containing the hostname (may be NULL to disable hostname verification). By default, hostname check is enforced for TLS clients.

- **TLS_CIPHERSUITE_LIST**
  Socket option to select ciphersuites to use. It accepts and returns an array of integers with IANA assigned ciphersuite identifiers. If not set, socket will allow all ciphersuites available in the system (mbedtls default behavior).

- **TLS_CIPHERSUITE_USED**
  Read-only socket option to read a ciphersuite chosen during TLS handshake. It returns an integer containing an IANA assigned ciphersuite identifier of chosen ciphersuite.

- **TLS_PEER_VERIFY**
  Write-only socket option to set peer verification level for TLS connection. This option accepts an integer with a peer verification level, compatible with mbedtls values:
  - 0 - none
  - 1 - optional
  - 2 - required
  If not set, socket will use mbedtls defaults (none for servers, required for clients).

- **TLS_DTLS_ROLE**
  Write-only socket option to set role for DTLS connection. This option is irrelevant for TLS connections, as for them role is selected based on connect()/listen() usage. By default, DTLS will assume client role. This option accepts an integer with a TLS role, compatible with mbedtls values:
  - 0 - client
• 1 - server

TLS_ALPN_LIST
Socket option for setting the supported Application Layer Protocols. It accepts and returns a const char array of NULL terminated strings representing the supported application layer protocols listed during the TLS handshake.

TLS_DTLS_HANDSHAKE_TIMEOUT_MIN
Socket option to set DTLS handshake timeout. The timeout starts at min, and upon retransmission the timeout is doubled until max is reached. Min and max arguments are separate options. The time unit is ms.

TLS_DTLS_HANDSHAKE_TIMEOUT_MAX

TLS_CERT_NOCOPY
Socket option for preventing certificates from being copied to the mbedTLS heap if possible. The option is only effective for DER certificates and is ignored for PEM certificates.

API Reference

BSD Sockets

*group bsd_sockets*
BSD Sockets compatible API.

*Defines*

ZSOCK_POLLIN
zsock_poll: Poll for readability

ZSOCK_POLLPRI
zsock_poll: Compatibility value, ignored

ZSOCK_POLLOUT
zsock_poll: Poll for writability

ZSOCK_POLLERR
zsock_poll: Poll results in error condition (output value only)

ZSOCK_POLLHUP
zsock_poll: Poll detected closed connection (output value only)

ZSOCK_POLLNVAL
zsock_poll: Invalid socket (output value only)

ZSOCK_MSG_PEEK
zsock_recv: Read data without removing it from socket input queue

ZSOCK_MSG_TRUNC
zsock_recv: return the real length of the datagram, even when it was longer than the passed buffer
ZSOCK_MSG_DONTWAIT
   zsock_recv/zsock_send: Override operation to non-blocking

ZSOCK_MSG_WAITALL
   zsock_recv: block until the full amount of data can be returned

ZSOCK_SHUT_RD
   zsock_shutdown: Shut down for reading

ZSOCK_SHUT_WR
   zsock_shutdown: Shut down for writing

ZSOCK_SHUT_RDWR
   zsock_shutdown: Shut down for both reading and writing

SOL_TLS
   Protocol level for TLS. Here, the same socket protocol level for TLS as in Linux was used.

TLS_PEER_VERIFY_NONE
   Peer verification disabled.

TLS_PEER_VERIFY_OPTIONAL
   Peer verification optional.

TLS_PEER_VERIFY_REQUIRED
   Peer verification required.

TLS_DTLS_ROLE_CLIENT
   Client role in a DTLS session.

TLS_DTLS_ROLE_SERVER
   Server role in a DTLS session.

TLS_CERT_NOCOPY_NONE
   Cert duplicated in heap

TLS_CERT_NOCOPY_OPTIONAL
   Cert not copied in heap if DER

AI_PASSIVE
   Address for bind() (vs for connect())

AI_CANONNAME
   Fill in ai_canonname

AI_NUMERICHOST
   Assume host address is in numeric notation, don’t DNS lookup

AI_V4MAPPED
   May return IPv4 mapped address for IPv6

AI_ALL
   May return both native IPv6 and mapped IPv4 address for IPv6
AI_ADDRCONFIG
IPv4/IPv6 support depends on local system config

AI_NUMERICSERV
Assume service (port) is numeric

NI_NUMERICHOST
zsock_getnameinfo(): Resolve to numeric address.

NI_NUMERICSERV
zsock_getnameinfo(): Resolve to numeric port number.

NI_NOFQDN
zsock_getnameinfo(): Return only hostname instead of FQDN

NI_NAMEREQD
zsock_getnameinfo(): Dummy option for compatibility

NI_DGRAM
zsock_getnameinfo(): Dummy option for compatibility

NI_MAXHOST
zsock_getnameinfo(): Max supported hostname length

IFNAMSIZ

SOL_SOCKET
sockopt: Socket-level option

SO_DEBUG
sockopt: Recording debugging information (ignored, for compatibility)

SO_REUSEADDR
sockopt: address reuse (ignored, for compatibility)

SO_TYPE
sockopt: Type of the socket

SO_ERROR
sockopt: Async error (ignored, for compatibility)

SO_DONTROUTE
sockopt: Bypass normal routing and send directly to host (ignored, for compatibility)

SO_BROADCAST
sockopt: Transmission of broadcast messages is supported (ignored, for compatibility)

SO_SNDBUF
sockopt: Size of socket socket send buffer (ignored, for compatibility)

SO_KEEPALIVE
sockopt: Enable sending keep-alive messages on connections (ignored, for compatibility)
SO_OOBINLINE
socket: Place out-of-band data into receive stream (ignored, for compatibility)

SO_REUSEPORT
socket: Allow multiple sockets to reuse a single port (ignored, for compatibility)

SO_RCVTIMEO
socket: Receive timeout Applies to receive functions like recv(), but not to connect()

SO_SNDDTIMEO
socket: Send timeout

SO_BINDTODEVICE
socket: Bind a socket to an interface

SO_ACCEPTCONN
socket: Socket accepts incoming connections (ignored, for compatibility)

SO_TIMESTAMPING
socket: Timestamp TX packets

SO_PROTOCOL
socket: Protocol used with the socket

SO_DOMAIN
socket: Domain used with SOCKET (ignored, for compatibility)

TCP_NODELAY
End Socket options for SOL_SOCKET level socketopt: Disable TCP buffering (ignored, for compatibility)

IPV6_V6ONLY
socket: Don’t support IPv4 access (ignored, for compatibility)

SO_PRIORITY
socket: Socket priority

SO_TXTIME
socket: Socket TX time (when the data should be sent)

SCM_TXTIME

SO_SOCKS5
socket: Enable SOCKS5 for Socket

ZSOCK_FD_SETSIZE
Number of file descriptors which can be added to zsock_fd_set

zsock_timeval
Typedefs

typedef struct zsock_fd_set zsock_fd_set

Functions

void *zsock_get_context_object(int sock)
Obtain a file descriptor's associated net context.

With CONFIG_USERSPACE enabled, the kernel's object permission system must apply to
socket file descriptors. When a socket is opened, by default only the caller has permission,
access by other threads will fail unless they have been specifically granted permission.

This is achieved by tagging data structure definitions that implement the underlying object
associated with a network socket file descriptor with '__net_socket'. All pointers to instances
of these will be known to the kernel as kernel objects with type K_OBJ_NET_SOCKET.

This API is intended for threads that need to grant access to the object associated with a
particular file descriptor to another thread. The returned pointer represents the underlying
K_OBJ_NET_SOCKET and may be passed to APIs like k_object_access_grant().

In a system like Linux which has the notion of threads running in processes in a shared vir-
tual address space, this sort of management is unnecessary as the scope of file descriptors is
implemented at the process level.

However in Zephyr the file descriptor scope is global, and MPU-based systems are not able to
implement a process-like model due to the lack of memory virtualization hardware. They use
discrete object permissions and memory domains instead to define thread access scope.

User threads will have no direct access to the returned object and will fault if they try to access
its memory; the pointer can only be used to make permission assignment calls, which follow
exactly the rules for other kernel objects like device drivers and IPC.

Parameters

• sock – file descriptor

Returns pointer to associated network socket object, or NULL if the file descriptor
wasn't valid or the caller had no access permission

int zsock_socket(int family, int type, int proto)
Create a network socket.

See POSIX.1-2017 article for normative description. This function is also exposed as socket() if
CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

If CONFIG_USERSPACE is enabled, the caller will be granted access to the context object
associated with the returned file descriptor.

See also:
zsock_get_context_object()

int zsock_socketpair(int family, int type, int proto, int *sv)
Create an unnamed pair of connected sockets.

See POSIX.1-2017 article for normative description. This function is also exposed as
socketpair() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

int zsock_close(int sock)
Close a network socket.
Close a network socket. This function is also exposed as `close()` if `CONFIG_NET_SOCKETS_POSIX_NAMES` is defined (in which case it may conflict with generic POSIX `close()` function).

```c
int zsock_shutdown(int sock, int how)
```

Shutdown socket send/receive operations.

See POSIX.1-2017 article for normative description, but currently this function has no effect in Zephyr and provided solely for compatibility with existing code. This function is also exposed as `shutdown()` if `CONFIG_NET_SOCKETS_POSIX_NAMES` is defined.

```c
int zsock_bind(int sock, const struct sockaddr *addr, socklen_t addrlen)
```

Bind a socket to a local network address.

See POSIX.1-2017 article for normative description. This function is also exposed as `bind()` if `CONFIG_NET_SOCKETS_POSIX_NAMES` is defined.

```c
int zsock_connect(int sock, const struct sockaddr *addr, socklen_t addrlen)
```

Connect a socket to a peer network address.

See POSIX.1-2017 article for normative description. This function is also exposed as `connect()` if `CONFIG_NET_SOCKETS_POSIX_NAMES` is defined.

```c
int zsock_listen(int sock, int backlog)
```

Set up a STREAM socket to accept peer connections.

See POSIX.1-2017 article for normative description. This function is also exposed as `listen()` if `CONFIG_NET_SOCKETS_POSIX_NAMES` is defined.

```c
int zsock_accept(int sock, struct sockaddr *addr, socklen_t *addrlen)
```

Accept a connection on listening socket.

See POSIX.1-2017 article for normative description. This function is also exposed as `accept()` if `CONFIG_NET_SOCKETS_POSIX_NAMES` is defined.

```c
ssize_t zsock_sendto(int sock, const void *buf, size_t len, int flags, const struct sockaddr *dest_addr, socklen_t addrlen)
```

Send data to an arbitrary network address.

See POSIX.1-2017 article for normative description. This function is also exposed as `sendto()` if `CONFIG_NET_SOCKETS_POSIX_NAMES` is defined.

```c
static inline ssize_t zsock_send(int sock, const void *buf, size_t len, int flags)
```

Send data to a connected peer.

See POSIX.1-2017 article for normative description. This function is also exposed as `send()` if `CONFIG_NET_SOCKETS_POSIX_NAMES` is defined.

```c
ssize_t zsock_sendmsg(int sock, const struct msghdr *msg, int flags)
```

Send data to an arbitrary network address.

See POSIX.1-2017 article for normative description. This function is also exposed as `sendmsg()` if `CONFIG_NET_SOCKETS_POSIX_NAMES` is defined.
ssize_t zsock_recvfrom(int sock, void *buf, size_t max_len, int flags, struct sockaddr *src_addr, socklen_t *addrlen)
Receive data from an arbitrary network address.

See POSIX.1-2017 article for normative description. This function is also exposed as recvfrom() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

static inline ssize_t zsock_recv(int sock, void *buf, size_t max_len, int flags)
Receive data from a connected peer.

See POSIX.1-2017 article for normative description. This function is also exposed as recv() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

int zsock_fcntl(int sock, int cmd, int flags)
Control blocking/non-blocking mode of a socket.

This functions allow to (only) configure a socket for blocking or non-blocking operation (O_NONBLOCK). This function is also exposed as fcntl() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined (in which case it may conflict with generic POSIX fcntl() function).

int zsock_poll(struct zsock_pollfd *fds, int nfds, int timeout)
Efficiently poll multiple sockets for events.

See POSIX.1-2017 article for normative description. (In Zephyr this function works only with sockets, not arbitrary file descriptors.) This function is also exposed as poll() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined (in which case it may conflict with generic POSIX poll() function).

int zsock_getsockopt(int sock, int level, int optname, void *optval, socklen_t *optlen)
Get various socket options.

See POSIX.1-2017 article for normative description. In Zephyr this function supports a subset of socket options described by POSIX, but also some additional options available in Linux (some options are dummy and provided to ease porting of existing code). This function is also exposed as getsockopt() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

int zsock_setsockopt(int sock, int level, int optname, const void *optval, socklen_t optlen)
Set various socket options.

See POSIX.1-2017 article for normative description. In Zephyr this function supports a subset of socket options described by POSIX, but also some additional options available in Linux (some options are dummy and provided to ease porting of existing code). This function is also exposed as setsockopt() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

int zsock_getsockname(int sock, struct sockaddr *addr, socklen_t *addrlen)
Get socket name.

See POSIX.1-2017 article for normative description. This function is also exposed as getsockname() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

int zsock_gethostname(char *buf, size_t len)
Get local host name.
See POSIX.1-2017 article for normative description. This function is also exposed as gethostname() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```
static inline char *zsock_inet_ntop(sa_family_t family, const void *src, char *dst, size_t size)
Convert network address from internal to numeric ASCII form.
```

See POSIX.1-2017 article for normative description. This function is also exposed as inet_ntop() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```
int zsock_inet_pton(sa_family_t family, const char *src, void *dst)
Convert network address from numeric ASCII form to internal representation.
```

See POSIX.1-2017 article for normative description. This function is also exposed as inet_pton() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```
int zsock_getaddrinfo(const char *host, const char *service, const struct zsock_addrinfo *hints, struct zsock_addrinfo **res)
Resolve a domain name to one or more network addresses.
```

See POSIX.1-2017 article for normative description. This function is also exposed as getaddrinfo() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```
void zsock_freeaddrinfo(struct zsock_addrinfo *ai)
Free results returned by zsock_getaddrinfo()
```

See POSIX.1-2017 article for normative description. This function is also exposed as freeaddrinfo() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```
const char *zsock_gai_strerror(int errcode)
Convert zsock_getaddrinfo() error code to textual message.
```

See POSIX.1-2017 article for normative description. This function is also exposed as gai_strerror() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```
int zsock_getnameinfo(const struct sockaddr *addr, socklen_t addrlen, char *host, socklen_t hostlen, char *serv, socklen_t servlen, int flags)
Resolve a network address to a domain name or ASCII address.
```

See POSIX.1-2017 article for normative description. This function is also exposed as getnameinfo() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```
int zsock_select(int nfds, zsock_fd_set *readfds, zsock_fd_set *writefds, zsock_fd_set *exceptfds, struct zsock_timeval *timeout)
Legacy function to poll multiple sockets for events.
```

See POSIX.1-2017 article for normative description. This function is provided to ease porting of existing code and not recommended for usage due to its inefficiency, use zsock_poll() instead. In Zephyr this function works only with sockets, not arbitrary file descriptors. This function is also exposed as select() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined (in which case it may conflict with generic POSIX select() function).

```
void ZSOCK_FD_ZERO(zsock_fd_set *set)
Initialize (clear) fd_set.
```
See POSIX.1-2017 article for normative description. This function is also exposed as FD_ZERO() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```c
int ZSOCK_FD_ISSET(int fd, zsock_fd_set *set)
```
Check whether socket is a member of fd_set.

See POSIX.1-2017 article for normative description. This function is also exposed as FD_ISSET() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```c
void ZSOCK_FD_CLR(int fd, zsock_fd_set *set)
```
Remove socket from fd_set.

See POSIX.1-2017 article for normative description. This function is also exposed as FD_CLR() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```c
void ZSOCK_FD_SET(int fd, zsock_fd_set *set)
```
Add socket to fd_set.

See POSIX.1-2017 article for normative description. This function is also exposed as FD_SET() if CONFIG_NET_SOCKETS_POSIX_NAMES is defined.

```c
struct zsock_pollfd
    #include <socket.h>
```

```c
struct zsock_addrinfo
    #include <socket.h>
```

```c
struct ifreq
    #include <socket.h> Interface description structure
```

```c
struct zsock_fd_set
    #include <socket_select.h>
```

TLS Credentials

**group tls_credentials**

TLS credentials management.

**Typedefs**

```c
typedef int sec_tag_t
```
Secure tag, a reference to TLS credential

Secure tag can be used to reference credential after it was registered in the system.

**Note:** Some TLS credentials come in pairs:

- TLS_CREDENTIAL_SERVER_CERTIFICATE with TLS_CREDENTIAL_PRIVATE_KEY,
- TLS_CREDENTIAL_PSK with TLS_CREDENTIAL_PSK_ID. Such pairs of credentials must be assigned the same secure tag to be correctly handled in the system.
Enums

```c
enum tls_credential_type
{
    TLS_CREDENTIAL_NONE, // Unspecified credential.
    TLS_CREDENTIAL_CA_CERTIFICATE, // A trusted CA certificate. Use this to authenticate remote servers. Used with certificate-based ciphersuites.
    TLS_CREDENTIAL_SERVER_CERTIFICATE, // A public server certificate. Use this to register your own server certificate. Should be registered together with a corresponding private key. Used with certificate-based ciphersuites.
    TLS_CREDENTIAL_PRIVATE_KEY, // Private key. Should be registered together with a corresponding public certificate. Used with certificate-based ciphersuites.
    TLS_CREDENTIAL_PSK, // Pre-shared key. Should be registered together with a corresponding PSK identity. Used with PSK-based ciphersuites.
    TLS_CREDENTIAL_PSK_ID, // Pre-shared key identity. Should be registered together with a corresponding PSK. Used with PSK-based ciphersuites.
};
```

Functions

```c
int tls_credential_add(sec_tag_t tag, enum tls_credential_type type, const void *cred, size_t credlen);
```

Add a TLS credential.

This function adds a TLS credential, that can be used by TLS/DTLS for authentication.

**Parameters**

- `tag` – A security tag that credential will be referenced with.
- `type` – A TLS/DTLS credential type.
- `cred` – A TLS/DTLS credential.
- `credlen` – A TLS/DTLS credential length.

**Return values**

- `0` – TLS credential successfully added.
- `-EACCES` – Access to the TLS credential subsystem was denied.
- `-ENOMEM` – Not enough memory to add new TLS credential.
- `-EEXIST` – TLS credential of specific tag and type already exists.

```c
int tls_credential_get(sec_tag_t tag, enum tls_credential_type type, void *cred, size_t *credlen);
```

Get a TLS credential.
This function gets an already registered TLS credential, referenced by tag secure tag of type.

Parameters

- `tag` – A security tag of requested credential.
- `type` – A TLS/DTLS credential type of requested credential.
- `cred` – A buffer for TLS/DTLS credential.
- `credlen` – A buffer size on input. TLS/DTLS credential length on output.

Return values

- `0` – TLS credential successfully obtained.
- `-EACCES` – Access to the TLS credential subsystem was denied.
- `-ENOENT` – Requested TLS credential was not found.
- `-EFBIG` – Requested TLS credential does not fit in the buffer provided.

```c
int tls_credential_get(sec_tag_t tag, enum tls_credential_type type, proc_t cred, size_t credlen);
```

Delete a TLS credential.

This function removes a TLS credential, referenced by tag secure tag of type.

Parameters

- `tag` – A security tag corresponding to removed credential.
- `type` – A TLS/DTLS credential type of removed credential.

Return values

- `0` – TLS credential successfully deleted.
- `-EACCES` – Access to the TLS credential subsystem was denied.
- `-ENOENT` – Requested TLS credential was not found.

IPv4/IPv6 Primitives and Helpers

- Overview
- API Reference

Overview  Miscellaneous defines and helper functions for IP addresses and IP protocols.

API Reference

group ip_4_6
IPv4/IPv6 primitives and helpers.

Defines

- `PF_UNSPEC`
  Unspecified protocol family.

- `PF_INET`
  IP protocol family version 4.
PF_INET6
    IP protocol family version 6.

PF_PACKET
    Packet family.

PF_CAN
    Controller Area Network.

PF_NET_MGMT
    Network management info.

PF_LOCAL
    Inter-process communication

PF_UNIX
    Inter-process communication

AF_UNSPEC
    Unspecified address family.

AF_INET
    IP protocol family version 4.

AF_INET6
    IP protocol family version 6.

AF_PACKET
    Packet family.

AF_CAN
    Controller Area Network.

AF_NET_MGMT
    Network management info.

AF_LOCAL
    Inter-process communication

AF_UNIX
    Inter-process communication

\texttt{ntohs(x)}
    Convert 16-bit value from network to host byte order.

    \textbf{Parameters}
    \begin{itemize}
    \item \texttt{x} – The network byte order value to convert.
    \end{itemize}

    \textbf{Returns} Host byte order value.

\texttt{ntohl(x)}
    Convert 32-bit value from network to host byte order.

    \textbf{Parameters}
    \begin{itemize}
    \item \texttt{x} – The network byte order value to convert.
    \end{itemize}

    \textbf{Returns} Host byte order value.
ntohl(x)
Convert 64-bit value from network to host byte order.

Parameters
• x – The network byte order value to convert.

Returns  Host byte order value.

htons(x)
Convert 16-bit value from host to network byte order.

Parameters
• x – The host byte order value to convert.

Returns  Network byte order value.

htonl(x)
Convert 32-bit value from host to network byte order.

Parameters
• x – The host byte order value to convert.

Returns  Network byte order value.

htonll(x)
Convert 64-bit value from host to network byte order.

Parameters
• x – The host byte order value to convert.

Returns  Network byte order value.

NET_IPV6_ADDR_SIZE

NET_IPV4_ADDR_SIZE

ALIGN_H(x)

ALIGN_D(x)

CMSG_FIRSTHDR(msghdr)

CMSG_NXTHDR(msghdr, cmsg)

CMSG_DATA(cmsg)

CMSG_SPACE(length)

CMSG_LEN(length)

INET_ADDRSTRLEN
Max length of the IPv4 address as a string. Defined by POSIX.

INET6_ADDRSTRLEN
Max length of the IPv6 address as a string. Takes into account possible mapped IPv4 addresses.
NET_MAX_PRIORITIES

net_ipaddr_copy(dest, src)
Copy an IPv4 or IPv6 address.

Parameters
- dest – Destination IP address.
- src – Source IP address.

Returns Destination address.

Typedefs

typedef unsigned short int sa_family_t
Socket address family type

typedef size_t socklen_t
Length of a socket address

Enums

enum net_ip_protocol
Protocol numbers from IANA/BSD

Values:

enumerator IPPROTO_IP = 0
IP protocol (pseudo-val for setsockopt())

enumerator IPPROTO_ICMP = 1
ICMP protocol

enumerator IPPROTO_IGMP = 2
IGMP protocol

enumerator IPPROTO_IPIP = 4
IPIP tunnels

enumerator IPPROTO_TCP = 6
TCP protocol

enumerator IPPROTO_UDP = 17
UDP protocol

enumerator IPPROTO_IPV6 = 41
IPv6 protocol

enumerator IPPROTO_ICMPV6 = 58
ICMPv6 protocol

enumerator IPPROTO_RAW = 255
RAW IP packets
enum net_ip_protocol_secure
Protocol numbers for TLS protocols

Values:

enumerator IPPROTO_TLS_1_0 = 256
   TLS 1.0 protocol
enumerator IPPROTO_TLS_1_1 = 257
   TLS 1.1 protocol
enumerator IPPROTO_TLS_1_2 = 258
   TLS 1.2 protocol
enumerator IPPROTO_DTLS_1_0 = 272
   DTLS 1.0 protocol
enumerator IPPROTO_DTLS_1_2 = 273
   DTLS 1.2 protocol

enum net_sock_type
Socket type

Values:

enumerator SOCK_STREAM = 1
   Stream socket type
enumerator SOCK_DGRAM
   Datagram socket type
enumerator SOCK_RAW
   RAW socket type

enum net_ip_mtu

Values:

enumerator NET_IPV6_MTU = 1280
   IPv6 MTU length. We must be able to receive this size IPv6 packet without fragmentation.
enumerator NET_IPV4_MTU = 576
   IPv4 MTU length. We must be able to receive this size IPv4 packet without fragmentation.

enum net_priority
Network packet priority settings described in IEEE 802.1Q Annex I.1

Values:

enumerator NET_PRIORITY_BK = 1
   Background (lowest)
enumerator NET_PRIORITY_BE = 0
   Best effort (default)
enumerator NET_PRIORITY_EE = 2
   Excellent effort
enumerator NET_PRIORITY_CA = 3
    Critical applications (highest)

enumerator NET_PRIORITY_VI = 4
    Video, < 100 ms latency and jitter

enumerator NET_PRIORITY_VO = 5
    Voice, < 10 ms latency and jitter

enumerator NET_PRIORITY_IC = 6
    Internetwork control

enumerator NET_PRIORITY_NC = 7
    Network control

definition net_addr_state
    What is the current state of the network address
    Values:

enumerator NET_ADDR_ANY_STATE = -1
    Default (invalid) address type

enumerator NET_ADDR_TENTATIVE = 0
    Tentative address

enumerator NET_ADDR_PREFERRED
    Preferred address

enumerator NET_ADDR_DEPRECATED
    Deprecated address

definition net_addr_type
    How the network address is assigned to network interface
    Values:

enumerator NET_ADDR_ANY = 0
    Default value. This is not a valid value.

enumerator NET_ADDR_AUTOCONF
    Auto configured address

enumerator NET_ADDR_DHCP
    Address is from DHCP

enumerator NET_ADDR_MANUAL
    Manually set address

enumerator NET_ADDR_OVERRIDABLE
    Manually set address which is overridable by DHCP
Functions

static inline bool net_ipv6_is_addr_loopback(struct in6_addr *addr)
Check if the IPv6 address is a loopback address (::1).

Parameters
• addr – IPv6 address

Returns True if address is a loopback address, False otherwise.

static inline bool net_ipv6_is_addr_mcast(const struct in6_addr *addr)
Check if the IPv6 address is a multicast address.

Parameters
• addr – IPv6 address

Returns True if address is multicast address, False otherwise.

struct net_if_addr *net_if_ipv6_addr_lookup(const struct in6_addr *addr, struct net_if **iface)
static inline bool net_ipv6_is_my_addr(struct in6_addr *addr)
Check if IPv6 address is found in one of the network interfaces.

Parameters
• addr – IPv6 address

Returns True if address was found, False otherwise.

struct net_if_mcast_addr *net_if_ipv6_maddr_lookup(const struct in6_addr *addr, struct net_if **iface)
static inline bool net_ipv6_is_my_maddr(struct in6_addr *maddr)
Check if IPv6 multicast address is found in one of the network interfaces.

Parameters
• maddr – Multicast IPv6 address

Returns True if address was found, False otherwise.

static inline bool net_ipv6_is_prefix(const uint8_t *addr1, const uint8_t *addr2, uint8_t length)
Check if two IPv6 addresses are same when compared after prefix mask.

Parameters
• addr1 – First IPv6 address.
• addr2 – Second IPv6 address.
• length – Prefix length (max length is 128).

Returns True if IPv6 prefixes are the same, False otherwise.

static inline bool net_ipv4_is_addr_loopback(struct in_addr *addr)
Check if the IPv4 address is a loopback address (127.0.0.0/8).

Parameters
• addr – IPv4 address

Returns True if address is a loopback address, False otherwise.

static inline bool net_ipv4_is_addr_unspecified(const struct in_addr *addr)
Check if the IPv4 address is unspecified (all bits zero)

Parameters
• addr – IPv4 address.

**Returns** True if the address is unspecified, false otherwise.

```c
static inline bool net_ipv4_is_addr_mcast(const struct in_addr *addr)
```

Check if the IPv4 address is a multicast address.

**Parameters**

• addr – IPv4 address

**Returns** True if address is multicast address, False otherwise.

```c
static inline bool net_ipv4_is_ll_addr(const struct in_addr *addr)
```

Check if the given IPv4 address is a link local address.

**Parameters**

• addr – A valid pointer on an IPv4 address

**Returns** True if it is, false otherwise.

```c
static inline void net_ipv4_addr_copy_raw(uint8_t *dest, const uint8_t *src)
```

Copy an IPv4 address raw buffer.

**Parameters**

• dest – Destination IP address.
• src – Source IP address.

```c
static inline void net_ipv6_addr_copy_raw(uint8_t *dest, const uint8_t *src)
```

Copy an IPv6 address raw buffer.

**Parameters**

• dest – Destination IP address.
• src – Source IP address.

```c
static inline bool net_ipv4_addr_cmp(const struct in_addr *addr1, const struct in_addr *addr2)
```

Compare two IPv4 addresses.

**Parameters**

• addr1 – Pointer to IPv4 address.
• addr2 – Pointer to IPv4 address.

**Returns** True if the addresses are the same, false otherwise.

```c
static inline bool net_ipv4_addr_cmp_raw(const uint8_t *addr1, const uint8_t *addr2)
```

Compare two raw IPv4 address buffers.

**Parameters**

• addr1 – Pointer to IPv4 address buffer.
• addr2 – Pointer to IPv4 address buffer.

**Returns** True if the addresses are the same, false otherwise.

```c
static inline bool net_ipv6_addr_cmp(const struct in6_addr *addr1, const struct in6_addr *addr2)
```

Compare two IPv6 addresses.

**Parameters**

• addr1 – Pointer to IPv6 address.
• addr2 – Pointer to IPv6 address.

**Returns** True if the addresses are the same, false otherwise.
static inline bool net_ipv6_addr_cmp_raw(const uint8_t *addr1, const uint8_t *addr2)

Compare two raw IPv6 address buffers.

Parameters
- addr1 – Pointer to IPv6 address buffer.
- addr2 – Pointer to IPv6 address buffer.

Returns True if the addresses are the same, false otherwise.

static inline bool net_ipv6_is_ll_addr(const struct in6_addr *addr)

Check if the given IPv6 address is a link local address.

Parameters
- addr – A valid pointer on an IPv6 address

Returns True if it is, false otherwise.

static inline bool net_ipv6_is_ula_addr(const struct in6_addr *addr)

Check if the given IPv6 address is a unique local address.

Parameters
- addr – A valid pointer on an IPv6 address

Returns True if it is, false otherwise.

const struct in6_addr *net_ipv6_unspecified_address(void)

Return pointer to any (all bits zeros) IPv6 address.

Returns Any IPv6 address.

const struct in_addr *net_ipv4_unspecified_address(void)

Return pointer to any (all bits zeros) IPv4 address.

Returns Any IPv4 address.

const struct in_addr *net_ipv4_broadcast_address(void)

Return pointer to broadcast (all bits ones) IPv4 address.

Returns Broadcast IPv4 address.

bool net_if_ipv4_addr_mask_cmp(struct net_if *iface, const struct in_addr *addr)

static inline bool net_if_ipv4_addr_mask_cmp(struct net_if *iface, const struct in_addr *addr)

Check if the given address belongs to same subnet that has been configured for the interface.

Parameters
- iface – A valid pointer on an interface
- addr – IPv4 address

Returns True if address is in same subnet, false otherwise.

bool net_if_ipv4_is_addr_bcast(struct net_if *iface, const struct in_addr *addr)

static inline bool net_if_ipv4_is_addr_bcast(struct net_if *iface, const struct in_addr *addr)

Check if the given IPv4 address is a broadcast address.

Parameters
- iface – Interface to use. Must be a valid pointer to an interface.
- addr – IPv4 address

Returns True if address is a broadcast address, false otherwise.
static inline bool net_ipv4_is_my_addr(const struct in_addr *addr)
    Check if the IPv4 address is assigned to any network interface in the system.
    
    Parameters
    • addr – A valid pointer on an IPv4 address
    
    Returns True if IPv4 address is found in one of the network interfaces, False otherwise.

static inline bool net_ipv6_is_addr_unspecified(const struct in6_addr *addr)
    Check if the IPv6 address is unspecified (all bits zero)
    
    Parameters
    • addr – IPv6 address.
    
    Returns True if the address is unspecified, false otherwise.

static inline bool net_ipv6_is_addr_solicited_node(const struct in6_addr *addr)
    Check if the IPv6 address is solicited node multicast address FF02:0:0:0:0:1:FFXX:XXXX defined in RFC 3513.
    
    Parameters
    • addr – IPv6 address.
    
    Returns True if the address is solicited node address, false otherwise.

static inline bool net_ipv6_is_addr_mcast_scope(const struct in6_addr *addr, int scope)
    Check if the IPv6 address is a given scope multicast address (FFyx::).
    
    Parameters
    • addr – IPv6 address
    • scope – Scope to check
    
    Returns True if the address is in given scope multicast address, false otherwise.

static inline bool net_ipv6_is_addr_mcast_global(const struct in6_addr *addr)
    Check if the IPv6 address is a global multicast address (FFxE::/16).
    
    Parameters
    • addr – IPv6 address.
    
    Returns True if the address is global multicast address, false otherwise.

static inline bool net_ipv6_is_addr_mcast_iface(const struct in6_addr *addr)
    Check if the IPv6 address is an interface scope multicast address (FFx1::).
    
    Parameters
    • addr – IPv6 address.
    
    Returns True if the address is a interface scope multicast address, false otherwise.
• addr – IPv6 address.

**Returns** True if the address is a link local scope multicast address, false otherwise.

```c
static inline bool net_ipv6_is_addr_mcast_mesh(const struct in6_addr *addr)
```

Check if the IPv6 address is a mesh-local scope multicast address (FFX3::).

**Parameters**

• addr – IPv6 address.

**Returns** True if the address is a mesh-local scope multicast address, false otherwise.

```c
static inline bool net_ipv6_is_addr_mcast_site(const struct in6_addr *addr)
```

Check if the IPv6 address is a site scope multicast address (FFX5::).

**Parameters**

• addr – IPv6 address.

**Returns** True if the address is a site scope multicast address, false otherwise.

```c
static inline bool net_ipv6_is_addr_mcast_org(const struct in6_addr *addr)
```

Check if the IPv6 address is an organization scope multicast address (FFX8::).

**Parameters**

• addr – IPv6 address.

**Returns** True if the address is an organization scope multicast address, false otherwise.

```c
static inline bool net_ipv6_is_addr_mcast_group(const struct in6_addr *addr, const struct in6_addr *group)
```

Check if the IPv6 address belongs to certain multicast group.

**Parameters**

• addr – IPv6 address.

• group – Group id IPv6 address, the values must be in network byte order

**Returns** True if the IPv6 multicast address belongs to given multicast group, false otherwise.

```c
static inline bool net_ipv6_is_addr_mcast_all_nodes_group(const struct in6_addr *addr)
```

Check if the IPv6 address belongs to the all nodes multicast group.

**Parameters**

• addr – IPv6 address

**Returns** True if the IPv6 multicast address belongs to the all nodes multicast group, false otherwise.

```c
static inline bool net_ipv6_is_addr_mcast_iface_all_nodes(const struct in6_addr *addr)
```

Check if the IPv6 address is a interface scope all nodes multicast address (FF01::1).

**Parameters**

• addr – IPv6 address

**Returns** True if the address is a interface scope all nodes multicast address, false otherwise.

```c
static inline bool net_ipv6_is_addr_mcast_link_all_nodes(const struct in6_addr *addr)
```

Check if the IPv6 address is a link local scope all nodes multicast address (FF02::1).

**Parameters**

• addr – IPv6 address.
Returns True if the address is a link local scope all nodes multicast address, false otherwise.

static inline void net_ipv6_addr_create_solicited_node(const struct in6_addr *src, struct in6_addr *dst)
Create solicited node IPv6 multicast address FF02:0:0:0:0:0:1:FFXX:XXXX defined in RFC 3513.

Parameters
- src – IPv6 address.
- dst – IPv6 address.

static inline void net_ipv6_addr_create(struct in6_addr *addr, uint16_t addr0, uint16_t addr1, uint16_t addr2, uint16_t addr3, uint16_t addr4, uint16_t addr5, uint16_t addr6, uint16_t addr7)
Construct an IPv6 address from eight 16-bit words.

Parameters
- addr – IPv6 address
- addr0 – 16-bit word which is part of the address
- addr1 – 16-bit word which is part of the address
- addr2 – 16-bit word which is part of the address
- addr3 – 16-bit word which is part of the address
- addr4 – 16-bit word which is part of the address
- addr5 – 16-bit word which is part of the address
- addr6 – 16-bit word which is part of the address
- addr7 – 16-bit word which is part of the address

static inline void net_ipv6_addr_create_ll_allnodes_mcast(struct in6_addr *addr)
Create link local allnodes multicast IPv6 address.

Parameters
- addr – IPv6 address

static inline void net_ipv6_addr_create_ll_allrouters_mcast(struct in6_addr *addr)
Create link local allrouters multicast IPv6 address.

Parameters
- addr – IPv6 address

static inline void net_ipv6_addr_create_iid(struct in6_addr *addr, struct net_linkaddr *lladdr)
Create IPv6 address interface identifier.

Parameters
- addr – IPv6 address
- lladdr – Link local address

static inline bool net_ipv6_addr_based_on_ll(const struct in6_addr *addr, const struct net_linkaddr *lladdr)
Check if given address is based on link layer address.

Returns True if it is, False otherwise

static inline struct sockaddr_in6 *net_sin6(const struct sockaddr *addr)
Get sockaddr_in6 from sockaddr. This is a helper so that the code calling this function can be made shorter.

Parameters
• addr – Socket address

>Returns Pointer to IPv6 socket address

static inline struct sockaddr_in *net_sin(const struct sockaddr *addr)
Get sockaddr_in from sockaddr. This is a helper so that the code calling this function can be made shorter.

Parameters
• addr – Socket address

Returns Pointer to IPv4 socket address

static inline struct sockaddr_in6_ptr *net_sin6_ptr(const struct sockaddr_ptr *addr)
Get sockaddr_in6_ptr from sockaddr_ptr. This is a helper so that the code calling this function can be made shorter.

Parameters
• addr – Socket address

Returns Pointer to IPv6 socket address

static inline struct sockaddr_in_ptr *net_sin_ptr(const struct sockaddr_ptr *addr)
Get sockaddr_in_ptr from sockaddr_ptr. This is a helper so that the code calling this function can be made shorter.

Parameters
• addr – Socket address

Returns Pointer to linklayer socket address

static inline struct sockaddr_can_ptr *net_sll_ptr(const struct sockaddr_ptr *addr)
Get sockaddr_can_ptr from sockaddr_ptr. This is a helper so that the code calling this function can be made shorter.

Parameters
• addr – Socket address

Returns Pointer to CAN socket address

int net_addr_pton(sa_family_t family, const char *src, void *dst)
Convert a string to IP address.

Note: This function doesn’t do precise error checking, do not use for untrusted strings.

Parameters
• family – IP address family (AF_INET or AF_INET6)
• src – IP address in a null terminated string
• dst – Pointer to struct in_addr if family is AF_INET or pointer to struct in6_addr
  if family is AF_INET6

Returns 0 if ok, < 0 if error
char *net_addr_ntop(sa_family_t family, const void *src, char *dst, size_t size)
Convert IP address to string form.

Parameters

- **family** – IP address family (AF_INET or AF_INET6)
- **src** – Pointer to struct in_addr if family is AF_INET or pointer to struct in6_addr if family is AF_INET6
- **dst** – Buffer for IP address as a null terminated string
- **size** – Number of bytes available in the buffer

Returns  dst pointer if ok, NULL if error

bool net_ipaddr_parse(const char *str, size_t str_len, struct sockaddr *addr)
Parse a string that contains either IPv4 or IPv6 address and optional port, and store the information in user supplied sockaddr struct.

Syntax of the IP address string: 192.0.2.1:80 192.0.2.42 [2001:db8::2] 2001:db::42 Note that the str_len parameter is used to restrict the amount of characters that are checked. If the string does not contain port number, then the port number in sockaddr is not modified.

Parameters

- **str** – String that contains the IP address.
- **str_len** – Length of the string to be parsed.
- **addr** – Pointer to user supplied struct sockaddr.

Returns  True if parsing could be done, false otherwise.

static inline int32_t net_tcp_seq_cmp(uint32_t seq1, uint32_t seq2)
Compare TCP sequence numbers.

This function compares TCP sequence numbers, accounting for wraparound effects.

Parameters

- **seq1** – First sequence number
- **seq2** – Seconds sequence number

Returns  < 0 if seq1 < seq2, 0 if seq1 == seq2, > 0 if seq > seq2

static inline bool net_tcp_seq_greater(uint32_t seq1, uint32_t seq2)
Check that one TCP sequence number is greater.

This is convenience function on top of net_tcp_seq_cmp().

Parameters

- **seq1** – First sequence number
- **seq2** – Seconds sequence number

Returns  True if seq > seq2

int net_bytes_from_str(uint8_t *buf, int buf_len, const char *src)
Convert a string of hex values to array of bytes.

The syntax of the string is “ab:02:98:fa:42:01”

Parameters

- **buf** – Pointer to memory where the bytes are written.
- **buf_len** – Length of the memory area.
- **src** – String of bytes.
Returns 0 if ok, <0 if error

int net_tx_priority2tc(enum net_priority prio)
   Convert Tx network packet priority to traffic class so we can place the packet into correct Tx queue.

Parameters
   • prio – Network priority

Returns Tx traffic class that handles that priority network traffic.

int net_rx_priority2tc(enum net_priority prio)
   Convert Rx network packet priority to traffic class so we can place the packet into correct Rx queue.

Parameters
   • prio – Network priority

Returns Rx traffic class that handles that priority network traffic.

static inline enum net_priority net_vlan2priority(uint8_t priority)
   Convert network packet VLAN priority to network packet priority so we can place the packet into correct queue.

Parameters
   • priority – VLAN priority

Returns Network priority

static inline uint8_t net_priority2vlan(enum net_priority priority)
   Convert network packet priority to network packet VLAN priority.

Parameters
   • priority – Packet priority

Returns VLAN priority (PCP)

const char *net_family2str(sa_family_t family)
   Return network address family value as a string. This is only usable for debugging.

Parameters
   • family – Network address family code

Returns Network address family as a string, or NULL if family is unknown.

struct in6_addr
   #include <net_ip.h> IPv6 address struct

struct in_addr
   #include <net_ip.h> IPv4 address struct

struct sockaddr_in6
   #include <net_ip.h> Socket address struct for IPv6.

struct sockaddr_in6_ptr
   #include <net_ip.h>

struct sockaddr_in
   #include <net_ip.h> Socket address struct for IPv4.

struct sockaddr_in_ptr
   #include <net_ip.h>
struct sockaddr_ll
   #include <net_ip.h> Socket address struct for packet socket.

struct sockaddr_ll_ptr
   #include <net_ip.h>

struct sockaddr_can_ptr
   #include <net_ip.h>

struct iovec
   #include <net_ip.h>

struct msghdr
   #include <net_ip.h>

struct cmshdr
   #include <net_ip.h>

struct sockaddr
   #include <net_ip.h> Generic sockaddr struct. Must be cast to proper type.

struct net_tuple
   #include <net_ip.h> IPv6/IPv4 network connection tuple

    **Public Members**

    struct net_addr *remote_addr
       IPv6/IPv4 remote address

    struct net_addr *local_addr
       IPv6/IPv4 local address

    uint16_t remote_port
       UDP/TCP remote port

    uint16_t local_port
       UDP/TCP local port

    enum net_ip_protocol ip_proto
       IP protocol

**DNS Resolve**

- **Overview**
- **Sample usage**
- **API Reference**
Overview  The DNS resolver implements a basic DNS resolver according to IETF RFC1035 on Domain Implementation and Specification. Supported DNS answers are IPv4/IPv6 addresses and CNAME.

If a CNAME is received, the DNS resolver will create another DNS query. The number of additional queries is controlled by the CONFIG_DNS_RESOLVER_ADDITIONAL_QUERIES Kconfig variable.

The multicast DNS (mDNS) client resolver support can be enabled by setting CONFIG_MDNS_RESOLVER Kconfig option. See IETF RFC6762 for more details about mDNS.

The link-local multicast name resolution (LLMNR) client resolver support can be enabled by setting the CONFIG_LLMNR_RESOLVER Kconfig variable. See IETF RFC4795 for more details about LLMNR.

For more information about DNS configuration variables, see: subsys/net/lib/dns/Kconfig. The DNS resolver API can be found at include/net/dns_resolve.h.

Sample usage  See DNS resolve sample application for details.

API Reference

group dns_resolve

DNS resolving library.

Defines

DNS_MAX_NAME_SIZE
Max size of the resolved name.

Typedefs

typedef void (*dns_resolve_cb_t)(enum dns_resolve_status status, struct dns_addrinfo *info, void *user_data)
DNS resolve callback.

The DNS resolve callback is called after a successful DNS resolving. The resolver can call this callback multiple times, one for each resolved address.

Param status  The status of the query: DNS_EAI_INPROGRESS returned for each resolved address DNS_EAI_ALLDONE mark end of the resolving, info is set to NULL in this case DNS_EAI_CANCELED if the query was canceled manually or timeout happened DNS_EAI_FAIL if the name cannot be resolved by the server DNS_EAI_NODATA if there is no such name other values means that an error happened.

Param info  Query results are stored here.

Param user_data  The user data given in dns_resolve_name() call.

Enums

enum dns_query_type
DNS query type enum

Values:

enumerator DNS_QUERY_TYPE_A = 1
IPv4 query
enumerator DNS_QUERY_TYPE_AAAA = 28
IPv6 query

```
enum dns_resolve_status
  Status values for the callback.
  Values:

  enumerator DNS_EAI_BADFLAGS = -1
     Invalid value for ai_flags field

  enumerator DNS_EAI_NONAME = -2
     NAME or SERVICE is unknown

  enumerator DNS_EAI_AGAIN = -3
     Temporary failure in name resolution

  enumerator DNS_EAI_FAIL = -4
     Non-recoverable failure in name resolution

  enumerator DNS_EAI_NODATA = -5
     No address associated with NAME

  enumerator DNS_EAI_FAMILY = -6
     ai_family not supported

  enumerator DNS_EAI_SOCKTYPE = -7
     ai_socktype not supported

  enumerator DNS_EAI_SERVICE = -8
     SRV not supported for ai_socktype

  enumerator DNS_EAI_ADDRFAMILY = -9
     Address family for NAME not supported

  enumerator DNS_EAI_MEMORY = -10
     Memory allocation failure

  enumerator DNS_EAI_SYSTEM = -11
     System error returned in errno

  enumerator DNS_EAI_OVERFLOW = -12
     Argument buffer overflow

  enumerator DNS_EAI_INPROGRESS = -100
     Processing request in progress

  enumerator DNS_EAI_CANCELED = -101
     Request canceled

  enumerator DNS_EAI_NOTCANCELED = -102
     Request not canceled
```
enumerator DNS_EAI_ALLDONE = -103
    All requests done

enumerator DNS_EAI_IDN_ENCODE = -105
    IDN encoding failed

denum dns_resolve_context_state
    Values:

enumerator DNS_RESOLVE_CONTEXT_ACTIVE

enumerator DNS_RESOLVE_CONTEXT_DEACTIVATING

enumerator DNS_RESOLVE_CONTEXT_INACTIVE

Functions

int dns_resolve_init(struct dns_resolve_context *ctx, const char *dns_servers_str[], const struct sockaddr *dns_servers_sa[])
    Init DNS resolving context.

This function sets the DNS server address and initializes the DNS context that is used by the actual resolver. DNS server addresses can be specified either in textual form, or as struct sockaddr (or both). Note that the recommended way to resolve DNS names is to use the dns_get_addr_info() API. In that case user does not need to call dns_resolve_init() as the DNS servers are already setup by the system.

Parameters

• ctx – DNS context. If the context variable is allocated from the stack, then the variable needs to be valid for the whole duration of the resolving. Caller does not need to fill the variable beforehand or edit the context afterwards.

• dns_servers_str – DNS server addresses using textual strings. The array is NULL terminated. The port number can be given in the string. Syntax for the server addresses with or without port numbers: IPv4 : 10.0.9.1 IPv4 + port : 10.0.9.1:5353 IPv6 : 2001:db8::22:42 IPv6 + port : [2001:db8::22:42]:5353

• dns_servers_sa – DNS server addresses as struct sockaddr. The array is NULL terminated. Port numbers are optional in struct sockaddr, the default will be used if set to 0.

Returns 0 if ok, <0 if error.

int dns_resolve_close(struct dns_resolve_context *ctx)
    Close DNS resolving context.

This releases DNS resolving context and marks the context unusable. Caller must call the dns_resolve_init() again to make context usable.

Parameters

• ctx – DNS context

Returns 0 if ok, <0 if error.
int dns_resolve_reconfigure(struct dns_resolve_context *ctx, const char *servers_str[], const struct sockaddr *servers_sa[])
Reconfigure DNS resolving context.
Reconfigures DNS context with new server list.

Parameters

- **ctx** – DNS context
- **servers_str** – DNS server addresses using textual strings. The array is NULL terminated. The port number can be given in the string. Syntax for the server addresses with or without port numbers: IPv4 : 10.0.9.1 IPv4 + port : 10.0.9.1:5353 IPv6 : 2001:db8::22:42 IPv6 + port : [2001:db8::22:42]:5353
- **servers_sa** – DNS server addresses as struct sockaddr. The array is NULL terminated. Port numbers are optional in struct sockaddr, the default will be used if set to 0.

Returns 0 if ok, <0 if error.

int dns_resolve_cancel(struct dns_resolve_context *ctx, uint16_t dns_id)
Cancel a pending DNS query.
This releases DNS resources used by a pending query.

Parameters

- **ctx** – DNS context
- **dns_id** – DNS id of the pending query

Returns 0 if ok, <0 if error.

int dns_resolve_cancel_with_name(struct dns_resolve_context *ctx, uint16_t dns_id, const char *query_name, enum dns_query_type query_type)
Cancel a pending DNS query using id, name and type.
This releases DNS resources used by a pending query.

Parameters

- **ctx** – DNS context
- **dns_id** – DNS id of the pending query
- **query_name** – Name of the resource we are trying to query (hostname)
- **query_type** – Type of the query (A or AAAA)

Returns 0 if ok, <0 if error.

int dns_resolve_name(struct dns_resolve_context *ctx, const char *query, enum dns_query_type type, uint16_t *dns_id, dns_resolve_cb_t cb, void *user_data, int32_t timeout)
Resolve DNS name.
This function can be used to resolve e.g., IPv4 or IPv6 address. Note that this is asynchronous call, the function will return immediately and system will call the callback after resolving has finished or timeout has occurred. We might send the query to multiple servers (if there are more than one server configured), but we only use the result of the first received response.

Parameters

- **ctx** – DNS context
- **query** – What the caller wants to resolve.
- **type** – What kind of data the caller wants to get.
- **dns_id** – DNS id is returned to the caller. This is needed if one wishes to cancel the query. This can be set to NULL if there is no need to cancel the query.
Zephyr Project Documentation, Release 3.0.99

- cb – Callback to call after the resolving has finished or timeout has happened.
- user_data – The user data.
- timeout – The timeout value for the query. Possible values:
  - SYS_FOREVER_MS: the query is tried forever, user needs to cancel it manually if it takes too long time to finish
  - >0: start the query and let the system timeout it after specified ms

**Returns** 0 if resolving was started ok, < 0 otherwise

```c
struct dns_resolve_context *dns_resolve_get_default(void)
```

Get default DNS context.

The system level DNS context uses DNS servers that are defined in project config file. If no DNS servers are defined by the user, then resolving DNS names using default DNS context will do nothing. The configuration options are described in subsys/net/lib/dns/Kconfig file.

**Returns** Default DNS context.

```c
static inline int dns_get_addr_info(const char *query, enum dns_query_type type, uint16_t *dns_id, dns_resolve_cb_t cb, void *user_data, int32_t timeout)
```

Get IP address info from DNS.

This function can be used to resolve e.g., IPv4 or IPv6 address. Note that this is asynchronous call, the function will return immediately and system will call the callback after resolving has finished or timeout has occurred. We might send the query to multiple servers (if there are more than one server configured), but we only use the result of the first received response. This variant uses system wide DNS servers.

**Parameters**
- query – What the caller wants to resolve.
- type – What kind of data the caller wants to get.
- dns_id – DNS id is returned to the caller. This is needed if one wishes to cancel the query. This can be set to NULL if there is no need to cancel the query.
- cb – Callback to call after the resolving has finished or timeout has happened.
- user_data – The user data.
- timeout – The timeout value for the connection. Possible values:
  - SYS_FOREVER_MS: the query is tried forever, user needs to cancel it manually if it takes too long time to finish
  - >0: start the query and let the system timeout it after specified ms

**Returns** 0 if resolving was started ok, < 0 otherwise

```c
static inline int dns_cancel_addr_info(uint16_t dns_id)
```

Cancel a pending DNS query.

This releases DNS resources used by a pending query.

**Parameters**
- dns_id – DNS id of the pending query

**Returns** 0 if ok, <0 if error.

```c
struct dns_addrinfo
#include <dns_resolve.h> Address info struct is passed to callback that gets all the results.

struct dns_resolve_context
#include <dns_resolve.h> DNS resolve context structure.
Public Members

struct sockaddr *dns_server
    DNS server information

struct net_context *net_ctx
    Connection to the DNS server

uint8_t is_mdns
    Is this server mDNS one

uint8_t is_llmnr
    Is this server LLMNR one

struct k_mutex lock
    Prevent concurrent access

k_timeout_t buf_timeout
    This timeout is also used when a buffer is required from the buffer pools.

enum dns_resolve_context_state state
    Is this context in use

struct dns_pending_query
    #include <dns_resolve.h> Result callbacks. We have multiple callbacks here so that it is possible to do multiple queries at the same time.
    Contents of this structure can be inspected and changed only when the lock is held.

Public Members

struct k_work_delayable timer
    Timeout timer

struct dns_resolve_context *ctx
    Back pointer to ctx, needed in timeout handler

dns_resolve_cb_t cb
    Result callback.
    A null value indicates the slot is not in use.

void *user_data
    User data

k_timeout_t timeout
    TX timeout

const char *query
    String containing the thing to resolve like www.example.com
    This is set to a non-null value when the query is started, and is not used thereafter.
If the query completed at a point where the work item was still pending the pointer is cleared to indicate that the query is complete, but release of the query slot will be deferred until a request for a slot determines that the work item has been released.

```c
enum dns_query_type
    query_type

uint16_t id
    DNS id of this query

uint16_t query_hash
    Hash of the DNS name + query type we are querying. This hash is calculated so we can match the response that we are receiving. This is needed mainly for mDNS which is setting the DNS id to 0, which means that the id alone cannot be used to find correct pending query.
```

### Network Management

- **Overview**
- **Requesting a defined procedure**
- **Listening to network events**
- **Defining a network management procedure**
- **Signaling a network event**
- **API Reference**

**Overview** The Network Management APIs allow applications, as well as network layer code itself, to call defined network routines at any level in the IP stack, or receive notifications on relevant network events. For example, by using these APIs, application code can request a scan be done on a Wi-Fi- or Bluetooth-based network interface, or request notification if a network interface IP address changes.

The Network Management API implementation is designed to save memory by eliminating code at build time for management routines that are not used. Distinct and statically defined APIs for network management procedures are not used. Instead, defined procedure handlers are registered by using a `NET_MGMT_REGISTER_REQUEST_HANDLER` macro. Procedure requests are done through a single `net_mgmt()` API that invokes the registered handler for the corresponding request.

The current implementation is experimental and may change and improve in future releases.

**Requesting a defined procedure** All network management requests are of the form `net_mgmt(mgmt_request, ...)`. The `mgmt_request` parameter is a bit mask that tells which stack layer is targeted, if a `net_if` object is implied, and the specific management procedure being requested. The available procedure requests depend on what has been implemented in the stack.

To avoid extra cost, all `net_mgmt()` calls are direct. Though this may change in a future release, it will not affect the users of this function.

**Listening to network events** You can receive notifications on network events by registering a callback function and specifying a set of events used to filter when your callback is invoked. The callback will have to be unique for a pair of layer and code, whereas on the command part it will be a mask of events.
Two functions are available, `net_mgmt_add_event_callback()` for registering the callback function, and `net_mgmt_del_event_callback()` for unregistering a callback. A helper function, `net_mgmt_init_event_callback()`, can be used to ease the initialization of the callback structure.

When an event occurs that matches a callback's event set, the associated callback function is invoked with the actual event code. This makes it possible for different events to be handled by the same callback function, if desired.

**Warning:** Event set filtering allows false positives for events that have the same layer and layer code. A callback handler function must check the event code (passed as an argument) against the specific network events it will handle, regardless of how many events were in the set passed to `net_mgmt_init_event_callback()`.

Note that in order to receive events from multiple layers, one must have multiple listeners registered, one for each layer being listened. The callback handler function can be shared between different layer events. (False positives can occur for events which have the same layer and layer code.)

An example follows.

```c
/*
 * Set of events to handle.
 * See e.g. include/net/net_event.h for some NET_EVENT_xxx values.
 */
#define EVENT_IFACE_SET (NET_EVENT_IF_xxx | NET_EVENT_IF_yyy)
#define EVENT_IPV4_SET (NET_EVENT_IPV4_xxx | NET_EVENT_IPV4_yyy)

struct net_mgmt_event_callback iface_callback;
struct net_mgmt_event_callback ipv4_callback;

void callback_handler(struct net_mgmt_event_callback *cb,
                      uint32_t mgmt_event,
                      struct net_if *iface)
{
    if (mgmt_event == NET_EVENT_IF_xxx) {
        /* Handle NET_EVENT_IF_xxx */
    } else if (mgmt_event == NET_EVENT_IF_yyy) {
        /* Handle NET_EVENT_IF_yyy */
    } else if (mgmt_event == NET_EVENT_IPV4_xxx) {
        /* Handle NET_EVENT_IPV4_xxx */
    } else if (mgmt_event == NET_EVENT_IPV4_yyy) {
        /* Handle NET_EVENT_IPV4_yyy */
    } else {
        /* Spurious (false positive) invocation. */
    } 
}

void register_cb(void)
{
    net_mgmt_init_event_callback(&iface_callback, callback_handler,
                                  EVENT_IFACE_SET);
    net_mgmt_init_event_callback(&ipv4_callback, callback_handler,
                                  EVENT_IPV4_SET);
    net_mgmt_add_event_callback(&iface_callback);
    net_mgmt_add_event_callback(&ipv4_callback);
}
```
See include/net/net_event.h for available generic core events that can be listened to.

**Defining a network management procedure**  You can provide additional management procedures specific to your stack implementation by defining a handler and registering it with an associated mgmt_request code.

Management request code are defined in relevant places depending on the targeted layer or eventually, if L2 is the layer, on the technology as well. For instance, all IP layer management request code will be found in the include/net/net_event.h header file. But in case of an L2 technology, let's say Ethernet, these would be found in include/net/ethernet.h.

You define your handler modeled with this signature:

```c
static int your_handler(uint32_t mgmt_event, struct net_if *iface, void *data, size_t len);
```

and then register it with an associated mgmt_request code:

```c
NET_MGMT_REGISTER_REQUEST_HANDLER(<mgmt_request code>, your_handler);
```

This new management procedure could then be called by using:

```c
net_mgmt(<mgmt_request code>, ...);
```

**Signaling a network event**  You can signal a specific network event using the `net_mgmt_notify()` function and provide the network event code. See include/net/net_mgmt.h for details. As for the management request code, event code can be also found on specific L2 technology mgmt headers, for example include/net/ieee802154_mgmt.h would be the right place if 802.15.4 L2 is the technology one wants to listen to events.

**API Reference**

*group net_mgmt*

Network Management.

*Defines*

- `net_mgmt(_mgmt_request, _iface, _data, _len)`
- `NET_MGMT_DEFINE_REQUEST_HANDLER(_mgmt_request)`
- `NET_MGMT_REGISTER_REQUEST_HANDLER(_mgmt_request, _func)`

*Typedefs*

```c
typedef int (*net_mgmt_request_handler_t)(uint32_t mgmt_request, struct net_if *iface, void *data, size_t len)
```

Signature which all Net MGMT request handler need to follow.

- **Param mgmt_request**  The exact request value the handler is being called through
- **Param iface**  A valid pointer on struct `net_if` if the request is meant to be tight to a network interface. NULL otherwise.
**Param data** A valid pointer on a data understood by the handler. NULL otherwise.

**Param len** Length in byte of the memory pointed by data.

typedef void (*net_mgmt_event_handler_t)(struct net_mgmt_event_callback *cb, uint32_t mgmt_event, struct net_if *iface)

Define the user's callback handler function signature.

- **Param cb** Original struct net_mgmt_event_callback owning this handler.
- **Param mgmt_event** The network event being notified.
- **Param iface** A pointer on a struct net_if to which the the event belongs to, if it's an event on an iface. NULL otherwise.

**Functions**

static inline void net_mgmt_init_event_callback(struct net_mgmt_event_callback *cb, net_mgmt_event_handler_t handler, uint32_t mgmt_event_mask)

Helper to initialize a struct net_mgmt_event_callback properly.

- **Parameters**
  - cb – A valid application's callback structure pointer.
  - handler – A valid handler function pointer.
  - mgmt_event_mask – A mask of relevant events for the handler

void net_mgmt_add_event_callback(struct net_mgmt_event_callback *cb)

Add a user callback.

- **Parameters**
  - cb – A valid pointer on user's callback to add.

void net_mgmt_del_event_callback(struct net_mgmt_event_callback *cb)

Delete a user callback.

- **Parameters**
  - cb – A valid pointer on user's callback to delete.

void net_mgmt_event_notify_with_info(uint32_t mgmt_event, struct net_if *iface, const void *info, size_t length)

Used by the system to notify an event.

Note: info and length are disabled if CONFIG_NET_MGMT_EVENT_INFO is not defined.

- **Parameters**
  - mgmt_event – The actual network event code to notify
  - iface – a valid pointer on a struct net_if if only the event is based on an iface. NULL otherwise.
  - info – a valid pointer on the information you want to pass along with the event. NULL otherwise. Note the data pointed there is normalized by the related event.
  - length – size of the data pointed by info pointer.

static inline void net_mgmt_event_notify(uint32_t mgmt_event, struct net_if *iface)
int net_mgmt_event_wait(uint32_t mgmt_event_mask, uint32_t *raised_event, struct net_if **iface, const void **info, size_t *info_length, k_timeout_t timeout)

Used to wait synchronously on an event mask.

Parameters

• mgmt_event_mask – A mask of relevant events to wait on.

• raised_event – a pointer on a uint32_t to get which event from the mask generated the event. Can be NULL if the caller is not interested in that information.

• iface – a pointer on a place holder for the iface on which the event has originated from. This is valid if only the event mask has bit NET_MGMT_IFACE_BIT set relevantly, depending on events the caller wants to listen to.

• info – a valid pointer if user wants to get the information the event might bring along. NULL otherwise.

• info_length – tells how long the info memory area is. Only valid if the info is not NULL.

• timeout – A timeout delay. K_FOREVER can be used to wait indefinitely.

Returns 0 on success, a negative error code otherwise. -ETIMEDOUT will be specifically returned if the timeout kick-in instead of an actual event.

int net_mgmt_event_wait_on_iface(struct net_if *iface, uint32_t mgmt_event_mask, uint32_t *raised_event, const void **info, size_t *info_length, k_timeout_t timeout)

Used to wait synchronously on an event mask for a specific iface.

Parameters

• iface – a pointer on a valid network interface to listen event to

• mgmt_event_mask – A mask of relevant events to wait on. Listened to events should be relevant to iface events and thus have the bit NET_MGMT_IFACE_BIT set.

• raised_event – a pointer on a uint32_t to get which event from the mask generated the event. Can be NULL if the caller is not interested in that information.

• info – a valid pointer if user wants to get the information the event might bring along. NULL otherwise.

• info_length – tells how long the info memory area is. Only valid if the info is not NULL.

• timeout – A timeout delay. K_FOREVER can be used to wait indefinitely.

Returns 0 on success, a negative error code otherwise. -ETIMEDOUT will be specifically returned if the timeout kick-in instead of an actual event.

void net_mgmt_event_init(void)

Used by the core of the network stack to initialize the network event processing.

struct net_mgmt_event_callback

#include <net_mgmt.h> Network Management event callback structure Used to register a callback into the network management event part, in order to let the owner of this struct to get network event notification based on given event mask.

Public Members

sys_snode_t node

Meant to be used internally, to insert the callback into a list. So nobody should mess with
Actual callback function being used to notify the owner

Semaphore meant to be used internally for the synchronous `net_mgmt_event_wait()` function.

A mask of network events on which the above handler should be called in case those events come. Note that only the command part is treated as a mask, matching one to several commands. Layer and layer code will be made of an exact match. This means that in order to receive events from multiple layers, one must have multiple listeners registered, one for each layer being listened.

Internal place holder when a synchronous event wait is successfully unlocked on a event.

A mask of network events on which the above handler should be called in case those events come. Such mask can be modified whenever necessary by the owner, and thus will affect the handler being called or not.

Network Statistics

- **Overview**
- **API Reference**

**Overview**  
Network statistics are collected if `CONFIG_NET_STATISTICS` is set. Individual component statistics for IPv4 or IPv6 can be turned off if those statistics are not needed. See various options in `subsys/net/ip/Kconfig.stats` file for details.

By default, the system collects network statistics per network interface. This can be controlled by `CONFIG_NET_STATISTICS_PER_INTERFACE` option.

The `CONFIG_NET_STATISTICS_USER_API` option can be set if the application wants to collect statistics for further processing. The network management interface API is used for that. See Network Management for details.

The `CONFIG_NET_STATISTICS_ETHERNET` option can be set to collect generic Ethernet statistics. If the `CONFIG_NET_STATISTICS_ETHERNET_VENDOR` option is set, then Ethernet device driver can collect Ethernet device specific statistics. These statistics can then be transferred to application for processing.

If the `CONFIG_NET_SHELL` option is set, then network shell can show statistics information with `net stats` command.

**API Reference**

group `net_stats`  
Network statistics library.

Number of received PPP frames with a bad checksum.
```

Network Timeout

- **Overview**

  Zephyr’s network infrastructure mostly uses the millisecond-resolution uptime clock to track timeouts, with both deadlines and durations measured with 32-bit unsigned values. The 32-bit value rolls over at 49 days 17 hours 2 minutes 47.296 seconds.

  Timeout processing is often affected by latency, so that the time at which the timeout is checked may be some time after it should have expired. Handling this correctly without arbitrary expectations of
maximum latency requires that the maximum delay that can be directly represented be a 31-bit non-negative number (\texttt{INT32\_MAX}), which overflows at 24 days 20 hours 31 minutes 23.648 seconds.

Most network timeouts are shorter than the delay rollover, but a few protocols allow for delays that are represented as unsigned 32-bit values counting seconds, which corresponds to a 42-bit millisecond count.

The \texttt{net\_timeout} API provides a generic timeout mechanism to correctly track the remaining time for these extended-duration timeouts.

\textbf{Use} The simplest use of this API is:

1. Configure a network timeout using \texttt{net\_timeout\_set()}.
2. Use \texttt{net\_timeout\_evaluate()} to determine how long it is until the timeout occurs. Schedule a timeout to occur after this delay.
3. When the timeout callback is invoked, use \texttt{net\_timeout\_evaluate()} again to determine whether the timeout has completed, or whether there is additional time remaining. If the latter, reschedule the callback.
4. While the timeout is running, use \texttt{net\_timeout\_remaining()} to get the number of seconds until the timeout expires. This may be used to explicitly update the timeout, which should be done by canceling any pending callback and restarting from step 1 with the new timeout.

The \texttt{net\_timeout} contains a \texttt{sys\_snode\_t} that allows multiple timeout instances to be aggregated to share a single kernel timer element. The application must use \texttt{net\_timeout\_evaluate()} on all instances to determine the next timeout event to occur.

\texttt{net\_timeout\_deadline()} may be used to reconstruct the full-precision deadline of the timeout. This exists primarily for testing but may have use in some applications, as it does allow a millisecond-resolution calculation of remaining time.

\textbf{API Reference}

\texttt{group net\_timeout}

Network long timeout primitives and helpers.

\textbf{Defines}

\texttt{NET\_TIMEOUT\_MAX\_VALUE}

Divisor used to support ms resolution timeouts.

Because delays are processed in work queues which are not invoked synchronously with clock changes we need to be able to detect timeouts after they occur, which requires comparing “deadline” to “now” with enough “slop” to handle any observable latency due to “now” advancing past “deadline”.

The simplest solution is to use the native conversion of the well-defined 32-bit unsigned difference to a 32-bit signed difference, which caps the maximum delay at \texttt{INT32\_MAX}. This is compatible with the standard mechanism for detecting completion of deadlines that do not overflow their representation.

\textbf{Functions}

\texttt{void net\_timeout\_set(struct net\_timeout *timeout, uint32\_t lifetime, uint32\_t now)}

Configure a network timeout structure.

\textbf{Parameters}
• **timeout** – a pointer to the timeout state.
• **lifetime** – the duration of the timeout in seconds.
• **now** – the time at which the timeout started counting down, in milliseconds. This is generally a captured value of \texttt{k_uptime_get\_32()}.

\texttt{int64\_t net\_timeout\_deadline(const struct net\_timeout *timeout, int64\_t now)}

Return the 64-bit system time at which the timeout will complete.

**Note:** Correct behavior requires invocation of \texttt{net\_timeout\_evaluate()} at its specified intervals.

**Parameters**

• **timeout** – state a pointer to the timeout state, initialized by \texttt{net\_timeout\_set()} and maintained by \texttt{net\_timeout\_evaluate()}.
• **now** – the full-precision value of \texttt{k\_uptime\_get()} relative to which the deadline will be calculated.

**Returns** the value of \texttt{k\_uptime\_get()} at which the timeout will expire.

\texttt{uint32\_t net\_timeout\_remaining(const struct net\_timeout *timeout, uint32\_t now)}

Calculate the remaining time to the timeout in whole seconds.

**Note:** This function rounds the remaining time down, i.e. if the timeout will occur in 3500 milliseconds the value 3 will be returned.

**Note:** Correct behavior requires invocation of \texttt{net\_timeout\_evaluate()} at its specified intervals.

**Parameters**

• **timeout** – a pointer to the timeout state
• **now** – the time relative to which the estimate of remaining time should be calculated. This should be recently captured value from \texttt{k\_uptime\_get\_32()}.

**Return values**

• 0 – if the timeout has completed.
• positive – the remaining duration of the timeout, in seconds.

\texttt{uint32\_t net\_timeout\_evaluate(struct net\_timeout *timeout, uint32\_t now)}

Update state to reflect elapsed time and get new delay.

This function must be invoked periodically to (1) apply the effect of elapsed time on what remains of a total delay that exceeded the maximum representable delay, and (2) determine that either the timeout has completed or that the infrastructure must wait a certain period before checking again for completion.

**Parameters**

• **timeout** – a pointer to the timeout state
• **now** – the time relative to which the estimate of remaining time should be calculated. This should be recently captured value from \texttt{k\_uptime\_get\_32()}.

**Return values**

• 0 – if the timeout has completed
• positive – the maximum delay until the state of this timeout should be re-evaluated, in milliseconds.

```c
struct net_timeout
    #include <net_timeout.h> Generic struct for handling network timeouts.

Except for the linking node, all access to state from these objects must go through the defined API.

Public Members

sys_snode_t node
    Used to link multiple timeouts that share a common timer infrastructure.
    For examples a set of related timers may use a single delayed work structure, which is always scheduled at the shortest time to a timeout event.

Networking Context

The net_context API is not meant for application use. Application should use BSD Sockets API instead.

Promiscuous Mode

- Overview
- Sample usage
- API Reference

Overview  Promiscuous mode is a mode for a network interface controller that causes it to pass all traffic it receives to the application rather than passing only the frames that the controller is specifically programmed to receive. This mode is normally used for packet sniffing as used to diagnose network connectivity issues by showing an application all the data being transferred over the network. (See the Wikipedia article on promiscuous mode for more information.)

The network promiscuous APIs are used to enable and disable this mode, and to wait for and receive a network data to arrive. Not all network technologies or network device drivers support promiscuous mode.

Sample usage  First the promiscuous mode needs to be turned ON by the application like this:

```c
ret = net_promisc_mode_on(iface);
if (ret < 0) {
    if (ret == -EALREADY) {
        printf("Promiscuous mode already enabled\n");
    } else {
        printf("Cannot enable promiscuous mode for "
            "interface %p (%d)\n", iface, ret);
    }
}
```
while (true) {
    pkt = net_promisc_mode_wait_data(K_FOREVER);
    if (pkt) {
        print_info(pkt);
    }
    net_pkt_unref(pkt);
}

Finally the promiscuous mode can be turned OFF by the application like this:

ret = net_promisc_mode_off(iface);
if (ret < 0) {
    if (ret == -EALREADY) {
        printf("Promiscuous mode already disabled\n");
    } else {
        printf("Cannot disable promiscuous mode for ">
                  "interface %p (%d)\n", iface, ret);
    }
}

See net-promiscuous-mode-sample for a more comprehensive example.

API Reference

group promiscuous
    Promiscuous mode support.

Functions

static inline struct net_pkt *net_promisc_mode_wait_data(k_timeout_t timeout)
    Start to wait received network packets.

    Parameters
    • timeout – How long to wait before returning.

    Returns Received net_pkt, NULL if not received any packet.

static inline int net_promisc_mode_on(struct net_if *iface)
    Enable promiscuous mode for a given network interface.

    Parameters
    • iface – Network interface

    Returns 0 if ok, <0 if error

static inline int net_promisc_mode_off(struct net_if *iface)
    Disable promiscuous mode for a given network interface.

    Parameters
    • iface – Network interface

    Returns 0 if ok, <0 if error

Simple Network Time Protocol Library
Overview  The SNTP library implements IETF RFC4330 (Simple Network Time Protocol v4). SNTP provides a way to synchronize clocks in computer networks.

API Reference

group sntp
Simple Network Time Protocol API.

Functions

int sntp_init(struct sntp_ctx *ctx, struct sockaddr *addr, socklen_t addr_len)
Initialize SNTP context.

Parameters
• ctx – Address of sntp context.
• addr – IP address of NTP/SNTP server.
• addr_len – IP address length of NTP/SNTP server.

Returns 0 if ok, <0 if error.

int sntp_query(struct sntp_ctx *ctx, uint32_t timeout, struct sntp_time *time)
Perform SNTP query.

Parameters
• ctx – Address of sntp context.
• timeout – Timeout of waiting for sntp response (in milliseconds).
• time – Timestamp including integer and fractional seconds since 1 Jan 1970 (output).

Returns 0 if ok, <0 if error (-ETIMEDOUT if timeout).

void sntp_close(struct sntp_ctx *ctx)
Release SNTP context.

int sntp_simple(const char *server, uint32_t timeout, struct sntp_time *time)
Convenience function to query SNTP in one-shot fashion.

Convenience wrapper which calls getaddrinfo(), sntp_init(), sntp_query(), and sntp_close().

Parameters
• server – Address of server in format addr[:port]
• timeout – Query timeout
• time – Timestamp including integer and fractional seconds since 1 Jan 1970 (output).

Returns 0 if ok, <0 if error (-ETIMEDOUT if timeout).
struct sntp_ctxt
   #include <sntp.h> SNTP context

Public Members

uint32_t expected_orig_ts
   Timestamp when the request was sent from client to server. This is used to check if the originated timestamp in the server reply matches the one in client request.

struct sntp_time
   #include <sntp.h> Time as returned by SNTP API, fractional seconds since 1 Jan 1970

SOCKS5 Proxy Support

- Overview
- SOCKS5 API
- SOCKS5 Proxy Usage in MQTT

Overview   The SOCKS library implements SOCKS5 support, which allows Zephyr to connect to peer devices via a network proxy.

See this [SOCKS5 Wikipedia article](https://en.wikipedia.org/wiki/SOCKS) for a detailed overview of how SOCKS5 works.

SOCKS5 API   The SOCKS5 support is enabled by CONFIG_SOCKS Kconfig variable. Application wanting to use the SOCKS5 must set the SOCKS5 proxy host address by calling setsockopt() like this:

```c
static int set_proxy(int sock, const struct sockaddr *proxy_addr,
                     socklen_t proxy_addrlen)
{
    int ret;

    ret = setsockopt(sock, SOL_SOCKET, SO_SOCKS5, 
                     proxy_addr, proxy_addrlen);
    if (ret < 0) {
        return -errno;
    }

    return 0;
}
```

SOCKS5 Proxy Usage in MQTT   For MQTT client, there is mqtt_client_set_proxy() API that the application can call to setup SOCKS5 proxy. See mqtt-publisher-sample for usage example.

Trickle Timer Library
Overview

The Trickle timer library implements IETF RFC6206 (Trickle Algorithm).
The Trickle algorithm allows nodes in a lossy shared medium (e.g., low-power and lossy networks) to exchange information in a highly robust, energy efficient, simple, and scalable manner.

API Reference

group trickle

Trickle algorithm library.

Typedefs

typedef void (*net_trickle_cb_t)(struct net_trickle *trickle, bool do_suppress, void *user_data)

Trickle timer callback.
The callback is called after Trickle timeout expires.

Param trickle The trickle context to use.
Param do_suppress Is TX allowed (true) or not (false).
Param user_data The user data given in net_trickle_start() call.

Functions

int net_trickle_create(struct net_trickle *trickle, uint32_t Imin, uint8_t Imax, uint8_t_t k)
Create a Trickle timer.

Parameters

• trickle – Pointer to Trickle struct.
• Imin – Imin configuration parameter in ms.
• Imax – Max number of doublings.
• k – Redundancy constant parameter. See RFC 6206 for details.

Returns Return 0 if ok and <0 if error.

int net_trickle_start(struct net_trickle *trickle, net_trickle_cb_t cb, void *user_data)
Start a Trickle timer.

Parameters

• trickle – Pointer to Trickle struct.
• cb – User callback to call at time T within the current trickle interval
• user_data – User pointer that is passed to callback.

Returns Return 0 if ok and <0 if error.

int net_trickle_stop(struct net_trickle *trickle)
Stop a Trickle timer.

Parameters

• trickle – Pointer to Trickle struct.
**Returns** Return 0 if ok and <0 if error.

```c
void net_trickle_consistency(struct net_trickle *trickle)
```
To be called by the protocol handler when it hears a consistent network transmission.

**Parameters**
- `trickle` – Pointer to Trickle struct.

```c
void net_trickle_inconsistency(struct net_trickle *trickle)
```
To be called by the protocol handler when it hears an inconsistent network transmission.

**Parameters**
- `trickle` – Pointer to Trickle struct.

```c
static inline bool net_trickle_is_running(struct net_trickle *trickle)
```
Check if the Trickle timer is running or not.

**Parameters**
- `trickle` – Pointer to Trickle struct.

**Returns** Return True if timer is running and False if not.

```c
struct net_trickle
#include <trickle.h>
```
The variable names are taken directly from RFC 6206 when applicable. Note that the struct members should not be accessed directly but only via the Trickle API.

**Public Members**

```c
uint32_t Imin
Min interval size in ms
```

```c
uint8_t Imax
Max number of doublings
```

```c
uint8_t k
Redundancy constant
```

```c
uint32_t I
Current interval size
```

```c
uint32_t Istart
Start of the interval in ms
```

```c
uint8_t c
Consistency counter
```

```c
uint32_t Imax_abs
Max interval size in ms (not doublings)
```

```c
net_trickle_cb_t cb
Callback to be called when timer expires
```

**Websocket Client API**
Overview

The Websocket client library allows Zephyr to connect to a Websocket server. The Websocket client API can be used directly by application to establish a Websocket connection to server, or it can be used as a transport for other network protocols like MQTT.

See this Websocket Wikipedia article for a detailed overview of how Websocket works.

For more information about the protocol itself, see IETF RFC6455 The WebSocket Protocol.

Websocket Transport

The Websocket API allows it to be used as a transport for other high level protocols like MQTT. The Zephyr MQTT client library can be configured to use Websocket transport by enabling CONFIG_MQTT_LIB_WEBSOCKET and CONFIG_WEBSOCKET_CLIENT Kconfig options.

First a socket needs to be created and connected to the Websocket server:

```c
sock = socket(family, SOCK_STREAM, IPPROTO_TCP);
...
ret = connect(sock, addr, addr_len);
...
```

The Websocket transport socket is then created like this:

```c
ws_sock = websocket_connect(sock, &config, timeout, user_data);
```

The Websocket socket can then be used to send or receive data, and the Websocket client API will encapsulate the sent or received data to/from Websocket packet payload. Both the websocket_xxx() API or normal BSD socket API functions can be used to send and receive application data.

```c
ret = websocket_send_msg(ws_sock, buf_to_send, buf_len,
WEB_SOCKET_OPCODE_DATA_BINARY, true, true,
K_FOREVER);
...
ret = send(ws_sock, buf_to_send, buf_len, 0);
```

If normal BSD socket functions are used, then currently only TEXT data is supported. In order to send BINARY data, the websocket_send_msg() must be used.

When done, the Websocket transport socket must be closed.

```c
ret = close(ws_sock);
or
ret = websocket_disconnect(ws_sock);
```

API Reference

```c

 group websocket
 Websocket API.

 Defines

 WEBSOCKET_FLAG_FINAL
 Message type values. Returned in websocket_recv_msg() Final frame
```

7.21. Networking
WEB SOCKET_FLAG_TEXT
Textual data

WEB SOCKET_FLAG_BINARY
Binary data

WEB SOCKET_FLAG_CLOSE
Closing connection

WEB SOCKET_FLAG_PING
Ping message

WEB SOCKET_FLAG_PONG
Pong message

**Typedefs**

typedef int (*websocket_connect_cb_t)(int ws_sock, struct http_request *req, void *user_data)
Callback called after Websocket connection is established.

- **Param ws_sock**  Websocket id
- **Param req**  HTTP handshake request
- **Param user_data** A valid pointer on some user data or NULL
- **Return**  0 if ok, <0 if there is an error and connection should be aborted

**Enums**

enum websocket_opcode

**Values:**

- enumerator WEB_SOCKET_OPCODE_CONTINUE = 0x00
- enumerator WEB_SOCKET_OPCODE_DATA_TEXT = 0x01
- enumerator WEB_SOCKET_OPCODE_DATA_BINARY = 0x02
- enumerator WEB_SOCKET_OPCODE_CLOSE = 0x08
- enumerator WEB_SOCKET_OPCODE_PING = 0x09
- enumerator WEB_SOCKET_OPCODE_PONG = 0x0A
Functions

int websocket_connect(int http_sock, struct websocket_request *req, int32_t timeout, void *user_data)

Connect to a server that provides Websocket service. The callback is called after connection is established. The returned value is a new socket descriptor that can be used to send / receive data using the BSD socket API.

Parameters
• http_sock – Socket id to the server. Note that this socket is used to do HTTP handshakes etc. The actual Websocket connectivity is done via the returned websocket id. Note that the http_sock must not be closed after this function returns as it is used to deliver the Websocket packets to the Websocket server.
• req – Websocket request. User should allocate and fill the request data.
• timeout – Max timeout to wait for the connection. The timeout value is in milliseconds. Value SYS_FOREVER_MS means to wait forever.
• user_data – User specified data that is passed to the callback.

Returns
Websocket id to be used when sending/receiving Websocket data.

int websocket_send_msg(int ws_sock, const uint8_t *payload, size_t payload_len, enum websocket_opcode opcode, bool mask, bool final, int32_t timeout)

Send websocket msg to peer.

The function will automatically add websocket header to the message.

Parameters
• ws_sock – Websocket id returned by websocket_connect().
• payload – Websocket data to send.
• payload_len – Length of the data to be sent.
• opcode – Operation code (text, binary, ping, pong, close)
• mask – Mask the data, see RFC 6455 for details
• final – Is this final message for this message send. If final == false, then the first message must have valid opcode and subsequent messages must have opcode WEB_SOCKET_OPCODE_CONTINUE. If final == true and this is the only message, then opcode should have proper opcode (text or binary) set.
• timeout – How long to try to send the message. The value is in milliseconds. Value SYS_FOREVER_MS means to wait forever.

Returns
<0 if error, >=0 amount of bytes sent

int websocket_recv_msg(int ws_sock, uint8_t *buf, size_t buf_len, uint32_t *message_type, uint64_t *remaining, int32_t timeout)

Receive websocket msg from peer.

The function will automatically remove websocket header from the message.

Parameters
• ws_sock – Websocket id returned by websocket_connect().
• buf – Buffer where websocket data is read.
• buf_len – Length of the data buffer.
• message_type – Type of the message.
• remaining – How much there is data left in the message after this read.
• **timeout** – How long to try to receive the message. The value is in milliseconds. Value SYS_FOREVER_MS means to wait forever.

**Returns**  
<0 if error, ≥0 amount of bytes received

```c
int websocket_disconnect(int ws_sock)
```

Close websocket.

One must call `websocket_connect()` after this call to re-establish the connection.

**Parameters**

• **ws_sock** – Websocket id returned by `websocket_connect()`.

static inline void websocket_init(void)

```c
struct websocket_request
```

Include `<websocket.h>` Websocket client connection request. This contains all the data that is needed when doing a Websocket connection request.

**Public Members**

const char *host
Host of the Websocket server when doing HTTP handshakes.

const char *url
URL of the Websocket.

```c
http_header_cb_t optional_headers_cb
```

User supplied callback function to call when optional headers need to be sent. This can be NULL, in which case the optional_headers field in http_request is used. The idea of this optional_headers callback is to allow user to send more HTTP header data that is practical to store in allocated memory.

```c
const char **optional_headers
```

A NULL terminated list of any optional headers that should be added to the HTTP request. May be NULL. If the optional_headers_cb is specified, then this field is ignored.

```c
websocket_connect_cb_t cb
```

User supplied callback function to call when a connection is established.

```c
const struct http_parser_settings *http_cb
```

User supplied list of callback functions if the calling application wants to know the parsing status or the HTTP fields during the handshake. This is optional parameter and normally not needed but is useful if the caller wants to know something about the fields that the server is sending.

```c
uint8_t *tmp_buf
```

User supplied buffer where HTTP connection data is stored

```c
size_t tmp_buf_len
```

Length of the user supplied temp buffer

**Network Packet Capture**
Overview  The 

net_capture

API allows user to monitor the network traffic in one of the Zephyr network interfaces and send that traffic to external system for analysis. The monitoring can be setup either manually using 

net-shell

or automatically by using the 

net_capture

API.

Sample usage  See Network capture sample application and  Monitor Network Traffic  for details.

API Reference

group net_capture

Network packet capture support functions.

Functions

int net_capture_setup(const char *remote_addr, const char *my_local_addr, const char *peer_addr, const struct device **dev)

Setup network packet capturing support.

Parameters  • remote_addr - The value tells the tunnel remote/outer endpoint IP address. The IP address can be either IPv4 or IPv6 address. This address is used to select the network interface where the tunnel is created.
  • my_local_addr - The local/inner IP address of the tunnel. Can contain also port number which is used as UDP source port.
  • peer_addr - The peer/inner IP address of the tunnel. Can contain also port number which is used as UDP destination port.
  • dev - Network capture device. This is returned to the caller.

Returns  0 if ok, <0 if network packet capture setup failed

static inline int net_capture_cleanup(const struct device *dev)

Cleanup network packet capturing support.

This should be called after the capturing is done and resources can be released.

Parameters  • dev - Network capture device. User must allocate using the net_capture_setup() function.

Returns  0 if ok, <0 if network packet capture cleanup failed

static inline int net_capture_enable(const struct device *dev, struct net_if *iface)

Enable network packet capturing support.

This creates tunnel network interface where all the captured packets are pushed. The captured network packets are placed in UDP packets that are sent to tunnel peer.

Parameters  • dev - Network capture device
  • iface - Network interface we are starting to capture packets.
Returns 0 if ok, <0 if network packet capture enable failed

static inline bool net_capture_is_enabled(const struct device *dev)
Is network packet capture enabled or disabled.

Parameters
• dev – Network capture device

Returns True if enabled, False if network capture is disabled.

static inline int net_capture_disable(const struct device *dev)
Disable network packet capturing support.

Parameters
• dev – Network capture device

Returns 0 if ok, <0 if network packet capture disable failed

static inline int net_capture_send(const struct device *dev, struct net_if *iface, struct net_pkt *pkt)
Send captured packet.

Parameters
• dev – Network capture device
• iface – Network interface the packet is being sent
• pkt – The network packet that is sent

Returns 0 if ok, <0 if network packet capture send failed

7.21.2 Network Buffer Management

Network Buffer

Overview Network buffers are a core concept of how the networking stack (as well as the Bluetooth stack) pass data around. The API for them is defined in include/net/buf.h:.

Creating buffers Network buffers are created by first defining a pool of them:

```
NET_BUF_POOL_DEFINE(pool_name, buf_count, buf_size, user_data_size, NULL);
```

The pool is a static variable, so if it’s needed to be exported to another module a separate pointer is needed.

Once the pool has been defined, buffers can be allocated from it with:

```
buf = net_buf_alloc(&pool_name, timeout);
```
There is no explicit initialization function for the pool or its buffers, rather this is done implicitly as `net_buf_alloc()` gets called.

If there is a need to reserve space in the buffer for protocol headers to be prepended later, it's possible to reserve this headroom with:

```c
net_buf_reserve(buf, headroom);
```

In addition to actual protocol data and generic parsing context, network buffers may also contain protocol-specific context, known as user data. Both the maximum data and user data capacity of the buffers is compile-time defined when declaring the buffer pool.

The buffers have native support for being passed through `k_fifo` kernel objects. This is a very practical feature when the buffers need to be passed from one thread to another. However, since a `net_buf` may have a fragment chain attached to it, instead of using the `k_fifo_put()` and `k_fifo_get()` APIs, special `net_buf_put()` and `net_buf_get()` APIs must be used when passing buffers through FIFOs. These APIs ensure that the buffer chains stay intact. The same applies for passing buffers through a singly linked list, in which case the `net_buf_slist_put()` and `net_buf_slist_get()` functions must be used instead of `sys_slist_append()` and `sys_slist_get()`.

**Common Operations**  The network buffer API provides some useful helpers for encoding and decoding data in the buffers. To fully understand these helpers it's good to understand the basic names of operations used with them:

**Add** Add data to the end of the buffer. Modifies the data length value while leaving the actual data pointer intact. Requires that there is enough tailroom in the buffer. Some examples of APIs for adding data:

```c
void *net_buf_add(struct net_buf *buf, size_t len);
void *net_buf_add_mem(struct net_buf *buf, const void *mem, size_t len);
uint8_t *net_buf_add_u8(struct net_buf *buf, uint8_t value);
void net_buf_add_le16(struct net_buf *buf, uint16_t value);
void net_buf_add_le32(struct net_buf *buf, uint32_t value);
```

**Remove** Remove data from the end of the buffer. Modifies the data length value while leaving the actual data pointer intact. Some examples of APIs for removing data:

```c
void *net_buf_remove_mem(struct net_buf *buf, size_t len);
uint8_t net_buf_remove_u8(struct net_buf *buf);
uint16_t net_buf_remove_le16(struct net_buf *buf);
uint32_t net_buf_remove_le32(struct net_buf *buf);
```

**Push** Prepend data to the beginning of the buffer. Modifies both the data length value as well as the data pointer. Requires that there is enough headroom in the buffer. Some examples of APIs for pushing data:

```c
void *net_buf_push(struct net_buf *buf, size_t len);
void *net_buf_push_mem(struct net_buf *buf, const void *mem, size_t len);
void net_buf_push_u8(struct net_buf *buf, uint8_t value);
void net_buf_push_le16(struct net_buf *buf, uint16_t value);
```

**Pull** Remove data from the beginning of the buffer. Modifies both the data length value as well as the data pointer. Some examples of APIs for pulling data:

```c
void *net_buf_pull(struct net_buf *buf, size_t len);
void *net_buf_pull_mem(struct net_buf *buf, size_t len);
uint8_t net_buf_pull_u8(struct net_buf *buf);
uint16_t net_buf_pull_le16(struct net_buf *buf);
uint32_t net_buf_pull_le32(struct net_buf *buf);
```
The Add and Push operations are used when encoding data into the buffer, whereas the Remove and Pull operations are used when decoding data from a buffer.

Reference Counting  Each network buffer is reference counted. The buffer is initially acquired from a free buffers pool by calling `net_buf_alloc()`, resulting in a buffer with reference count 1. The reference count can be incremented with `net_buf_ref()` or decremented with `net_buf_unref()`. When the count drops to zero the buffer is automatically placed back to the free buffers pool.

API Reference

*group net_buf*

Network buffer library.

*Defines*

**NET_BUF_SIMPLE_DEFINE(_name, _size)**

Define a `net_buf_simple` stack variable.

This is a helper macro which is used to define a `net_buf_simple` object on the stack.

**Parameters**

- `_name` – Name of the `net_buf_simple` object.
- `_size` – Maximum data storage for the buffer.

**NET_BUF_SIMPLE_DEFINE_STATIC(_name, _size)**

Define a static `net_buf_simple` variable.

This is a helper macro which is used to define a static `net_buf_simple` object.

**Parameters**

- `_name` – Name of the `net_buf_simple` object.
- `_size` – Maximum data storage for the buffer.

**NET_BUF_SIMPLE(_size)**

Define a `net_buf_simple` stack variable and get a pointer to it.

This is a helper macro which is used to define a `net_buf_simple` object on the stack and the get a pointer to it as follows:

```c
struct net_buf_simple *my_buf = NET_BUF_SIMPLE(10);
```

After creating the object it needs to be initialized by calling `net_buf_simple_init()`.

**Parameters**

- `_size` – Maximum data storage for the buffer.

**Returns**  Pointer to stack-allocated `net_buf_simple` object.

**NET_BUF_FRAGS**

Flag indicating that the buffer has associated fragments. Only used internally by the buffer handling code while the buffer is inside a FIFO, meaning this never needs to be explicitly set or unset by the `net_buf` API user. As long as the buffer is outside of a FIFO, i.e. in practice always for the user for this API, the `buf->frags` pointer should be used instead.

**NET_BUF_EXTERNAL_DATA**

Flag indicating that the buffer’s associated data pointer, points to externally allocated memory. Therefore once ref goes down to zero, the pointed data will not need to be deallocated. This never needs to be explicitly set or unset by the `net_buf` API user. Such `net_buf` is exclusively
instantiated via \textit{net_buf_alloc_with_data()} function. Reference count mechanism however will behave the same way, and ref count going to 0 will free the \textit{net_buf} but no the data pointer in it.

\texttt{NET_BUF_POOL_HEAP_DEFINE(_name, _count, _ud_size, _destroy)}

Define a new pool for buffers using the heap for the data.

Defines a \textit{net_buf_pool} struct and the necessary memory storage (array of structs) for the needed amount of buffers. After this, the buffers can be accessed from the pool through \texttt{net_buf_alloc}. The pool is defined as a static variable, so if it needs to be exported outside the current module this needs to happen with the help of a separate pointer rather than an extern declaration.

The data payload of the buffers will be allocated from the heap using \texttt{k_malloc}, so \texttt{CONFIG_HEAP_MEM_POOL_SIZE} must be set to a positive value. This kind of pool does not support blocking on the data allocation, so the timeout passed to \texttt{net_buf_alloc} will be always treated as K\_NO\_WAIT when trying to allocate the data. This means that allocation failures, i.e. NULL returns, must always be handled cleanly.

If provided with a custom destroy callback, this callback is responsible for eventually calling \textit{net_buf_destroy()} to complete the process of returning the buffer to the pool.

\textbf{Parameters}

- \texttt{\_name} – Name of the pool variable.
- \texttt{\_count} – Number of buffers in the pool.
- \texttt{\_ud_size} – User data space to reserve per buffer.
- \texttt{\_destroy} – Optional destroy callback when buffer is freed.

\texttt{NET_BUF_POOL_FIXED_DEFINE(_name, _count, _data_size, _ud_size, _destroy)}

Define a new pool for buffers based on fixed-size data.

Defines a \textit{net_buf_pool} struct and the necessary memory storage (array of structs) for the needed amount of buffers. After this, the buffers can be accessed from the pool through \texttt{net_buf_alloc}. The pool is defined as a static variable, so if it needs to be exported outside the current module this needs to happen with the help of a separate pointer rather than an extern declaration.

The data payload of the buffers will be allocated from a byte array of fixed sized chunks. This kind of pool does not support blocking on the data allocation, so the timeout passed to \texttt{net_buf_alloc} will be always treated as K\_NO\_WAIT when trying to allocate the data. This means that allocation failures, i.e. NULL returns, must always be handled cleanly.

If provided with a custom destroy callback, this callback is responsible for eventually calling \textit{net_buf_destroy()} to complete the process of returning the buffer to the pool.

\textbf{Parameters}

- \texttt{\_name} – Name of the pool variable.
- \texttt{\_count} – Number of buffers in the pool.
- \texttt{\_data_size} – Maximum data payload per buffer.
- \texttt{\_ud_size} – User data space to reserve per buffer.
- \texttt{\_destroy} – Optional destroy callback when buffer is freed.

\texttt{NET_BUF_POOL_VAR_DEFINE(_name, _count, _data_size, _ud_size, _destroy)}

Define a new pool for buffers with variable size payloads.

Defines a \textit{net_buf_pool} struct and the necessary memory storage (array of structs) for the needed amount of buffers. After this, the buffers can be accessed from the pool through \texttt{net_buf_alloc}. The pool is defined as a static variable, so if it needs to be exported outside the current module this needs to happen with the help of a separate pointer rather than an extern declaration.
The data payload of the buffers will be based on a memory pool from which variable size payloads may be allocated.

If provided with a custom destroy callback, this callback is responsible for eventually calling \texttt{net_buf_destroy()} to complete the process of returning the buffer to the pool.

**Parameters**

- \texttt{\_name} – Name of the pool variable.
- \texttt{\_count} – Number of buffers in the pool.
- \texttt{\_data\_size} – Total amount of memory available for data payloads.
- \texttt{\_ud\_size} – User data space to reserve per buffer.
- \texttt{\_destroy} – Optional destroy callback when buffer is freed.

\texttt{NET\_BUF\_POOL\_DEFINE( name, count, size, ud\_size, destroy )}

Define a new pool for buffers.

Defines a \texttt{net_buf_pool} struct and the necessary memory storage (array of structs) for the needed amount of buffers. After this, the buffers can be accessed from the pool through \texttt{net_buf Alloc}. The pool is defined as a static variable, so if it needs to be exported outside the current module this needs to happen with the help of a separate pointer rather than an extern declaration.

If provided with a custom destroy callback this callback is responsible for eventually calling \texttt{net_buf_destroy()} to complete the process of returning the buffer to the pool.

**Parameters**

- \texttt{\_name} – Name of the pool variable.
- \texttt{\_count} – Number of buffers in the pool.
- \texttt{\_size} – Maximum data size for each buffer.
- \texttt{\_ud\_size} – Amount of user data space to reserve.
- \texttt{\_destroy} – Optional destroy callback when buffer is freed.

**Typedefs**

\texttt{typedef struct net_buf *(net_buf allocator cb)(k_timeout t timeout, void *user data)}

Network buffer allocator callback. The allocator callback is called when \texttt{net_buf append bytes} needs to allocate a new \texttt{net_buf}.

**Param timeout** Affects the action taken should the net buf pool be empty. If \texttt{K\_NO\_WAIT}, then return immediately. If \texttt{K\_FOREVER}, then wait as long as necessary. Otherwise, wait until the specified timeout.

**Param user data** The user data given in \texttt{net_buf append bytes} call.

**Return** pointer to allocated \texttt{net_buf} or NULL on error.

**Functions**

\texttt{static inline void net_buf simple init(struct net_buf simple *buf, size t reserve head)}

Initialize a \texttt{net_buf simple} object.

This needs to be called after creating a \texttt{net_buf simple} object using the \texttt{NET\_BUF\_SIMPLE} macro.

**Parameters**
• buf – Buffer to initialize.
• reserve_head – Headroom to reserve.

void net_buf_simple_init_with_data(struct net_buf_simple *buf, void *data, size_t size)
Initialize a net_buf_simple object with data.

Parameters
• buf – Buffer to initialize.
• data – External data pointer
• size – Amount of data the pointed data buffer if able to fit.

static inline void net_buf_simple_reset(struct net_buf_simple *buf)
Reset buffer.

Parameters
• buf – Buffer to reset.

void net_buf_simple_clone(const struct net_buf_simple *original, struct net_buf_simple *clone)
Clone buffer state, using the same data buffer.

Parameters
• original – Buffer to clone.
• clone – The new clone.

void *net_buf_simple_add(struct net_buf_simple *buf, size_t len)
Prepare data to be added at the end of the buffer.

Parameters
• buf – Buffer to update.
• len – Number of bytes to increment the length with.

Returns The original tail of the buffer.

void *net_buf_simple_add_mem(struct net_buf_simple *buf, const void *mem, size_t len)
Copy given number of bytes from memory to the end of the buffer.

Parameters
• buf – Buffer to update.
• mem – Location of data to be added.
• len – Length of data to be added

Returns The original tail of the buffer.

uint8_t *net_buf_simple_add_u8(struct net_buf_simple *buf, uint8_t val)
Add (8-bit) byte at the end of the buffer.

Parameters
• buf – Buffer to update.
• val – byte value to be added.

**Returns** Pointer to the value added

```c
void net_buf_simple_add_le16(struct net_buf_simple *buf, uint16_t val)
```

Add 16-bit value at the end of the buffer.

Adds 16-bit value in little endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• buf – Buffer to update.

• val – 16-bit value to be added.

```c
void net_buf_simple_add_be16(struct net_buf_simple *buf, uint16_t val)
```

Add 16-bit value at the end of the buffer.

Adds 16-bit value in big endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• buf – Buffer to update.

• val – 16-bit value to be added.

```c
void net_buf_simple_add_le24(struct net_buf_simple *buf, uint32_t val)
```

Add 24-bit value at the end of the buffer.

Adds 24-bit value in little endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• buf – Buffer to update.

• val – 24-bit value to be added.

```c
void net_buf_simple_add_be24(struct net_buf_simple *buf, uint32_t val)
```

Add 24-bit value at the end of the buffer.

Adds 24-bit value in big endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• buf – Buffer to update.

• val – 24-bit value to be added.

```c
void net_buf_simple_add_le32(struct net_buf_simple *buf, uint32_t val)
```

Add 32-bit value at the end of the buffer.

Adds 32-bit value in little endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• buf – Buffer to update.

• val – 32-bit value to be added.

```c
void net_buf_simple_add_be32(struct net_buf_simple *buf, uint32_t val)
```

Add 32-bit value at the end of the buffer.

Adds 32-bit value in big endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• buf – Buffer to update.
void net_buf_simple_add_le48(struct net_buf_simple *buf, uint64_t val)
Add 48-bit value at the end of the buffer.

Parameters
- buf – Buffer to update.
- val – 48-bit value to be added.

void net_buf_simple_add_be48(struct net_buf_simple *buf, uint64_t val)
Add 48-bit value at the end of the buffer.

Parameters
- buf – Buffer to update.
- val – 48-bit value to be added.

void net_buf_simple_add_le64(struct net_buf_simple *buf, uint64_t val)
Add 64-bit value at the end of the buffer.

Parameters
- buf – Buffer to update.
- val – 64-bit value to be added.

void net_buf_simple_add_be64(struct net_buf_simple *buf, uint64_t val)
Add 64-bit value at the end of the buffer.

Parameters
- buf – Buffer to update.
- val – 64-bit value to be added.

void *net_buf_simple_remove_mem(struct net_buf_simple *buf, size_t len)
Remove data from the end of the buffer.

Parameters
- buf – Buffer to update.
- len – Number of bytes to remove.

Returns
New end of the buffer data.

uint8_t net_buf_simple_remove_u8(struct net_buf_simple *buf)
Remove a 8-bit value from the end of the buffer.

Same idea as with net_buf_simple_remove_mem(), but a helper for operating on 8-bit values.

Parameters
- buf – A valid pointer on a buffer.

Returns
The 8-bit removed value
**uint16_t net_buf_simple_remove_le16(struct net_buf_simple *buf)**

Remove and convert 16 bits from the end of the buffer.

Same idea as with `net_buf_simple_remove_mem()`, but a helper for operating on 16-bit little endian data.

**Parameters**

- buf – A valid pointer on a buffer.

**Returns** 16-bit value converted from little endian to host endian.

**uint16_t net_buf_simple_remove_be16(struct net_buf_simple *buf)**

Remove and convert 16 bits from the end of the buffer.

Same idea as with `net_buf_simple_remove_mem()`, but a helper for operating on 16-bit big endian data.

**Parameters**

- buf – A valid pointer on a buffer.

**Returns** 16-bit value converted from big endian to host endian.

**uint32_t net_buf_simple_remove_le24(struct net_buf_simple *buf)**

Remove and convert 24 bits from the end of the buffer.

Same idea as with `net_buf_simple_remove_mem()`, but a helper for operating on 24-bit little endian data.

**Parameters**

- buf – A valid pointer on a buffer.

**Returns** 24-bit value converted from little endian to host endian.

**uint32_t net_buf_simple_remove_be24(struct net_buf_simple *buf)**

Remove and convert 24 bits from the end of the buffer.

Same idea as with `net_buf_simple_remove_mem()`, but a helper for operating on 24-bit big endian data.

**Parameters**

- buf – A valid pointer on a buffer.

**Returns** 24-bit value converted from big endian to host endian.

**uint32_t net_buf_simple_remove_le32(struct net_buf_simple *buf)**

Remove and convert 32 bits from the end of the buffer.

Same idea as with `net_buf_simple_remove_mem()`, but a helper for operating on 32-bit little endian data.

**Parameters**

- buf – A valid pointer on a buffer.

**Returns** 32-bit value converted from little endian to host endian.

**uint32_t net_buf_simple_remove_be32(struct net_buf_simple *buf)**

Remove and convert 32 bits from the end of the buffer.

Same idea as with `net_buf_simple_remove_mem()`, but a helper for operating on 32-bit big endian data.

**Parameters**

- buf – A valid pointer on a buffer.

**Returns** 32-bit value converted from big endian to host endian.
void *net_buf_simple_push(struct net_buf_simple *buf, size_t len)
Prepare data to be added to the start of the buffer.
Modifies the data pointer and buffer length to account for more data in the beginning of the buffer.

Parameters

• buf – Buffer to update.

• len – Number of bytes to add to the beginning.

Returns The new beginning of the buffer data.

void *net_buf_simple_push_mem(struct net_buf_simple *buf, const void *mem, size_t len)
Copy given number of bytes from memory to the start of the buffer.
Modifies the data pointer and buffer length to account for more data in the beginning of the buffer.

Parameters

• buf – Buffer to update.

• mem – Location of data to be added.
• len – Length of data to be added.

**Returns**  The new beginning of the buffer data.

```c
void net_buf_simple_push_le16(struct net_buf_simple *buf, uint16_t val)
```

Push 16-bit value to the beginning of the buffer.

Adds 16-bit value in little endian format to the beginning of the buffer.

**Parameters**

- `buf` – Buffer to update.
- `val` – 16-bit value to be pushed to the buffer.

```c
void net_buf_simple_push_be16(struct net_buf_simple *buf, uint16_t val)
```

Push 16-bit value to the beginning of the buffer.

Adds 16-bit value in big endian format to the beginning of the buffer.

**Parameters**

- `buf` – Buffer to update.
- `val` – 16-bit value to be pushed to the buffer.

```c
void net_buf_simple_push_u8(struct net_buf_simple *buf, uint8_t val)
```

Push 8-bit value to the beginning of the buffer.

Adds 8-bit value the beginning of the buffer.

**Parameters**

- `buf` – Buffer to update.
- `val` – 8-bit value to be pushed to the buffer.

```c
void net_buf_simple_push_le24(struct net_buf_simple *buf, uint32_t val)
```

Push 24-bit value to the beginning of the buffer.

Adds 24-bit value in little endian format to the beginning of the buffer.

**Parameters**

- `buf` – Buffer to update.
- `val` – 24-bit value to be pushed to the buffer.

```c
void net_buf_simple_push_be24(struct net_buf_simple *buf, uint32_t val)
```

Push 24-bit value to the beginning of the buffer.

Adds 24-bit value in big endian format to the beginning of the buffer.

**Parameters**

- `buf` – Buffer to update.
- `val` – 24-bit value to be pushed to the buffer.

```c
void net_buf_simple_push_le32(struct net_buf_simple *buf, uint32_t val)
```

Push 32-bit value to the beginning of the buffer.

Adds 32-bit value in little endian format to the beginning of the buffer.

**Parameters**

- `buf` – Buffer to update.
- `val` – 32-bit value to be pushed to the buffer.

```c
void net_buf_simple_push_be32(struct net_buf_simple *buf, uint32_t val)
```

Push 32-bit value to the beginning of the buffer.

Adds 32-bit value in big endian format to the beginning of the buffer.
Parameters

- buf – Buffer to update.
- val – 32-bit value to be pushed to the buffer.

void net_buf_simple_push_le48(struct net_buf_simple *buf, uint64_t val)
Push 48-bit value to the beginning of the buffer.

Parameters

- buf – Buffer to update.
- val – 48-bit value to be pushed to the buffer.

void net_buf_simple_push_be48(struct net_buf_simple *buf, uint64_t val)
Push 48-bit value to the beginning of the buffer.

Parameters

- buf – Buffer to update.
- val – 64-bit value to be pushed to the buffer.

void net_buf_simple_push_le64(struct net_buf_simple *buf, uint64_t val)
Push 64-bit value to the beginning of the buffer.

Parameters

- buf – Buffer to update.
- val – 64-bit value to be pushed to the buffer.

void net_buf_simple_push_be64(struct net_buf_simple *buf, uint64_t val)
Push 64-bit value to the beginning of the buffer.

Parameters

- buf – Buffer to update.
- len – Number of bytes to remove.

Returns New beginning of the buffer data.

void *net_buf_simple_pull_mem(struct net_buf_simple *buf, size_t len)
Remove data from the beginning of the buffer.

Parameters

- buf – Buffer to update.
- len – Number of bytes to remove.
**Returns**  Pointer to the old location of the buffer data.

`uint8_t net_buf_simple_pull_u8(struct net_buf_simple *buf)`
Remove a 8-bit value from the beginning of the buffer.

Same idea as with `net_buf_simple_pull()`, but a helper for operating on 8-bit values.

**Parameters**
- `buf` – A valid pointer on a buffer.

**Returns**  The 8-bit removed value

`uint16_t net_buf_simple_pull_le16(struct net_buf_simple *buf)`
Remove and convert 16 bits from the beginning of the buffer.

Same idea as with `net_buf_simple_pull()`, but a helper for operating on 16-bit little endian data.

**Parameters**
- `buf` – A valid pointer on a buffer.

**Returns**  16-bit value converted from little endian to host endian.

`uint16_t net_buf_simple_pull_be16(struct net_buf_simple *buf)`
Remove and convert 16 bits from the beginning of the buffer.

Same idea as with `net_buf_simple_pull()`, but a helper for operating on 16-bit big endian data.

**Parameters**
- `buf` – A valid pointer on a buffer.

**Returns**  16-bit value converted from big endian to host endian.

`uint32_t net_buf_simple_pull_le24(struct net_buf_simple *buf)`
Remove and convert 24 bits from the beginning of the buffer.

Same idea as with `net_buf_simple_pull()`, but a helper for operating on 24-bit little endian data.

**Parameters**
- `buf` – A valid pointer on a buffer.

**Returns**  24-bit value converted from little endian to host endian.

`uint32_t net_buf_simple_pull_be24(struct net_buf_simple *buf)`
Remove and convert 24 bits from the beginning of the buffer.

Same idea as with `net_buf_simple_pull()`, but a helper for operating on 24-bit big endian data.

**Parameters**
- `buf` – A valid pointer on a buffer.

**Returns**  24-bit value converted from big endian to host endian.

`uint32_t net_buf_simple_pull_le32(struct net_buf_simple *buf)`
Remove and convert 32 bits from the beginning of the buffer.

Same idea as with `net_buf_simple_pull()`, but a helper for operating on 32-bit little endian data.

**Parameters**
- `buf` – A valid pointer on a buffer.

**Returns**  32-bit value converted from little endian to host endian.
uint32_t net_buf_simple_pull_be32(struct net_buf_simple *buf)
Remove and convert 32 bits from the beginning of the buffer.

Same idea as with net_buf_simple_pull(), but a helper for operating on 32-bit big endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns

32-bit value converted from big endian to host endian.

uint64_t net_buf_simple_pull_le48(struct net_buf_simple *buf)
Remove and convert 48 bits from the beginning of the buffer.

Same idea as with net_buf_simple_pull(), but a helper for operating on 48-bit little endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns

48-bit value converted from little endian to host endian.

uint64_t net_buf_simple_pull_be48(struct net_buf_simple *buf)
Remove and convert 48 bits from the beginning of the buffer.

Same idea as with net_buf_simple_pull(), but a helper for operating on 48-bit big endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns

48-bit value converted from big endian to host endian.

uint64_t net_buf_simple_pull_le64(struct net_buf_simple *buf)
Remove and convert 64 bits from the beginning of the buffer.

Same idea as with net_buf_simple_pull(), but a helper for operating on 64-bit little endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns

64-bit value converted from little endian to host endian.

uint64_t net_buf_simple_pull_be64(struct net_buf_simple *buf)
Remove and convert 64 bits from the beginning of the buffer.

Same idea as with net_buf_simple_pull(), but a helper for operating on 64-bit big endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns

64-bit value converted from big endian to host endian.

static inline uint8_t *net_buf_simple_tail(struct net_buf_simple *buf)
Get the tail pointer for a buffer.

Get a pointer to the end of the data in a buffer.

Parameters

- buf – Buffer.

Returns

Tail pointer for the buffer.

size_t net_buf_simple_headroom(struct net_buf_simple *buf)
Check buffer headroom.

Check how much free space there is in the beginning of the buffer.

buf A valid pointer on a buffer
**size_t** net_buf_simple_tailroom(struct net_buf_simple *buf)

Check buffer tailroom.

**Parameters**

• buf – A valid pointer on a buffer

**Returns** Number of bytes available at the end of the buffer.

**uint16_t** net_buf_simple_max_len(struct net_buf_simple *buf)

Check maximum net_buf_simple::len value.

This value is depending on the number of bytes being reserved as headroom.

**Parameters**

• buf – A valid pointer on a buffer

**static inline void** net_buf_simple_save(struct net_buf_simple *buf, struct net_buf_simple_state *state)

Save the parsing state of a buffer.

Saves the parsing state of a buffer so it can be restored later.

**Parameters**

• buf – Buffer from which the state should be saved.
• state – Storage for the state.

**static inline void** net_buf_simple_restore(struct net_buf_simple *buf, struct net_buf_simple_state *state)

Restore the parsing state of a buffer.

Restores the parsing state of a buffer from a state previously stored by net_buf_simple_save().

**Parameters**

• buf – Buffer to which the state should be restored.
• state – Stored state.

**struct net_buf_pool **net_buf_pool_get(int id)

Looks up a pool based on its ID.

**Parameters**

• id – Pool ID (e.g. from buf->pool_id).

**Returns** Pointer to pool.

**int** net_buf_id(struct net_buf *buf)

Get a zero-based index for a buffer.

This function will translate a buffer into a zero-based index, based on its placement in its buffer pool. This can be useful if you want to associate an external array of meta-data contexts with the buffers of a pool.

**Parameters**

• buf – Network buffer.

**Returns** Zero-based index for the buffer.

**struct net_buf **net_buf_alloc_fixed(struct net_buf_pool *pool, k_timeout_t timeout)

Allocate a new fixed buffer from a pool.

**Parameters**
• pool – Which pool to allocate the buffer from.
• timeout – Affects the action taken should the pool be empty. If K_NO_WAIT, then return immediately. If K_FOREVER, then wait as long as necessary. Otherwise, wait until the specified timeout. Note that some types of data allocators do not support blocking (such as the HEAP type). In this case it's still possible for net_buf_alloc() to fail (return NULL) even if it was given K_FOREVER.

Returns New buffer or NULL if out of buffers.

static inline struct net_buf *net_buf_alloc(struct net_buf_pool *pool, k_timeout_t timeout)

Parameters
• pool – Which pool to allocate the buffer from.
• timeout – Affects the action taken should the pool be empty. If K_NO_WAIT, then return immediately. If K_FOREVER, then wait as long as necessary. Otherwise, wait until the specified timeout. Note that some types of data allocators do not support blocking (such as the HEAP type). In this case it's still possible for net_buf_alloc() to fail (return NULL) even if it was given K_FOREVER.

Returns New buffer or NULL if out of buffers.

struct net_buf *net_buf_alloc_len(struct net_buf_pool *pool, size_t size, k_timeout_t timeout)

Allocate a new variable length buffer from a pool.

Parameters
• pool – Which pool to allocate the buffer from.
• size – Amount of data the buffer must be able to fit.
• timeout – Affects the action taken should the pool be empty. If K_NO_WAIT, then return immediately. If K_FOREVER, then wait as long as necessary. Otherwise, wait until the specified timeout. Note that some types of data allocators do not support blocking (such as the HEAP type). In this case it's still possible for net_buf_alloc() to fail (return NULL) even if it was given K_FOREVER.

Returns New buffer or NULL if out of buffers.

struct net_buf *net_buf_alloc_with_data(struct net_buf_pool *pool, void *data, size_t size, k_timeout_t timeout)

Allocate a new buffer from a pool but with external data pointer.

Allocate a new buffer from a pool, where the data pointer comes from the user and not from the pool.

Parameters
• pool – Which pool to allocate the buffer from.
• data – External data pointer
• size – Amount of data the pointed data buffer if able to fit.
• timeout – Affects the action taken should the pool be empty. If K_NO_WAIT, then return immediately. If K_FOREVER, then wait as long as necessary. Otherwise, wait until the specified timeout. Note that some types of data allocators do not support blocking (such as the HEAP type). In this case it's still possible for net_buf_alloc() to fail (return NULL) even if it was given K_FOREVER.

Returns New buffer or NULL if out of buffers.

struct net_buf *net_buf_get(struct k_fifo *fifo, k_timeout_t timeout)

Get a buffer from a FIFO.

This function is NOT thread-safe if the buffers in the FIFO contain fragments.
Parameters

- `fifo` – Which FIFO to take the buffer from.
- `timeout` – Affects the action taken should the FIFO be empty. If K_NO_WAIT, then return immediately. If K_FOREVER, then wait as long as necessary. Otherwise, wait until the specified timeout.

Returns

New buffer or NULL if the FIFO is empty.

```c
static inline void net_buf_destroy(struct net_buf *buf)

Destroy buffer from custom destroy callback.
```

This helper is only intended to be used from custom destroy callbacks. If no custom destroy callback is given to NET_BUF_POOL_*_DEFINE() then there is no need to use this API.

Parameters

- `buf` – Buffer to destroy.

```c
void net_buf_reset(struct net_buf *buf)

Reset buffer.
```

Reset buffer data and flags so it can be reused for other purposes.

Parameters

- `buf` – Buffer to reset.

```c
void net_buf_simple_reserve(struct net_buf_simple *buf, size_t reserve)

Initialize buffer with the given headroom.
```

The buffer is not expected to contain any data when this API is called.

Parameters

- `buf` – Buffer to initialize.
- `reserve` – How much headroom to reserve.

```c
void net_buf_slist_put(sys_slist_t *list, struct net_buf *buf)

Put a buffer into a list.
```

If the buffer contains follow-up fragments this function will take care of inserting them as well into the list.

Parameters

- `list` – Which list to append the buffer to.
- `buf` – Buffer.

```c
struct net_buf *net_buf_slist_get(sys_slist_t *list)

Get a buffer from a list.
```

If the buffer had any fragments, these will automatically be recovered from the list as well and be placed to the buffer's fragment list.

Parameters

- `list` – Which list to take the buffer from.

Returns

New buffer or NULL if the FIFO is empty.

```c
void net_buf_put(struct k_fifo *fifo, struct net_buf *buf)

Put a buffer to the end of a FIFO.
```

If the buffer contains follow-up fragments this function will take care of inserting them as well into the FIFO.

Parameters

- `fifo` – Which FIFO to put the buffer to.
void net_buf_unref(struct net_buf *buf)
Decrement the reference count of a buffer.

Parameters
• buf – A valid pointer on a buffer

struct net_buf *net_buf_ref(struct net_buf *buf)
Increment the reference count of a buffer.

Parameters
• buf – A valid pointer on a buffer

Returns the buffer newly referenced

struct net_buf *net_buf_clone(struct net_buf *buf, k_timeout_t timeout)
Clone buffer.

Duplicate given buffer including any data and headers currently stored.

Parameters
• buf – A valid pointer on a buffer
• timeout – Affects the action taken should the pool be empty. If K_NO_WAIT, then return immediately. If K_FOREVER, then wait as long as necessary. Otherwise, wait until the specified timeout.

Returns Cloned buffer or NULL if out of buffers.

static inline void *net_buf_user_data(const struct net_buf *buf)
Get a pointer to the user data of a buffer.

Parameters
• buf – A valid pointer on a buffer

Returns Pointer to the user data of the buffer.

static inline void net_buf_reserve(struct net_buf *buf, size_t reserve)
Initialize buffer with the given headroom.

The buffer is not expected to contain any data when this API is called.

Parameters
• buf – Buffer to initialize.
• reserve – How much headroom to reserve.

static inline void *net_buf_add(struct net_buf *buf, size_t len)
Prepare data to be added at the end of the buffer.

Increments the data length of a buffer to account for more data at the end.

Parameters
• buf – Buffer to update.
• len – Number of bytes to increment the length with.

Returns The original tail of the buffer.

static inline void *net_buf_add_mem(struct net_buf *buf, const void *mem, size_t len)
Copies the given number of bytes to the end of the buffer.

Increments the data length of the buffer to account for more data at the end.

Parameters
• **buf** – Buffer to update.
• **mem** – Location of data to be added.
• **len** – Length of data to be added

**Returns** The original tail of the buffer.

```c
static inline uint8_t * net_buf_add_u8(struct net_buf *buf, uint8_t val)
```

Add (8-bit) byte at the end of the buffer.

Increments the data length of the buffer to account for more data at the end.

**Parameters**

• **buf** – Buffer to update.
• **val** – byte value to be added.

**Returns** Pointer to the value added

```c
static inline void net_buf_add_le16(struct net_buf *buf, uint16_t val)
```

Add 16-bit value at the end of the buffer.

Adds 16-bit value in little endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• **buf** – Buffer to update.
• **val** – 16-bit value to be added.

```c
static inline void net_buf_add_be16(struct net_buf *buf, uint16_t val)
```

Add 16-bit value at the end of the buffer.

Adds 16-bit value in big endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• **buf** – Buffer to update.
• **val** – 16-bit value to be added.

```c
static inline void net_buf_add_le24(struct net_buf *buf, uint32_t val)
```

Add 24-bit value at the end of the buffer.

Adds 24-bit value in little endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• **buf** – Buffer to update.
• **val** – 24-bit value to be added.

```c
static inline void net_buf_add_be24(struct net_buf *buf, uint32_t val)
```

Add 24-bit value at the end of the buffer.

Adds 24-bit value in big endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• **buf** – Buffer to update.
• **val** – 24-bit value to be added.

```c
static inline void net_buf_add_le32(struct net_buf *buf, uint32_t val)
```

Add 32-bit value at the end of the buffer.

Adds 32-bit value in little endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

**Parameters**

• **buf** – Buffer to update.
• **val** – 32-bit value to be added.
Parameters
- buf – Buffer to update.
- val – 32-bit value to be added.

static inline void net_buf_add_be32(struct net_buf *buf, uint32_t val)
Add 32-bit value at the end of the buffer.

Adds 32-bit value in big endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

Parameters
- buf – Buffer to update.
- val – 32-bit value to be added.

static inline void net_buf_add_le48(struct net_buf *buf, uint64_t val)
Add 48-bit value at the end of the buffer.

Adds 48-bit value in little endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

Parameters
- buf – Buffer to update.
- val – 48-bit value to be added.

static inline void net_buf_add_be48(struct net_buf *buf, uint64_t val)
Add 48-bit value at the end of the buffer.

Adds 48-bit value in big endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

Parameters
- buf – Buffer to update.
- val – 48-bit value to be added.

static inline void net_buf_add_le64(struct net_buf *buf, uint64_t val)
Add 64-bit value at the end of the buffer.

Adds 64-bit value in little endian format at the end of buffer. Increments the data length of a buffer to account for more data at the end.

Parameters
- buf – Buffer to update.
- val – 64-bit value to be added.

static inline void *net_buf_remove_mem(struct net_buf *buf, size_t len)
Remove data from the end of the buffer.

Removes data from the end of the buffer by modifying the buffer length.

Parameters
- buf – Buffer to update.
• len – Number of bytes to remove.

Returns New end of the buffer data.

static inline uint8_t net_buf_remove_u8(struct net_buf *buf)
Remove a 8-bit value from the end of the buffer.

Same idea as with net_buf_remove_mem(), but a helper for operating on 8-bit values.

Parameters
• buf – A valid pointer on a buffer.

Returns The 8-bit removed value.

static inline uint16_t net_buf_remove_le16(struct net_buf *buf)
Remove and convert 16 bits from the end of the buffer.

Same idea as with net_buf_remove_mem(), but a helper for operating on 16-bit little endian data.

Parameters
• buf – A valid pointer on a buffer.

Returns 16-bit value converted from little endian to host endian.

static inline uint16_t net_buf_remove_be16(struct net_buf *buf)
Remove and convert 16 bits from the end of the buffer.

Same idea as with net_buf_remove_mem(), but a helper for operating on 16-bit big endian data.

Parameters
• buf – A valid pointer on a buffer.

Returns 16-bit value converted from big endian to host endian.

static inline uint32_t net_buf_remove_be24(struct net_buf *buf)
Remove and convert 24 bits from the end of the buffer.

Same idea as with net_buf_remove_mem(), but a helper for operating on 24-bit big endian data.

Parameters
• buf – A valid pointer on a buffer.

Returns 24-bit value converted from big endian to host endian.

static inline uint32_t net_buf_remove_le24(struct net_buf *buf)
Remove and convert 24 bits from the end of the buffer.

Same idea as with net_buf_remove_mem(), but a helper for operating on 24-bit little endian data.

Parameters
• buf – A valid pointer on a buffer.

Returns 24-bit value converted from little endian to host endian.
static inline uint32_t net_buf_remove_be32(struct net_buf *buf)
    Remove and convert 32 bits from the end of the buffer.
    Same idea as with net_buf_remove_mem(), but a helper for operating on 32-bit big endian
data.

Parameters
    • buf – A valid pointer on a buffer

Returns 32-bit value converted from big endian to host endian.

static inline uint64_t net_buf_remove_le48(struct net_buf *buf)
    Remove and convert 48 bits from the end of the buffer.
    Same idea as with net_buf_remove_mem(), but a helper for operating on 48-bit little endian
data.

Parameters
    • buf – A valid pointer on a buffer.

Returns 48-bit value converted from little endian to host endian.

static inline uint64_t net_buf_remove_be48(struct net_buf *buf)
    Remove and convert 48 bits from the end of the buffer.
    Same idea as with net_buf_remove_mem(), but a helper for operating on 48-bit big endian
data.

Parameters
    • buf – A valid pointer on a buffer

Returns 48-bit value converted from big endian to host endian.

static inline uint64_t net_buf_remove_le64(struct net_buf *buf)
    Remove and convert 64 bits from the end of the buffer.
    Same idea as with net_buf_remove_mem(), but a helper for operating on 64-bit little endian
data.

Parameters
    • buf – A valid pointer on a buffer.

Returns 64-bit value converted from little endian to host endian.

static inline void *net_buf_push(struct net_buf *buf, size_t len)
    Prepare data to be added at the start of the buffer.
    Modifies the data pointer and buffer length to account for more data in the beginning of
the buffer.

Parameters
    • buf – Buffer to update.
    • len – Number of bytes to add to the beginning.

Returns The new beginning of the buffer data.
static inline void *net_buf_push_mem(struct net_buf *buf, const void *mem, size_t len)
Copies the given number of bytes to the start of the buffer.
Modifies the data pointer and buffer length to account for more data in the beginning of the buffer.

Parameters
• buf – Buffer to update.
• mem – Location of data to be added.
• len – Length of data to be added.

Returns The new beginning of the buffer data.

static inline void net_buf_push_u8(struct net_buf *buf, uint8_t val)
Push 8-bit value to the beginning of the buffer.
Adds 8-bit value the beginning of the buffer.

Parameters
• buf – Buffer to update.
• val – 8-bit value to be pushed to the buffer.

static inline void net_buf_push_le16(struct net_buf *buf, uint16_t val)
Push 16-bit value in little endian format to the beginning of the buffer.

Parameters
• buf – Buffer to update.
• val – 16-bit value to be pushed to the buffer.

static inline void net_buf_push_be16(struct net_buf *buf, uint16_t val)
Push 16-bit value in big endian format to the beginning of the buffer.

Parameters
• buf – Buffer to update.
• val – 16-bit value to be pushed to the buffer.

static inline void net_buf_push_le24(struct net_buf *buf, uint32_t val)
Push 24-bit value in little endian format to the beginning of the buffer.

Parameters
• buf – Buffer to update.
• val – 24-bit value to be pushed to the buffer.

static inline void net_buf_push_be24(struct net_buf *buf, uint32_t val)
Push 24-bit value in big endian format to the beginning of the buffer.

Parameters
• buf – Buffer to update.
• val – 24-bit value to be pushed to the buffer.

static inline void net_buf_push_le32(struct net_buf *buf, uint32_t val)
Push 32-bit value in little endian format to the beginning of the buffer.

Parameters
• buf – Buffer to update.
• val – 24-bit value to be pushed to the buffer.
Parameters

- **buf** – Buffer to update.
- **val** – 32-bit value to be pushed to the buffer.

static inline void net_buf_push_be32(struct net_buf *buf, uint32_t val)
Push 32-bit value to the beginning of the buffer.

Adds 32-bit value in big endian format to the beginning of the buffer.

Parameters

- **buf** – Buffer to update.
- **val** – 32-bit value to be pushed to the buffer.

static inline void net_buf_push_le48(struct net_buf *buf, uint64_t val)
Push 48-bit value to the beginning of the buffer.

Adds 48-bit value in little endian format to the beginning of the buffer.

Parameters

- **buf** – Buffer to update.
- **val** – 48-bit value to be pushed to the buffer.

static inline void net_buf_push_be48(struct net_buf *buf, uint64_t val)
Push 48-bit value to the beginning of the buffer.

Adds 48-bit value in big endian format to the beginning of the buffer.

Parameters

- **buf** – Buffer to update.
- **val** – 48-bit value to be pushed to the buffer.

static inline void net_buf_push_le64(struct net_buf *buf, uint64_t val)
Push 64-bit value to the beginning of the buffer.

Adds 64-bit value in little endian format to the beginning of the buffer.

Parameters

- **buf** – Buffer to update.
- **val** – 64-bit value to be pushed to the buffer.

static inline void net_buf_push_be64(struct net_buf *buf, uint64_t val)
Push 64-bit value to the beginning of the buffer.

Adds 64-bit value in big endian format to the beginning of the buffer.

Parameters

- **buf** – Buffer to update.
- **len** – Number of bytes to remove.

static inline void *net_buf_pull(struct net_buf *buf, size_t len)
Remove data from the beginning of the buffer.

Removes data from the beginning of the buffer by modifying the data pointer and buffer length.

Parameters

- **buf** – Buffer to update.
- **len** – Number of bytes to remove.

Returns New beginning of the buffer data.
static inline void *net_buf_pull_mem(struct net_buf *buf, size_t len)
Remove data from the beginning of the buffer.
Removes data from the beginning of the buffer by modifying the data pointer and buffer length.

Parameters

- buf – Buffer to update.
- len – Number of bytes to remove.

Returns Pointer to the old beginning of the buffer data.

static inline uint8_t net_buf_pull_u8(struct net_buf *buf)
Remove a 8-bit value from the beginning of the buffer.
Same idea as with net_buf_pull(), but a helper for operating on 8-bit values.

Parameters

- buf – A valid pointer on a buffer.

Returns The 8-bit removed value

static inline uint16_t net_buf_pull_le16(struct net_buf *buf)
Remove and convert 16 bits from the beginning of the buffer.
Same idea as with net_buf_pull(), but a helper for operating on 16-bit little endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns 16-bit value converted from little endian to host endian.

static inline uint16_t net_buf_pull_be16(struct net_buf *buf)
Remove and convert 16 bits from the beginning of the buffer.
Same idea as with net_buf_pull(), but a helper for operating on 16-bit big endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns 16-bit value converted from big endian to host endian.

static inline uint32_t net_buf_pull_le24(struct net_buf *buf)
Remove and convert 24 bits from the beginning of the buffer.
Same idea as with net_buf_pull(), but a helper for operating on 24-bit little endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns 24-bit value converted from little endian to host endian.

static inline uint32_t net_buf_pull_be24(struct net_buf *buf)
Remove and convert 24 bits from the beginning of the buffer.
Same idea as with net_buf_pull(), but a helper for operating on 24-bit big endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns 24-bit value converted from big endian to host endian.

static inline uint32_t net_buf_pull_le32(struct net_buf *buf)
Remove and convert 32 bits from the beginning of the buffer.
Same idea as with net_buf_pull(), but a helper for operating on 32-bit little endian data.

Parameters

- buf – A valid pointer on a buffer.

Returns 32-bit value converted from little endian to host endian.
• buf – A valid pointer on a buffer.

**Returns** 32-bit value converted from little endian to host endian.

```c
static inline uint32_t net_buf_pull_be32(struct net_buf *buf)
```

Remove and convert 32 bits from the beginning of the buffer.

Same idea as with `net_buf_pull()`, but a helper for operating on 32-bit big endian data.

**Parameters**

• buf – A valid pointer on a buffer

**Returns** 32-bit value converted from big endian to host endian.

```c
static inline uint64_t net_buf_pull_le48(struct net_buf *buf)
```

Remove and convert 48 bits from the beginning of the buffer.

Same idea as with `net_buf_pull()`, but a helper for operating on 48-bit little endian data.

**Parameters**

• buf – A valid pointer on a buffer

**Returns** 48-bit value converted from little endian to host endian.

```c
static inline uint64_t net_buf_pull_be48(struct net_buf *buf)
```

Remove and convert 48 bits from the beginning of the buffer.

Same idea as with `net_buf_pull()`, but a helper for operating on 48-bit big endian data.

**Parameters**

• buf – A valid pointer on a buffer

**Returns** 48-bit value converted from big endian to host endian.

```c
static inline uint64_t net_buf_pull_le64(struct net_buf *buf)
```

Remove and convert 64 bits from the beginning of the buffer.

Same idea as with `net_buf_pull()`, but a helper for operating on 64-bit little endian data.

**Parameters**

• buf – A valid pointer on a buffer

**Returns** 64-bit value converted from little endian to host endian.

```c
static inline size_t net_buf_tailroom(struct net_buf *buf)
```

Check buffer tailroom.

Check how much free space there is at the end of the buffer.

**Parameters**

• buf – A valid pointer on a buffer

**Returns** Number of bytes available at the end of the buffer.

```c
static inline size_t net_buf_headroom(struct net_buf *buf)
```

Check buffer headroom.

Check how much free space there is in the beginning of the buffer.
buf A valid pointer on a buffer

**Returns** Number of bytes available in the beginning of the buffer.

static inline uint16_t net_buf_max_len(struct net_buf *buf)
Check maximum net_buf::len value.

This value is depending on the number of bytes being reserved as headroom.

**Parameters**
- buf – A valid pointer on a buffer

**Returns** Number of bytes usable behind the net_buf::data pointer.

static inline uint8_t *net_buf_tail(struct net_buf *buf)
Get the tail pointer for a buffer.

Get a pointer to the end of the data in a buffer.

**Parameters**
- buf – Buffer.

**Returns** Tail pointer for the buffer.

struct net_buf *net_buf_frag_last(struct net_buf *frags)
Find the last fragment in the fragment list.

**Returns** Pointer to last fragment in the list.

void net_buf_frag_insert(struct net_buf *parent, struct net_buf *frag)
Insert a new fragment to a chain of bufs.

Insert a new fragment into the buffer fragments list after the parent.

Note: This function takes ownership of the fragment reference so the caller is not required to unref.

**Parameters**
- parent – Parent buffer/fragment.
- frag – Fragment to insert.

struct net_buf *net_buf_frag_add(struct net_buf *head, struct net_buf *frag)
Add a new fragment to the end of a chain of bufs.

Append a new fragment into the buffer fragments list.

Note: This function takes ownership of the fragment reference so the caller is not required to unref.

**Parameters**
- head – Head of the fragment chain.
- frag – Fragment to add.

**Returns** New head of the fragment chain. Either head (if head was non-NULL) or frag (if head was NULL).

struct net_buf *net_buf_frag_del(struct net_buf *parent, struct net_buf *frag)
Delete existing fragment from a chain of bufs.

**Parameters**
- parent – Parent buffer/fragment, or NULL if there is no parent.
- frag – Fragment to delete.

**Returns** Pointer to the buffer following the fragment, or NULL if it had no further fragments.
size_t net_buf_linearize(void *dst, size_t dst_len, struct net_buf *src, size_t offset, size_t len)
Copy bytes from net_buf chain starting at offset to linear buffer.

Copy (extract) len bytes from src net_buf chain, starting from offset in it, to a linear buffer dst. Return number of bytes actually copied, which may be less than requested, if net_buf chain doesn’t have enough data, or destination buffer is too small.

Parameters
• dst – Destination buffer
• dst_len – Destination buffer length
• src – Source net_buf chain
• offset – Starting offset to copy from
• len – Number of bytes to copy

Returns number of bytes actually copied

size_t net_buf_append_bytes(struct net_buf *buf, size_t len, const void *value, k_timeout_t timeout, net_buf_allocator_cb allocate_cb, void *user_data)
Append data to a list of net_buf.

Append data to a net_buf. If there is not enough space in the net_buf then more net_buf will be added, unless there are no free net_buf and timeout occurs. If not allocator is provided it attempts to allocate from the same pool as the original buffer.

Parameters
• buf – Network buffer.
• len – Total length of input data
• value – Data to be added
• timeout – Timeout is passed to the net_buf allocator callback.
• allocate_cb – When a new net_buf is required, use this callback.
• user_data – A user data pointer to be supplied to the allocate_cb. This pointer is can be anything from a mem_pool or a net_pkt, the logic is left up to the allocate_cb function.

Returns Length of data actually added. This may be less than input length if other timeout than K_FOREVER was used, and there were no free fragments in a pool to accommodate all data.

static inline struct net_buf *net_buf_skip(struct net_buf *buf, size_t len)
Skip N number of bytes in a net_buf.

Skip N number of bytes starting from fragment’s offset. If the total length of data is placed in multiple fragments, this function will skip from all fragments until it reaches N number of bytes. Any fully skipped buffers are removed from the net_buf list.

Parameters
• buf – Network buffer.
• len – Total length of data to be skipped.

Returns Pointer to the fragment or NULL and pos is 0 after successful skip, NULL and pos is 0xffff otherwise.

static inline size_t net_buf_frags_len(struct net_buf *buf)
Calculate amount of bytes stored in fragments.

Calculates the total amount of data stored in the given buffer and the fragments linked to it.

Parameters
• buf – Buffer to start off with.

**Returns**  Number of bytes in the buffer and its fragments.

```c
struct net_buf_simple
#include <buf.h> Simple network buffer representation.

This is a simpler variant of the net_buf object (in fact net_buf uses net_buf_simple internally). It doesn’t provide any kind of reference counting, user data, dynamic allocation, or in general the ability to pass through kernel objects such as FIFOs.

The main use of this is for scenarios where the meta-data of the normal net_buf isn’t needed and causes too much overhead. This could be e.g. when the buffer only needs to be allocated on the stack or when the access to and lifetime of the buffer is well controlled and constrained.

Public Members

```c
uint8_t *data
  Pointer to the start of data in the buffer.

uint16_t len
  Length of the data behind the data pointer.

To determine the max length, use net_buf_simple_max_len(), not size!

uint16_t size
  Amount of data that net_buf_simple::__buf can store.
```

```c
struct net_buf_simple_state
#include <buf.h> Parsing state of a buffer.

This is used for temporarily storing the parsing state of a buffer while giving control of the parsing to a routine which we don’t control.

Public Members

```c
uint16_t offset
  Offset of the data pointer from the beginning of the storage

uint16_t len
  Length of data
```

```c
struct net_buf
#include <buf.h> Network buffer representation.

This struct is used to represent network buffers. Such buffers are normally defined through the NET_BUF_POOL_ * _DEFINE() APIs and allocated using the net_buf_alloc() API.

Public Members

```c
sys_snode_t node
  Allow placing the buffer into sys_slist_t

struct net_buf *frags
  Fragments associated with this buffer.
```
# Zephyr Project Documentation, Release 3.0.99

## Networking

```c
uint8_t ref
    Reference count.

uint8_t flags
    Bit-field of buffer flags.

uint8_t pool_id
    Where the buffer should go when freed up.

uint8_t *data
    Pointer to the start of data in the buffer.

uint16_t len
    Length of the data behind the data pointer.

uint16_t size
    Amount of data that this buffer can store.

uint8_t user_data[]
    System metadata for this buffer.

struct net_buf_data_cb
    #include <buf.h>

struct net_buf_data_alloc
    #include <buf.h>

struct net_buf_pool
    #include <buf.h> Network buffer pool representation.

    This struct is used to represent a pool of network buffers.

**Public Members**

```c
struct k_lifo free
    LIFO to place the buffer into when free

const uint16_t buf_count
    Number of buffers in pool

uint16_t uninit_count
    Number of uninitialized buffers

void (*const destroy)(struct net_buf *buf)
    Optional destroy callback when buffer is freed.

const struct net_buf_data_alloc *alloc
    Data allocation handlers.

struct net_buf_pool_fixed
    #include <buf.h>
```
Packet Management

  - Data access

- **API Reference**

**Overview**  Network packets are the main data the networking stack manipulates. Such data is represented through the net_pkt structure which provides a means to hold the packet, write and read it, as well as necessary metadata for the core to hold important information. Such an object is called net_pkt in this document.

The data structure and the whole API around it are defined in include/net/net_pkt.h.

**Architectural notes**  There are two network packets flows within the stack, TX for the transmission path, and RX for the reception one. In both paths, each net_pkt is written and read from the beginning to the end, or more specifically from the headers to the payload.

**Memory management**

**Allocation**  All net_pkt objects come from a pre-defined pool of struct net_pkt. Such pool is defined via

```c
NET_PKT_SLAB_DEFINE(name, count)
```

Note, however, one will rarely have to use it, as the core provides already two pools, one for the TX path and one for the RX path.

Allocating a raw net_pkt can be done through:

```c
pkt = net_pkt_alloc(timeout);
```

However, by its nature, a raw net_pkt is useless without a buffer and needs various metadata information to become relevant as well. It requires at least to get the network interface it is meant to be sent through or through which it was received. As this is a very common operation, a helper exist:

```c
pkt = net_pkt_alloc_on_iface(iface, timeout);
```

A more complete allocator exists, where both the net_pkt and its buffer can be allocated at once:

```c
pkt = net_pkt_alloc_with_buffer(iface, size, family, proto, timeout);
```

See below how the buffer is allocated.
Buffer allocation  The net_pkt object does not define its own buffer, but instead uses an existing object for this: net_buf. (See Network Buffer for more information). However, it mostly hides the usage of such a buffer because net_pkt brings network awareness to buffer allocation and, as we will see later, its operation too.

To allocate a buffer, a net_pkt needs to have at least its network interface set. This works if the family of the packet is unknown at the time of buffer allocation. Then one could do:

```
net_pkt_alloc_buffer(pkt, size, proto, timeout);
```

Where proto could be 0 if unknown (there is no IPPROTO_UNSPEC).

As seen previously, the net_pkt and its buffer can be allocated at once via `net_pkt_alloc_with_buffer()`. It is actually the most widely used allocator.

The network interface, the family, and the protocol of the packet are used by the buffer allocation to determine if the requested size can be allocated. Indeed, the allocator will use the network interface to know the MTU and then the family and protocol for the headers space (if only these 2 are specified). If the whole fits within the MTU, the allocated space will be of the requested size plus, eventually, the headers space. If there is insufficient MTU space, the requested size will be shrunk so the possible headers space and new size will fit within the MTU.

For instance, on an Ethernet network interface, with an MTU of 1500 bytes:

```
pkt = net_pkt_alloc_with_buffer(iface, 800, AF_INET4, IPPROTO_UDP, K_FOREVER);
```

will successfully allocate 800 + 20 + 8 bytes of buffer for the new net_pkt where:

```
pkt = net_pkt_alloc_with_buffer(iface, 1600, AF_INET4, IPPROTO_UDP, K_FOREVER);
```

will successfully allocate 1500 bytes, and where 20 + 8 bytes (IPv4 + UDP headers) will not be used for the payload.

On the receiving side, when the family and protocol are not known:

```
pkt = net_pkt_rx_alloc_with_buffer(iface, 800, AF_UNSPEC, 0, K_FOREVER);
```

will allocate 800 bytes and no extra header space. But a:

```
pkt = net_pkt_rx_alloc_with_buffer(iface, 1600, AF_UNSPEC, 0, K_FOREVER);
```

will allocate 1514 bytes, the MTU + Ethernet header space.

One can increase the amount of buffer space allocated by calling `net_pkt_alloc_buffer()`, as it will take into account the existing buffer. It will also account for the header space if net_pkt's family is a valid one, as well as the proto parameter. In that case, the newly allocated buffer space will be appended to the existing one, and not inserted in the front. Note however such a use case is rather limited. Usually, one should know from the start how much size should be requested.

Deallocation  Each net_pkt is reference counted. At allocation, the reference is set to 1. The reference count can be incremented with `net_pkt_ref()` or decremented with `net_pkt_unref()`. When the count drops to zero the buffer is also un-referenced and net_pkt is automatically placed back into the free net_pkt_slabs

If net_pkt's buffer is needed even after net_pkt deallocation, one will need to reference once more all the chain of net_buf before calling last net_pkt_unref. See Network Buffer for more information.

Operations  There are two ways to access the net_pkt buffer, explained in the following sections: basic read/write access and data access, the latter being the preferred way.
Read and Write access  As said earlier, though net_pkt uses net_buf for its buffer, it provides its own API to access it. Indeed, a network packet might be scattered over a chain of net_buf objects, the functions provided by net_buf are then limited for such case. Instead, net_pkt provides functions which hide all the complexity of potential non-contiguous access.

Data movement into the buffer is made through a cursor maintained within each net_pkt. All read/write operations affect this cursor. Note as well that read or write functions are strict on their length parameters: if it cannot r/w the given length it will fail. Length is not interpreted as an upper limit, it is instead the exact amount of data that must be read or written.

As there are two paths, TX and RX, there are two access modes: write and overwrite. This might sound a bit unusual, but is in fact simple and provides flexibility.

In write mode, whatever is written in the buffer affects the length of actual data present in the buffer. Buffer length should not be confused with the buffer size which is a limit any mode cannot pass. In overwrite mode then, whatever is written must happen on valid data, and will not affect the buffer length. By default, a newly allocated net_pkt is on write mode, and its cursor points to the beginning of its buffer.

Let's see now, step by step, the functions and how they behave depending on the mode.

When freshly allocated with a buffer of 500 bytes, a net_pkt has 0 length, which means no valid data is in its buffer. One could verify this by:

```c
len = net_pkt_get_len(pkt);
```

Now, let's write 8 bytes:

```c
net_pkt_write(pkt, data, 8);
```

The buffer length is now 8 bytes. There are various helpers to write a byte, or big endian uint16_t, uint32_t.

```c
net_pkt_write_u8(pkt, &foo);
net_pkt_write_be16(pkt, &ba);
net_pkt_write_be32(pkt, &bar);
```

Logically, net_pkt's length is now 15. But if we try to read at this point, it will fail because there is nothing to read at the cursor where we are at in the net_pkt. It is possible, while in write mode, to read what has been already written by resetting the cursor of the net_pkt. For instance:

```c
net_pkt_cursor_init(pkt);
net_pkt_read(pkt, data, 15);
```

This will reset the cursor of the pkt to the beginning of the buffer and then let you read the actual 15 bytes present. The cursor is then again pointing at the end of the buffer.

To set a large area with the same byte, a memset function is provided:

```c
net_pkt_memcpy(pkt, 0, 5);
```

Our net_pkt has now a length of 20 bytes.

Switching between modes can be achieved via net_pkt_set_overwrite() function. It is possible to switch mode back and forth at any time. The net_pkt will be set to overwrite and its cursor reset:

```c
net_pkt_set_overwrite(pkt, true);
net_pkt_cursor_init(pkt);
```

Now the same operators can be used, but it will be limited to the existing data in the buffer, i.e. 20 bytes. If it is necessary to know how much space is available in the net_pkt call:
net_pkt_available_buffer(pkt);

Or, if headers space needs to be accounted for, call:

net_pkt_available_payload_buffer(pkt, proto);

If you want to place the cursor at a known position use the function net_pkt_skip(). For example, to

go after the IP header, use:

net_pkt_cursor_init(pkt);
net_pkt_skip(pkt, net_pkt_ip_header_len(pkt));

Data access Though the API shown previously is rather simple, it involves always copying things to
and from the net_pkt buffer. In many occasions, it is more relevant to access the information stored in
the buffer contiguously, especially with network packets which embed headers.

These headers are, most of the time, a known fixed set of bytes. It is then more natural to have a
structure representing a certain type of header. In addition to this, if it is known the header size appears
in a contiguous area of the buffer, it will be way more efficient to cast the actual position in the buffer to
the type of header. Either for reading or writing the fields of such header, accessing it directly will save
memory.

Net pkt comes with a dedicated API for this, built on top of the previously described API. It is able to
handle both contiguous and non-contiguous access transparently.

There are two macros used to define a data access descriptor: NET_PKT_DATA_ACCESS_DEFINE when it is not possible to tell if the data will be in a contiguous area, and
NET_PKT_DATA_ACCESS_CONTIGUOUS_DEFINE when it is guaranteed the data is in a contiguous
area.

Let’s take the example of IP and UDP. Both IPv4 and IPv6 headers are always found at the beginning of
the packet and are small enough to fit in a net_buf of 128 bytes (for instance, though 64 bytes could be
chosen).

NET_PKT_DATA_ACCESS_CONTIGUOUS_DEFINE(ipv4_access, struct net_ipv4_hdr);
struct net_ipv4_hdr *ipv4_hdr;
ipv4_hdr = (struct net_ipv4_hdr *)net_pkt_get_data(pkt, &ipv4_access);

It would be the same for struct net_ipv4_hdr. For a UDP header it is likely not to be in a contiguous area
in IPv6 for instance so:

NET_PKT_DATA_ACCESS_DEFINE(udp_access, struct net_udp_hdr);
struct net_udp_hdr *udp_hdr;
udp_hdr = (struct net_udp_hdr *)net_pkt_get_data(pkt, &udp_access);

At this point, the cursor of the net_pkt points at the beginning of the requested data. On the RX path,
these headers will be read but not modified so to proceed further the cursor needs to advance past the
data. There is a function dedicated for this:

net_pkt_acknowledge_data(pkt, &ipv4_access);

On the TX path, however, the header fields have been modified. In such a case:

net_pkt_set_data(pkt, &ipv4_access);

If the data are in a contiguous area, it will advance the cursor relevantly. If not, it will write the data and
the cursor will be updated. Note that net_pkt_set_data() could be used in the RX path as well, but it
is slightly faster to use `net_pkt_acknowledge_data()` as this one does not care about contiguity at all, it just advances the cursor via `net_pkt_skip()` directly.

API Reference

**group net_pkt**

Network packet management library.

**Defines**

**NET_PKT_SLAB_DEFINE**(name, count)

Create a `net_pkt` slab.

A `net_pkt` slab is used to store meta-information about network packets. It must be coupled with a data fragment pool (c:macro:**NET_PKT_DATA_POOL_DEFINE**) used to store the actual packet data. The macro can be used by an application to define additional custom per-context TX packet slabs (see `:c:func:`net_context_setup_pools`).

**Parameters**

- **name** – Name of the slab.
- **count** – Number of `net_pkt` in this slab.

**NET_PKT_TX_SLAB_DEFINE**(name, count)

**NET_PKT_DATA_POOL_DEFINE**(name, count)

Create a data fragment `net_buf` pool.

A `net_buf` pool is used to store actual data for network packets. It must be coupled with a `net_pkt` slab (c:macro:**NET_PKT_SLAB_DEFINE**) used to store the packet meta-information. The macro can be used by an application to define additional custom per-context TX packet pools (see `:c:func:`net_context_setup_pools`).

**Parameters**

- **name** – Name of the pool.
- **count** – Number of `net_buf` in this pool.

**net_pkt_print_frags**(pkt)

Print fragment list and the fragment sizes.

Only available if debugging is activated.

**Parameters**

- **pkt** – Network pkt.

**NET_PKT_DATA_ACCESS_DEFINE**(name, type)

**NET_PKT_DATA_ACCESS_CONTIGUOUS_DEFINE**(name, type)

**Functions**

**struct net_buf **net_pkt_get_reserve_rx_data**(k_timeout_t timeout)**

Get RX DATA buffer from pool. Normally you should use `net_pkt_get_frag()` instead.

Normally this version is not useful for applications but is mainly used by network fragmentation code.

**Parameters**
• timeout – Affects the action taken should the net buf pool be empty. If K_NO_WAIT, then return immediately. If K_FOREVER, then wait as long as necessary. Otherwise, wait up to the specified time.

Returns Network buffer if successful, NULL otherwise.

`struct net_buf *net_pkt_get_reserve_tx_data(k_timeout_t timeout)`

Get TX DATA buffer from pool. Normally you should use `net_pkt_get_frag()` instead.

Normally this version is not useful for applications but is mainly used by network fragmentation code.

Parameters

• timeout – Affects the action taken should the net buf pool be empty. If K_NO_WAIT, then return immediately. If K_FOREVER, then wait as long as necessary. Otherwise, wait up to the specified time.

Returns Network buffer if successful, NULL otherwise.

`struct net_buf *net_pkt_get_frag(struct net_pkt *pkt, k_timeout_t timeout)`

Get a data fragment that might be from user specific buffer pool or from global DATA pool.

Parameters

• pkt – Network packet.
• timeout – Affects the action taken should the net buf pool be empty. If K_NO_WAIT, then return immediately. If K_FOREVER, then wait as long as necessary. Otherwise, wait up to the specified time.

Returns Network buffer if successful, NULL otherwise.

`void net_pkt_unref(struct net_pkt *pkt)`

Place packet back into the available packets slab.

Releases the packet to other use. This needs to be called by application after it has finished with the packet.

Parameters

• pkt – Network packet to release.

`struct net_pkt *net_pkt_ref(struct net_pkt *pkt)`

Increase the packet ref count.

Mark the packet to be used still.

Parameters

• pkt – Network packet to ref.

Returns Network packet if successful, NULL otherwise.

`struct net_buf *net_pkt_frag_ref(struct net_buf *frag)`

Increase the packet fragment ref count.

Mark the fragment to be used still.

Parameters

• frag – Network fragment to ref.

Returns a pointer on the referenced Network fragment.

`void net_pkt_frag_unref(struct net_buf *frag)`

Decrease the packet fragment ref count.

Parameters

• frag – Network fragment to unref.
struct net_buf *net_pkt_frag_del(struct net_pkt *pkt, struct net_buf *parent, struct net_buf *frag)

Delete existing fragment from a packet.

Parameters

• pkt – Network packet from which frag belongs to.
• parent – parent fragment of frag, or NULL if none.
• frag – Fragment to delete.

Returns Pointer to the following fragment, or NULL if it had no further fragments.

void net_pkt_frag_add(struct net_pkt *pkt, struct net_buf *frag)

Add a fragment to a packet at the end of its fragment list.

Parameters

• pkt – pkt Network packet where to add the fragment
• frag – Fragment to add

void net_pkt_frag_insert(struct net_pkt *pkt, struct net_buf *frag)

Insert a fragment to a packet at the beginning of its fragment list.

Parameters

• pkt – pkt Network packet where to insert the fragment
• frag – Fragment to insert

bool net_pkt_compact(struct net_pkt *pkt)

Compact the fragment list of a packet.

After this there is no more any free space in individual fragments.

Parameters

• pkt – Network packet.

Returns True if compact success, False otherwise.

void net_pkt_get_info(struct k_mem_slab **rx, struct k_mem_slab **tx, struct net_buf_pool **rx_data, struct net_buf_pool **tx_data)

Get information about predefined RX, TX and DATA pools.

Parameters

• rx – Pointer to RX pool is returned.
• tx – Pointer to TX pool is returned.
• rx_data – Pointer to RX DATA pool is returned.
• tx_data – Pointer to TX DATA pool is returned.

struct net_pkt *net_pkt_alloc(k_timeout_t timeout)

Allocate an initialized net_pkt.

for the time being, 2 pools are used. One for TX and one for RX. This allocator has to be used for TX.

Parameters

• timeout – Maximum time to wait for an allocation.

Returns a pointer to a newly allocated net_pkt on success, NULL otherwise.

struct net_pkt *net_pkt_alloc_from_slab(struct k_mem_slab *slab, k_timeout_t timeout)

Allocate an initialized net_pkt from a specific slab.

unlike net_pkt_alloc() which uses core slabs, this one will use an external slab (see NET_PKT_SLAB_DEFINE()). Do not use it unless you know what you are doing. Basically,
only net_context should be using this, in order to allocate packet and then buffer on its local slab/pool (if any).

**Parameters**
- **slab** – The slab to use for allocating the packet
- **timeout** – Maximum time to wait for an allocation.

**Returns** a pointer to a newly allocated net_pkt on success, NULL otherwise.

```c
struct net_pkt *net_pkt_rx_alloc(k_timeout_t timeout)
```

Allocate an initialized net_pkt for RX.

for the time being, 2 pools are used. One for TX and one for RX. This allocator has to be used for RX.

**Parameters**
- **timeout** – Maximum time to wait for an allocation.

**Returns** a pointer to a newly allocated net_pkt on success, NULL otherwise.

```c
struct net_pkt *net_pkt_alloc_on_iface(struct net_if *iface, k_timeout_t timeout)
```

Allocate a network packet for a specific network interface.

**Parameters**
- **iface** – The network interface the packet is supposed to go through.
- **timeout** – Maximum time to wait for an allocation.

**Returns** a pointer to a newly allocated net_pkt on success, NULL otherwise.

```c
struct net_pkt *net_pkt_rx_alloc_on_iface(struct net_if *iface, k_timeout_t timeout)
```

Allocate buffer for a net_pkt.

: such allocator will take into account space necessary for headers, MTU, and existing buffer (if any). Beware that, due to all these criteria, the allocated size might be smaller/bigger than requested one.

**Parameters**
- **pkt** – The network packet requiring buffer to be allocated.
- **size** – The size of buffer being requested.
- **proto** – The IP protocol type (can be 0 for none).
- **timeout** – Maximum time to wait for an allocation.

**Returns** 0 on success, negative errno code otherwise.

```c
struct net_pkt *net_pkt_alloc_with_buffer(struct net_if *iface, size_t size, sa_family_t family, enum net_ip_protocol proto, k_timeout_t timeout)
```

Allocate a network packet and buffer at once.

**Parameters**
- **iface** – The network interface the packet is supposed to go through.
- **size** – The size of buffer.
- **family** – The family to which the packet belongs.
- **proto** – The IP protocol type (can be 0 for none).
- **timeout** – Maximum time to wait for an allocation.

**Returns** a pointer to a newly allocated net_pkt on success, NULL otherwise.
struct net_pkt *net_pkt_rx_alloc_with_buffer(struct net_if *iface, size_t size, sa_family_t family, enum net_ip_protocol proto, k_timeout_t timeout)

void net_pkt_append_buffer(struct net_pkt *pkt, struct net_buf *buffer)
Append a buffer in packet.

Parameters
• pkt – Network packet where to append the buffer
• buffer – Buffer to append

size_t net_pkt_available_buffer(struct net_pkt *pkt)
Get available buffer space from a pkt.

Note: Reserved bytes (headroom) in any of the fragments are not considered to be available.

Parameters
• pkt – The net_pkt which buffer availability should be evaluated

Returns the amount of buffer available

size_t net_pkt_available_payload_buffer(struct net_pkt *pkt, enum net_ip_protocol proto)
Get available buffer space for payload from a pkt.

Unlike net_pkt_available_buffer(), this will take into account the headers space.

Note: Reserved bytes (headroom) in any of the fragments are not considered to be available.

Parameters
• pkt – The net_pkt which payload buffer availability should be evaluated
• proto – The IP protocol type (can be 0 for none).

Returns the amount of buffer available for payload

void net_pkt_trim_buffer(struct net_pkt *pkt)
Trim net_pkt buffer.
This will basically check for unused buffers and deallocates them relevantly

Parameters
• pkt – The net_pkt which buffer will be trimmed

int net_pkt_remove_tail(struct net_pkt *pkt, size_t length)
Remove length bytes from tail of packet.
This function does not take packet cursor into account. It is a helper to remove unneeded bytes from tail of packet (like appended CRC). It takes care of buffer deallocation if removed bytes span whole buffer(s).

Parameters
• pkt – Network packet
• length – Number of bytes to removed

Return values
void net_pkt_cursor_init(struct net_pkt *pkt)
    Initialize net_pkt cursor.

This will initialize the net_pkt cursor from its buffer.

Parameters

• pkt – The net_pkt whose cursor is going to be initialized

static inline void net_pkt_cursor_backup(struct net_pkt *pkt, struct net_pkt_cursor *backup)
    Backup net_pkt cursor.

Parameters

• pkt – The net_pkt whose cursor is going to be backed up
• backup – The cursor where to backup net_pkt cursor

static inline void net_pkt_cursor_restore(struct net_pkt *pkt, struct net_pkt_cursor *backup)
    Restore net_pkt cursor from a backup.

Parameters

• pkt – The net_pkt whose cursor is going to be restored
• backup – The cursor from where to restore net_pkt cursor

static inline void *net_pkt_cursor_get_pos(struct net_pkt *pkt)
    Returns current position of the cursor.

Parameters

• pkt – The net_pkt whose cursor position is going to be returned

Returns cursor's position

int net_pkt_skip(struct net_pkt *pkt, size_t length)
    Skip some data from a net_pkt.

net_pkt's cursor should be properly initialized Cursor position will be updated after the operation. Depending on the value of pkt->overwrite bit, this function will affect the buffer length or not. If it's true, it will advance the cursor to the requested length. If it's false, it will do the same but if the cursor was already also at the end of existing data, it will increment the buffer length. So in this case, its behavior is just like net_pkt_write or net_pkt_memset, difference being that it will not affect the buffer content itself (which may be just garbage then).

Parameters

• pkt – The net_pkt whose cursor will be updated to skip given amount of data from the buffer.
• length – Amount of data to skip in the buffer

Returns 0 in success, negative errno code otherwise.

int net_pkt_memset(struct net_pkt *pkt, int byte, size_t length)
    Memset some data in a net_pkt.

net_pkt's cursor should be properly initialized and, if needed, positioned using net_pkt_skip. Cursor position will be updated after the operation.

Parameters

• pkt – The net_pkt whose buffer to fill starting at the current cursor position.
• byte – The byte to write in memory
• length – Amount of data to memset with given byte
Returns 0 in success, negative errno code otherwise.

int net_pkt_copy(struct net_pkt *pkt_dst, struct net_pkt *pkt_src, size_t length)
Copy data from a packet into another one.

Both net_pkt cursors should be properly initialized and, if needed, positioned using net_pkt_skip. The cursors will be updated after the operation.

Parameters
• pkt_dst – Destination network packet.
• pkt_src – Source network packet.
• length – Length of data to be copied.

Returns 0 on success, negative errno code otherwise.

struct net_pkt *net_pkt_clone(struct net_pkt *pkt, k_timeout_t timeout)
Clone pkt and its buffer.

Parameters
• pkt – Original pkt to be cloned
• timeout – Timeout to wait for free buffer

Returns NULL if error, cloned packet otherwise.

struct net_pkt *net_pkt_shallow_clone(struct net_pkt *pkt, k_timeout_t timeout)
Clone pkt and increase the refcount of its buffer.

Parameters
• pkt – Original pkt to be shallow cloned
• timeout – Timeout to wait for free packet

Returns NULL if error, cloned packet otherwise.

int net_pkt_read(struct net_pkt *pkt, void *data, size_t length)
Read some data from a net_pkt.

net_pkt’s cursor should be properly initialized and, if needed, positioned using net_pkt_skip. Cursor position will be updated after the operation.

Parameters
• pkt – The network packet from where to read some data
• data – The destination buffer where to copy the data
• length – The amount of data to copy

Returns 0 on success, negative errno code otherwise.

static inline int net_pkt_read_u8(struct net_pkt *pkt, uint8_t *data)

int net_pkt_read_be16(struct net_pkt *pkt, uint16_t *data)
Read uint16_t big endian data from a net_pkt.

net_pkt’s cursor should be properly initialized and, if needed, positioned using net_pkt_skip. Cursor position will be updated after the operation.

Parameters
• pkt – The network packet from where to read
• data – The destination uint16_t where to copy the data

Returns 0 on success, negative errno code otherwise.
int net_pkt_read_le16(struct net_pkt *pkt, uint16_t *data)
    Read uint16_t little endian data from a net_pkt.
    net_pkt’s cursor should be properly initialized and, if needed, positioned using net_pkt_skip.
    Cursor position will be updated after the operation.

Parameters
• pkt – The network packet from where to read
• data – The destination uint16_t where to copy the data

Returns 0 on success, negative errno code otherwise.

int net_pkt_read_be32(struct net_pkt *pkt, uint32_t *data)
    Read uint32_t big endian data from a net_pkt.
    net_pkt’s cursor should be properly initialized and, if needed, positioned using net_pkt_skip.
    Cursor position will be updated after the operation.

Parameters
• pkt – The network packet from where to read
• data – The destination uint32_t where to copy the data

Returns 0 on success, negative errno code otherwise.

int net_pkt_write(struct net_pkt *pkt, const void *data, size_t length)
    Write data into a net_pkt.
    net_pkt’s cursor should be properly initialized and, if needed, positioned using net_pkt_skip.
    Cursor position will be updated after the operation.

Parameters
• pkt – The network packet where to write
• data – Data to be written
• length – Length of the data to be written

Returns 0 on success, negative errno code otherwise.

size_t net_pkt_remaining_data(struct net_pkt *pkt)
    Get the amount of data which can be read from current cursor position.

Parameters
• pkt – Network packet

Returns Amount of data which can be read from current pkt cursor

int net_pkt_update_length(struct net_pkt *pkt, size_t length)
    Update the overall length of a packet.
    Unlike net_pkt_pull() below, this does not take packet cursor into account. It’s mainly a helper
dedicated for ipv4 and ipv6 input functions. It shrinks the overall length by given parameter.
Parameters
- pkt – Network packet
- length – The new length of the packet

Returns 0 on success, negative errno code otherwise.

```
int net_pkt_pull(struct net_pkt *pkt, size_t length)
```

Remove data from the packet at current location.

**net_pkt**’s cursor should be properly initialized and, eventually, properly positioned using net_pkt_skip/read/write. Note that **net_pkt**’s cursor is reset by this function.

Parameters
- pkt – Network packet
- length – Number of bytes to be removed

Returns 0 on success, negative errno code otherwise.

```
uint16_t net_pkt_get_current_offset(struct net_pkt *pkt)
```

Get the actual offset in the packet from its cursor.

Parameters
- pkt – Network packet.

Returns a valid offset on success, 0 otherwise as there is nothing that can be done to evaluate the offset.

```
bool net_pkt_is_contiguous(struct net_pkt *pkt, size_t size)
```

Check if a data size could fit contiguously.

**net_pkt**’s cursor should be properly initialized and, if needed, positioned using net_pkt_skip.

Parameters
- pkt – Network packet.
- size – The size to check for contiguity

Returns true if that is the case, false otherwise.

```
size_t net_pkt_get_contiguous_len(struct net_pkt *pkt)
```

Get the contiguous buffer space

Parameters
- pkt – Network packet

Returns The available contiguous buffer space in bytes starting from the current cursor position. 0 in case of an error.

```
void *net_pkt_get_data(struct net_pkt *pkt, struct net_pkt_data_access *access)
```

Get data from a network packet in a contiguous way.

**net_pkt**’s cursor should be properly initialized and, if needed, positioned using net_pkt_skip. Cursor position will be updated after the operation.

Parameters
- pkt – The network packet from where to get the data.
- access – A pointer to a valid **net_pkt_data_access** describing the data to get in a contiguous way.

Returns a pointer to the requested contiguous data, NULL otherwise.
int net_pkt_set_data(struct net_pkt *pkt, struct net_pkt_data_access *access)
Set contiguous data into a network packet.

net_pkt's cursor should be properly initialized and, if needed, positioned using net_pkt_skip. Cursor position will be updated after the operation.

Parameters

- pkt – The network packet to where the data should be set.
- access – A pointer to a valid net_pkt_data_access describing the data to set.

Returns 0 on success, a negative errno otherwise.

static inline int net_pkt_acknowledge_data(struct net_pkt *pkt, struct net_pkt_data_access *access)

Acknowledge previously contiguous data taken from a network packet Packet needs to be set to overwrite mode.

struct net_pkt_cursor
#include <net_pkt.h>

Public Members

struct net_buf *buf
Current net_buf pointer by the cursor

uint8_t *pos
Current position in the data buffer of the net_buf

struct net_pkt
#include <net_pkt.h> Network packet.
Note that if you add new fields into net_pkt, remember to update net_pkt_clone() function.

Public Members

intptr_t fifo
The fifo is used by RX/TX threads and by socket layer. The net_pkt is queued via fifo to the processing thread.

struct k_mem_slab *slab
Slab pointer from where it belongs to

union net_pkt.[anonymous] [anonymous]
buffer holding the packet

struct net_pkt_cursor cursor
Internal buffer iterator used for reading/writing

struct net_context *context
Network connection context

struct net_if *iface
Network interface
7.21.3 Networking Technologies

Ethernet

Virtual LAN (VLAN) Support

Overview

Virtual LAN (VLAN) is a partitioned and isolated computer network at the data link layer (OSI layer 2). For ethernet network this refers to IEEE 802.1Q.

In Zephyr, each individual VLAN is modeled as a virtual network interface. This means that there is an ethernet network interface that corresponds to a real physical ethernet port in the system. A virtual network interface is created for each VLAN, and this virtual network interface connects to the real network interface. This is similar to how Linux implements VLANs. The eth0 is the real network interface and vlan0 is a virtual network interface that is run on top of eth0.

VLAN support must be enabled at compile time by setting option CONFIG_NET_VLAN and CONFIG_NET_VLAN_COUNT to reflect how many network interfaces there will be in the system. For example, if there is one network interface without VLAN support, and two with VLAN support, the CONFIG_NET_VLAN_COUNT option should be set to 3.

Even if VLAN is enabled in a prj.conf file, the VLAN needs to be activated at runtime by the application. The VLAN API provides a net_eth_vlan_enable() function to do that. The application needs to give the network interface and desired VLAN tag as a parameter to that function. The VLAN tagging for a given network interface can be disabled by a net_eth_vlan_disable() function. The application needs to configure the VLAN network interface itself, such as setting the IP address, etc.

See also the VLAN sample application for API usage example. The source code for that sample application can be found at samples/net/vlan.

The net-shell module contains net vlan add and net vlan del commands that can be used to enable or disable VLAN tags for a given network interface.

See the IEEE 802.1Q spec for more information about ethernet VLANs.

API Reference

group vlan_api

VLAN definitions and helpers.
Defines

`NET_VLAN_TAG_UNSPEC`
Unspecified VLAN tag value

Functions

static inline uint16_t net_eth_vlan_get_vid(uint16_t tci)
Get VLAN identifier from TCI.

Parameters
- `tci` – VLAN tag control information.

Returns VLAN identifier.

static inline uint8_t net_eth_vlan_get_dei(uint16_t tci)
Get Drop Eligible Indicator from TCI.

Parameters
- `tci` – VLAN tag control information.

Returns Drop eligible indicator.

static inline uint8_t net_eth_vlan_get_pcp(uint16_t tci)
Get Priority Code Point from TCI.

Parameters
- `tci` – VLAN tag control information.

Returns Priority code point.

static inline uint16_t net_eth_vlan_set_vid(uint16_t tci, uint16_t vid)
Set VLAN identifier to TCI.

Parameters
- `tci` – VLAN tag control information.
- `vid` – VLAN identifier.

Returns New TCI value.

static inline uint16_t net_eth_vlan_set_dei(uint16_t tci, bool dei)
Set Drop Eligible Indicator to TCI.

Parameters
- `tci` – VLAN tag control information.
- `dei` – Drop eligible indicator.

Returns New TCI value.

static inline uint16_t net_eth_vlan_set_pcp(uint16_t tci, uint8_t pcp)
Set Priority Code Point to TCI.

Parameters
- `tci` – VLAN tag control information.
- `pcp` – Priority code point.

Returns New TCI value.
Link Layer Discovery Protocol

**Overview**  The Link Layer Discovery Protocol (LLDP) is a vendor-neutral link layer protocol used by network devices for advertising their identity, capabilities, and neighbors on a wired Ethernet network. For more information, see this LLDP Wikipedia article.

**API Reference**

group lldp

LLDP definitions and helpers.

**Defines**

```c
net_lldp_set_lldpdu(iface)
```
Set LLDP protocol data unit (LLDPDU) for the network interface.

**Parameters**

- `iface` – Network interface

**Returns**  
- `<0 if error, index in lldp array if iface is found there`  

```c
net_lldp_unset_lldpdu(iface)
```
Unset LLDP protocol data unit (LLDPDU) for the network interface.

**Parameters**

- `iface` – Network interface

**Typedefs**

```c
typedef enum net_verdict (*net_lldp_recv_cb_t)(struct net_if *iface, struct net_pkt *pkt)
```
LLDP Receive packet callback.

 Callback gets called upon receiving packet. It is responsible for freeing packet or indicating to the stack that it needs to free packet by returning correct net_verdict.

**Returns:**

- `NET_DROP`, if packet was invalid, rejected or we want the stack to free it. In this case the core stack will free the packet.
- `NET_OK`, if the packet was accepted, in this case the ownership of the `net_pkt` goes to callback and core network stack will forget it.

** Enums**

```c
enum net_lldp_tlv_type
```
TLV Types. Please refer to table 8-1 from IEEE 802.1AB standard.

**Values:**
enumerator LLDP_TLV_END_LLDPDU = 0  
   End Of LLDPDU (optional)

enumerator LLDP_TLV_CHASSIS_ID = 1  
   Chassis ID (mandatory)

enumerator LLDP_TLV_PORT_ID = 2  
   Port ID (mandatory)

enumerator LLDP_TLV_TTL = 3  
   Time To Live (mandatory)

enumerator LLDP_TLV_PORT_DESC = 4  
   Port Description (optional)

enumerator LLDP_TLV_SYSTEM_NAME = 5  
   System Name (optional)

enumerator LLDP_TLV_SYSTEM_DESC = 6  
   System Description (optional)

enumerator LLDP_TLV_SYSTEM_CAPABILITIES = 7  
   System Capability (optional)

enumerator LLDP_TLV_MANAGEMENT_ADDR = 8  
   Management Address (optional)

enumerator LLDP_TLV_ORG_SPECIFIC = 127  
   Org specific TLVs (optional)

**Functions**

int net_lldp_config(struct net_if *iface, const struct net_lldpdu *lldpdu)
   Set the LLDP data unit for a network interface.

   **Parameters**
   
   • iface – Network interface
   • lldpdu – LLDP data unit struct

   **Returns** 0 if ok, <0 if error

int net_lldp_config_optional(struct net_if *iface, const uint8_t *tlv, size_t len)
   Set the Optional LLDP TLVs for a network interface.

   **Parameters**
   
   • iface – Network interface
   • tlv – LLDP optional TLVs following mandatory part
   • len – Length of the optional TLVs

   **Returns** 0 if ok, <0 if error

void net_lldp_init(void)
   Initialize LLDP engine.

int net_lldp_register_callback(struct net_if *iface, net_lldp_recv_cb_t cb)
   Register LLDP Rx callback function.
enum net_verdict net_lldp_recv(struct net_if *iface, struct net_pkt *pkt)

Parse LLDP packet.

Parameters

- iface – Network interface
- cb – Callback function

Returns

0 if ok, < 0 if error

define net_lldp_chassis_tlv

#include <lldp.h> Chassis ID TLV, see chapter 8.5.2 in IEEE 802.1AB

Public Members

- uint16_t type_length
  7 bits for type, 9 bits for length

- uint8_t subtype
  ID subtype

- uint8_t value[NET_LLDP_CHASSIS_ID_VALUE_LEN]
  Chassis ID value

define net_lldp_port_tlv

#include <lldp.h> Port ID TLV, see chapter 8.5.3 in IEEE 802.1AB

Public Members

- uint16_t type_length
  7 bits for type, 9 bits for length

- uint8_t subtype
  ID subtype

- uint8_t value[NET_LLDP_PORT_ID_VALUE_LEN]
  Port ID value

define net_lldp_time_to_live_tlv

#include <lldp.h> Time To Live TLV, see chapter 8.5.4 in IEEE 802.1AB

Public Members

- uint16_t type_length
  7 bits for type, 9 bits for length
uint16_t ttl
   Time To Live (TTL) value

struct net_lldpdu
   #include <lldp.h> LLDP Data Unit (LLDPDU) shall contain the following ordered TLVs as
   stated in "8.2 LLDPDU format" from the IEEE 802.1AB

Public Members

struct net_lldp_chassis_tlv chassis_id
   Mandatory Chassis TLV

struct net_lldp_port_tlv port_id
   Mandatory Port TLV

struct net_lldp_time_to_live_tlv ttl
   Mandatory TTL TLV

IEEE 802.1Qav

Overview  Credit-based shaping is an alternative scheduling algorithm used in network schedulers to
   achieve fairness when sharing a limited network resource. Zephyr has support for configuring a credit-
   based shaper described in the IEEE 802.1Qav-2009 standard. Zephyr does not implement the actual
   shaper; it only provides a way to configure the shaper implemented by the Ethernet device driver.

Enabling 802.1Qav  To enable 802.1Qav shaper, the Ethernet device driver must declare that it sup-
   ports credit-based shaping. The Ethernet driver's capability function must return ETHERNET_QAV value
   for this purpose. Typically also priority queues ETHERNET_PRIORITY_QUEUES need to be supported.

static enum ethernet_hw_caps eth_get_capabilities(const struct device *dev)
{
   ARG_UNUSED(dev);

   return ETHERNET_QAV | ETHERNET_PRIORITY_QUEUES |
            ETHERNET_HW_VLAN | ETHERNET_LINK_10BASE_T |
            ETHERNET_LINK_100BASE_T;
}

See sam-e70-xplained board Ethernet driver drivers/ethernet/eth_sam_gmac.c for an example.

Configuring 802.1Qav  The application can configure the credit-based shaper like this:

#include <net/net_if.h>
#include <net/ethernet.h>
#include <net/ethernet_mgmt.h>

static void qav_set_status(struct net_if *iface,
   int queue_id, bool enable)
{
   struct ethernet_req_params params;
   int ret;

   (continues on next page)
memset(&params, 0, sizeof(params));
params.qav_param.queue_id = queue_id;
params.qav_param.enabled = enable;
params.qav_param.type = ETHERNET_QAV_PARAM_TYPE_STATUS;

/* Disable or enable Qav for a queue */
ret = net_mgmt(NET_REQUEST_ETHERNET_SET_QAV_PARAM,
               iface, &params,
               sizeof(struct ethernet_req_params));
if (ret) {
    LOG_ERR("Cannot %s Qav for queue %d for interface %p",
             enable ? "enable" : "disable",
             queue_id, iface);
}

static void qav_set_bandwidth_and_slope(struct net_if *iface,
                                          int queue_id,
                                          unsigned int bandwidth,
                                          unsigned int idle_slope)
{
    struct ethernet_req_params params;
    int ret;
    memset(&params, 0, sizeof(params));
    params.qav_param.queue_id = queue_id;
    params.qav_param.delta_bandwidth = bandwidth;
    params.qav_param.type = ETHERNET_QAV_PARAM_TYPE_DELTA_BANDWIDTH;

                 idle_slope, queue_id, iface);
    }
}

Overview
Ethernet is a networking technology commonly used in local area networks (LAN). For more information, see this Ethernet Wikipedia article.
Zephyr supports following Ethernet features:

- 10, 100 and 1000 Mbit/sec links
- Auto negotiation
- Half/full duplex
- Promiscuous mode
- TX and RX checksum offloading
- MAC address filtering
- Virtual LANs
- Priority queues
- IEEE 802.1AS (gPTP)
- IEEE 802.1Qav (credit based shaping)
- LLDP (Link Layer Discovery Protocol)

Not all Ethernet device drivers support all of these features. You can see what is supported by `net iface net-shell` command. It will print currently supported Ethernet features.

**API Reference**

**group ethernet**

Ethernet support functions.

**Defines**

`ETH_NET_DEVICE_INIT(dev_name, drv_name, init_fn, pm_action_cb, data, cfg, prio, api, mtu)`

Create an Ethernet network interface and bind it to network device.

**Parameters**

- `dev_name` – Network device name.
- `drv_name` – The name this instance of the driver exposes to the system.
- `init_fn` – Address to the init function of the driver.
- `pm_action_cb` – Pointer to PM action callback. Can be NULL if not implemented.
- `data` – Pointer to the device's private data.
- `cfg` – The address to the structure containing the configuration information for this instance of the driver.
- `prio` – The initialization level at which configuration occurs.
- `api` – Provides an initial pointer to the API function struct used by the driver. Can be NULL.
- `mtu` – Maximum transfer unit in bytes for this network interface.

`ETH_NET_DEVICE_DT_DEFINE(node_id, init_fn, pm_action_cb, data, cfg, prio, api, mtu)`

Like `ETH_NET_DEVICE_INIT` but taking metadata from a devicetree. Create an Ethernet network interface and bind it to network device.

**Parameters**

- `node_id` – The devicetree node identifier.
- `init_fn` – Address to the init function of the driver.
- `pm_action_cb` – Pointer to PM action callback. Can be NULL if not implemented.
- `data` – Pointer to the device's private data.
- `cfg` – The address to the structure containing the configuration information for this instance of the driver.
- `prio` – The initialization level at which configuration occurs.
- `api` – Provides an initial pointer to the API function struct used by the driver. Can be NULL.
- `mtu` – Maximum transfer unit in bytes for this network interface.

```
ETH_NETDEVICE_DTIINST_DEFINE(inst, ...)
```

Like `ETH_NETDEVICE_DDEFINE` for an instance of a `DT_DRV_COMPAT` compatible.

**Parameters**

- `inst` – instance number. This is replaced by `DT_DRV_COMPAT(inst)` in the call to `ETH_NETDEVICE_DTIINST_DEFINE`.
- `...` – other parameters as expected by `ETH_NETDEVICE_DTIINST_DEFINE`.

**Enums**

```c
enum ethernet_hw_caps
    Ethernet hardware capabilities

Values:

enumerator ETHERNET_HW_TX_CHKSUM_OFFLOAD = BIT(0)
    TX Checksum offloading supported for all of IPv4, UDP, TCP

denumerator ETHERNET_HW_RX_CHKSUM_OFFLOAD = BIT(1)
    RX Checksum offloading supported for all of IPv4, UDP, TCP

denumerator ETHERNET_HW_VLAN = BIT(2)
    VLAN supported

denumerator ETHERNET_AUTO_NEGOTIATION_SET = BIT(3)
    Enabling/disabling auto negotiation supported

denumerator ETHERNET_LINK_10BASE_T = BIT(4)
    10 Mbits link supported

denumerator ETHERNET_LINK_100BASE_T = BIT(5)
    100 Mbits link supported

denumerator ETHERNET_LINK_1000BASE_T = BIT(6)
    1 Gbits link supported

denumerator ETHERNET_DUPLEX_SET = BIT(7)
    Changing duplex (half/full) supported

denumerator ETHERNET_PTP = BIT(8)
    IEEE 802.1AS (gPTP) clock supported
```
enumerator ETHERNET_QAV = BIT(9)
IEEE 802.1Qav (credit-based shaping) supported

enumerator ETHERNET_Promisc_mode = BIT(10)
Promiscuous mode supported

enumerator ETHERNET_PRIORITY_QUEUES = BIT(11)
Priority queues available

enumerator ETHERNET_HW_Filtering = BIT(12)
MAC address filtering supported

enumerator ETHERNET_LLDP = BIT(13)
Link Layer Discovery Protocol supported

enumerator ETHERNET_HW_VLAN_TAG_STRIP = BIT(14)
VLAN Tag stripping

enumerator ETHERNET_DSA_SLAVE_PORT = BIT(15)
DSA switch

enumerator ETHERNET_DSA_MASTER_PORT = BIT(16)

enumerator ETHERNET_QBV = BIT(17)
IEEE 802.1Qbv (scheduled traffic) supported

enumerator ETHERNET_QBU = BIT(18)
IEEE 802.1Qbu (frame preemption) supported

enumerator ETHERNET_TXTIME = BIT(19)
TXTIME supported

enum ethernet_flags
Values:

enumerator ETH_CARRIER_UP

Functions

void ethernet_init(struct net_if *iface)
Initialize Ethernet L2 stack for a given interface.

Parameters
• iface – A valid pointer to a network interface

void net_eth_ipv4_mcast_to_mac_addr(const struct in_addr *ipv4_addr, struct net_eth_addr *mac_addr)
Convert IPv4 multicast address to Ethernet address.

Parameters
• ipv4_addr – IPv4 multicast address
• mac_addr – Output buffer for Ethernet address

7.21. Networking
void net_eth_ipv6_mcast_to_mac_addr(const struct in6_addr *ipv6_addr, struct net_eth_addr *mac_addr)

Convert IPv6 multicast address to Ethernet address.

Parameters

• ipv6_addr – IPv6 multicast address
• mac_addr – Output buffer for Ethernet address

static inline enum ethernet_hw_caps net_eth_get_hw_capabilities(struct net_if *iface)

Return ethernet device hardware capability information.

Parameters

• iface – Network interface

Returns

Hardware capabilities

static inline int net_eth_vlan_enable(struct net_if *iface, uint16_t tag)

Add VLAN tag to the interface.

Parameters

• iface – Interface to use.
• tag – VLAN tag to add

Returns

0 if ok, <0 if error

static inline int net_eth_vlan_disable(struct net_if *iface, uint16_t tag)

Remove VLAN tag from the interface.

Parameters

• iface – Interface to use.
• tag – VLAN tag to remove

Returns

0 if ok, <0 if error

static inline uint16_t net_eth_get_vlan_tag(struct net_if *iface)

Return VLAN tag specified to network interface.

Parameters

• iface – Network interface.

Returns

VLAN tag for this interface or NET_VLAN_TAG_UNSPEC if VLAN is not configured for that interface.

static inline struct net_if *net_eth_get_vlan_iface(struct net_if *iface, uint16_t tag)

Return network interface related to this VLAN tag.

Parameters

• iface – Master network interface. This is used to get the pointer to ethernet L2 context
• tag – VLAN tag

Returns

Network interface related to this tag or NULL if no such interface exists.

static inline bool net_eth_is_vlan_enabled(struct ethernet_context *ctx, struct net_if *iface)

Check if VLAN is enabled for a specific network interface.

Parameters

• ctx – Ethernet context
• iface – Network interface

Returns

True if VLAN is enabled for this network interface, false if not.
static inline bool net_eth_get_vlan_status(struct net_if *iface)
    Get VLAN status for a given network interface (enabled or not).

    Parameters
    • iface – Network interface

    Returns  True if VLAN is enabled for this network interface, false if not.

void net_eth_carrier_on(struct net_if *iface)
    Inform ethernet L2 driver that ethernet carrier is detected. This happens when cable is connected.

    Parameters
    • iface – Network interface

void net_eth_carrier_off(struct net_if *iface)
    Inform ethernet L2 driver that ethernet carrier was lost. This happens when cable is disconnected.

    Parameters
    • iface – Network interface

int net_eth_promisc_mode(struct net_if *iface, bool enable)
    Set promiscuous mode either ON or OFF.

    Parameters
    • iface – Network interface
    • enable – on (true) or off (false)

    Returns  0 if mode set or unset was successful, <0 otherwise.

static inline const struct device *net_eth_get_ptp_clock(struct net_if *iface)
    Return PTP clock that is tied to this ethernet network interface.

    Parameters
    • iface – Network interface

    Returns  Pointer to PTP clock if found, NULL if not found or if this ethernet interface does not support PTP.

const struct device *net_eth_get_ptp_clock_by_index(int index)
    Return PTP clock that is tied to this ethernet network interface index.

    Parameters
    • index – Network interface index

    Returns  Pointer to PTP clock if found, NULL if not found or if this ethernet interface index does not support PTP.

static inline int net_eth_get_ptp_port(struct net_if *iface)
    Return PTP port number attached to this interface.

    Parameters
    • iface – Network interface

    Returns  Port number, no such port if < 0

struct ethernet_qav_param
    #include <ethernet.h>
Public Members

int queue_id
ID of the priority queue to use

default ethernet_qav_param_type type
Type of Qav parameter

bool enabled
True if Qav is enabled for queue

unsigned int delta_bandwidth
Delta Bandwidth (percentage of bandwidth)

unsigned int idle_slope
Idle Slope (bits per second)

unsigned int oper_idle_slope
Oper Idle Slope (bits per second)

unsigned int traffic_class
Traffic class the queue is bound to

struct ethernet_qbv_param
#include <ethernet.h>

Public Members

int port_id
Port id

default ethernet_qbv_param_type type
Type of Qbv parameter

enum ethernet_qbv_state_type state
What state (Admin/Oper) parameters are these

bool enabled
True if Qbv is enabled or not

bool gate_status[NET_TC_TX_COUNT]
True = open, False = closed

default ethernet_gate_state_operation operation
GateState operation

uint32_t time_interval
Time interval ticks (nanoseconds)

uint16_t row
Gate control list row

Chapter 7. API Reference
uint32_t gate_control_list_len  
Number of entries in gate control list

struct net_ptp_extended_time base_time  
Base time

struct net_ptp_time cycle_time  
Cycle time

uint32_t extension_time  
Extension time (nanoseconds)

struct ethernet_qbu_param  
#include <ethernet.h>

Public Members

int port_id  
Port id

denum ethernet_qbu_param_type type  
Type of Qbu parameter

uint32_t hold_advance  
Hold advance (nanoseconds)

uint32_t release_advance  
Release advance (nanoseconds)

denum ethernet_qbu_preempt_status frame_preempt_statuses[NET_TC_TX_COUNT]  
sequence of framePreemptionAdminStatus values.

bool enabled  
True if Qbu is enabled or not

bool link_partner_status  
Link partner status (from Qbr)

uint8_t additional_fragment_size  
Additional fragment size (from Qbr). The minimum non-final fragment size is (additional_fragment_size + 1) * 64 octets

struct ethernet_filter  
#include <ethernet.h>

Public Members

denum ethernet_filter_type type  
Type of filter

struct net_eth_addr mac_address  
MAC address to filter

7.21. Networking
bool set
    Set (true) or unset (false) the filter

struct ethernet_txtime_param
    #include <ethernet.h>

Public Members

denum ethernet_txtime_param_type type
    Type of TXTIME parameter

int queue_id
    Queue number for configuring TXTIME

bool enable_txtime
    Enable or disable TXTIME per queue

struct ethernet_api
    #include <ethernet.h>

Public Members

struct net_if_api iface_api
    The net_if_api must be placed in first position in this struct so that we are compatible
    with network interface API.

int (*start)(const struct device *dev)
    Start the device

int (*stop)(const struct device *dev)
    Stop the device

denum ethernet_hw_caps (*get_capabilities)(const struct device *dev)
    Get the device capabilities

int (*set_config)(const struct device *dev, enum ethernet_config_type type, const struct ethernet_config *config)
    Set specific hardware configuration

int (*get_config)(const struct device *dev, enum ethernet_config_type type, struct ethernet_config *config)
    Get hardware specific configuration

int (*send)(const struct device *dev, struct net_pkt *pkt)
    Send a network packet

struct ethernet_context
    #include <ethernet.h> Ethernet L2 context that is needed for VLAN
Public Members

atomic_t flags
    Flags representing ethernet state, which are accessed from multiple threads.

struct k_work carrier_work
    Carrier ON/OFF handler worker. This is used to create network interface UP/DOWN event
    when ethernet L2 driver notices carrier ON/OFF situation. We must not create another
    network management event from inside management handler thus we use worker thread
    to trigger the UP/DOWN event.

struct net_if *iface
    Network interface.

enum net_l2_flags ethernet_l2_flags
    This tells what L2 features does ethernet support.

bool is_net_carrier_up
    Is network carrier up

bool is_init
    Is this context already initialized

group ethernet_mii
    Ethernet MII (media independent interface) functions.

Defines

MII_BMCR
    Basic Mode Control Register

MII_BMSR
    Basic Mode Status Register

MII_PHYID1R
    PHY ID 1 Register

MII_PHYID2R
    PHY ID 2 Register

MII_ANAR
    Auto-Negotiation Advertisement Register

MII_ANLPAR
    Auto-Negotiation Link Partner Ability Reg

MII_ANER
    Auto-Negotiation Expansion Register

MII_ANNPTR
    Auto-Negotiation Next Page Transmit Register
MII_ANLPRNPR
    Auto-Negotiation Link Partner Received Next Page Reg

MII_MMD_ACR
    MMD Access Control Register

MII_MMD_AADR
    MMD Access Address Data Register

MII_ESTAT
    Extended Status Register

MII_BMCR_RESET
    PHY reset

MII_BMCR_LOOPBACK
    enable loopback mode

MII_BMCR_SPEED_LSB
    10=1000Mbps 01=100Mbps; 00=10Mbps

MII_BMCR_AUTONEG_ENABLE
    Auto-Negotiation enable

MII_BMCR_POWER_DOWN
    power down mode

MII_BMCR_ISOLATE
    isolate electrically PHY from MII

MII_BMCR_AUTONEG_RESTART
    restart auto-negotiation

MII_BMCR_DUPLX_MODE
    full duplex mode

MII_BMCR_SPEED_MSB
    10=1000Mbps 01=100Mbps; 00=10Mbps

MII_BMCR_SPEED_MASK
    Link Speed Field

MII_BMCR_SPEED_10
    select speed 10 Mb/s

MII_BMCR_SPEED_100
    select speed 100 Mb/s

MII_BMCR_SPEED_1000
    select speed 1000 Mb/s

MII_BMSR_100BASE_T4
    100BASE-T4 capable
MII_BMSR_100BASE_X_FULL
100BASE-X full duplex capable

MII_BMSR_100BASE_X_HALF
100BASE-X half duplex capable

MII_BMSR_10_FULL
10 Mb/s full duplex capable

MII_BMSR_10_HALF
10 Mb/s half duplex capable

MII_BMSR_100BASE_T2_FULL
100BASE-T2 full duplex capable

MII_BMSR_100BASE_T2_HALF
100BASE-T2 half duplex capable

MII_BMSR_EXTEND_STATUS
extend status information in reg 15

MII_BMSR_MF_PREAMB_SUPPR
PHY accepts management frames with preamble suppressed

MII_BMSR_AUTONEG_COMPLETE
Auto-negotiation process completed

MII_BMSR_REMOTE_FAULT
remote fault detected

MII_BMSR_AUTONEG_ABILITY
PHY is able to perform Auto-Negotiation

MII_BMSR_LINK_STATUS
link is up

MII_BMSR_JABBER_DETECT
jabber condition detected

MII_BMSR_EXTEND_CAPAB
extended register capabilities

MII_ADVERTISE_NEXT_PAGE
next page

MII_ADVERTISE_LPACK
link partner acknowledge response

MII_ADVERTISE_REMOTE_FAULT
remote fault

MII_ADVERTISE_ASYM_PAUSE
try for asymmetric pause
MII_ADVERTISE_PAUSE
try for pause

MII_ADVERTISE_100BASE_T4
try for 100BASE-T4 support

MII_ADVERTISE_100_FULL
try for 100BASE-X full duplex support

MII_ADVERTISE_100_HALF
try for 100BASE-X support

MII_ADVERTISE_10_FULL
try for 10 Mb/s full duplex support

MII_ADVERTISE_10_HALF
try for 10 Mb/s half duplex support

MII_ADVERTISE_SEL_MASK
Selector Field

MII_ADVERTISE_SEL_IEEE_802_3

MII_ADVERTISE_ALL

IEEE 802.15.4

Overview
IEEE 802.15.4 is a technical standard which defines the operation of low-rate wireless personal area networks (LR-WPANs). For more detailed overview of this standard, see this IEEE 802.15.4 Wikipedia article. Also, see IEEE GET Program for creating an IEEE account and downloading the specification.

Zephyr supports IEEE 802.15.4 with Thread and 6LoWPAN. The Thread implementation is based on OpenThread. The IPv6 header compression in 6LoWPAN is shared with the Bluetooth IPSP (IP support profile).

API Reference

IEEE 802.15.4

group ieee802154
IEEE 802.15.4 library.
Defines

IEEE802154_MAX_ADDR_LENGTH

IEEE802154_NO_CHANNEL

IEEE802154_L2_CTX_TYPE

IEEE802154_AR_FLAG_SET

Typedefs

typedef void (*energy_scan_done_cb_t)(const struct device *dev, int16_t max_ed)

typedef void (*ieee802154_event_cb_t)(const struct device *dev, enum ieee802154_event evt, void *event_params)

 Enums

enum ieee802154_channel
    IEEE 802.15.4 Channel assignments.
    Channel numbering for 868 MHz, 915 MHz, and 2450 MHz bands.

    • Channel 0 is for 868.3 MHz.
    • Channels 1-10 are for 906 to 924 MHz with 2 MHz channel spacing.
    • Channels 11-26 are for 2405 to 2530 MHz with 5 MHz channel spacing.

    For more information, please refer to 802.15.4-2015 Section 10.1.2.2.

    Values:

        enumerator IEEE802154_SUB_GHZ_CHANNEL_MIN = 0

   enumerator IEEE802154_EVENT_RX_FAILED

   enumerator IEEE802154_EVENT_SLEEP

enum ieee802154_rx_fail_reason
   Values:

   enumerator IEEE802154_RX_FAIL_NOT_RECEIVED

   enumerator IEEE802154_RX_FAIL_INVALID_FCS

   enumerator IEEE802154_RX_FAIL_ADDR_FILTERED

   enumerator IEEE802154_RX_FAIL_OTHER

enum ieee802154_tx_mode
   IEEE802.15.4 Transmission mode.
   Values:

   enumerator IEEE802154_TX_MODE_DIRECT
       Transmit packet immediately, no CCA.

   enumerator IEEE802154_TX_MODE_CCA
       Perform CCA before packet transmission.

   enumerator IEEE802154_TX_MODE_CSMA_CA
       Perform full CSMA CA procedure before packet transmission.

   enumerator IEEE802154_TX_MODE_TXTIME
       Transmit packet in the future, at specified time, no CCA.

   enumerator IEEE802154_TX_MODE_TXTIME_CCA
       Transmit packet in the future, perform CCA before transmission.

enum ieee802154_fpb_mode
   IEEE802.15.4 Frame Pending Bit table address matching mode.
   Values:

   enumerator IEEE802154_FPB_ADDR_MATCH_THREAD
       The pending bit shall be set only for addresses found in the list.
enumerator IEEE802154_FPB_ADDR_MATCH_ZIGBEE
The pending bit shall be cleared for short addresses found in the list.

enum iee802154_config_type
IEEE802.15.4 driver configuration types.

Values:

enumerator IEEE802154_CONFIG_AUTO_ACK_FPB
Indicates how radio driver should set Frame Pending bit in ACK responses for Data Requests. If enabled, radio driver should determine whether to set the bit or not based on the information provided with IEEE802154_CONFIG_ACK_FPB config and FPB address matching mode specified. Otherwise, Frame Pending bit should be set to 1 (see IEEE Std 802.15.4-2006, 7.2.2.3.1).

e Num IEEE802154_CONFIG_ACK_FPB
Indicates whether to set ACK Frame Pending bit for specific address or not. Disabling the Frame Pending bit with no address provided (NULL pointer) should disable it for all enabled addresses.

e Num IEEE802154_CONFIG_PAN_COORDINATOR
Indicates whether the device is a PAN coordinator.

e Num IEEE802154_CONFIG_PROMISCUOUS
Enable/disable promiscuous mode.

e Num IEEE802154_CONFIG_EVENT_HANDLER
Specifies new radio event handler. Specifying NULL as a handler will disable radio events notification.

e Num IEEE802154_CONFIG_MAC_KEYS
Updates MAC keys and key index for radios supporting transmit security.

e Num IEEE802154_CONFIG_FRAME_COUNTER
Sets the current MAC frame counter value for radios supporting transmit security.

e Num IEEE802154_CONFIG_RX_SLOT
Configure a radio reception slot. This can be used for any scheduler reception, e.g.: Zigbee GP device, CSL, TSCH, etc.

In order to configure a CSL receiver the upper layer should combine several configuration options in the following way:

i. Use IEEE802154_CONFIG_ENH_ACK_HEADER_IE once to inform the radio driver of the short and extended addresses of the peer to which it should inject CSL IEs.
