      2.2.3 Install a Toolchain .................................... 20  
      2.2.4 Updating the Zephyr SDK toolchain ..................... 20  
      2.2.5 Cloning the Zephyr Repositories ........................ 20  
      2.2.6 Export Zephyr CMake package ........................... 21  
      2.2.7 Board Aliases ......................................... 21  
      2.2.8 Build and Run an Application ........................... 21  
   2.3 Environment Variables .................................... 23  
      2.3.1 Setting Variables ..................................... 23  
      2.3.2 Zephyr Environment Scripts ............................. 25  
      2.3.3 Important Environment Variables ....................... 25  
   2.4 Application Development .................................. 26  
      2.4.1 Overview ............................................ 26  
      2.4.2 Application types ..................................... 27  
      2.4.3 Example workspace application .......................... 28  
      2.4.4 Creating an Application ............................... 29  
      2.4.5 Important Build System Variables ....................... 30  
      2.4.6 Application CMakeLists.txt ............................ 30  
      2.4.7 CMakeCache.txt ...................................... 32  
      2.4.8 Application Configuration .............................. 32  
      2.4.9 Experimental features ................................ 33  
      2.4.10 Application-Specific Code ............................. 33  
      2.4.11 Building an Application ............................... 34  
      2.4.12 Run an Application ................................... 37  
      2.4.13 Application Debugging ................................. 38  
      2.4.14 Custom Board, Devicetree and SOC Definitions ........... 40
### 3 Kernel

#### 3.1 Kernel Services
- Scheduling, Interrupts, and Synchronization .............................................. 225
- Memory Passing ......................................................................................... 328
- Memory Management ............................................................................... 370
- Timing ......................................................................................................... 370
- Other .......................................................................................................... 386

#### 3.2 Device Driver Model
- Introduction ............................................................................................... 406
- Standard Drivers ...................................................................................... 406
- Synchronous Calls .................................................................................... 406
- Driver APIs ............................................................................................... 407
- Driver Data Structures ............................................................................. 407
- Subsystems and API Structures ................................................................. 407
- Device-Specific API Extensions ................................................................. 408
- Single Driver, Multiple Instances .............................................................. 409
- Initialization Levels .................................................................................. 411
- System Drivers .......................................................................................... 411
- Error handling ......................................................................................... 412
- Memory Mapping ...................................................................................... 412
- API Reference ........................................................................................... 415

#### 3.3 User Mode
- Overview ..................................................................................................... 424
- Memory Protection Design ....................................................................... 426
- Kernel Objects ........................................................................................... 435
- System Calls ............................................................................................. 440
- MPU Stack Objects ................................................................................... 449
- MPU Backed Userspace ............................................................................ 450
- Memory Protection Design ....................................................................... 450
- Memory Heaps .......................................................................................... 460
- Shared Multi Heap .................................................................................... 464
- Memory Slabs ........................................................................................... 464
- Memory Blocks Allocator ......................................................................... 469
- Demand Paging .......................................................................................... 476

#### 3.4 Memory Management
- Single-linked List ...................................................................................... 483
- Double-linked List ..................................................................................... 494
- Multi Producer Single Consumer Packet Buffer ..................................... 501
- Single Producer Single Consumer Packet Buffer .................................... 503
- Balanced Red/Black Tree ........................................................................ 503
- Ring Buffers ............................................................................................... 506

#### 3.5 Data Structures
- Configuration ............................................................................................. 518
- Usage .......................................................................................................... 518
- API documentation ................................................................................... 519

#### 3.6 Executing Time Functions
- Overview ..................................................................................................... 521
- Time Utility APIs ..................................................................................... 521
- Concepts Underlying Time Support in Zephyr ........................................... 526

#### 3.7 Time Utilities
- Time Utility APIs ...................................................................................... 521
- Concepts Underlying Time Support in Zephyr ........................................... 526

#### 3.8 Utilities
- Usage .......................................................................................................... 543
- API Reference ........................................................................................... 543

#### 3.9 Iterable Sections
- Usage .......................................................................................................... 543
- API Reference ........................................................................................... 543

#### 3.10 Code And Data Relocation

4 OS Services 549
4.1 Cryptography .................................................................................................................. 549
  4.1.1 TinyCrypt Cryptographic Library ............................................................................. 549
  4.1.2 Random Number Generation ................................................................................... 553
  4.1.3 Crypto APIs ................................................................................................................ 555
4.2 Debugging .......................................................................................................................... 562
  4.2.1 Thread analyzer ......................................................................................................... 562
  4.2.2 Core Dump ................................................................................................................ 564
  4.2.3 GDB stub .................................................................................................................. 570
4.3 Device Management .......................................................................................................... 574
  4.3.1 MCUmgr ................................................................................................................... 574
  4.3.2 MCUmgr Callbacks .................................................................................................. 582
  4.3.3 Fixing and backporting fixes to Zephyr v2.7 MCUmgr ........................................... 591
  4.3.4 SMP Protocol Specification ...................................................................................... 593
  4.3.5 SMP Transport Specification ................................................................................... 613
  4.3.6 Device Firmware Upgrade ....................................................................................... 615
  4.3.7 Over-the-Air Update ............................................................................................... 616
  4.3.8 SMP Groups ............................................................................................................ 617
4.4 File Systems ...................................................................................................................... 617
  4.4.1 Samples .................................................................................................................... 617
  4.4.2 API Reference ........................................................................................................... 618
4.5 Formatted Output .............................................................................................................. 630
  4.5.1 Cprintf Packaging .................................................................................................... 630
  4.5.2 API Reference ........................................................................................................... 632
4.6 Interprocessor Communication (IPC) ............................................................................... 642
  4.6.1 IPC service ............................................................................................................... 642
4.7 Logging ............................................................................................................................. 656
  4.7.1 Global Kconfig Options ............................................................................................ 658
  4.7.2 Usage ....................................................................................................................... 659
  4.7.3 Logging panic ............................................................................................................ 661
  4.7.4 Printk ........................................................................................................................ 661
  4.7.5 Architecture .............................................................................................................. 662
  4.7.6 Recommendations ................................................................................................... 667
  4.7.7 Benchmark ............................................................................................................... 667
  4.7.8 Stack usage ............................................................................................................... 668
  4.7.9 API Reference ........................................................................................................... 668
4.8 Tracing ............................................................................................................................... 686
  4.8.1 Overview ................................................................................................................... 686
  4.8.2 Serialization Formats ............................................................................................... 687
  4.8.3 Transport Backends ................................................................................................. 689
  4.8.4 Using Tracing .......................................................................................................... 689
  4.8.5 Visualisation Tools ................................................................................................. 690
  4.8.6 Future LTTng Inspiration ......................................................................................... 690
  4.8.7 Object tracking ........................................................................................................ 691
  4.8.8 API ............................................................................................................................ 692
4.9 Resource Management ..................................................................................................... 721
  4.9.1 On-Off Manager ....................................................................................................... 722
4.10 Modbus ............................................................................................................................ 730
  4.10.1 Samples ................................................................................................................... 730
  4.10.2 API Reference .......................................................................................................... 730
4.11 Asynchronous Notifications .......................................................................................... 739
  4.11.1 API Reference .......................................................................................................... 739
4.12 Power Management ......................................................................................................... 742
  4.12.1 Overview ................................................................................................................ 742
  4.12.2 System Power Management .................................................................................... 743
4.12.3 Device Power Management ................................. 746
4.12.4 Device Runtime Power Management ......................... 749
4.12.5 Power Domain ............................................. 754
4.12.6 Power Management ......................................... 757

4.13 OS Abstraction .................................................. 776
4.13.1 POSIX Support ............................................... 776
4.13.2 CMSIS RTOS v1 .............................................. 783
4.13.3 CMSIS RTOS v2 .............................................. 784

4.14 Shell ............................................................. 785
4.14.1 Overview ..................................................... 785
4.14.2 Commands ..................................................... 786
4.14.3 Tab Feature ................................................... 792
4.14.4 History Feature .............................................. 792
4.14.5 Wildcards Feature ............................................ 792
4.14.6 Meta Keys Feature .......................................... 793
4.14.7 Getopt Feature ............................................... 793
4.14.8 Obscured Input Feature ...................................... 794
4.14.9 Shell Logger Backend Feature ............................... 794
4.14.10 Usage ......................................................... 796
4.14.11 API Reference ............................................... 796

4.15 Settings .......................................................... 815
4.15.1 Handlers ....................................................... 815
4.15.2 Backends ...................................................... 815
4.15.3 Zephyr Storage Backends ................................... 816
4.15.4 Storage Location ............................................. 816
4.15.5 Loading data from persisted storage ......................... 816
4.15.6 Storing data to persistent storage .......................... 816
4.15.7 Secure domain settings ..................................... 817
4.15.8 Example: Device Configuration ............................. 817
4.15.9 Example: Persist Runtime State ............................. 818
4.15.10 Example: Custom Backend Implementation ................ 819
4.15.11 API Reference .............................................. 819

4.16 State Machine Framework ..................................... 828
4.16.1 Overview ..................................................... 828
4.16.2 State Creation ............................................... 828
4.16.3 State Machine Creation ..................................... 829
4.16.4 State Machine Execution ................................... 829
4.16.5 State Machine Termination .................................. 829
4.16.6 Flat State Machine Example ................................. 829
4.16.7 Hierarchical State Machine Example ....................... 831
4.16.8 Event Driven State Machine Example ....................... 834

4.17 Storage .......................................................... 836
4.17.1 Non-Volatile Storage (NVS) ............................... 836
4.17.2 Disk Access ................................................... 841
4.17.3 Flash map ...................................................... 845
4.17.4 Flash Image .................................................... 851
4.17.5 Flash Circular Buffer (FCB) ................................ 853
4.17.6 Stream Flash .................................................. 858

Chapter 1

Introduction

The Zephyr OS is based on a small-footprint kernel designed for use on resource-constrained and embedded systems: from simple embedded environmental sensors and LED wearables to sophisticated embedded controllers, smart watches, and IoT wireless applications.

The Zephyr kernel supports multiple architectures, including:

- ARCv2 (EM and HS) and ARCv3 (HS6X)
- ARMv6-M, ARMv7-M, and ARMv8-M (Cortex-M)
- ARMv7-A and ARMv8-A (Cortex-A, 32- and 64-bit)
- ARMv7-R, ARMv8-R (Cortex-R, 32- and 64-bit)
- Intel x86 (32- and 64-bit)
- MIPS (MIPS32 Release 1 specification)
- NIOS II Gen 2
- RISC-V (32- and 64-bit)
- SPARC V8
- Tensilica Xtensa

The full list of supported boards based on these architectures can be found here.

1.1 Licensing

Zephyr is permissively licensed using the Apache 2.0 license (as found in the LICENSE file in the project’s GitHub repo). There are some imported or reused components of the Zephyr project that use other licensing, as described in Licensing of Zephyr Project components.

1.2 Distinguishing Features

Zephyr offers a large and ever growing number of features including:

Extensive suite of Kernel services

Zephyr offers a number of familiar services for development:

- Multi-threading Services for cooperative, priority-based, non-preemptive, and preemptive threads with optional round robin time-slicing. Includes POSIX pthreads compatible API support.
- Interrupt Services for compile-time registration of interrupt handlers.
• Memory Allocation Services for dynamic allocation and freeing of fixed-size or variable-size memory blocks.

• Inter-thread Synchronization Services for binary semaphores, counting semaphores, and mutex semaphores.

• Inter-thread Data Passing Services for basic message queues, enhanced message queues, and byte streams.

• Power Management Services such as tickless idle and an advanced idling infrastructure.

Multiple Scheduling Algorithms
Zephyr provides a comprehensive set of thread scheduling choices:

• Cooperative and Preemptive Scheduling

• Earliest Deadline First (EDF)

• Meta IRQ scheduling implementing “interrupt bottom half” or “tasklet” behavior

• Timeslicing: Enables time slicing between preemptible threads of equal priority

• Multiple queuing strategies:
  – Simple linked-list ready queue
  – Red/black tree ready queue
  – Traditional multi-queue ready queue

Highly configurable / Modular for flexibility
Allows an application to incorporate only the capabilities it needs as it needs them, and to specify their quantity and size.

Cross Architecture
Supports a wide variety of supported boards with different CPU architectures and developer tools. Contributions have added support for an increasing number of SoCs, platforms, and drivers.

Memory Protection
Implements configurable architecture-specific stack-overflow protection, kernel object and device driver permission tracking, and thread isolation with thread-level memory protection on x86, ARC, and ARM architectures, userspace, and memory domains.

For platforms without MMU/MPU and memory constrained devices, supports combining application-specific code with a custom kernel to create a monolithic image that gets loaded and executed on a system's hardware. Both the application code and kernel code execute in a single shared address space.

Compile-time resource definition
Allows system resources to be defined at compile-time, which reduces code size and increases performance for resource-limited systems.

Optimized Device Driver Model
Provides a consistent device model for configuring the drivers that are part of the platform/system and a consistent model for initializing all the drivers configured into the system and Allows the reuse of drivers across platforms that have common devices/IP blocks

Devicetree Support
Use of devicetree to describe hardware. Information from devicetree is used to create the application image.

Native Networking Stack supporting multiple protocols
Networking support is fully featured and optimized, including LwM2M and BSD sockets compatible support. OpenThread support (on Nordic chipsets) is also provided - a mesh network designed to securely and reliably connect hundreds of products around the home.

Bluetooth Low Energy 5.0 support
Bluetooth 5.0 compliant (ESR10) and Bluetooth Low Energy Controller support (LE Link Layer). Includes Bluetooth mesh and a Bluetooth qualification-ready Bluetooth controller.
• Generic Access Profile (GAP) with all possible LE roles.
• GATT (Generic Attribute Profile)
• Pairing support, including the Secure Connections feature from Bluetooth 4.2
• Clean HCI driver abstraction
• Raw HCI interface to run Zephyr as a Controller instead of a full Host stack
• Verified with multiple popular controllers
• Highly configurable

Mesh Support:
• Relay, Friend Node, Low-Power Node (LPN) and GATT Proxy features
• Both Provisioning bearers supported (PB-ADV & PB-GATT)
• Highly configurable, fitting in devices with at least 16k RAM

Native Linux, macOS, and Windows Development
A command-line CMake build environment runs on popular developer OS systems. A native POSIX port, lets you build and run Zephyr as a native application on Linux and other OSes, aiding development and testing.

Virtual File System Interface with LittleFS and FATFS Support
LittleFS and FATFS Support, FCB (Flash Circular Buffer) for memory constrained applications, and file system enhancements for logging and configuration.

Powerful multi-backend logging Framework
Support for log filtering, object dumping, panic mode, multiple backends (memory, networking, filesystem, console, ..) and integration with the shell subsystem.

User friendly and full-featured Shell interface
A multi-instance shell subsystem with user-friendly features such as autocompletion, wildcards, coloring, metakeys (arrows, backspace, ctrl+u, etc.) and history. Support for static commands and dynamic sub-commands.

Settings on non-volatile storage
The settings subsystem gives modules a way to store persistent per-device configuration and run-time state. Settings items are stored as key-value pair strings.

Non-volatile storage (NVS)
NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Native POSIX port
Supports running Zephyr as a Linux application with support for various subsystems and networking.

1.3 Community Support

Community support is provided via mailing lists and Discord; see the Resources below for details.

1.4 Resources

Here's a quick summary of resources to help you find your way around:
• Help: Asking for Help Tips
• Documentation: http://docs.zephyrproject.org (Getting Started Guide)
1.5 Fundamental Terms and Concepts

See glossary
Chapter 2

Developing with Zephyr

2.1 Getting Started Guide

Follow this guide to:

• Set up a command-line Zephyr development environment on Ubuntu, macOS, or Windows (instructions for other Linux distributions are discussed in Install Linux Host Dependencies)

• Get the source code

• Build, flash, and run a sample application

2.1.1 Select and Update OS

Click the operating system you are using.

Ubuntu

This guide covers Ubuntu version 18.04 LTS and later.

```
sudo apt update
sudo apt upgrade
```

macOS

On macOS Mojave or later, select System Preferences > Software Update. Click Update Now if necessary.

On other versions, see this Apple support topic.

Windows

Select Start > Settings > Update & Security > Windows Update. Click Check for updates and install any that are available.

2.1.2 Install dependencies

Next, you’ll install some host dependencies using your package manager.

The current minimum required version for the main dependencies are:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Min. Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMake</td>
<td>3.20.0</td>
</tr>
<tr>
<td>Python</td>
<td>3.8</td>
</tr>
<tr>
<td>Devicetree compiler</td>
<td>1.4.6</td>
</tr>
</tbody>
</table>
Ubuntu

1. If using an Ubuntu version older than 22.04, it is necessary to add extra repositories to meet the minimum required versions for the main dependencies listed above. In that case, download, inspect and execute the Kitware archive script to add the Kitware APT repository to your sources list. A detailed explanation of kitware-archive.sh can be found here kitware third-party apt repository:

   `wget https://apt.kitware.com/kitware-archive.sh`
   `sudo bash kitware-archive.sh`

2. Use apt to install the required dependencies:

   `sudo apt install --no-install-recommends git cmake ninja-build gperf \`
   `ccache dfu-util device-tree-compiler wget \`
   `python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils \`
   `--file \`
   `make gcc gcc-multilib g++-multilib libstdc++-dev libmagic1`

3. Verify the versions of the main dependencies installed on your system by entering:

   `cmake --version`
   `python3 --version`
   `dtc --version`

   Check those against the versions in the table in the beginning of this section. Refer to the Install Linux Host Dependencies page for additional information on updating the dependencies manually.

macOS

1. Install Homebrew:

   `/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/HEAD/install.sh)"

2. Use brew to install the required dependencies:

   `brew install cmake ninja gperf python3 ccache qemu dtc wget libmagic`

Windows

**Note:** Due to issues finding executables, the Zephyr Project doesn't currently support application flashing using the Windows Subsystem for Linux (WSL) (WSL). Therefore, we don't recommend using WSL when getting started.

These instructions must be run in a `cmd.exe` command prompt. The required commands differ on PowerShell.

These instructions rely on Chocolatey. If Chocolatey isn't an option, you can install dependencies from their respective websites and ensure the command line tools are on your `PATH environment variable`.

1. Install chocolatey.

2. Open a `cmd.exe` window as Administrator. To do so, press the Windows key, type “cmd.exe”, right-click the result, and choose Run as Administrator.

3. Disable global confirmation to avoid having to confirm the installation of individual programs:

   `choco feature enable -n allowGlobalConfirmation`

4. Use choco to install the required dependencies:
5. Close the window and open a new cmd.exe window as a regular user to continue.

### 2.1.3 Get Zephyr and install Python dependencies

Next, clone Zephyr and its modules into a new west workspace named zephyrproject. You'll also install Zephyr's additional Python dependencies.

**Note:** It is easy to run into Python package incompatibilities when installing dependencies at a system or user level. This situation can happen, for example, if working on multiple Zephyr versions or other projects using Python on the same machine.

For this reason it is suggested to use Python virtual environments.

**Ubuntu**

Install within virtual environment

1. Use apt to install Python venv package:
   ```bash
   sudo apt install python3-venv
   ```

2. Create a new virtual environment:
   ```bash
   python3 -m venv ~/zephyrproject/.venv
   ```

3. Activate the virtual environment:
   ```bash
   source ~/zephyrproject/.venv/bin/activate
   ```
   Once activated your shell will be prefixed with (.venv). The virtual environment can be deactivated at any time by running deactivate.

   **Note:** Remember to activate the virtual environment every time you start working.

4. Install west:
   ```bash
   pip install west
   ```

5. Get the Zephyr source code:
   ```bash
   west init ~/zephyrproject
cd ~/zephyrproject
west update
   ```

6. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.
   ```bash
   west zephyr-export
   ```

7. Zephyr's scripts/requirements.txt file declares additional Python dependencies. Install them with pip.
   ```bash
   pip install -r ~/zephyrproject/zephyr/scripts/requirements.txt
   ```

Install globally
1. Install west, and make sure ~/.local/bin is on your PATH environment variable:

   ```bash
   pip3 install --user -U west
   echo 'export PATH=~/local/bin:$PATH' >> ~/.bashrc
   source ~/.bashrc
   ```

2. Get the Zephyr source code:

   ```bash
   west init ~/zephyrproject
   cd ~/zephyrproject
   west update
   ```

3. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   ```bash
   west zephyr-export
   ```

4. Zephyr's scripts/requirements.txt file declares additional Python dependencies. Install them with pip3.

   ```bash
   pip3 install --user -r ~/zephyrproject/zephyr/scripts/requirements.txt
   ```

**macOS**

Install within virtual environment

1. Create a new virtual environment:

   ```bash
   python3 -m venv ~/zephyrproject/.venv
   ```

2. Activate the virtual environment:

   ```bash
   source ~/zephyrproject/.venv/bin/activate
   ```

   Once activated your shell will be prefixed with (.venv). The virtual environment can be deactivated at any time by running deactivate.

   **Note:** Remember to activate the virtual environment every time you start working.

3. Install west:

   ```bash
   pip install west
   ```

4. Get the Zephyr source code:

   ```bash
   west init ~/zephyrproject
   cd ~/zephyrproject
   west update
   ```

5. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   ```bash
   west zephyr-export
   ```

6. Zephyr's scripts/requirements.txt file declares additional Python dependencies. Install them with pip.

   ```bash
   pip install -r ~/zephyrproject/zephyr/scripts/requirements.txt
   ```

Install globally
1. Install west:

   pip3 install -U west

2. Get the Zephyr source code:

   west init ~/zephyrproject
   cd ~/zephyrproject
   west update

3. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   west zephyr-export

4. Zephyr's scripts/requirements.txt file declares additional Python dependencies. Install them with pip3.

   pip3 install -r ~/zephyrproject/zephyr/scripts/requirements.txt

**Windows**

Install within virtual environment

1. Create a new virtual environment:

   cd %HOMEPATH%
   python -m venv zephyrproject\.venv

2. Activate the virtual environment:

   :: cmd.exe
   zephyrproject\.venv\Scripts\activate.bat
   :: PowerShell
   zephyrproject\.venv\Scripts\Activate.ps1

   Once activated your shell will be prefixed with (.venv). The virtual environment can be deacti-
   vated at any time by running deactivate.

   **Note:** Remember to activate the virtual environment every time you start working.

3. Install west:

   pip install west

4. Get the Zephyr source code:

   west init zephyrproject
   cd zephyrproject
   west update

5. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   west zephyr-export

6. Zephyr's scripts/requirements.txt file declares additional Python dependencies. Install them with pip.

   pip install -r %HOMEPATH%\zephyrproject\zephyr\scripts\requirements.txt
Install globally

1. Install west:
   
   ```bash
   pip3 install -U west
   ```

2. Get the Zephyr source code:

   ```bash
   cd %HOMEPATH%
   west init zephyrproject
   cd zephyrproject
   west update
   ```

3. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   ```bash
   west zephyr-export
   ```

4. Zephyr's `scripts\requirements.txt` file declares additional Python dependencies. Install them with `pip3`.

   ```bash
   pip3 install -r %HOMEPATH%\zephyrproject\zephyr\scripts\requirements.txt
   ```

### 2.1.4 Install Zephyr SDK

The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr's supported architectures, which include a compiler, assembler, linker and other programs required to build Zephyr applications.

It also contains additional host tools, such as custom QEMU and OpenOCD builds that are used to emulate, flash and debug Zephyr applications.

#### Ubuntu

1. Download and verify the latest Zephyr SDK bundle:

   ```bash
   cd ~
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/zephyr-sdk-0.15.2_linux-x86_64.tar.gz
   wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/\sha256.sum | shasum --check --ignore-missing
   ```

   If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace `x86_64` with `aarch64` in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

   ```bash
   tar xvf zephyr-sdk-0.15.2_linux-x86_64.tar.gz
   ```

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following locations:

- `$HOME`
- `$HOME/.local`
- `$HOME/.local/opt`
- `$HOME/bin`
- `/opt`
- `/usr/local`
The Zephyr SDK bundle archive contains the zephyr-sdk-0.15.2 directory and, when extracted under $HOME, the resulting installation path will be $HOME/zephyr-sdk-0.15.2.

3. Run the Zephyr SDK bundle setup script:

```bash
cd zephyr-sdk-0.15.2
./setup.sh
```

**Note:** You only need to run the setup script once after extracting the Zephyr SDK bundle.

You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

4. Install udev rules, which allow you to flash most Zephyr boards as a regular user:

```bash
sudo cp ~/zephyr-sdk-0.15.2/sysroots/x86_64-pokysdk-linux/usr/share/openocd/
   \---contrib/60-openocd.rules /etc/udev/rules.d
sudo udevadm control --reload
```

**macOS**

1. Download and verify the latest Zephyr SDK bundle:

```bash
cd ~
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/
   \---zephyr-sdk-0.15.2_macos-x86_64.tar.gz
wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/
   \---sha256.sum | shasum --check --ignore-missing
```

If your host architecture is 64-bit ARM (Apple Silicon, also known as M1), replace x86_64 with aarch64 in order to download the 64-bit ARM macOS SDK.

2. Extract the Zephyr SDK bundle archive:

```bash
tar xvf zephyr-sdk-0.15.2_macos-x86_64.tar.gz
```

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following locations:

- $HOME
- $HOME/.local
- $HOME/.local/opt
- $HOME/bin
- /opt
- /usr/local

The Zephyr SDK bundle archive contains the zephyr-sdk-0.15.2 directory and, when extracted under $HOME, the resulting installation path will be $HOME/zephyr-sdk-0.15.2.

3. Run the Zephyr SDK bundle setup script:

```bash
cd zephyr-sdk-0.15.2
./setup.sh
```

**Note:** You only need to run the setup script once after extracting the Zephyr SDK bundle.
You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

Windows

1. Open a `cmd.exe` window by pressing the Windows key typing “cmd.exe”.
2. Download the latest Zephyr SDK bundle:

   ```bash
   cd %HOMEPATH%
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/zephyr-sdk-0.15.2_windows-x86_64.zip
   ```

3. Extract the Zephyr SDK bundle archive:

   ```bash
   unzip zephyr-sdk-0.15.2_windows-x86_64.zip
   ```

   **Note:** It is recommended to extract the Zephyr SDK bundle at one of the following locations:
   - `%HOMEPATH%`
   - `%PROGRAMFILES%`

   The Zephyr SDK bundle archive contains the `zephyr-sdk-0.15.2` directory and, when extracted under `%HOMEPATH%`, the resulting installation path will be `%HOMEPATH%\zephyr-sdk-0.15.2`.

4. Run the Zephyr SDK bundle setup script:

   ```bash
   cd zephyr-sdk-0.15.2
   setup.cmd
   ```

   **Note:** You only need to run the setup script once after extracting the Zephyr SDK bundle.

   You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

### 2.1.5 Build the Blinky Sample

**Note:** Blinky is compatible with most, but not all, boards. If your board does not meet Blinky’s `blinky-sample-requirements`, then `hello_world` is a good alternative.

If you are unsure what name west uses for your board, `west boards` can be used to obtain a list of all boards Zephyr supports.

Build the `blinky-sample` with `west build`, changing `<your-board-name>` appropriately for your board:

**Ubuntu**

```bash
cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

**macOS**

```bash
cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

**Windows**

```bash
```
```bash
cd %HOMEPATH%\zephyrproject\zephyr
west build -p always -b <your-board-name> samples\basic\blinky
```

The `-p always` option forces a pristine build, and is recommended for new users. Users may also use the `-p auto` option, which will use heuristics to determine if a pristine build is required, such as when building another sample.

### 2.1.6 Flash the Sample

Connect your board, usually via USB, and turn it on if there’s a power switch. If in doubt about what to do, check your board’s page in boards.

Then flash the sample using `west flash`:

```bash
west flash
```

You may need to install additional host tools required by your board. The `west flash` command will print an error if any required dependencies are missing.

If you’re using `blinky`, the LED will start to blink as shown in this figure:

![Fig. 2.1: Phytec reel_board running blinky](image)

### 2.1.7 Next Steps

Here are some next steps for exploring Zephyr:

- Try other samples-and-demos
- Learn about Application Development and the `west` tool
- Find out about west’s flashing and debugging features, or more about Flashing and Hardware Debugging in general
- Check out Beyond the Getting Started Guide for additional setup alternatives and ideas
- Discover Resources for getting help from the Zephyr community
2.1.8 Troubleshooting Installation

Here are some tips for fixing some issues related to the installation process.

Double Check the Zephyr SDK Variables When Updating

When updating Zephyr SDK, check whether the `ZEPHYR_TOOLCHAIN_VARIANT` or `ZEPHYR_SDK_INSTALL_DIR` environment variables are already set. See Updating the Zephyr SDK toolchain for more information.

For more information about these environment variables in Zephyr, see Important Environment Variables.

2.1.9 Asking for Help

You can ask for help on a mailing list or on Discord. Please send bug reports and feature requests to GitHub.

- **Mailing Lists:** users@lists.zephyrproject.org is usually the right list to ask for help. Search archives and sign up here.
- **Discord:** You can join with this Discord invite.
- **GitHub:** Use GitHub issues for bugs and feature requests.

How to Ask

**Important:** Please search this documentation and the mailing list archives first. Your question may have an answer there.

Don’t just say “this isn’t working” or ask “is this working?”. Include as much detail as you can about:

1. What you want to do
2. What you tried (commands you typed, etc.)
3. What happened (output of each command, etc.)

Use Copy/Paste

Please copy/paste text instead of taking a picture or a screenshot of it. Text includes source code, terminal commands, and their output.

Doing this makes it easier for people to help you, and also helps other users search the archives.

When copy/pasting more than 5 lines of text into Discord, create a snippet using three backticks to delimit the snippet.

2.2 Beyond the Getting Started Guide

The Getting Started Guide gives a straight-forward path to set up your Linux, macOS, or Windows environment for Zephyr development. In this document, we delve deeper into Zephyr development setup issues and alternatives.
2.2.1 Python and pip

Python 3 and its package manager, pip\(^1\), are used extensively by Zephyr to install and run scripts required to compile and run Zephyr applications, set up and maintain the Zephyr development environment, and build project documentation.

Depending on your operating system, you may need to provide the --user flag to the pip3 command when installing new packages. This is documented throughout the instructions. See Installing Packages in the Python Packaging User Guide for more information about pip\(^1\), including information on --user.

- On Linux, make sure ~/.local/bin is at the front of your PATH environment variable, or programs installed with --user won't be found. Installing with --user avoids conflicts between pip and the system package manager, and is the default on Debian-based distributions.
- On macOS, Homebrew disables --user.
- On Windows, see the Installing Packages information on --user if you require using this option.

On all operating systems, pip's -U flag installs or updates the package if the package is already installed locally but a more recent version is available. It is good practice to use this flag if the latest version of a package is required. (Check the scripts/requirements.txt file to see if a specific Python package version is expected.)

2.2.2 Advanced Platform Setup

Here are some alternative instructions for more advanced platform setup configurations for supported development platforms:

Install Linux Host Dependencies

Documentation is available for these Linux distributions:

- Ubuntu
- Fedora
- Clear Linux
- Arch Linux

For distributions that are not based on rolling releases, some of the requirements and dependencies may not be met by your package manager. In that case please follow the additional instructions that are provided to find software from sources other than the package manager.

Note: If you’re working behind a corporate firewall, you’ll likely need to configure a proxy for accessing the internet, if you haven’t done so already. While some tools use the environment variables http_proxy and https_proxy to get their proxy settings, some use their own configuration files, most notably apt and git.

Update Your Operating System

Ensure your host system is up to date.

Ubuntu

---

\(^1\) pip is Python’s package installer. Its install command first tries to re-use packages and package dependencies already installed on your computer. If that is not possible, pip install downloads them from the Python Package Index (PyPI) on the Internet.

\(^2\) The package versions requested by Zephyr’s requirements.txt may conflict with other requirements on your system, in which case you may want to set up a virtualenv for Zephyr development.
Install Requirements and Dependencies  Note that both Ninja and Make are installed with these instructions; you only need one.

Ubuntu

```bash
sudo apt-get install --no-install-recommends git cmake ninja-build gperf \
   ccache dfu-util device-tree-compiler wget \
   python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils file␣
   → libpython3.8-dev \
   make gcc gcc-multilib g++-multilib libstdc++ libmagic1
```

Fedora

```bash
sudo dnf group install "Development Tools" "C Development Tools and Libraries"
sudo dnf install git cmake ninja-build gperf ccache dfu-util dtc wget \
   python3-pip python3-tkinter xz file glibc-devel.i686 libstdc++-devel.i686 python38 \
   SDL2-devel
```

Clear Linux

```bash
sudo swupd bundle-add c-basic dev-utils dfu-util dtc os-core-dev python-basic python3-tcl
```

The Clear Linux focus is on native performance and security and not cross-compilation. For that reason it uniquely exports by default to the environment of all users a list of compiler and linker flags. Zephyr's CMake build system will either warn or fail because of these. To clear the C/C++ flags among these and fix the Zephyr build, run the following command as root then log out and back in:

```bash
echo 'unset CFLAGS CXXFLAGS' >> /etc/profile.d/unset_cflags.sh
```

Note this command unsets the C/C++ flags for all users on the system. Each Linux distribution has a unique, relatively complex and potentially evolving sequence of bash initialization files sourcing each other and Clear Linux is no exception. If you need a more flexible solution, start by looking at the logic in /usr/share/defaults/etc/profile.

Arch Linux

```bash
sudo pacman -S git cmake ninja gperf ccache dfu-util dtc wget \
   python-pip python-setuptools python-wheel tk xz file make
```

CMake  A recent CMake version is required. Check what version you have by using cmake --version. If you have an older version, there are several ways of obtaining a more recent one:
• On Ubuntu, you can follow the instructions for adding the kitware third-party apt repository to get an updated version of cmake using apt.

• Download and install a packaged cmake from the CMake project site. (Note this won’t uninstall the previous version of cmake.)

```
cd ~
wget https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-˓
  --Linux-x86_64.sh
chmod +x cmake-3.21.1-Linux-x86_64.sh
sudo ./cmake-3.21.1-Linux-x86_64.sh --skip-license --prefix=/usr/local
hash -r
```

The `hash -r` command may be necessary if the installation script put cmake into a new location on your PATH.

• Download and install from the pre-built binaries provided by the CMake project itself in the CMake Downloads page. For example, to install version 3.21.1 in `~/bin/cmake`:

```
mkdir $HOME/bin/cmake & cd $HOME/bin/cmake
wget https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-˓
  --Linux-x86_64.sh
yes | sh cmake-3.21.1-Linux-x86_64.sh | cat
echo "export PATH=$PWD/cmake-3.21.1-Linux-x86_64/bin:\$PATH" >> $HOME/.zephyrrc
```

• Use `pip3`:

```
pip3 install --user cmake
```

Note this won’t uninstall the previous version of cmake and will install the new cmake into your `~/local/bin` folder so you’ll need to add `~/local/bin` to your PATH. (See Python and pip for details.)

• Check your distribution’s beta or unstable release package library for an update.

• On Ubuntu you can also use snap to get the latest version available:

```
sudo snap install cmake
```

After updating cmake, verify that the newly installed cmake is found using `cmake --version`. You might also want to uninstall the CMake provided by your package manager to avoid conflicts. (Use `whereis cmake` to find other installed versions.)

**DTC (Device Tree Compiler)** A recent DTC version is required. Check what version you have by using `dtc --version`. If you have an older version, either install a more recent one by building from source, or use the one that is bundled in the Zephyr SDK by installing it.

**Python** A modern Python 3 version is required. Check what version you have by using `python3 --version`. If you have an older version, you will need to install a more recent Python 3. You can build from source, or use a backport from your distribution’s package manager channels if one is available. Isolating this Python in a virtual environment is recommended to avoid interfering with your system Python.

**Install the Zephyr Software Development Kit (SDK)** The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr’s supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).
The Zephyr SDK supports the following target architectures:

- ARC (32-bit and 64-bit; ARCv1, ARCv2, ARCv3)
- ARM (32-bit and 64-bit; ARMv6, ARMv7, ARMv8; A/R/M Profiles)
- MIPS (32-bit and 64-bit)
- Nios II
- RISC-V (32-bit and 64-bit; RV32I, RV32E, RV64I)
- x86 (32-bit and 64-bit)
- Xtensa

Follow these steps to install the Zephyr SDK:

1. Download and verify the latest Zephyr SDK bundle:

   ```bash
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/
   → zephyr-sdk-0.15.2_linux-x86_64.tar.gz
   get -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/
   → sha256.sum | shasum --check --ignore-missing
   ```

   You can change 0.15.2 to another version if needed; the Zephyr SDK Releases page contains all available SDK releases.

   If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace x86_64 with aarch64 in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

   ```bash
   cd <sdk download directory>
   tar xvf zephyr-sdk-0.15.2_linux-x86_64.tar.gz
   ```

3. Run the Zephyr SDK bundle setup script:

   ```bash
   cd zephyr-sdk-0.15.2
   ./setup.sh
   ```

   If this fails, make sure Zephyr's dependencies were installed as described in Install Requirements and Dependencies.

If you want to uninstall the SDK, remove the directory where you installed it. If you relocate the SDK directory, you need to re-run the setup script.

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following locations:

- `$HOME`
- `$HOME/.local`
- `$HOME/.local/opt`
- `$HOME/bin`
- `/opt`
- `/usr/local`

The Zephyr SDK bundle archive contains the zephyr-sdk-0.15.2 directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-0.15.2`.

If you install the Zephyr SDK outside any of these locations, you must register the Zephyr SDK in the CMake package registry by running the setup script, or set `ZEPHYR_SDK_INSTALL_DIR` to point to the Zephyr SDK installation directory.
You can also use `ZEPHYR_SDK_INSTALL_DIR` for pointing to a directory containing multiple Zephyr SDKs, allowing for automatic toolchain selection. For example, `ZEPHYR_SDK_INSTALL_DIR=/company/tools`, where the `company/tools` folder contains the following subfolders:

- /company/tools/zephyr-sdk-0.13.2
- /company/tools/zephyr-sdk-a.b.c
- /company/tools/zephyr-sdk-x.y.z

This allows the Zephyr build system to choose the correct version of the SDK, while allowing multiple Zephyr SDKs to be grouped together at a specific path.

**Building on Linux without the Zephyr SDK**  
The Zephyr SDK is provided for convenience and ease of use. It provides toolchains for all Zephyr target architectures, and does not require any extra flags when building applications or running tests. In addition to cross-compilers, the Zephyr SDK also provides pre-built host tools. It is, however, possible to build without the SDK's toolchain by using another toolchain as described in the [Toolchains](#) section.

As already noted above, the SDK also includes prebuilt host tools. To use the SDK's prebuilt host tools with a toolchain from another source, you must set the `ZEPHYR_SDK_INSTALL_DIR` environment variable to the Zephyr SDK installation directory. To build without the Zephyr SDK's prebuilt host tools, the `ZEPHYR_SDK_INSTALL_DIR` environment variable must be unset.

To make sure this variable is unset, run:

```
unset ZEPHYR_SDK_INSTALL_DIR
```

**macOS alternative setup instructions**

**Important note about Gatekeeper**  
Starting with macOS 10.15 Catalina, applications launched from the macOS Terminal application (or any other terminal emulator) are subject to the same system security policies that are applied to applications launched from the Dock. This means that if you download executable binaries using a web browser, macOS will not let you execute those from the Terminal by default. In order to get around this issue you can take two different approaches:

- Run `xattr -r -d com.apple.quarantine /path/to/folder` where `/path/to/folder` is the path to the enclosing folder where the executables you want to run are located.
- Open “System Preferences” -> “Security and Privacy” -> “Privacy” and then scroll down to “Developer Tools”. Then unlock the lock to be able to make changes and check the checkbox corresponding to your terminal emulator of choice. This will apply to any executable being launched from such terminal program.

Note that this section does not apply to executables installed with Homebrew, since those are automatically un-quarantined by brew itself. This is however relevant for most Toolchains.

**Additional notes for MacPorts users**  
While MacPorts is not officially supported in this guide, it is possible to use MacPorts instead of Homebrew to get all the required dependencies on macOS. Note also that you may need to install rust and cargo for the Python dependencies to install correctly.

**Windows alternative setup instructions**

**Windows 10 WSL (Windows Subsystem for Linux)**  
If you are running a recent version of Windows 10 you can make use of the built-in functionality to natively run Ubuntu binaries directly on a standard command-prompt. This allows you to use software such as the Zephyr SDK without setting up a virtual machine.
Warning: Windows 10 version 1803 has an issue that will cause CMake to not work properly and is fixed in version 1809 (and later). More information can be found in Zephyr Issue 10420.

1. Install the Windows Subsystem for Linux (WSL).

   Note: For the Zephyr SDK to function properly you will need Windows 10 build 15002 or greater. You can check which Windows 10 build you are running in the “About your PC” section of the System Settings. If you are running an older Windows 10 build you might need to install the Creator’s Update.

2. Follow the Ubuntu instructions in the Install Linux Host Dependencies document.

2.2.3 Install a Toolchain

Zephyr binaries are compiled and linked by a toolchain comprised of a cross-compiler and related tools which are different from the compiler and tools used for developing software that runs natively on your host operating system.

You can install the Zephyr SDK to get toolchains for all supported architectures, or install an alternate toolchain recommended by the SoC vendor or a specific board (check your specific board-level documentation).

You can configure the Zephyr build system to use a specific toolchain by setting environment variables such as ZEPHYR_TOOLCHAIN_VARIANT to a supported value, along with additional variable(s) specific to the toolchain variant.

2.2.4 Updating the Zephyr SDK toolchain

When updating Zephyr SDK, check whether the ZEPHYR_TOOLCHAIN_VARIANT or ZEPHYR_SDK_INSTALL_DIR environment variables are already set.

- If the variables are not set, the latest compatible version of Zephyr SDK will be selected by default. Proceed to next step without making any changes.

- If ZEPHYR_TOOLCHAIN_VARIANT is set, the corresponding toolchain will be selected at build time. Zephyr SDK is identified by the value zephyr. If the ZEPHYR_TOOLCHAIN_VARIANT environment variable is not zephyr, then either unset it or change its value to zephyr to make sure Zephyr SDK is selected.

- If the ZEPHYR_SDK_INSTALL_DIR environment variable is set, it will override the default lookup location for Zephyr SDK. If you install Zephyr SDK to one of the recommended locations, you can unset this variable. Otherwise, set it to your chosen install location.

For more information about these environment variables in Zephyr, see Important Environment Variables.

2.2.5 Cloning the Zephyr Repositories

The Zephyr project source is maintained in the GitHub zephyr repo. External modules used by Zephyr are found in the parent GitHub Zephyr project. Because of these dependencies, it’s convenient to use the Zephyr-created west tool to fetch and manage the Zephyr and external module source code. See Basics for more details.

Once your development tools are installed, use West (Zephyr’s meta-tool) to create, initialize, and download sources from the zephyr and external module repos. We’ll use the name zephyrproject, but you can choose any name that does not contain a space anywhere in the path.
west init zephyrproject
cd zephyrproject
west update

The `west update` command fetches and keeps *Modules (External projects)* in the `zephyrproject` folder in sync with the code in the local `zephyr` repo.

**Warning:** You must run `west update` any time the `zephyr/west.yml` changes, caused, for example, when you pull the `zephyr` repository, switch branches in it, or perform a `git bisect` inside of it.

### Keeping Zephyr updated

To update the Zephyr project source code, you need to get the latest changes via git. Afterwards, run `west update` as mentioned in the previous paragraph.

```
# replace zephyrproject with the path you gave west init
cd zephyrproject/zephyr
git pull
west update
```

#### 2.2.6 Export Zephyr CMake package

The *Zephyr CMake Package* can be exported to CMake’s user package registry if it has not already been done as part of *Getting Started Guide*.

#### 2.2.7 Board Aliases

Developers who work with multiple boards may find explicit board names cumbersome and want to use aliases for common targets. This is supported by a CMake file with content like this:

```
# Variable `foo_BOARD_ALIAS=bar` replaces `BOARD=foo` with `BOARD=bar` and
# sets `BOARD_ALIAS=foo` in the CMake cache.
set(pca10028_BOARD_ALIAS nrf51dk_nrf51422)
set(pca10056_BOARD_ALIAS nrf52840dk_nrf52840)
set(k64f_BOARD_ALIAS frdm_k64f)
set(sltb004a_BOARD_ALIAS efr32mg_sltb004a)
```

and specifying its location in `ZEPHYR_BOARD_ALIASES`. This enables use of aliases pca10028 in contexts like `cmake -DBOARD=pca10028` and `west -b pca10028`.

#### 2.2.8 Build and Run an Application

You can build, flash, and run Zephyr applications on real hardware using a supported host system. Depending on your operating system, you can also run it in emulation with QEMU, or as a native POSIX application. Additional information about building applications can be found in the *Building an Application* section.

**Build Blinky**

Let's build the blinky-sample sample application.
Zephyr applications are built to run on specific hardware, called a “board”. We’ll use the Phytec reel_board here, but you can change the reel_board build target to another value if you have a different board. See boards or run west boards from anywhere inside the zephyrproject directory for a list of supported boards.

1. Go to the zephyr repository:
   ```
   cd zephyrproject/zephyr
   ```

2. Build the blinky sample for the reel_board:
   ```
   west build -b reel_board samples/basic/blinky
   ```

   The main build products will be in build/zephyr; build/zephyr/zephyr.elf is the blinky application binary in ELF format. Other binary formats, disassembly, and map files may be present depending on your board.

   The other sample applications in the samples folder are documented in samples-and-demos.

   **Note:** If you want to re-use an existing build directory for another board or application, you need to add the parameter `-p=auto` to `west build` to clean out settings and artifacts from the previous build.

### Run the Application by Flashing to a Board

Most hardware boards supported by Zephyr can be flashed by running `west flash`. This may require board-specific tool installation and configuration to work properly.

See [Run an Application](run-an-application-overview) and your specific board’s documentation in boards for additional details.

### Setting udev rules

Flashing a board requires permission to directly access the board hardware, usually managed by installation of the flashing tools. On Linux systems, if the `west flash` command fails, you likely need to define udev rules to grant the needed access permission.

Udev is a device manager for the Linux kernel and the udev daemon handles all user space events raised when a hardware device is added (or removed) from the system. We can add a rules file to grant access permission by non-root users to certain USB-connected devices.

The OpenOCD (On-Chip Debugger) project conveniently provides a rules file that defined board-specific rules for most Zephyr-supported arm-based boards, so we recommend installing this rules file by downloading it from their sourceforge repo, or if you've installed the Zephyr SDK there is a copy of this rules file in the SDK folder:

- Either download the OpenOCD rules file and copy it to the right location:

  ```
  wget -O 60-openocd.rules https://sf.net/p/openocd/code/ci/master/tree/contrib/60-
  --openocd.rules?format=raw
  sudo cp 60-openocd.rules /etc/udev/rules.d
  ```

- or copy the rules file from the Zephyr SDK folder:

  ```
  sudo cp ${ZEPHYR_SDK_INSTALL_DIR}/sysroots/x86_64-pokysdk-linux/usr/share/
  --openocd/contrib/60-openocd.rules /etc/udev/rules.d
  ```

---

2 This has become something of a misnomer over time. While the target can be, and often is, a microprocessor running on its own dedicated hardware board, Zephyr also supports using QEMU to run targets built for other architectures in emulation, targets which produce native host system binaries that implement Zephyr’s driver interfaces with POSIX APIs, and even running different Zephyr-based binaries on CPU cores of differing architectures on the same physical chip. Each of these hardware configurations is called a “board,” even though that doesn’t always make perfect sense in context.
Then, in either case, ask the udev daemon to reload these rules:

```
sudo udevadm control --reload
```

Unplug and plug in the USB connection to your board, and you should have permission to access the board hardware for flashing. Check your board-specific documentation (boards) for further information if needed.

### Run the Application in QEMU

On Linux and macOS, you can run Zephyr applications via emulation on your host system using QEMU when targeting either the x86 or ARM Cortex-M3 architectures. (QEMU is included with the Zephyr SDK installation.)

For example, you can build and run the `hello_world` sample using the x86 emulation board configuration (`qemu_x86`), with:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
west build -t run
```

To exit QEMU, type Ctrl-a, then x.

Use `qemu_cortex_m3` to target an emulated Arm Cortex-M3 sample.

### Run a Sample Application natively (POSIX OS)

You can compile some samples to run as host processes on a POSIX OS. This is currently only tested on Linux hosts. See `native_posix` for more information. On 64-bit host operating systems, you need to install a 32-bit C library; see `native_posix_deps` for details.

First, build Hello World for `native_posix`.

```
# From the root of the zephyr repository
west build -b native_posix samples/hello_world
```

Next, run the application.

```
west build -t run
# or just run zephyr.exe directly:
./build/zephyr/zephyr.exe
```

Press Ctrl-C to exit.

You can run `./build/zephyr/zephyr.exe --help` to get a list of available options.

This executable can be instrumented using standard tools, such as gdb or valgrind.

### 2.3 Environment Variables

Various pages in this documentation refer to setting Zephyr-specific environment variables. This page describes how.

#### 2.3.1 Setting Variables
Option 1: Just Once

To set the environment variable `MY_VARIABLE` to `foo` for the lifetime of your current terminal window:

**Linux/macOS**

```bash
export MY_VARIABLE=foo
```

**Windows**

```cmd
set MY_VARIABLE=foo
```

**Warning:** This is best for experimentation. If you close your terminal window, use another terminal window or tab, restart your computer, etc., this setting will be lost forever.

Using options 2 or 3 is recommended if you want to keep using the setting.

Option 2: In all Terminals

**Linux/macOS**

Add the `export MY_VARIABLE=foo` line to your shell's startup script in your home directory. For Bash, this is usually `~/.bashrc` on Linux or `~/.bash_profile` on macOS. Changes in these startup scripts don't affect shell instances already started; try opening a new terminal window to get the new settings.

**Windows**

You can use the `setx` program in `cmd.exe` or the third-party RapidEE program.

To use `setx`, type this command, then close the terminal window. Any new `cmd.exe` windows will have `MY_VARIABLE` set to `foo`.

```cmd
setx MY_VARIABLE foo
```

To install RapidEE, a freeware graphical environment variable editor, using Chocolatey in an Administrator command prompt:

```bash
choco install rapidee
```

You can then run `rapidee` from your terminal to launch the program and set environment variables. Make sure to use the "User" environment variables area – otherwise, you have to run RapidEE as administrator. Also make sure to save your changes by clicking the Save button at top left before exiting. Settings you make in RapidEE will be available whenever you open a new terminal window.

Option 3: Using `zephyr.rc` files

Choose this option if you don't want to make the variable's setting available to all of your terminals, but still want to save the value for loading into your environment when you are using Zephyr.

**Linux/macOS**

Create a file named `~/.zephyr.rc` if it doesn't exist, then add this line to it:

```bash
export MY_VARIABLE=foo
```

To get this value back into your current terminal environment, **you must run** `source zephyr-env.sh` from the main `zephyr` repository. Among other things, this script sources `~/.zephyr.rc`.

The value will be lost if you close the window, etc.; run `source zephyr-env.sh` again to get it back.

**Windows**
Add the line `set MY_VARIABLE=foo` to the file `%userprofile%\zephyrrc.cmd` using a text editor such as Notepad to save the value.

To get this value back into your current terminal environment, **you must run** `zephyr-env.cmd` in a `cmd.exe` window after changing directory to the main zephyr repository. Among other things, this script runs `%userprofile%\zephyrrc.cmd`. The value will be lost if you close the window, etc.; run `zephyr-env.cmd` again to get it back.

These scripts:

- set `ZEPHYR_BASE` to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your `PATH` environment variable
- loads any settings from the `zephyrrc` files described above in Option 3: Using `zephyrrc` files.

You can thus use them any time you need any of these settings.

### 2.3.2 Zephyr Environment Scripts

You can use the zephyr repository scripts `zephyr-env.sh` (for macOS and Linux) and `zephyr-env.cmd` (for Windows) to load Zephyr-specific settings into your current terminal's environment. To do so, run this command from the zephyr repository:

**Linux/macOS**

```
source zephyr-env.sh
```

**Windows**

```
zephyr-env.cmd
```

These scripts:

- set `ZEPHYR_BASE` to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your `PATH` environment variable
- loads any settings from the `zephyrrc` files described above in Option 3: Using `zephyrrc` files.

You can thus use them any time you need any of these settings.

### 2.3.3 Important Environment Variables

Some **Important Build System Variables** can also be set in the environment. Here is a description of some of these important environment variables. This is not a comprehensive list.

- **BOARD**
  
  See Important Build System Variables.

- **CONF_FILE**
  
  See Important Build System Variables.

- **SHIELD**
  
  See Shields.

- **ZEPHYR_BASE**
  
  See Important Build System Variables.
The following additional environment variables are significant when configuring the toolchain used to build Zephyr applications.

**ZEPHYR_SDK_INSTALL_DIR**
Path where Zephyr SDK is installed.

**ZEPHYR_TOOLCHAIN_VARIANT**
The name of the toolchain to use.

**{TOOLCHAIN}_TOOLCHAIN_PATH**
Path to the toolchain specified by **ZEPHYR_TOOLCHAIN_VARIANT**. For example, if ZEPHYR_TOOLCHAIN_VARIANT=llvm, use LLVM_TOOLCHAIN_PATH. (Note the capitalization when forming the environment variable name.)

You might need to update some of these variables when you update the Zephyr SDK toolchain.

Emulators and boards may also depend on additional programs. The build system will try to locate those programs automatically, but may rely on additional CMake or environment variables to do so. Please consult your emulator's or board's documentation for more information. The following environment variables may be useful in such situations:

**PATH**
PATH is an environment variable used on Unix-like or Microsoft Windows operating systems to specify a set of directories where executable programs are located.

## 2.4 Application Development

**Note:** In this document, we'll assume your application directory is `<home>/app`, and that its build directory is `<home>/app/build`. (These terms are defined in the following Overview.) On Linux/macOS, `<home>` is equivalent to `~`, whereas on Windows it's `%userprofile%`.

### 2.4.1 Overview

Zephyr's build system is based on CMake.

The build system is application-centric, and requires Zephyr-based applications to initiate building the kernel source tree. The application build controls the configuration and build process of both the application and Zephyr itself, compiling them into a single binary.

Zephyr's base directory hosts Zephyr's own source code, its kernel configuration options, and its build definitions.

The files in the application directory link Zephyr with the application. This directory contains all application-specific files, such as configuration options and source code.

An application in its simplest form has the following contents:
These contents are:

- **CMakeLists.txt**: This file tells the build system where to find the other application files, and links the application directory with Zephyr's CMake build system. This link provides features supported by Zephyr's build system, such as board-specific kernel configuration files, the ability to run and debug compiled binaries on real or emulated hardware, and more.

- **Kernel configuration files**: An application typically provides a Kconfig configuration file (usually called `prj.conf`) that specifies application-specific values for one or more kernel configuration options. These application settings are merged with board-specific settings to produce a kernel configuration. See [Kconfig Configuration](#) below for more information.

- **Application source code files**: An application typically provides one or more application-specific files, written in C or assembly language. These files are usually located in a sub-directory called `src`.

Once an application has been defined, you can use CMake to create project files for building it from a directory where you want to host these files. This is known as the **build directory**. Application build artifacts are always generated in a build directory; Zephyr does not support “in-tree” builds.

The following sections describe how to create, build, and run Zephyr applications, followed by more detailed reference material.

### 2.4.2 Application types

Based on where the source code of the application is located we can distinguish between three basic application types.

- Zephyr repository application
- Zephyr workspace application
- Zephyr freestanding application

You can find out more about how the build system supports all the application types described in this section in the [Zephyr CMake Package](#) section.

#### Zephyr repository application

An application located within the `zephyr` folder in a Zephyr `west workspace` is referred to as a Zephyr repository application. In the following example, the `hello_world` sample is a Zephyr repository application:
Zephyr workspace application

An application located within a workspace, but outside the Zephyr repository (and thus folder) itself, is referred to as a Zephyr workspace application. In the following example, `app` is a Zephyr workspace application:

```
zephyrproject/
  .west/
    config
  zephyr/
  bootloader/
  modules/
  tools/
  <vendor/private-repositories>/
  applications/
    app/
```

Zephyr freestanding application

A Zephyr application located outside of a Zephyr workspace is referred to as a Zephyr freestanding application. In the following example, `app` is a Zephyr freestanding application:

```
<home>/
  zephyrproject/
    .west/
      config
    zephyr/
    bootloader/
    modules/
    ...
  app/
    CMakeLists.txt
    prj.conf
    src/
      main.c
```

2.4.3 Example workspace application

A reference workspace application contained in its own Git repository can be found in the Example Application repository. It can be used as a reference on how to structure out-of-tree, Zephyr-based workspace applications using the T2 star topology. It also demonstrates the out-of-tree use of features commonly used in applications such as:

- Custom boards
- Custom devicetree bindings
- Custom drivers
- Continuous Integration (CI) setup
• An example west extension command

## 2.4.4 Creating an Application

Follow these steps to create a new application directory. (Refer to the Example Application repository for a reference standalone application in its own Git repository or to samples-and-demos for existing applications provided as part of Zephyr.)

1. Create an application directory on your workstation computer, outside of the Zephyr base directory. Usually you’ll want to create it somewhere under your user’s home directory.

   For example, in a Unix shell or Windows cmd.exe prompt, navigate to where you want to create your application, then enter:

   ```bash
   mkdir app
   ```

   **Warning:** Building Zephyr or creating an application in a directory with spaces anywhere on the path is not supported. So the Windows path `C:\Users\YourName\app` will work, but `C:\Users\Your Name\app` will not.

2. It’s recommended to place all application source code in a subdirectory named `src`. This makes it easier to distinguish between project files and sources.

   Continuing the previous example, enter:

   ```bash
   cd app
   mkdir src
   ```

3. Place your application source code in the `src` sub-directory. For this example, we’ll assume you created a file named `src/main.c`.

4. Create a file named `CMakeLists.txt` in the `app` directory with the following contents:

   ```cmake
   cmake_minimum_required(VERSION 3.20.0)
   find_package(Zephyr)
   project(my_zephyr_app)
   target_sources(app PRIVATE src/main.c)
   ```

   `cmake_minimum_required()` is required to be in your `CMakeLists.txt` by CMake. It is also invoked by the Zephyr package. The most recent of the two versions will be enforced by CMake.

   `find_package(Zephyr)` pulls in the Zephyr build system, which creates a CMake target named `app` (see Zephyr CMake Package). Adding sources to this target is how you include them in the build. The Zephyr package will define `Zephyr-Kernel` as a CMake project and enable support for the C, CXX, ASM languages.

   `project(my_zephyr_app)` is required for defining your application project. This must be called after `find_package(Zephyr)` to avoid interference with Zephyr's `project(Zephyr-Kernel)`.

   `target_sources(app PRIVATE src/main.c)` is to add your source file to the `app` target. This must come after `find_package(Zephyr)` which defines the target.

5. Set Kconfig configuration options. See Kconfig Configuration.

6. Configure any devicetree overlays needed by your application. See Set devicetree overlays.
2.4.5 Important Build System Variables

You can control the Zephyr build system using many variables. This section describes the most important ones that every Zephyr developer should know about.

Note: The variables BOARD, CONF_FILE, and DTC_OVERLAY_FILE can be supplied to the build system in 3 ways (in order of precedence):

- As a parameter to the west build or cmake invocation via the -D command-line switch. If you have multiple overlay files, you should use quotations, "file1.overlay;file2.overlay"
- As Environment Variables.
- As a set(<VARIABLE> <VALUE>) statement in your CMakeLists.txt

- ZEPHYR_BASE: Zephyr base variable used by the build system. find_package(Zephyr) will automatically set this as a cached CMake variable. But ZEPHYR_BASE can also be set as an environment variable in order to force CMake to use a specific Zephyr installation.

- BOARD: Selects the board that the application’s build will use for the default configuration. See boards for built-in boards, and Board Porting Guide for information on adding board support.

- CONF_FILE: Indicates the name of one or more Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. Each file includes Kconfig configuration values that override the default configuration values. See The Initial Configuration for more information.

- OVERLAY_CONFIG: Additional Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. This can be useful in order to leave CONF_FILE at its default value, but “mix in” some additional configuration options.

- DTC_OVERLAY_FILE: One or more devicetree overlay files to use. Multiple files can be separated with semicolons. See Set devicetree overlays for examples and Introduction to devicetree for information about devicetree and Zephyr.

- SHIELD: see Shields

- ZEPHYR_MODULES: A CMake list containing absolute paths of additional directories with source code, Kconfig, etc. that should be used in the application build. See Modules (External projects) for details. If you set this variable, it must be a complete list of all modules to use, as the build system will not automatically pick up any modules from west.

- ZEPHYR_EXTRA_MODULES: Like ZEPHYR_MODULES, except these will be added to the list of modules found via west, instead of replacing it.

Note: You can use a Zephyr Build Configuration CMake package to share common settings for these variables.

2.4.6 Application CMakeLists.txt

Every application must have a CMakeLists.txt file. This file is the entry point, or top level, of the build system. The final zephyr.elf image contains both the application and the kernel libraries.
This section describes some of what you can do in your CMakeLists.txt. Make sure to follow these steps in order:

1. If you only want to build for one board, add the name of the board configuration for your application on a new line. For example:

```
set(BOARD qemu_x86)
```

Refer to boards for more information on available boards.

The Zephyr build system determines a value for BOARD by checking the following, in order (when a BOARD value is found, CMake stops looking further down the list):

- Any previously used value as determined by the CMake cache takes highest precedence. This ensures you don't try to run a build with a different BOARD value than you set during the build configuration step.
- Any value given on the CMake command line (directly or indirectly via west build) using `-DBOARD=YOUR_BOARD` will be checked for and used next.
- If an environment variable BOARD is set, its value will then be used.
- Finally, if you set BOARD in your application CMakeLists.txt as described in this step, this value will be used.

2. If your application uses a configuration file or files other than the usual prj.conf (or prj_YOUR_BOARD.conf, where YOUR_BOARD is a board name), add lines setting the CONF_FILE variable to these files appropriately. If multiple filenames are given, separate them by a single space or semicolon. CMake lists can be used to build up configuration fragment files in a modular way when you want to avoid setting CONF_FILE in a single place. For example:

```
set(CONF_FILE "fragment_file1.conf")
list(APPEND CONF_FILE "fragment_file2.conf")
```

See The Initial Configuration for more information.

3. If your application uses devicetree overlays, you may need to set DTC_OVERLAY_FILE. See Set devicetree overlays.

4. If your application has its own kernel configuration options, create a Kconfig file in the same directory as your application's CMakeLists.txt.

   See the Kconfig section of the manual for detailed Kconfig documentation.

An (unlikely) advanced use case would be if your application has its own unique configuration options that are set differently depending on the build configuration.

If you just want to set application specific values for existing Zephyr configuration options, refer to the CONF_FILE description above.

Structure your Kconfig file like this:

```
# SPDX-License-Identifier: Apache-2.0

mainmenu "Your Application Name"

# Your application configuration options go here

# Sources Kconfig.zephyr in the Zephyr root directory.
#
# Note: All 'source' statements work relative to the Zephyr root directory (due
# to the $srctree environment variable being set to $ZEPHYR_BASE). If you want
# to 'source' relative to the current Kconfig file instead, use 'rsource' (or a
# path relative to the Zephyr root).
source "Kconfig.zephyr"
```
Note: Environment variables in source statements are expanded directly, so you do not need to define an option env="ZEPHYR_BASE" Kconfig "bounce" symbol. If you use such a symbol, it must have the same name as the environment variable.

See Kconfig extensions for more information.

The Kconfig file is automatically detected when placed in the application directory, but it is also possible for it to be found elsewhere if the CMake variable KCONFIG_ROOT is set with an absolute path.

5. Specify that the application requires Zephyr on a new line, after any lines added from the steps above:

```cmake
find_package(Zephyr)
project(my_zephyr_app)
```

Note: find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE}) can be used if enforcing a specific Zephyr installation by explicitly setting the ZEPHYR_BASE environment variable should be supported. All samples in Zephyr supports the ZEPHYR_BASE environment variable.

6. Now add any application source files to the 'app' target library, each on their own line, like so:

```cmake
target_sources(app PRIVATE src/main.c)
```

Below is a simple example CMakeList.txt:

```cmake
set(BOARD qemu_x86)
find_package(Zephyr)
project(my_zephyr_app)
target_sources(app PRIVATE src/main.c)
```

The Cmake property HEX_FILES_TO_MERGE leverages the application configuration provided by Kconfig and CMake to let you merge externally built hex files with the hex file generated when building the Zephyr application. For example:

```cmake
set_property(GLOBAL APPEND PROPERTY HEX_FILES_TO_MERGE
 ${app_bootloader_hex}
 ${PROJECT_BINARY_DIR}/${KERNEL_HEX_NAME}
 ${app_provision_hex})
```

### 2.4.7 CMakeCache.txt

CMake uses a CMakeCache.txt file as persistent key/value string storage used to cache values between runs, including compile and build options and paths to library dependencies. This cache file is created when CMake is run in an empty build folder.

For more details about the CMakeCache.txt file see the official CMake documentation runningcmake.

### 2.4.8 Application Configuration
Application Configuration Directory

Zephyr will use configuration files from the application's configuration directory except for files with an absolute path provided by the arguments described earlier, for example CONF_FILE, OVERLAY_CONFIG, and DTC_OVERLAY_FILE.

The application configuration directory is defined by the APPLICATION_CONFIG_DIR variable. APPLICATION_CONFIG_DIR will be set by one of the sources below with the highest priority listed first.

1. If APPLICATION_CONFIG_DIR is specified by the user with -DAPPLICATION_CONFIG_DIR=<path> or in a CMake file before find_package(Zephyr) then this folder is used as the application's configuration directory.
2. The application's source directory.

Kconfig Configuration

Application configuration options are usually set in prj.conf in the application directory. For example, C++ support could be enabled with this assignment:

```
CONFIG_CPLUSPLUS=y
```

Looking at existing samples is a good way to get started.

See Setting Kconfig configuration values for detailed documentation on setting Kconfig configuration values. The The Initial Configuration section on the same page explains how the initial configuration is derived. See kconfig-search for a complete list of configuration options. See Hardening Tool for security information related with Kconfig options.

The other pages in the Kconfig section of the manual are also worth going through, especially if you planning to add new configuration options.

2.4.9 Experimental features

Zephyr is a project under constant development and thus there are features that are still in early stages of their development cycle. Such features will be marked [EXPERIMENTAL] in their Kconfig title.

The CONFIG_WARN_EXPERIMENTAL setting can be used to enable warnings at CMake configure time if any experimental feature is enabled.

```
CONFIG_WARN_EXPERIMENTAL=y
```

For example, if option CONFIG_FOO is experimental, then enabling it and CONFIG_WARN_EXPERIMENTAL will print the following warning at CMake configure time when you build an application:

```
warning: Experimental symbol FOO is enabled.
```

Devicetree Overlays

See Set devicetree overlays.

2.4.10 Application-Specific Code

Application-specific source code files are normally added to the application's src directory. If the application adds a large number of files the developer can group them into sub-directories under src, to whatever depth is needed.
Application-specific source code should not use symbol name prefixes that have been reserved by the kernel for its own use. For more information, see Naming Conventions.

Third-party Library Code

It is possible to build library code outside the application’s src directory but it is important that both application and library code targets the same Application Binary Interface (ABI). On most architectures there are compiler flags that control the ABI targeted, making it important that both libraries and applications have certain compiler flags in common. It may also be useful for glue code to have access to Zephyr kernel header files.

To make it easier to integrate third-party components, the Zephyr build system has defined CMake functions that give application build scripts access to the Zephyr compiler options. The functions are documented and defined in cmake/extensions.cmake and follow the naming convention zephyr_get_<type>_<format>.

The following variables will often need to be exported to the third-party build system.

- CMAKE_C_COMPILER, CMAKE_AR.
- ARCH and BOARD, together with several variables that identify the Zephyr kernel version.

samples/application_development/external_lib is a sample project that demonstrates some of these features.

2.4.11 Building an Application

The Zephyr build system compiles and links all components of an application into a single application image that can be run on simulated hardware or real hardware.

Like any other CMake-based system, the build process takes place in two stages. First, build files (also known as a buildsystem) are generated using the cmake command-line tool while specifying a generator. This generator determines the native build tool the buildsystem will use in the second stage. The second stage runs the native build tool to actually build the source files and generate an image. To learn more about these concepts refer to the CMake introduction in the official CMake documentation.

Although the default build tool in Zephyr is west, Zephyr’s meta-tool, which invokes cmake and the underlying build tool (ninja or make) behind the scenes, you can also choose to invoke cmake directly if you prefer. On Linux and macOS you can choose between the make and ninja generators (i.e. build tools), whereas on Windows you need to use ninja, since make is not supported on this platform. For simplicity we will use ninja throughout this guide, and if you choose to use west build to build your application know that it will default to ninja under the hood.

As an example, let’s build the Hello World sample for the reel_board:

Using west:

west build -b reel_board samples/hello_world

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild
```

On Linux and macOS, you can also build with make instead of ninja:

Using west:

```
west build -b reel_board samples/hello_world
```
to use `make` just once, add `-- -G"Unix Makefiles"` to the west build command line; see the west build documentation for an example.

- to use `make` by default from now on, run `west config build.generator "Unix Makefiles"`

### Using CMake directly:

```bash
# Use cmake to configure a Make-based build system:
cmake -B build -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
make -C build
```

### Basics

**Note:** In the below example, west is used outside of a west workspace. For this to work, you must set the ZEPHYR_BASE environment variable to the path of your zephyr git repository, using one of the methods on the Environment Variables page.

1. Navigate to the application directory `<home>/app`.
2. Enter the following commands to build the application’s `zephyr.elf` image for the board specified in the command-line parameters:

   - **Using west:**
     ```
     west build -b <board>
     ```

   - **Using CMake and ninja:**
     ```
     mkdir build & cd build
     # Use cmake to configure a Ninja-based build system:
     cmake -GNinja -DBOARD=<board> ..
     # Now run ninja on the generated build system:
     ninja
     ```

   If desired, you can build the application using the configuration settings specified in an alternate `.conf` file using the `CONF_FILE` parameter. These settings will override the settings in the application’s `.config` file or its default `.conf` file. For example:

   - **Using west:**
     ```
     west build -b <board> -- -DCONF_FILE=prj.alternate.conf
     ```

   - **Using CMake and ninja:**
     ```
     mkdir build & cd build
     cmake -GNinja -DBOARD=<board> -DCONF_FILE=prj.alternate.conf ..
     ninja
     ```

   As described in the previous section, you can instead choose to permanently set the board and configuration settings by either exporting `BOARD` and `CONF_FILE` environment variables or by setting their values in your `CMakeLists.txt` using `set()` statements. Additionally, `west` allows you to **set a default board**.
Build Directory Contents

When using the Ninja generator a build directory looks like this:

```plaintext
<home>/app/build
  └─ build.ninja
  └─ CMakeCache.txt
  └─ CMakeFiles
  └─ cmake_install.cmake
  └─ rules.ninja
  └─ zephyr
```

The most notable files in the build directory are:

- `build.ninja`, which can be invoked to build the application.
- A `zephyr` directory, which is the working directory of the generated build system, and where most generated files are created and stored.

After running `ninja`, the following build output files will be written to the `zephyr` sub-directory of the build directory. (This is **not the Zephyr base directory**, which contains the Zephyr source code etc. and is described above.)

- `.config`, which contains the configuration settings used to build the application.

__Note__: The previous version of `.config` is saved to `.config.old` whenever the configuration is updated. This is for convenience, as comparing the old and new versions can be handy.

- Various object files (`.o` files and `.a` files) containing compiled kernel and application code.
- `zephyr.elf`, which contains the final combined application and kernel binary. Other binary output formats, such as `.hex` and `.bin`, are also supported.

Rebuilding an Application

Application development is usually fastest when changes are continually tested. Frequently rebuilding your application makes debugging less painful as the application becomes more complex. It’s usually a good idea to rebuild and test after any major changes to the application's source files, CMakeLists.txt files, or configuration settings.

__Important__: The Zephyr build system rebuilds only the parts of the application image potentially affected by the changes. Consequently, rebuilding an application is often significantly faster than building it the first time.

Sometimes the build system doesn’t rebuild the application correctly because it fails to recompile one or more necessary files. You can force the build system to rebuild the entire application from scratch with the following procedure:

1. Open a terminal console on your host computer, and navigate to the build directory `<home>/app/build`.
2. Enter one of the following commands, depending on whether you want to use `west` or `cmake` directly to delete the application's generated files, except for the `.config` file that contains the application's current configuration information.

   ```bash
   west build -t clean
   ```

   or

   ```bash
   cmake --build . --target clean
   ```
ninja clean

Alternatively, enter one of the following commands to delete all generated files, including the .config files that contain the application’s current configuration information for those board types.

west build -t pristine

or

ninja pristine

If you use west, you can take advantage of its capability to automatically make the build folder pristine whenever it is required.

3. Rebuild the application normally following the steps specified in Building an Application above.

Building for a board revision

The Zephyr build system has support for specifying multiple hardware revisions of a single board with small variations. Using revisions allows the board support files to make minor adjustments to a board configuration without duplicating all the files described in Create your board directory for each revision.

To build for a particular revision, use <board>@<revision> instead of plain <board>. For example:

Using west:

west build -b <board>@<revision>

Using CMake and ninja:

mkdir build && cd build

cmake -GNinja -DBOARD=<board>@<revision> ..
ninja

Check your board's documentation for details on whether it has multiple revisions, and what revisions are supported.

When targeting a board revision, the active revision will be printed at CMake configure time, like this:

-- Board: plank, Revision: 1.5.0

2.4.12 Run an Application

An application image can be run on a real board or emulated hardware.

Running on a Board

Most boards supported by Zephyr let you flash a compiled binary using the flash target to copy the binary to the board and run it. Follow these instructions to flash and run an application on real hardware:

1. Build your application, as described in Building an Application.

2. Make sure your board is attached to your host computer. Usually, you’ll do this via USB.

3. Run one of these console commands from the build directory, <home>/app/build, to flash the compiled Zephyr image and run it on your board:

west flash
The Zephyr build system integrates with the board support files to use hardware-specific tools to flash the Zephyr binary to your hardware, then run it.

Each time you run the flash command, your application is rebuilt and flashed again.

In cases where board support is incomplete, flashing via the Zephyr build system may not be supported. If you receive an error message about flash support being unavailable, consult your board’s documentation for additional information on how to flash your board.

Note: When developing on Linux, it’s common to need to install board-specific udev rules to enable USB device access to your board as a non-root user. If flashing fails, consult your board’s documentation to see if this is necessary.

Running in an Emulator

The kernel has built-in emulator support for QEMU (on Linux/macOS only, this is not yet supported on Windows). It allows you to run and test an application virtually, before (or in lieu of) loading and running it on actual target hardware. Follow these instructions to run an application via QEMU:

1. Build your application for one of the QEMU boards, as described in Building an Application.

   For example, you could set BOARD to:

   • qemu_x86 to emulate running on an x86-based board
   • qemu_cortex_m3 to emulate running on an ARM Cortex M3-based board

2. Run one of these console commands from the build directory, <home>/app/build, to run the Zephyr binary in QEMU:

   west build -t run

   or

   ninja run

3. Press Ctrl A, X to stop the application from running in QEMU.

   The application stops running and the terminal console prompt redisplays.

   Each time you execute the run command, your application is rebuilt and run again.

   Note: If the (Linux only) Zephyr SDK is installed, the run target will use the SDK’s QEMU binary by default. To use another version of QEMU, set the environment variable QEMU_BIN_PATH to the path of the QEMU binary you want to use instead.

   Note: You can choose a specific emulator by appending_<emulator> to your target name, for example west build -t run_qemu or ninja run_qemu for QEMU.

2.4.13 Application Debugging

This section is a quick hands-on reference to start debugging your application with QEMU. Most content in this section is already covered in QEMU and GNU_Debugger reference manuals.
In this quick reference, you'll find shortcuts, specific environmental variables, and parameters that can help you to quickly set up your debugging environment.

The simplest way to debug an application running in QEMU is using the GNU Debugger and setting a local GDB server in your development system through QEMU.

You will need an Executable and Linkable Format (ELF) binary image for debugging purposes. The build system generates the image in the build directory. By default, the kernel binary name is `zephyr.elf`. The name can be changed using a Kconfig option.

We will use the standard 1234 TCP port to open a GDB (GNU Debugger) server instance. This port number can be changed for a port that best suits the development environment.

You can run QEMU to listen for a “gdb connection” before it starts executing any code to debug it.

```
qemu -s -S <image>
```

will setup Qemu to listen on port 1234 and wait for a GDB connection to it.

The options used above have the following meaning:

- `-S` Do not start CPU at startup; rather, you must type `c` in the monitor.
- `-s` Shorthand for `-gdb tcp::1234`: open a GDB server on TCP port 1234.

To debug with QEMU and to start a GDB server and wait for a remote connect, run either of the following inside the build directory of an application:

```
ninja debugserver
```

The build system will start a QEMU instance with the CPU halted at startup and with a GDB server instance listening at the TCP port 1234.

Using a local GDB configuration `.gdbinit` can help initialize your GDB instance on every run. In this example, the initialization file points to the GDB server instance. It configures a connection to a remote target at the local host on the TCP port 1234. The initialization sets the kernel's root directory as a reference.

The `.gdbinit` file contains the following lines:

```
target remote localhost:1234
dir ZEPHYR_BASE
```

**Note:** Substitute the correct `ZEPHYR_BASE` for your system.

Execute the application to debug from the same directory that you chose for the `.gdbinit` file. The command can include the `--tui` option to enable the use of a terminal user interface. The following commands connects to the GDB server using gdb. The command loads the symbol table from the elf binary file. In this example, the elf binary file name corresponds to `zephyr.elf` file:

```
....../path/to/gdb --tui zephyr.elf
```

**Note:** The GDB version on the development system might not support the `--tui` option. Please make sure you use the GDB binary from the SDK which corresponds to the toolchain that has been used to build the binary.

If you are not using a `.gdbinit` file, issue the following command inside GDB to connect to the remote GDB server on port 1234:

```
(gdb) target remote localhost:1234
```
Finally, the command below connects to the GDB server using the Data Displayer Debugger (ddd). The command loads the symbol table from the elf binary file, in this instance, the zephyr.elf file.

The DDD (Data Displayer Debugger) may not be installed in your development system by default. Follow your system instructions to install it. For example, use `sudo apt-get install ddd` on an Ubuntu system.

```
ddd --gdb --debugger "gdb zephyr.elf"
```

Both commands execute the GDB (GNU Debugger). The command name might change depending on the toolchain you are using and your cross-development tools.

### 2.4.14 Custom Board, Devicetree and SOC Definitions

In cases where the board or platform you are developing for is not yet supported by Zephyr, you can add board, Devicetree and SOC definitions to your application without having to add them to the Zephyr tree.

The structure needed to support out-of-tree board and SOC development is similar to how boards and SOCs are maintained in the Zephyr tree. By using this structure, it will be much easier to upstream your platform related work into the Zephyr tree after your initial development is done.

Add the custom board to your application or a dedicated repository using the following structure:

```
boards/
soc/
CMakeLists.txt
prj.conf
README.rst
src/
```

where the `boards` directory hosts the board you are building for:

```
    boards
    └── x86
        └── my_custom_board
            └── doc
                └── img
            └── support
        └── src
```

and the `soc` directory hosts any SOC code. You can also have boards that are supported by a SOC that is available in the Zephyr tree.

#### Boards

Use the proper architecture folder name (e.g., x86, arm, etc.) under `boards` for `my_custom_board`. (See boards for a list of board architectures.)

Documentation (under `doc/`) and support files (under `support/`) are optional, but will be needed when submitting to Zephyr.

The contents of `my_custom_board` should follow the same guidelines for any Zephyr board, and provide the following files:

```
my_custom_board_defconfig
my_custom_board.dts
my_custom_board.yaml
```

(continues on next page)
Once the board structure is in place, you can build your application targeting this board by specifying the location of your custom board information with the \texttt{-DBOARD\_ROOT} parameter to the CMake build system:

Using west:

\begin{verbatim}
west build -b <board name> -- -DBOARD\_ROOT=<path to boards>
\end{verbatim}

Using CMake and ninja:

\begin{verbatim}
cmake -Bbuild -GNinja -DBOARD=<board name> -DBOARD\_ROOT=<path to boards> .
ninja -Cbuild
\end{verbatim}

This will use your custom board configuration and will generate the Zephyr binary into your application directory.

You can also define the \texttt{BOARD\_ROOT} variable in the application \texttt{CMakeLists.txt} file. Make sure to do so before pulling in the Zephyr boilerplate with \texttt{find\_package(Zephyr \ldots).}

\textbf{Note:} When specifying \texttt{BOARD\_ROOT} in a \texttt{CMakeLists.txt}, then an absolute path must be provided, for example \texttt{list(APPEND BOARD\_ROOT \{CMAKE\_CURRENT\_SOURCE\_DIR}/<extra-board-root>\}). When using \texttt{-DBOARD\_ROOT=<board-root>} both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

\section*{SOC Definitions}

Similar to board support, the structure is similar to how SOCs are maintained in the Zephyr tree, for example:

\begin{verbatim}
soc
  \hspace{1cm} arm
    \hspace{1cm} st_stm32
      \hspace{1cm} common
      \hspace{1cm} stm32l0
\end{verbatim}

The file \texttt{soc/Kconfig} will create the top-level SoC/CPU/Configuration Selection menu in Kconfig.

Out of tree SoC definitions can be added to this menu using the \texttt{SOC\_ROOT} CMake variable. This variable contains a semicolon-separated list of directories which contain SoC support files.

Following the structure above, the following files can be added to load more SoCs into the menu.

\begin{verbatim}
soc
  \hspace{1cm} arm
    \hspace{1cm} st_stm32
      \hspace{1cm} Kconfig
      \hspace{1cm} Kconfig.soc
      \hspace{1cm} Kconfig.defconfig
\end{verbatim}
The Kconfig files above may describe the SoC or load additional SoC Kconfig files.

An example of loading stm31l0 specific Kconfig files in this structure:

```
soc
  ^ arm
    | st_stm32
      ^ Kconfig.soc
          stm32l0
      Kconfig.series
```

can be done with the following content in st_stm32/Kconfig.soc:

```
rsource "*/Kconfig.series"
```

Once the SOC structure is in place, you can build your application targeting this platform by specifying the location of your custom platform information with the -DSOC_ROOT parameter to the CMake build system:

Using west:

```
wester build -b <board name> -- -DSOC_ROOT=<path to soc> -DBOARD_ROOT=<path to boards>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DSOC_ROOT=<path to soc> -DBOARD_ROOT=<path to boards>
ninja -Cbuild
```

This will use your custom platform configurations and will generate the Zephyr binary into your application directory.

See Build settings for information on setting SOC_ROOT in a module's zephyr/module.yml file.

Or you can define the SOC_ROOT variable in the application CMakeLists.txt file. Make sure to do so before pulling in the Zephyr boilerplate with find_package(Zephyr ...).

**Note:** When specifying SOC_ROOT in a CMakeLists.txt, then an absolute path must be provided, for example list(APPEND SOC_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-soc-root>). When using -DSOC_ROOT=<soc-root> both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

**Devicetree Definitions**

Devicetree directory trees are found in APPLICATION_SOURCE_DIR, BOARD_DIR, and ZEPHYR_BASE, but additional trees, or DTS_ROOTs, can be added by creating this directory tree:

```
include/
dts/common/
dts/arm/
dts/
dts/bindings/
```

Where ‘arm’ is changed to the appropriate architecture. Each directory is optional. The binding directory contains bindings and the other directories contain files that can be included from DT sources.

Once the directory structure is in place, you can use it by specifying its location through the DTS_ROOT CMake Cache variable:

Using west:
west build -b <board name> -- -DDTS_ROOT=<path to dts root>

Using CMake and ninja:

cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_ROOT=<path to dts root> .
ninja -Cbuild

You can also define the variable in the application CMakeLists.txt file. Make sure to do so before pulling in the Zephyr boilerplate with find_package(Zephyr ...).

Note: When specifying DTS_ROOT in a CMakeLists.txt, then an absolute path must be provided, for example list(APPEND DTS_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-dts-root>). When using -DDTS_ROOT=<dts-root> both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Devicetree source are passed through the C preprocessor, so you can include files that can be located in a DTS_ROOT directory. By convention devicetree include files have a .dtsi extension.

You can also use the preprocessor to control the content of a devicetree file, by specifying directives through the DTS_EXTRA_CPPFLAGS CMake Cache variable:

Using west:

west build -b <board name> -- -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_FEATURE

Using CMake and ninja:

cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_FEATURE

ninja -Cbuild

2.4.15 Debug with Eclipse

Overview

CMake supports generating a project description file that can be imported into the Eclipse Integrated Development Environment (IDE) and used for graphical debugging.

The GNU MCU Eclipse plug-ins provide a mechanism to debug ARM projects in Eclipse with pyOCD, Segger J-Link, and OpenOCD debugging tools.

The following tutorial demonstrates how to debug a Zephyr application in Eclipse with pyOCD in Windows. It assumes you have already installed the GCC ARM Embedded toolchain and pyOCD.

Set Up the Eclipse Development Environment

1. Download and install Eclipse IDE for C/C++ Developers.

2. In Eclipse, install the GNU MCU Eclipse plug-ins by opening the menu Window->Eclipse Marketplace..., searching for GNU MCU Eclipse, and clicking Install on the matching result.

3. Configure the path to the pyOCD GDB server by opening the menu Window->Preferences, navigating to MCU, and setting the Global pyOCD Path.
Generate and Import an Eclipse Project

1. Set up a GNU Arm Embedded toolchain as described in GNU Arm Embedded.

2. Navigate to a folder outside of the Zephyr tree to build your application.

   # On Windows
   cd %userprofile%

   **Note:** If the build directory is a subdirectory of the source directory, as is usually done in Zephyr, CMake will warn:
   “The build directory is a subdirectory of the source directory.
   This is not supported well by Eclipse. It is strongly recommended to use a build directory which is a sibling of the source directory.”

3. Configure your application with CMake and build it with ninja. Note the different CMake generator specified by the `-G"Eclipse CDT4 - Ninja"` argument. This will generate an Eclipse project description file, `.project`, in addition to the usual ninja build files.

   Using west:
   ```
   west build -b frdm_k64f %ZEPHYR_BASE%\samples\synchronization -- -G"Eclipse CDT4 - Ninja"
   ```

   Using CMake and ninja:
   ```
   cmake -Bbuild -GNinja -DBOARD=frdm_k64f -G"Eclipse CDT4 - Ninja" %ZEPHYR_BASE%\samples\synchronization
   ninja -Cbuild
   ```

4. In Eclipse, import your generated project by opening the menu File->Import... and selecting the option Existing Projects into Workspace. Browse to your application build directory in the choice, Select root directory:. Check the box for your project in the list of projects found and click the Finish button.

Create a Debugger Configuration

1. Open the menu Run->Debug Configurations....

2. Select GDB PyOCD Debugging, click the New button, and configure the following options:
   - In the Main tab:
     - Project: my_zephyr_app@build
     - C/C++ Application: zephyr/zephyr.elf
   - In the Debugger tab:
     - pyOCD Setup
       - Executable path: $pyocd_path$/pyocd_executable
       - Uncheck “Allocate console for semihosting”
     - Board Setup
       - Bus speed: 8000000 Hz
       - Uncheck “Enable semihosting”
     - GDB Client Setup
* Executable path example (use your GNUARMMB_TOOLCHAIN_PATH): C:\gcc-arm-none-eabi-6_2017-q2-update\bin\arm-none-eabi-gdb.exe

- In the SVD Path tab:
  - File path: <workspace top>\modules\hal\nxp\mcux\devices\MK64F12\MK64F12.xml

Note: This is optional. It provides the SoC’s memory-mapped register addresses and bitfields to the debugger.

3. Click the Debug button to start debugging.

RTOS Awareness

Support for Zephyr RTOS awareness is implemented in pyOCD v0.11.0 and later. It is compatible with GDB PyOCD Debugging in Eclipse, but you must enable CONFIG_DEBUG_THREAD_INFO=y in your application.

2.5 API Status and Guidelines

2.5.1 API Overview

The table lists Zephyr’s APIs and information about them, including their current stability level. More details about API changes between major releases are available in the zephyr_release_notes.

2.5.2 API Lifecycle

Developers using Zephyr’s APIs need to know how long they can trust that a given API will not change in future releases. At the same time, developers maintaining and extending Zephyr’s APIs need to be
able to introduce new APIs that aren’t yet fully proven, and to potentially retire old APIs when they’re no longer optimal or supported by the underlying platforms.

Fig. 2.2: API Life Cycle

An up-to-date table of all APIs and their maturity level can be found in the API Overview page.

**Experimental**

Experimental APIs denote that a feature was introduced recently, and may change or be removed in future versions. Try it out and provide feedback to the community via the Developer mailing list.

The following requirements apply to all new APIs:

- Documentation of the API (usage) explaining its design and assumptions, how it is to be used, current implementation limitations, and future potential, if appropriate.
- The API introduction should be accompanied by at least one implementation of said API (in the case of peripheral APIs, this corresponds to one driver)
- At least one sample using the new API (may only build on one single board)

**Peripheral APIs (Hardware Related)** When introducing an API (public header file with documentation) for a new peripheral or driver subsystem, review of the API is enforced and is driven by the API working group consisting of representatives from different vendors.

The API shall be promoted to unstable when it has at least two implementations on different hardware platforms.

**Unstable**

The API is in the process of settling, but has not yet had sufficient real-world testing to be considered stable. The API is considered generic in nature and can be used on different hardware platforms.

**Note:** Changes will not be announced.
Peripheral APIs (Hardware Related) The API shall be promoted from experimental to unstable when it has at least two implementations on different hardware platforms.

Hardware Agnostic APIs For hardware agnostic APIs, multiple applications using it are required to promote an API from experimental to unstable.

Stable

The API has proven satisfactory, but cleanup in the underlying code may cause minor changes. Backwards-compatibility will be maintained if reasonable.

An API can be declared stable after fulfilling the following requirements:

- Test cases for the new API with 100% coverage
- Complete documentation in code. All public interfaces shall be documented and available in online documentation.
- The API has been in-use and was available in at least 2 development releases
- Stable APIs can get backward compatible updates, bug fixes and security fixes at any time.

In order to declare an API stable, the following steps need to be followed:

1. A Pull Request must be opened that changes the corresponding entry in the API Overview table
2. An email must be sent to the devel mailing list announcing the API upgrade request
3. The Pull Request must be submitted for discussion in the next Zephyr Architecture meeting where, barring any objections, the Pull Request will be merged

Introducing incompatible changes A stable API, as described above strives to remain backwards-compatible through its life-cycle. There are however cases where fulfilling this objective prevents technical progress or is simply unfeasible without unreasonable burden on the maintenance of the API and its implementation(s).

An incompatible change is defined as one that forces users to modify their existing code in order to maintain the current behavior of their application. The need for recompilation of applications (without changing the application itself) is not considered an incompatible change.

In order to restrict and control the introduction of a change that breaks the promise of backwards compatibility the following steps must be followed whenever such a change is considered necessary in order to accept it in the project:

1. An RFC issue must be opened on GitHub with the following content:

<table>
<thead>
<tr>
<th>Title: RFC: API Change: &lt;subsystem&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contents:</td>
</tr>
<tr>
<td>- Problem Description:</td>
</tr>
<tr>
<td>- Background information on why</td>
</tr>
<tr>
<td>the change is required</td>
</tr>
<tr>
<td>- Proposed Change (detailed):</td>
</tr>
<tr>
<td>- Brief description of the API</td>
</tr>
<tr>
<td>change</td>
</tr>
<tr>
<td>- Detailed RFC:</td>
</tr>
<tr>
<td>- Function call changes</td>
</tr>
<tr>
<td>- Device Tree changes (source</td>
</tr>
<tr>
<td>and bindings)</td>
</tr>
<tr>
<td>- Kconfig option changes</td>
</tr>
<tr>
<td>- Dependencies:</td>
</tr>
<tr>
<td>- Impact to users of the API,</td>
</tr>
<tr>
<td>including the steps required</td>
</tr>
<tr>
<td>to adapt out-of-tree users of</td>
</tr>
<tr>
<td>the API to the change</td>
</tr>
</tbody>
</table>

   Instead of a written description of the changes, the RFC issue may link to a Pull Request containing those changes in code form.
2. The RFC issue must be labeled with the GitHub Stable API Change label
3. The RFC issue must be submitted for discussion in the next Zephyr Architecture meeting
4. An email must be sent to the devel mailing list with a subject identical to the RFC issue title and that links to the RFC issue

The RFC will then receive feedback through issue comments and will also be discussed in the Zephyr Architecture meeting, where the stakeholders and the community at large will have a chance to discuss it in detail.

Finally, and if not done as part of the first step, a Pull Request must be opened on GitHub. It is left to the person proposing the change to decide whether to introduce both the RFC and the Pull Request at the same time or to wait until the RFC has gathered consensus enough so that the implementation can proceed with confidence that it will be accepted. The Pull Request must include the following:

- A title that matches the RFC issue
- A link to the RFC issue
- The actual changes to the API
  - Changes to the API header file
  - Changes to the API implementation(s)
  - Changes to the relevant API documentation
  - Changes to Device Tree source and bindings
- The changes required to adapt in-tree users of the API to the change. Depending on the scope of this task this might require additional help from the corresponding maintainers
- An entry in the “API Changes” section of the release notes for the next upcoming release
- The labels API, Stable API Change and Release Notes, as well as any others that are applicable

Once the steps above have been completed, the outcome of the proposal will depend on the approval of the actual Pull Request by the maintainer of the corresponding subsystem. As with any other Pull Request, the author can request for it to be discussed and ultimately even voted on in the Zephyr TSC meeting.

If the Pull Request is merged then an email must be sent to the devel and user mailing lists informing them of the change.

**Note:** Incompatible changes will be announced in the “API Changes” section of the release notes.

---

**Deprecated**

**Note:** Unstable APIs can be removed without deprecation at any time. Deprecation and removal of APIs will be announced in the “API Changes” section of the release notes.

The following are the requirements for deprecating an existing API:

- **Deprecation Time (stable APIs):** 2 Releases The API needs to be marked as deprecated in at least two full releases. For example, if an API was first deprecated in release 1.14, it will be ready to be removed in 1.16 at the earliest. There may be special circumstances, determined by the API working group, where an API is deprecated sooner.

- **What is required when deprecating:**
  - Mark as deprecated. This can be done by using the compiler itself (\_\_depre\_\_cated for function declarations and \_\_DEPRE\_\_CATED_MACR\_\_0 for macro definitions), or by introducing a Kconfig
option (typically one that contains the DEPRECATED word in it) that, when enabled, reverts the APIs back to their previous form

- Document the deprecation
- Include the deprecation in the “API Changes” of the release notes for the next upcoming release
- Code using the deprecated API needs to be modified to remove usage of said API
- The change needs to be atomic and bisectable
- Create a GitHub issue to track the removal of the deprecated API, and add it to the roadmap targeting the appropriate release (in the example above, 1.16).

During the deprecation waiting period, the API will be in the deprecated state. The Zephyr maintainers will track usage of deprecated APIs on docs.zephyrproject.org and support developers migrating their code. Zephyr will continue to provide warnings:

- API documentation will inform users that the API is deprecated.
- Attempts to use a deprecated API at build time will log a warning to the console.

Retired

In this phase, the API is removed.

The target removal date is 2 releases after deprecation is announced. The Zephyr maintainers will decide when to actually remove the API: this will depend on how many developers have successfully migrated from the deprecated API, and on how urgently the API needs to be removed.

If it’s OK to remove the API, it will be removed. The maintainers will remove the corresponding documentation, and communicate the removal in the usual ways: the release notes, mailing lists, Github issues and pull-requests.

If it’s not OK to remove the API, the maintainers will continue to support migration and update the roadmap with the aim to remove the API in the next release.

2.5.3 API Design Guidelines

Zephyr development and evolution is a group effort, and to simplify maintenance and enhancements there are some general policies that should be followed when developing a new capability or interface.

Using Callbacks

Many APIs involve passing a callback as a parameter or as a member of a configuration structure. The following policies should be followed when specifying the signature of a callback:

- The first parameter should be a pointer to the object most closely associated with the callback. In the case of device drivers this would be const struct device *dev. For library functions it may be a pointer to another object that was referenced when the callback was provided.
- The next parameter(s) should be additional information specific to the callback invocation, such as a channel identifier, new status value, and/or a message pointer followed by the message length.
- The final parameter should be a void *user_data pointer carrying context that allows a shared callback function to locate additional material necessary to process the callback.

An exception to providing user_data as the last parameter may be allowed when the callback itself was provided through a structure that will be embedded in another structure. An example of such a case is gpio_callback, normally defined within a data structure specific to the code that also defines the callback function. In those cases further context can be accessed by the callback indirectly by CONTAINER_OF.
Examples

- The requirements of `k_timer_expiry_t` invoked when a system timer alarm fires are satisfied by:

  ```c
  void handle_timeout(struct k_timer *timer)
  { ... }
  ```

  The assumption here, as with `gpio_callback`, is that the timer is embedded in a structure reachable from `CONTAINER_OF` that can provide additional context to the callback.

- The requirements of `counter_alarm_callback_t` invoked when a counter device alarm fires are satisfied by:

  ```c
  void handle_alarm(const struct device *dev,
                   uint8_t chan_id,
                   uint32_t ticks,
                   void *user_data)
  { ... }
  ```

  This provides more complete useful information, including which counter channel timed-out and the counter value at which the timeout occurred, as well as user context which may or may not be the `counter_alarm_cfg` used to register the callback, depending on user needs.

Conditional Data and APIs

APIs and libraries may provide features that are expensive in RAM or code size but are optional in the sense that some applications can be implemented without them. Examples of such feature include capturing a timestamp or providing an alternative interface. The developer in coordination with the community must determine whether enabling the features is to be controllable through a Kconfig option.

In the case where a feature is determined to be optional the following practices should be followed.

- Any data that is accessed only when the feature is enabled should be conditionally included via `#ifdef CONFIG_MYFEATURE` in the structure or union declaration. This reduces memory use for applications that don't need the capability.

- Function declarations that are available only when the option is enabled should be provided unconditionally. Add a note in the description that the function is available only when the specified feature is enabled, referencing the required Kconfig symbol by name. In the cases where the function is used but not enabled the definition of the function shall be excluded from compilation, so references to the unsupported API will result in a link-time error.

- Where code specific to the feature is isolated in a source file that has no other content that file should be conditionally included in `CMakeLists.txt`:

  ```
  zephyr_sources_ifdef(CONFIG_MYFEATURE foo_funcs.c)
  ```

- Where code specific to the feature is part of a source file that has other content the feature-specific code should be conditionally processed using `#ifdef CONFIG_MYFEATURE`.

The Kconfig flag used to enable the feature should be added to the `PREDEFINED` variable in `doc/zephyr/doxyfile.in` to ensure the conditional API and functions appear in generated documentation.

Return Codes

Implementations of an API, for example an API for accessing a peripheral might implement only a subset of the functions that is required for minimal operation. A distinction is needed between APIs that are not supported and those that are not implemented or optional:

- APIs that are supported but not implemented shall return `-ENOSYS`. 

2.5. API Status and Guidelines
• Optional APIs that are not supported by the hardware should be implemented and the return code in this case shall be -ENOTSUP.

• When an API is implemented, but the particular combination of options requested in the call cannot be satisfied by the implementation the call shall return -ENOTSUP. (For example, a request for a level-triggered GPIO interrupt on hardware that supports only edge-triggered interrupts)

2.5.4 API Terminology

The following terms may be used as shorthand API tags to indicate the allowed calling context (thread, ISR, pre-kernel), the effect of a call on the current thread state, and other behavioral characteristics.

reschedule
  if executing the function reaches a reschedule point

sleep
  if executing the function can cause the invoking thread to sleep

no-wait
  if a parameter to the function can prevent the invoking thread from trying to sleep

isr-ok
  if the function can be safely called and will have its specified effect whether invoked from interrupt or thread context

pre-kernel-ok
  if the function can be safely called before the kernel has been fully initialized and will have its specified effect when invoked from that context.

async
  if the function may return before the operation it initializes is complete (i.e. function return and operation completion are asynchronous)

supervisor
  if the calling thread must have supervisor privileges to execute the function

Details on the behavioral impact of each attribute are in the following sections.

reschedule

The reschedule attribute is used on a function that can reach a reschedule point within its execution.

Details  The significance of this attribute is that when a rescheduling function is invoked by a thread it is possible for that thread to be suspended as a consequence of a higher-priority thread being made ready. Whether the suspension actually occurs depends on the operation associated with the reschedule point and the relative priorities of the invoking thread and the head of the ready queue.

Note that in the case of timeslicing, or reschedule points executed from interrupts, any thread may be suspended in any function.

Functions that are not reschedule may be invoked from either thread or interrupt context.

Functions that are reschedule may be invoked from thread context.

Functions that are reschedule but not sleep may be invoked from interrupt context.

sleep

The sleep attribute is used on a function that can cause the invoking thread to sleep.
**Explanation**  This attribute is of relevance specifically when considering applications that use only non-preemptible threads, because the kernel will not replace a running cooperative-only thread at a reschedule point unless that thread has explicitly invoked an operation that caused it to sleep.

This attribute does not imply the function will sleep unconditionally, but that the operation may require an invoking thread that would have to suspend, wait, or invoke `k_yield()` before it can complete its operation. This behavior may be mediated by no-wait.

Functions that are `sleep` are implicitly `reschedule`.

Functions that are `sleep` may be invoked from thread context.

Functions that are `sleep` may be invoked from interrupt and pre-kernel contexts if and only if invoked in no-wait mode.

**no-wait**

The no-wait attribute is used on a function that is also `sleep` to indicate that a parameter to the function can force an execution path that will not cause the invoking thread to sleep.

**Explanation**  The paradigmatic case of a no-wait function is a function that takes a timeout, to which `K_NO_WAIT` can be passed. The semantics of this special timeout value are to execute the function’s operation as long as it can be completed immediately, and to return an error code rather than sleep if it cannot.

It is use of the no-wait feature that allows functions like `k_sem_take()` to be invoked from ISRs, since it is not permitted to sleep in interrupt context.

A function with a no-wait path does not imply that taking that path guarantees the function is synchronous.

Functions with this attribute may be invoked from interrupt and pre-kernel contexts only when the parameter selects the no-wait path.

**isr-ok**

The isr-ok attribute is used on a function to indicate that it works whether it is being invoked from interrupt or thread context.

**Explanation**  Any function that is not `sleep` is inherently `isr-ok`. Functions that are `sleep` are `isr-ok` if the implementation ensures that the documented behavior is implemented even if called from an interrupt context. This may be achieved by having the implementation detect the calling context and transfer the operation that would sleep to a thread, or by documenting that when invoked from a non-thread context the function will return a specific error (generally `-EWOULDBLOCK`).

Note that a function that is no-wait is safe to call from interrupt context only when the no-wait path is selected. `isr-ok` functions need not provide a no-wait path.

**pre-kernel-ok**

The pre-kernel-ok attribute is used on a function to indicate that it works as documented even when invoked before the kernel main thread has been started.
**Explanation**  This attribute is similar to **isr-ok** in function, but is intended for use by any API that is expected to be called in `DEVICE_DEFINE()` or `SYS_INIT()` calls that may be invoked with `PRE_KERNEL_1` or `PRE_KERNEL_2` initialization levels.

Generally a function that is **pre-kernel-ok** checks `k_is_pre_kernel()` when determining whether it can fulfill its required behavior. In many cases it would also check `k_is_in_isr()` so it can be **isr-ok** as well.

**async**

A function is **async** (i.e. asynchronous) if it may return before the operation it initiates has completed. An asynchronous function will generally provide a mechanism by which operation completion is reported, e.g. a callback or event.

A function that is not asynchronous is synchronous, i.e. the operation will always be complete when the function returns. As most functions are synchronous this behavior does not have a distinct attribute to identify it.

**Explanation**  Be aware that **async** is orthogonal to context-switching. Some APIs may provide completion information through a callback, but may suspend while waiting for the resource necessary to initiate the operation; an example is `spi_transceive_async()`.

If a function is both **no-wait** and **async** then selecting the no-wait path only guarantees that the function will not sleep. It does not affect whether the operation will be completed before the function returns.

**supervisor**

The supervisor attribute is relevant only in user-mode applications, and indicates that the function cannot be invoked from user mode.

## 2.6 Language Support

### 2.6.1 C Language Support

C is a general-purpose low-level programming language that is widely used for writing code for embedded systems.

Zephyr is primarily written in C and natively supports applications written in the C language. All Zephyr API functions and macros are implemented in C and available as part of the C header files under the `include` directory, so writing Zephyr applications in C gives the developers access to the most features.

**Language Standards**

Zephyr does not target a specific version of the C standards; however, the Zephyr codebase makes extensive use of the features newly introduced in the 1999 release of the ISO C standard (ISO/IEC 9899:1999, hereinafter referred to as C99) such as those listed below, effectively requiring the use of a compiler toolchain that supports the C99 standard and above:

- inline functions
- standard boolean types (`stdbool.h`)
- fixed-width integer types (`stdint.h`)
- designated initializers
- variadic macros
- `restrict` qualification
Some Zephyr components make use of the features newly introduced in the 2011 release of the ISO C standard (ISO/IEC 9899:2011, hereinafter referred to as C11) such as the type-generic expressions using the _Generic keyword. For example, the cbprintf() component, used as the default formatted output processor for Zephyr, makes use of the C11 type-generic expressions, and this effectively requires most Zephyr applications to be compiled using a compiler toolchain that supports the C11 standard and above.

In summary, it is recommended to use a compiler toolchain that supports at least the C11 standard for developing with Zephyr. It is, however, important to note that some optional Zephyr components and external modules may make use of the C language features that have been introduced in more recent versions of the standards, in which case it will be necessary to use a more up-to-date compiler toolchain that supports such standards.

**Standard Library**

The C Standard Library is an integral part of any C program, and Zephyr provides the support for a number of different C libraries for the applications to choose from, depending on the compiler toolchain being used to build the application.

**Minimal libc**  The most basic C library, named “minimal libc”, is part of the Zephyr codebase and provides the minimal subset of the standard C library required to meet the needs of Zephyr and its subsystems, primarily in the areas of string manipulation and display.

It is very low footprint and is suitable for projects that do not rely on less frequently used portions of the ISO C standard library. It can also be used with a number of different toolchains.

The minimal libc implementation can be found in lib/libc/minimal in the main Zephyr tree.

**Formatted Output**  The minimal libc does not implement its own formatted output processor; instead, it maps the C standard formatted output functions such as printf and sprintf to the cbprintf() function, which is Zephyr’s own C99-compatible formatted output implementation.

For more details, refer to the Formatted Output OS service documentation.

**Dynamic Memory Management**  Dynamic memory management in the minimal libc can be enabled by selecting the CONFIG_MINIMAL_LIBC_MALLOC in the application configuration file.

The minimal libc internally uses the kernel memory heap API to manage the memory heap used by the standard dynamic memory management interface functions such as malloc() and free().

The internal memory heap is normally located in the .bss section. When userspace is enabled, however, it is placed in a dedicated memory partition called z_malloc_partition, which can be accessed from the user mode threads. The size of the internal memory heap is specified by the CONFIG_MINIMAL_LIBC_MALLOC_ARENA_SIZE.

The standard dynamic memory management interface functions implemented by the minimal libc are thread safe and may be simultaneously called by multiple threads. These functions are implemented in lib/libc/minimal/source/stdlib/malloc.c.

**Error numbers**  Error numbers are used throughout Zephyr APIs to signal error conditions as return values from functions. They are typically returned as the negative value of the integer literals defined in this section, and are defined in the errno.h header file.

A subset of the error numbers defined in the POSIX errno.h specification and other de-facto standard sources have been added to the minimal libc.

A conscious effort is made in Zephyr to keep the values of the minimal libc error numbers consistent with the different implementations of the C standard libraries supported by Zephyr. The minimal libc errno.h is checked against that of the Newlib to ensure that the error numbers are kept aligned.
Below is a list of the error number definitions. For the actual numeric values please refer to `errno.h`.

**group system_errno**

System error numbers Error codes returned by functions. Includes a list of those defined by IEEE Std 1003.1-2017.

**Defines**

**errno**

EPERM

Not owner

ENOENT

No such file or directory

ESRCH

No such context

EINTR

Interrupted system call

EIO

I/O error

ENXIO

No such device or address

E2BIG

Arg list too long

ENOEXEC

Exec format error

EBADF

Bad file number

ECHILD

No children

EAGAIN

No more contexts

ENOMEM

Not enough core

EACCES

Permission denied
EFAULT
   Bad address

ENOTBLK
   Block device required

EBUSY
   Mount device busy

EEXIST
   File exists

EXDEV
   Cross-device link

ENODEV
   No such device

ENOTDIR
   Not a directory

EISDIR
   Is a directory

EINVAL
   Invalid argument

ENFILE
   File table overflow

EMFILE
   Too many open files

ENOTTY
   Not a typewriter

ETXTBSY
   Text file busy

EBIG
   File too large

ENOSPC
   No space left on device

ESPIPE
   Illegal seek
EROFS
   Read-only file system

EMLINK
   Too many links

EPIPE
   Broken pipe

EDOM
   Argument too large

ERANGE
   Result too large

ENOMSG
   Unexpected message type

EDEADLK
   Resource deadlock avoided

ENOLCK
   No locks available

ENOSSR
   STREAMS device required

ENODATA
   Missing expected message data

ETIME
   STREAMS timeout occurred

ENOSR
   Insufficient memory

EPROTO
   Generic STREAMS error

EBADMSG
   Invalid STREAMS message

ENOSYS
   Function not implemented

ENOTEMPTY
   Directory not empty
ENAMETOOLONG
   File name too long

ELOOP
   Too many levels of symbolic links

EOPNOTSUPP
   Operation not supported on socket

EPFNOSUPPORT
   Protocol family not supported

ECONNRESET
   Connection reset by peer

ENOBUFS
   No buffer space available

EAFNOSUPPORT
   Addr family not supported

EPROTOTYPE
   Protocol wrong type for socket

ENOTSOCK
   Socket operation on non-socket

ENOPROTOOPT
   Protocol not available

ESHUTDOWN
   Can’t send after socket shutdown

ECONNREFUSED
   Connection refused

EADDRINUSE
   Address already in use

ECONNABORTED
   Software caused connection abort

ENETUNREACH
   Network is unreachable

ENETDOWN
   Network is down

2.6. Language Support
ETIMEDOUT
   Connection timed out

EHOSTDOWN
   Host is down

EHOSTUNREACH
   No route to host

EINPROGRESS
   Operation now in progress

EALREADY
   Operation already in progress

EDESTADDRREQ
   Destination address required

EMSGSIZE
   Message size

EPROTONOSUPPORT
   Protocol not supported

ESOCKTNOSUPPORT
   Socket type not supported

EADDRNOTAVAIL
   Can't assign requested address

ENETRESET
   Network dropped connection on reset

EISCONN
   Socket is already connected

ENOTCONN
   Socket is not connected

ETOOMANYREFS
   Too many references: can't splice

ENOTSUP
   Unsupported value

EILSEQ
   Illegal byte sequence
EOVERFLOW
Value overflow

ECANCELED
Operation canceled

EWOULDBLOCK
Operation would block

Newlib
Newlib is a complete C library implementation written for the embedded systems. It is a separate open source project and is not included in source code form with Zephyr. Instead, the Zephyr SDK includes a precompiled library for each supported architecture (libc.a and libm.a).

Note: Other 3rd-party toolchains, such as GNU Arm Embedded, also bundle the Newlib as a precompiled library.

Zephyr implements the “API hook” functions that are invoked by the C standard library functions in the Newlib. These hook functions are implemented in lib/libc/newlib/libc-hooks.c and translate the library internal system calls to the equivalent Zephyr API calls.

Types of Newlib
The Newlib included in the Zephyr SDK comes in two versions: ‘full’ and ‘nano’ variants.

Full Newlib
The Newlib full variant (libc.a and libm.a) is the most capable variant of the Newlib available in the Zephyr SDK, and supports almost all standard C library features. It is optimized for performance (prefers performance over code size) and its footprint is significantly larger than the the nano variant.

This variant can be enabled by selecting the CONFIG_NEWLIB_LIBC and de-selecting the CONFIG_NEWLIB_LIBC_NANO in the application configuration file.

Nano Newlib
The Newlib nano variant (libc_nano.a and libm_nano.a) is the size-optimized version of the Newlib, and supports all features that the full variant supports except the new format specifiers introduced in C99, such as the char, long long type format specifiers (i.e. %hhX and %llX).

This variant can be enabled by selecting the CONFIG_NEWLIB_LIBC and CONFIG_NEWLIB_LIBC_NANO in the application configuration file.

Note that the Newlib nano variant is not available for all architectures. The availability of the nano variant is specified by the CONFIG_HAS_NEWLIB_LIBC_NANO.

Formatted Output
Newlib supports all standard C formatted input and output functions, including printf, fprintf, sprintf and sscanf.

The Newlib formatted input and output function implementation supports all format specifiers defined by the C standard with the following exceptions:

- Floating point format specifiers (e.g. %f) require CONFIG_NEWLIB_LIBC_FLOAT_PRINTF and CONFIG_NEWLIB_LIBC_FLOAT_SCANF to be enabled.
- C99 format specifiers are not supported in the Newlib nano variant (i.e. %hhX for char, %llX for long long, %jX for intmax_t, %zX for size_t, %tX for ptrdiff_t).
Dynamic Memory Management  Newlib implements an internal heap allocator to manage the memory blocks used by the standard dynamic memory management interface functions (for example, malloc() and free()).

The internal heap allocator implemented by the Newlib may vary across the different types of the Newlib used. For example, the heap allocator implemented in the Full Newlib (libc.a and libm.a) of the Zephyr SDK requests larger memory chunks to the operating system and has a significantly higher minimum memory requirement compared to that of the Nano Newlib (libc_nano.a and libm_nano.a).

The only interface between the Newlib dynamic memory management functions and the Zephyr-side libc hooks is the sbrk() function, which is used by the Newlib to manage the size of the memory pool reserved for its internal heap allocator.

The _sbrk() hook function, implemented in libc-hooks.c, handles the memory pool size change requests from the Newlib and ensures that the Newlib internal heap allocator memory pool size does not exceed the amount of available memory space by returning an error when the system is out of memory.

When userspace is enabled, the Newlib internal heap allocator memory pool is placed in a dedicated memory partition called z_malloc_partition, which can be accessed from the user mode threads.

The amount of memory space available for the Newlib heap depends on the system configurations:

- When MMU is enabled (CONFIG_MMU is selected), the amount of memory space reserved for the Newlib heap is set by the size of the free memory space returned by the k_mem_free_get() function or the CONFIG_NEWLIB_LIBC_MAX_MAPPED_REGION_SIZE, whichever is the smallest.
- When MPU is enabled and the MPU requires power-of-two partition size and address alignment (CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE is set to a non-zero value), the amount of memory space reserved for the Newlib heap is set by the CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE.
- Otherwise, the amount of memory space reserved for the Newlib heap is equal to the amount of free (unallocated) memory in the SRAM region.

The standard dynamic memory management interface functions implemented by the Newlib are thread safe and may be simultaneously called by multiple threads.

Formatted Output

C defines standard formatted output functions such as printf and sprintf and these functions are implemented by the C standard libraries.

Each C standard library has its own set of requirements and configurations for selecting the formatted output modes and capabilities. Refer to each C standard library documentation for more details.

Dynamic Memory Management

C defines a standard dynamic memory management interface (for example, malloc() and free()) and these functions are implemented by the C standard libraries.

While the details of the dynamic memory management implementation varies across different C standard libraries, all supported libraries must conform to the following conventions. Every supported C standard library shall:

- manage its own memory heap either internally or by invoking the hook functions (for example, sbrk()) implemented in libc-hooks.c.
- maintain the architecture- and memory region-specific alignment requirements for the memory blocks allocated by the standard dynamic memory allocation interface (for example, malloc()).
- allocate memory blocks inside the z_malloc_partition memory partition when userspace is enabled. See Pre-defined Memory Partitions.
For more details regarding the C standard library-specific memory management implementation, refer to each C standard library documentation.

**Note:** Native Zephyr applications should use the memory management API supported by the Zephyr kernel such as `k malloc()` in order to take advantage of the advanced features that they offer.

C standard dynamic memory management interface functions such as `malloc()` should be used only by the portable applications and libraries that target multiple operating systems.

### 2.6.2 C++ Language Support

C++ is a general-purpose object-oriented programming language that is based on the C language.

#### Enabling C++ Support

Zephyr supports applications written in both C and C++. However, to use C++ in an application you must configure Zephyr to include C++ support by selecting the `CONFIG_CPLUSPLUS` in the application configuration file.

To enable C++ support, the compiler toolchain must also include a C++ compiler and the included compiler must be supported by the Zephyr build system. The Zephyr SDK, which includes the GNU C++ Compiler (part of GCC), is supported by Zephyr, and the features and their availability documented here assume the use of the Zephyr SDK.

When compiling a source file, the build system selects the C++ compiler based on the suffix (extension) of the files. Files identified with either a `cpp` or a `cxx` suffix are compiled using the C++ compiler. For example, `myCplusplusApp.cpp` is compiled using C++.

The C++ standard requires the `main()` function to have the return type of `int` while Zephyr uses `void` by default. If your `main()` is defined in a C++ source file, you must select `CONFIG_CPP_MAIN` in the application configuration file so that Zephyr uses `int main(void)` instead of `void main(void)`.

**Note:** Do not use C++ for kernel, driver, or system initialization code.

#### Language Features

Zephyr currently provides only a subset of C++ functionality. The following features are *not* supported:

- Static global object destruction
- OS-specific C++ standard library classes (e.g. `std::thread`, `std::mutex`)

While not an exhaustive list, support for the following functionality is included:

- Inheritance
- Virtual functions
- Virtual tables
- Static global object constructors
- Dynamic object management with the `new` and `delete` operators
- Exceptions
- RTTI (runtime type information)
- Standard Template Library (STL)
Static global object constructors are initialized after the drivers are initialized but before the application main() function. Therefore, use of C++ is restricted to application code.

In order to make use of the C++ exceptions, the CONFIG_EXCEPTIONS must be selected in the application configuration file.

Zephyr C++ Subsystem

Zephyr C++ subsystem (subsys/cpp) provides a minimal subset of the C++ standard library and application binary interface (ABI) functions to enable basic C++ language support. This includes:

- new and delete operators
- virtual function stub and vtables
- static global initializers for global constructors

The scope of the C++ subsystem is strictly limited to providing the basic C++ language support, and it does not implement any Standard Template Library (STL) classes and functions. For this reason, it is only suitable for use in the applications that implement their own (non-standard) class library and do rely on the Standard Template Library (STL) components.

Any application that makes use of the Standard Template Library (STL) components, such as std::string and std::vector, must enable the C++ standard library support.

C++ Standard Library

The C++ Standard Library is a collection of classes and functions that are part of the ISO C++ standard (std namespace).

Zephyr does not include any C++ standard library implementation in source code form. Instead, it allows configuring the build system to link against the pre-built C++ standard library included in the C++ compiler toolchain.

For instance, when building with the Zephyr SDK, the build system can be configured to link against the GNU C++ Standard Library (libstdc++.a) included in the Zephyr SDK, which is a fully featured C++ standard library that provides all features required by the ISO C++ standard including the Standard Template Library (STL).

To enable C++ standard library, select the CONFIG_LIB_CPLUSPLUS in the application configuration file.

2.7 Optimizations

Guides on how to optimize Zephyr for performance, power and footprint.

2.7.1 Optimizing for Footprint

Stack Sizes

Stack sizes of various system threads are specified generously to allow for usage in different scenarios on as many supported platforms as possible. You should start the optimization process by reviewing all stack sizes and adjusting them for your application:

CONFIG_ISR_STACK_SIZE
Set to 2048 by default

CONFIG_MAIN_STACK_SIZE
Set to 1024 by default
CONFIG_IDLE_STACK_SIZE
Set to 320 by default

CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE
Set to 1024 by default

CONFIG_PRIVILEGED_STACK_SIZE
Set to 1024 by default, depends on userspace feature.

Unused Peripherals

Some peripherals are enabled by default. You can disable unused peripherals in your project configuration, for example:

CONFIG_GPIO=n
CONFIG_SPI=n

Various Debug/Informational Options

The following options are enabled by default to provide more information about the running application and to provide means for debugging and error handling:

CONFIG_BOOT_BANNER
This option can be disabled to save a few bytes.

CONFIG_DEBUG
This option can be disabled for production builds

MPU/MMU Support

Depending on your application and platform needs, you can disable MPU/MMU support to gain some memory and improve performance. Consider the consequences of this configuration choice though, because you’ll lose advanced stack checking and support.

2.7.2 Optimization Tools

Footprint and Memory Usage

The build system offers 3 targets to view and analyse RAM, ROM and stack usage in generated images. The tools run on the final image and give information about size of symbols and code being used in both RAM and ROM. Additionally, with features available through the compiler, we can also generate worst-case stack usage analysis:

Tools that are available as build system targets:

Build Target: pncover  This target uses a 3rd party tools called pncover which can be found here. When this target is built, it will launch a local web server which will allow you to open a web client and browse the files and view their ROM, RAM and stack usage. Before you can use this target, you will have to install the pncover python module:

`pip3 install git+https://github.com/HBehrens/pncover --user`

Then:

Using west:
west build -b reel_board samples/hello_world
west build -t puncover

Using CMake and ninja:

# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild puncover

To view worst-case stack usage analysis, build this with the CONFIG_STACK_USAGE enabled.

Using west:

west build -b reel_board samples/hello_world -- -DCONFIG_STACK_USAGE=y
west build -t puncover

Using CMake and ninja:

# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board -DCONFIG_STACK_USAGE=y samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild puncover

**Build Target: ram_report** List all compiled objects and their RAM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the ram_report target with your board:

Using west:

west build -b reel_board samples/hello_world
west build -t ram_report

Using CMake and ninja:

# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild ram_report

which will generate something similar to the output below:

```
Path                  Size  %  
--------------------- ----- ----

...                      ...     ...

SystemCoreClock         4     0.08%
_kernel                 48    0.99%
_sw_isr_table           384   7.94%
cli.10544
```

(continues on next page)
Build Target: `rom_report` List all compiled objects and their ROM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `rom_report` to get the ROM report:

Using west:

```bash
west build -b reel_board samples/hello_world
west build -t rom_report
```

Using CMake and ninja:
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild rom_report

which will generate something similar to the output below:

<table>
<thead>
<tr>
<th>Path</th>
<th>Size %</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>CSWITCH.5</td>

</tbody>
</table>
Data Structures

Build Target: pahole  Poke-a-hole (pahole) is an object-file analysis tool to find the size of the data structures, and the holes caused due to aligning the data elements to the word-size of the CPU by the compiler.

Poke-a-hole (pahole) must be installed prior to using this target. It can be obtained from https://git.kernel.org/pub/scm/devel/pahole/pahole.git and is available in the dwarves package in both fedora and ubuntu:

```
sudo apt-get install dwarves
```

or in fedora:

```
sudo dnf install dwarves
```

Using west:

```
w west build -b reel_board samples/hello_world
west build -t pahole
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild pahole
```

After running this target, pahole will output the results to the console:

```
2.7. Optimizations
```
2.8 Flashing and Hardware Debugging

2.8.1 Flash & Debug Host Tools

This guide describes the software tools you can run on your host workstation to flash and debug Zephyr applications.

Zephyr’s west tool has built-in support for all of these in its flash, debug, debugserver, and attach commands, provided your board hardware supports them and your Zephyr board directory’s board.
cmake file declares that support properly. See Building, Flashing and Debugging for more information on these commands.

SAM Boot Assistant (SAM-BA)

Atmel SAM Boot Assistant (Atmel SAM-BA) allows In-System Programming (ISP) from USB or UART host without any external programming interface. Zephyr allows users to develop and program boards with SAM-BA support using west. Zephyr supports devices with/without ROM bootloader and both extensions from Arduino and Adafruit. Full support was introduced in Zephyr SDK 0.12.0.

The typical command to flash the board is:

```
wester flash [-r bossac] [-p /dev/ttyX]
```

Flash configuration for devices:

With ROM bootloader
These devices don’t need any special configuration. After building your application, just run `west flash` to flash the board.

Without ROM bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see `Flash map` for details.

2. Have board `.defconfig` file with the `CONFIG_USE_DT_CODE_PARTITION` Kconfig option set to `y` to instruct the build system to use these partitions for code relocation. This option can also be set in `prj.conf` or any other Kconfig fragment.

3. Build and flash the SAM-BA bootloader on the device.

With compatible SAM-BA bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see `Flash map` for details.

2. Have board `.defconfig` file with the `CONFIG_BOOTLOADER_BOSSA` Kconfig option set to `y`. This will automatically select the `CONFIG_USE_DT_CODE_PARTITION` Kconfig option which instruct the build system to use these partitions for code relocation. The board `.defconfig` file should have `CONFIG_BOOTLOADER_BOSSA_ADUINO`, `CONFIG_BOOTLOADER_BOSSA_ADAFRUIT_UF2` or the `CONFIG_BOOTLOADER_BOSSA_LEGACY` Kconfig option set to `y` to select the right compatible SAM-BA bootloader mode. These options can also be set in `prj.conf` or any other Kconfig fragment.

3. Build and flash the SAM-BA bootloader on the device.

**Note:** The `CONFIG_BOOTLOADER_BOSSA_LEGACY` Kconfig option should be used as last resource. Try configure first with Devices without ROM bootloader.

**Typical flash layout and configuration** For bootloaders that reside on flash, the devicetree partition layout is mandatory. For devices that have a ROM bootloader, they are mandatory when the application uses a storage or other non-application partition. In this special case, the boot partition should be omitted and code_partition should start from offset 0. It is necessary to define the partitions with sizes that avoid overlaps, always.

A typical flash layout for devices without a ROM bootloader is:

```
/ {
    chosen {
        zephyr,code-partition = &code_partition;
    };
};

&flash0 {
    partitions {
        compatible = "fixed-partitions";
        #address-cells = <1>;
        #size-cells = <1>;

        boot_partition: partition@0 {
            label = "sam-ba";
            reg = <0x00000000 0x2000>;
            read-only;
        };
    }
}
```

(continues on next page)
A typical flash layout for devices with a ROM bootloader and storage partition is:

```c
/ {
  chosen {
    zephyr,code-partition = &code_partition;
  }
};

&flash0 {
  partitions {
    compatible = "fixed-partitions";
    #address-cells = <1>;
    #size-cells = <1>;

    code_partition: partition@0 {
      label = "code";
      reg = <0x0 0xF0000>;
      read-only;
    }

    /*
    * The final 64 KiB is reserved for the application.
    * Storage partition will be used by FCB/LittleFS/NVS
    * if enabled.
    */
    storage_partition: partition@F0000 {
      label = "storage";
      reg = <0x000F0000 0x00100000>;
    }
  }
};
```

**Enabling SAM-BA runner** In order to instruct Zephyr west tool to use the SAM-BA bootloader the `board.cmake` file must have include(`${ZEPHYR_BASE}/boards/common/bossac.board.cmake`) entry. Note that Zephyr tool accept more entries to define multiple runners. By default, the first one will be selected when using `west flash` command. The remaining options are available passing the runner option, for instance `west flash -r bossac`.
More implementation details can be found in the boards documentation. As a quick reference, see these three board documentation pages:

- sam4e_xpro (ROM bootloader)
- adafruit_feather_m0_basic_proto (Adafruit UF2 bootloader)
- arduino_nano_33_iot (Arduino bootloader)
- arduino_nano_33_ble (Arduino legacy bootloader)

**J-Link Debug Host Tools**

Segger provides a suite of debug host tools for Linux, macOS, and Windows operating systems:

- J-Link GDB Server: GDB remote debugging
- J-Link Commander: Command-line control and flash programming
- RTT Viewer: RTT terminal input and output
- SystemView: Real-time event visualization and recording

These debug host tools are compatible with the following debug probes:

- LPC-Link2 J-Link Onboard Debug Probe
- OpenSDA J-Link Onboard Debug Probe
- J-Link External Debug Probe
- ST-LINK/V2-1 Onboard Debug Probe

Check if your SoC is listed in J-Link Supported Devices.

Download and install the J-Link Software and Documentation Pack to get the J-Link GDB Server and Commander, and to install the associated USB device drivers. RTT Viewer and SystemView can be downloaded separately, but are not required.

Note that the J-Link GDB server does not yet support Zephyr RTOS-awareness.

**OpenOCD Debug Host Tools**

OpenOCD is a community open source project that provides GDB remote debugging and flash programming support for a wide range of SoCs. A fork that adds Zephyr RTOS-awareness is included in the Zephyr SDK; otherwise see Getting OpenOCD for options to download OpenOCD from official repositories.

These debug host tools are compatible with the following debug probes:

- OpenSDA DAPLink Onboard Debug Probe
- J-Link External Debug Probe
- ST-LINK/V2-1 Onboard Debug Probe

Check if your SoC is listed in OpenOCD Supported Devices.

**Note:** On Linux, openocd is available though the Zephyr SDK. Windows users should use the following steps to install openocd:

- Download openocd for Windows from here: OpenOCD Windows
- Copy bin and share dirs to C:\Program Files\OpenOCD\bin
- Add C:\Program Files\OpenOCD\bin to ‘PATH’ environment variable

2.8. Flashing and Hardware Debugging
pyOCD Debug Host Tools

pyOCD is an open source project from Arm that provides GDB remote debugging and flash programming support for Arm Cortex-M SoCs. It is distributed on PyPi and installed when you complete the Get Zephyr and install Python dependencies step in the Getting Started Guide. pyOCD includes support for Zephyr RTOS-awareness.

These debug host tools are compatible with the following debug probes:

- OpenSDA DAPLink Onboard Debug Probe
- ST-LINK/V2-1 Onboard Debug Probe

Check if your SoC is listed in pyOCD Supported Devices.

Lauterbach TRACE32 Debug Host Tools

Lauterbach TRACE32 is a product line of microprocessor development tools, debuggers and real-time tracer with support for JTAG, SWD, NEXUS or ETM over multiple core architectures, including Arm Cortex-A/-R/-M, RISC-V, Xtensa, etc. Zephyr allows users to develop and program boards with Lauterbach TRACE32 support using `west`.

The runner consists of a wrapper around TRACE32 software, and allows a Zephyr board to execute a custom start-up script (Practice Script) for the different commands supported, including the ability to pass extra arguments from CMake. It is up to the board using this runner to define the actions performed on each command.

Install Lauterbach TRACE32 Software  Download Lauterbach TRACE32 software from the Lauterbach TRACE32 download website (registration required) and follow the installation steps described in Lauterbach TRACE32 Installation Guide.

Flashing and Debugging  Set the environment variable `T32_DIR` to the TRACE32 system directory. Then execute `west flash` or `west debug` commands to flash or debug the Zephyr application as detailed in Building, Flashing and Debugging. The `debug` command launches TRACE32 GUI to allow debug the Zephyr application, while the `flash` command hides the GUI and perform all operations in the background.

By default, the `t32` runner will launch TRACE32 using the default configuration file named `config.t32` located in the TRACE32 system directory. To use a different configuration file, supply the argument `--config CONFIG` to the runner, for example:

```
west flash --config myconfig.t32
```

For more options, run `west flash --context -r t32` to print the usage.

Zephyr RTOS Awareness  To enable Zephyr RTOS awareness follow the steps described in Lauterbach TRACE32 Zephyr OS Awareness Manual.

2.8.2 Debug Probes

A debug probe is special hardware which allows you to control execution of a Zephyr application running on a separate board. Debug probes usually allow reading and writing registers and memory, and support breakpoint debugging of the Zephyr application on your host workstation using tools like GDB. They may also support other debug software and more advanced features such as tracing program execution. For details on the related host software supported by Zephyr, see Flash & Debug Host Tools.

Debug probes are usually connected to your host workstation via USB; they are sometimes also accessible via an IP network or other means. They usually connect to the device running Zephyr using the JTAG or
SWD protocols. Debug probes are either separate hardware devices or circuitry integrated into the same board which runs Zephyr.

Many supported boards in Zephyr include a second microcontroller that serves as an onboard debug probe, usb-to-serial adapter, and sometimes a drag-and-drop flash programmer. This eliminates the need to purchase an external debug probe and provides a variety of debug host tool options.

Several hardware vendors have their own branded onboard debug probe implementations: NXP LPC boards have LPC-Link2, NXP Kinetis (former Freescale) boards have OpenSDA, and ST boards have ST-LINK. Each onboard debug probe microcontroller can support one or more types of firmware that communicate with their respective debug host tools. For example, an OpenSDA microcontroller can be programmed with DAPLink firmware to communicate with pyOCD or OpenOCD debug host tools, or with J-Link firmware to communicate with J-Link debug host tools.

<table>

</tr>
</tbody>
</table>

Some supported boards in Zephyr do not include an onboard debug probe and therefore require an external debug probe. In addition, boards that do include an onboard debug probe often also have an SWD or JTAG header to enable the use of an external debug probe instead. One reason this may be useful is that the onboard debug probe may have limitations, such as lack of support for advanced debuggers or high-speed tracing. You may need to adjust jumpers to prevent the onboard debug probe from interfering with the external debug probe.

**LPC-Link2 J-Link Onboard Debug Probe**

The LPC-Link2 J-Link is an onboard debug probe and usb-to-serial adapter supported on many NXP LPC and i.MX RT development boards.

This debug probe is compatible with the following debug host tools:

- **J-Link Debug Host Tools**

This probe is realized by programming the LPC-Link2 microcontroller with J-Link LPC-Link2 firmware. Download and install LPCScrypt to get the firmware and programming scripts.

**Note:** Verify the firmware supports your board by visiting Firmware for LPCXpresso

1. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then powering up the board.
2. Run the program_JLINK script.
3. Remove the DFU jumper and power cycle the board.

**OpenSDA DAPLink Onboard Debug Probe**

The OpenSDA DAPLink is an onboard debug probe and usb-to-serial adapter supported on many NXP Kinetis and i.MX RT development boards. It also includes drag-and-drop flash programming support.
This debug probe is compatible with the following debug host tools:

- pyOCD Debug Host Tools
- OpenOCD Debug Host Tools

This probe is realized by programming the OpenSDA microcontroller with DAPLink OpenSDA firmware. NXP provides OpenSDA DAPLink Board-Specific Firmwares.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you power on the board. Note that “bootloader mode” in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.

2. After you power on the board, release the reset button. A USB mass storage device called BOOT-LOADER or MAINTENANCE will enumerate.

3. Copy the OpenSDA firmware binary to the USB mass storage device.

4. Power cycle the board, this time without holding the reset button. You should see three USB devices enumerate: a CDC device (serial port), a HID device (debug port), and a mass storage device (drag-and-drop flash programming).

OpenSDA J-Link Onboard Debug Probe

The OpenSDA J-Link is an onboard debug probe and usb-to-serial adapter supported on many NXP Kinetis and i.MX RT development boards.

This debug probe is compatible with the following debug host tools:

- J-Link Debug Host Tools

This probe is realized by programming the OpenSDA microcontroller with J-Link OpenSDA firmware. Segger provides OpenSDA J-Link Generic Firmwares and OpenSDA J-Link Board-Specific Firmwares, where the latter is generally recommended when available. Board-specific firmwares are required for i.MX RT boards to support their external flash memories, whereas generic firmwares are compatible with all Kinetis boards.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you power on the board. Note that “bootloader mode” in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.

2. After you power on the board, release the reset button. A USB mass storage device called BOOT-LOADER or MAINTENANCE will enumerate.

3. Copy the OpenSDA firmware binary to the USB mass storage device.

4. Power cycle the board, this time without holding the reset button. You should see two USB devices enumerate: a CDC device (serial port) and a vendor-specific device (debug port).

J-Link External Debug Probe

Segger J-Link is a family of external debug probes, including J-Link EDU, J-Link PLUS, J-Link ULTRA+, and J-Link PRO, that support a large number of devices from different hardware architectures and vendors.

This debug probe is compatible with the following debug host tools:

- J-Link Debug Host Tools
Install the debug host tools before you program the firmware.

**ST-LINK/V2-1 Onboard Debug Probe**

ST-LINK/V2-1 is a serial and debug adapter built into all Nucleo and Discovery boards. It provides a bridge between your computer (or other USB host) and the embedded target processor, which can be used for debugging, flash programming, and serial communication, all over a simple USB cable.

It is compatible with the following host debug tools:

- **OpenOCD Debug Host Tools**
- **J-Link Debug Host Tools**

For some STM32 based boards, it is also compatible with:

- **pyOCD Debug Host Tools**

While it works out of the box with OpenOCD, it requires some flashing to work with J-Link. To do this, SEGGER offers a firmware upgrading the ST-LINK/V2-1 on board on the Nucleo and Discovery boards. This firmware makes the ST-LINK/V2-1 compatible with J-LinkOB, allowing users to take advantage of most J-Link features like the ultra fast flash download and debugging speed or the free-to-use GDBServer.

More information about upgrading ST-LINK/V2-1 to JLink or restore ST-Link/V2-1 firmware please visit: Segger over ST-Link

### Flash and debug with ST-Link Using OpenOCD

OpenOCD is available by default on ST-Link and configured as the default flash and debug tool. Flash and debug can be done as follows:

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west flash
```

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west debug
```

Using Segger J-Link

Once STLink is flashed with SEGGER FW and J-Link GDB server is installed on your host computer, you can flash and debug as follows:

Use CMake with `-DBOARD_FLASH_RUNNER=jlink` to change the default OpenOCD runner to J-Link. Alternatively, you might add the following line to your application CMakeList.txt file.

```cmake
set(BOARD_FLASH_RUNNER jlink)
```

If you use West (Zephyr's meta-tool) you can modify the default runner using the `--runner (or -r)` option.

```
w west flash --runner jlink
```

To attach a debugger to your board and open up a debug console with jlink.

```
w west debug --runner jlink
```

For more information about West and available options, see West (Zephyr's meta-tool).

If you configured your Zephyr application to use Segger RTT console instead, open telnet:
$ telnet localhost 19021
Trying ::1...
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
SEGGER J-Link V6.30f - Real time terminal output
J-Link STLink V21 compiled Jun 26 2017 10:35:16 V1.0, SN=773895351
Process: JLinkGDBServerCLExe
Zephyr Shell, Zephyr version: 1.12.99
Type 'help' for a list of available commands
shell>

If you get no RTT output you might need to disable other consoles which conflict with the RTT one if they are enabled by default in the particular sample or application you are running, such as disable UART_CONSOLE in menuconfig

**Updating or restoring ST-Link firmware** ST-Link firmware can be updated using STM32CubeProgrammer Tool. It is usually useful when facing flashing issues, for instance when using twister's device-testing option.

Once installed, you can update attached board ST-Link firmware with the following command

```
s java -jar ~/STMicroelectronics/STM32Cube/STM32CubeProgrammer/Drivers/FirmwareUpgrade/STLinkUpgrade.jar -sn <board_uid>
```

Where board_uid can be obtained using twister's generate-hardware-map option. For more information about twister and available options, see *Test Runner (Twister)*.

## 2.9 Modules (External projects)

Zephyr relies on the source code of several externally maintained projects in order to avoid reinventing the wheel and to reuse as much well-established, mature code as possible when it makes sense. In the context of Zephyr's build system those are called *modules*. These modules must be integrated with the Zephyr build system, as described in more detail in other sections on this page.

To be classified as a candidate for being included in the default list of modules, an external project is required to have its own life-cycle outside the Zephyr Project, that is, reside in its own repository, and have its own contribution and maintenance workflow and release process. Zephyr modules should not contain code that is written exclusively for Zephyr. Instead, such code should be contributed to the main zephyr tree.

Modules to be included in the default manifest of the Zephyr project need to provide functionality or features endorsed and approved by the project Technical Steering Committee and should comply with the *module licensing requirements* and *contribution guidelines*. They should also have a Zephyr developer that is committed to maintain the module codebase.

Zephyr depends on several categories of modules, including but not limited to:

- Debugger integration
- Silicon vendor Hardware Abstraction Layers (HALs)
- Cryptography libraries
- File Systems
- Inter-Process Communication (IPC) libraries

Additionally, in some cases modules (particularly vendor HALs) can contain references to optional *binary blobs*. 

---

78 Chapter 2. Developing with Zephyr
This page summarizes a list of policies and best practices which aim at better organizing the workflow in Zephyr modules.

2.9.1 Module Repositories

- All modules included in the default manifest shall be hosted in repositories under the zephyrproject-rtos GitHub organization.
- The module repository codebase shall include a `module.yml` file in a `zephyr/` folder at the root of the repository.
- Module repository names should follow the convention of using lowercase letters and dashes instead of underscores. This rule will apply to all new module repositories, except for repositories that are directly tracking external projects (hosted in Git repositories); such modules may be named as their external project counterparts.

Note: Existing module repositories that do not conform to the above convention do not need to be renamed to comply with the above convention.

- Module repositories names should be explicitly set in the `zephyr/module.yml` file.
- Modules should use “zephyr” as the default name for the repository main branch. Branches for specific purposes, for example, a module branch for an LTS Zephyr version, shall have names starting with the ‘zephyr_’ prefix.
- If the module has an external (upstream) project repository, the module repository should preserve the upstream repository folder structure.

Note: It is not required in module repositories to maintain a ‘master’ branch mirroring the master branch of the external repository. It is not recommended as this may generate confusion around the module’s main branch, which should be ‘zephyr’.

- Modules should expose all provided header files with an include pathname beginning with the module-name. (E.g., mcuboot should expose its `bootutil/bootutil.h` as “mcu-boot/bootutil/bootutil.h”.)

Synchronizing with upstream

It is preferred to synchronize a module repository with the latest stable release of the corresponding external project. It is permitted, however, to update a Zephyr module repository with the latest development branch tip, if this is required to get important updates in the module codebase. When synchronizing a module with upstream it is mandatory to document the rationale for performing the particular update.

Requirements for allowed practices

Changes to the main branch of a module repository, including synchronization with upstream code base, may only be applied via pull requests. These pull requests shall be verifiable by Zephyr CI and mergeable (e.g. with the Rebase and merge, or Create a merge commit option using Github UI). This ensures that the incoming changes are always reviewable, and the downstream module repository history is incremental (that is, existing commits, tags, etc. are always preserved). This policy also allows to run Zephyr CI, git lint, identity, and license checks directly on the set of changes that are to be brought into the module repository.

Note: Force-pushing to a module’s main branch is not allowed.
Allowed practices  The following practices conform to the above requirements and should be followed in all modules repositories. It is up to the module code owner to select the preferred synchronization practice, however, it is required that the selected practice is consistently followed in the respective module repository.

Updating modules with a diff from upstream: Upstream changes brought as a single snapshot commit (manual diff) in a pull request against the module’s main branch, which may be merged using the Rebase & merge operation. This approach is simple and should be applicable to all modules with the downside of suppressing the upstream history in the module repository.

Note: The above practice is the only allowed practice in modules where the external project is not hosted in an upstream Git repository.

The commit message is expected to identify the upstream project URL, the version to which the module is updated (upstream version, tag, commit SHA, if applicable, etc.), and the reason for the doing the update.

Updating modules by merging the upstream branch: Upstream changes brought in by performing a Git merge of the intended upstream branch (e.g. main branch, latest release branch, etc.) submitting the result in pull request against the module main branch, and merging the pull request using the Create a merge commit operation. This approach is applicable to modules with an upstream project Git repository. The main advantages of this approach is that the upstream repository history (that is, the original commit SHAs) is preserved in the module repository. The downside of this approach is that two additional merge commits are generated in the downstream main branch.

2.9.2 Contributing to Zephyr modules

Individual Roles & Responsibilities

To facilitate management of Zephyr module repositories, the following individual roles are defined.

Administrator: Each Zephyr module shall have an administrator who is responsible for managing access to the module repository, for example, for adding individuals as Collaborators in the repository at the request of the module owner. Module administrators are members of the Administrators team, that is a group of project members with admin rights to module GitHub repositories.

Module owner: Each module shall have a module code owner. Module owners will have the overall responsibility of the contents of a Zephyr module repository. In particular, a module owner will:

• coordinate code reviewing in the module repository
• be the default assignee in pull-requests against the repository’s main branch
• request additional collaborators to be added to the repository, as they see fit
• regularly synchronize the module repository with its upstream counterpart following the policies described in Synchronizing with upstream
• be aware of security vulnerability issues in the external project and update the module repository to include security fixes, as soon as the fixes are available in the upstream code base
• list any known security vulnerability issues, present in the module codebase, in Zephyr release notes.

Note: Module owners are not required to be Zephyr Maintainers.

Merger: The Zephyr Release Engineering team has the right and the responsibility to merge approved pull requests in the main branch of a module repository.
Maintaining the module codebase

Updates in the zephyr main tree, for example, in public Zephyr APIs, may require patching a module's codebase. The responsibility for keeping the module codebase up to date is shared between the contributor of such updates in Zephyr and the module owner. In particular:

- the contributor of the original changes in Zephyr is required to submit the corresponding changes that are required in module repositories, to ensure that Zephyr CI on the pull request with the original changes, as well as the module integration testing are successful.
- the module owner has the overall responsibility for synchronizing and testing the module codebase with the zephyr main tree. This includes occasional advanced testing of the module's codebase in addition to the testing performed by Zephyr's CI. The module owner is required to fix issues in the module's codebase that have not been caught by Zephyr pull request CI runs.

Contributing changes to modules

Submitting and merging changes directly to a module's codebase, that is, before they have been merged in the corresponding external project repository, should be limited to:

- changes required due to updates in the zephyr main tree
- urgent changes that should not wait to be merged in the external project first, such as fixes to security vulnerabilities.

Non-trivial changes to a module's codebase, including changes in the module design or functionality should be discouraged, if the module has an upstream project repository. In that case, such changes shall be submitted to the upstream project, directly.

Submitting changes to modules describes in detail the process of contributing changes to module repositories.

Contribution guidelines

Contributing to Zephyr modules shall follow the generic project Contribution guidelines.

Pull Requests: may be merged with minimum of 2 approvals, including an approval by the PR assignee. In addition to this, pull requests in module repositories may only be merged if the introduced changes are verified with Zephyr CI tools, as described in more detail in other sections on this page.

The merging of pull requests in the main branch of a module repository must be coupled with the corresponding manifest file update in the zephyr main tree.

Issue Reporting: GitHub issues are intentionally disabled in module repositories, in favor of a centralized policy for issue reporting. Tickets concerning, for example, bugs or enhancements in modules shall be opened in the main zephyr repository. Issues should be appropriately labeled using GitHub labels corresponding to each module, where applicable.

Note: It is allowed to file bug reports for zephyr modules to track the corresponding upstream project bugs in Zephyr. These bug reports shall not affect the Release Quality Criteria.

2.9.3 Licensing requirements and policies

All source files in a module's codebase shall include a license header, unless the module repository has main license file that covers source files that do not include license headers.

Main license files shall be added in the module's codebase by Zephyr developers, only if they exist as part of the external project, and they contain a permissive OSI-compliant license. Main license files should preferably contain the full license text instead of including an SPDX license identifier. If multiple main
license files are present it shall be made clear which license applies to each source file in a module's codebase.

Individual license headers in module source files supersede the main license.

Any new content to be added in a module repository will require to have license coverage.

---

**Note:** Zephyr recommends conveying module licensing via individual license headers and main license files. This is not a hard requirement; should an external project have its own practice of conveying how licensing applies in the module's codebase (for example, by having a single or multiple main license files), this practice may be accepted by and be referred to in the Zephyr module, as long as licensing requirements, for example OSI compliance, are satisfied.

---

**License policies**

When creating a module repository a developer shall:

- import the main license files, if they exist in the external project, and
- document (for example in the module README or .yml file) the default license that covers the module's codebase.

---

**License checks** License checks (via CI tools) shall be enabled on every pull request that adds new content in module repositories.

---

### 2.9.4 Documentation requirements

All Zephyr module repositories shall include an .rst file documenting:

- the scope and the purpose of the module
- how the module integrates with Zephyr
- the owner of the module repository
- synchronization information with the external project (commit, SHA, version etc.)
- licensing information as described in **Licensing requirements and policies**.

The file shall be required for the inclusion of the module and the contained information should be kept up to date.

---

### 2.9.5 Testing requirements

All Zephyr modules should provide some level of **integration** testing, ensuring that the integration with Zephyr works correctly. Integration tests:

- may be in the form of a minimal set of samples and tests that reside in the zephyr main tree
- should verify basic usage of the module (configuration, functional APIs, etc.) that is integrated with Zephyr.
- shall be built and executed (for example in QEMU) as part of twister runs in pull requests that introduce changes in module repositories.

**Note:** New modules, that are candidates for being included in the Zephyr default manifest, shall provide some level of integration testing.
The purpose of integration testing is not to provide functional verification of the module; this should be part of the testing framework of the external project.

Certain external projects provide test suites that reside in the upstream testing infrastructure but are written explicitly for Zephyr. These tests may (but are not required to) be part of the Zephyr test framework.

### 2.9.6 Deprecating and removing modules

Modules may be deprecated for reasons including, but not limited to:

- Lack of maintainership in the module
- Licensing changes in the external project
- Codebase becoming obsolete

The module information shall indicate whether a module is deprecated and the build system shall issue a warning when trying to build Zephyr using a deprecated module.

Deprecated modules may be removed from the Zephyr default manifest after 2 Zephyr releases.

**Note:** Repositories of removed modules shall remain accessible via their original URL, as they are required by older Zephyr versions.

### 2.9.7 Integrate modules in Zephyr build system

The build system variable `ZEPHYR_MODULES` is a CMake list of absolute paths to the directories containing Zephyr modules. These modules contain CMakeLists.txt and Kconfig files describing how to build and configure them, respectively. Module CMakeLists.txt files are added to the build using CMake's `add_subdirectory()` command, and the Kconfig files are included in the build's Kconfig menu tree.

If you have `west` installed, you don't need to worry about how this variable is defined unless you are adding a new module. The build system knows how to use west to set `ZEPHYR_MODULES`. You can add additional modules to this list by setting the `ZEPHYR_EXTRA_MODULES` CMake variable or by adding a `ZEPHYR_EXTRA_MODULES` line to `.zephyrrc` (See the section on Environment Variables for more details). This can be useful if you want to keep the list of modules found with west and also add your own.

**Note:** If the module `FOO` is provided by `west` but also given with `-DZEPHYR_EXTRA_MODULES=<path>/foo` then the module given by the command line variable `ZEPHYR_EXTRA_MODULES` will take precedence. This allows you to use a custom version of `FOO` when building and still use other Zephyr modules provided by `west`. This can for example be useful for special test purposes.

If you want to permanently add modules to the zephyr workspace and you are using zephyr as your manifest repository, you can also add a west manifest file into the submanifests directory. See submanifests/README.txt for more details.

See Basics for more on west workspaces.

Finally, you can also specify the list of modules yourself in various ways, or not use modules at all if your application doesn't need them.
2.9.8 Module yaml file description

A module can be described using a file named `zephyr/module.yml`. The format of `zephyr/module.yml` is described in the following:

**Module name**

Each Zephyr module is given a name by which it can be referred to in the build system. The name should be specified in the `zephyr/module.yml` file. This will ensure the module name is not changeable through user-defined directory names or `west` manifest files:

```yaml
name: <name>
```

In CMake the location of the Zephyr module can then be referred to using the CMake variable `ZEPHYR_<MODULE_NAME>_MODULE_DIR` and the variable `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` holds the location of the directory containing the module's `CMakeLists.txt` file.

**Note:** When used for CMake and Kconfig variables, all letters in module names are converted to uppercase and all non-alphanumeric characters are converted to underscores (_). As example, the module `foo-bar` must be referred to as `ZEPHYR_FOO_BAR_MODULE_DIR` in CMake and Kconfig.

Here is an example for the Zephyr module `foo`:

```yaml
name: foo
```

**Note:** If the `name` field is not specified then the Zephyr module name will be set to the name of the module folder. As example, the Zephyr module located in `<workspace>/modules/bar` will use `bar` as its module name if nothing is specified in `zephyr/module.yml`.

**Module integration files (in-module)**

Inclusion of build files, `CMakeLists.txt` and `Kconfig`, can be described as:

```yaml
build:
  cmake: <cmake-directory>
  kconfig: <directory>/Kconfig
```

The `cmake: <cmake-directory>` part specifies that `<cmake-directory>` contains the `CMakeLists.txt` to use. The `kconfig: <directory>/Kconfig` part specifies the `Kconfig` file to use. Neither is required: `cmake` defaults to `zephyr`, and `kconfig` defaults to `zephyr/Kconfig`.

Here is an example `module.yml` file referring to `CMakeLists.txt` and `Kconfig` files in the root directory of the module:

```yaml
build:
  cmake: .
  kconfig: Kconfig
```

**Build system integration**

When a module has a `module.yml` file, it will automatically be included into the Zephyr build system. The path to the module is then accessible through Kconfig and CMake variables.
In both Kconfig and CMake, the variable `ZEPHYR_<MODULE_NAME>_MODULE_DIR` contains the absolute path to the module.

In CMake, `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` contains the absolute path to the directory containing the `CMakeLists.txt` file that is included into CMake build system. This variable's value is empty if the module.yml file does not specify a `CMakeLists.txt`.

To read these variables for a Zephyr module named `foo`:

- In CMake: use `${ZEPHYR_FOO_MODULE_DIR}` for the module's top level directory, and `${ZEPHYR_FOO_CMAKE_DIR}` for the directory containing its `CMakeLists.txt`
- In Kconfig: use `$(ZEPHYR_FOO_MODULE_DIR)` for the module's top level directory

Notice how a lowercase module name `foo` is capitalized to `FOO` in both CMake and Kconfig.

These variables can also be used to test whether a given module exists. For example, to verify that `foo` is the name of a Zephyr module:

```cpp
if(ZEPHYR_FOO_MODULE_DIR)
    # Do something if FOO exists.
endif()
```

In Kconfig, the variable may be used to find additional files to include. For example, to include the file `some/Kconfig` in module `foo`:

```cpp
source "$(ZEPHYR_FOO_MODULE_DIR)/some/Kconfig"
```

During CMake processing of each Zephyr module, the following two variables are also available:

- the current module's top level directory: `${ZEPHYR_CURRENT_MODULE_DIR}`
- the current module's `CMakeLists.txt` directory: `${ZEPHYR_CURRENT_CMAKE_DIR}`

This removes the need for a Zephyr module to know its own name during CMake processing. The module can source additional CMake files using these `CURRENT` variables. For example:

```cpp
include(${ZEPHYR_CURRENT_MODULE_DIR}/cmake/code.cmake)
```

It is possible to append values to a Zephyr CMake list variable from the module's first `CMakeLists.txt` file. To do so, append the value to the list and then set the list in the `PARENT_SCOPE` of the `CMakeLists.txt` file. For example, to append `bar` to the `FOO_LIST` variable in the Zephyr `CMakeLists.txt` scope:

```cpp
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

An example of a Zephyr list where this is useful is when adding additional directories to the `SYSCALL_INCLUDE_DIRS` list.

### Zephyr module dependencies

A Zephyr module may be dependent on other Zephyr modules to be present in order to function correctly. Or it might be that a given Zephyr module must be processed after another Zephyr module, due to dependencies of certain CMake targets.

Such a dependency can be described using the `depends` field.

```cpp
build:
    depends:
        - <module>
```

Here is an example for the Zephyr module `foo` that is dependent on the Zephyr module `bar` to be present in the build system:
name: foo
build:
  depends:
    - bar

This example will ensure that bar is present when foo is included into the build system, and it will also ensure that bar is processed before foo.

**Module integration files (external)**

Module integration files can be located externally to the Zephyr module itself. The `MODULE_EXT_ROOT` variable holds a list of roots containing integration files located externally to Zephyr modules.

**Module integration files in Zephyr** The Zephyr repository contain `CMakeLists.txt` and `Kconfig` build files for certain known Zephyr modules.

Those files are located under

```
<ZEPHYR_BASE>
  modules
    <module_name>
      CMakeLists.txt
      Kconfig
```

**Module integration files in a custom location** You can create a similar `MODULE_EXT_ROOT` for additional modules, and make those modules known to Zephyr build system.

Create a `MODULE_EXT_ROOT` with the following structure

```
<MODULE_EXT_ROOT>
  modules
    modules.cmake
    <module_name>
      CMakeLists.txt
      Kconfig
```

and then build your application by specifying `-DMODULE_EXT_ROOT` parameter to the CMake build system. The `MODULE_EXT_ROOT` accepts a CMake list of roots as argument.

A Zephyr module can automatically be added to the `MODULE Ext_ROOT` list using the module description file `zephyr/module.yml`, see *Build settings*.

**Note:** `ZEPHYR_BASE` is always added as a `MODULE Ext_ROOT` with the lowest priority. This allows you to overrule any integration files under `<ZEPHYR_BASE>/modules/<module_name>` with your own implementation your own `MODULE Ext_ROOT`.

The `modules.cmake` file must contain the logic that specifies the integration files for Zephyr modules via specifically named CMake variables.

To include a module's CMake file, set the variable `ZEPHYR-_MODULE_NAME_-CMAKE_DIR` to the path containing the CMake file.

To include a module's Kconfig file, set the variable `ZEPHYR-_MODULE_NAME_-KCONFIG` to the path to the Kconfig file.

The following is an example on how to add support the the FOO module.

Create the following structure
and inside the `modules.cmake` file, add the following content:

```cmake
set(ZEPHYR_FOO_CMAKE_DIR ${CMAKE_CURRENT_LIST_DIR}/foo)
set(ZEPHYR_FOO_KCONFIG  ${CMAKE_CURRENT_LIST_DIR}/foo/Kconfig)
```

**Module integration files (zephyr/module.yml)** The module description file `zephyr/module.yml` can be used to specify that the build files, CMakeLists.txt and Kconfig, are located in a Module integration files (external).

Build files located in a `MODULE_EXT_ROOT` can be described as:

```yaml
build:
  cmake-ext: True
  kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.

The Zephyr repository itself is always added as a Zephyr module ext root.

**Build settings**

It is possible to specify additional build settings that must be used when including the module into the build system.

All root settings are relative to the root of the module.

Build settings supported in the `module.yml` file are:

- `board_root`: Contains additional boards that are available to the build system. Additional boards must be located in a `<board_root>/boards` folder.
- `dts_root`: Contains additional dts files related to the architecture/soc families. Additional dts files must be located in a `<dts_root>/dts` folder.
- `soc_root`: Contains additional SoCs that are available to the build system. Additional SoCs must be located in a `<soc_root>/soc` folder.
- `arch_root`: Contains additional architectures that are available to the build system. Additional architectures must be located in a `<arch_root>/arch` folder.
- `module_ext_root`: Contains CMakeLists.txt and Kconfig files for Zephyr modules, see also Module integration files (external).

Example of a `module.yml` file containing additional roots, and the corresponding file system layout.

```yaml
build:
  settings:
    board_root: .
    dts_root: .
    soc_root: .
    arch_root: .
    module_ext_root: .
```

requires the following folder structure:
Twister (Test Runner)

To execute both tests and samples available in modules, the Zephyr test runner (twister) should be pointed to the directories containing those samples and tests. This can be done by specifying the path to both samples and tests in the `zephyr/module.yml` file. Additionally, if a module defines out of tree boards, the module file can point twister to the path where those files are maintained in the module. For example:

```
build:
  cmake: .
samples:
  - samples
tests:
  - tests
boards:
  - boards
```

Binary Blobs

Zephyr supports fetching and using binary blobs, and their metadata is contained entirely in `zephyr/module.yml`. This is because a binary blob must always be associated with a Zephyr module, and thus the blob metadata belongs in the module’s description itself.

Binary blobs are fetched using `west blobs`. If `west` is not used, they must be downloaded and verified manually.

The `blobs` section in `zephyr/module.yml` consists of a sequence of maps, each of which has the following entries:

- **path**: The path to the binary blob, relative to the `zephyr/blobs/` folder in the module repository
- **sha256**: SHA-256 checksum of the binary blob file
- **type**: The type of binary blob. Currently limited to `img` or `lib`
- **version**: A version string
- **license-path**: Path to the license file for this blob, relative to the root of the module repository
- **url**: URL that identifies the location the blob will be fetched from, as well as the fetching scheme to use
- **description**: Human-readable description of the binary blob
- **doc-url**: A URL pointing to the location of the official documentation for this blob

Module Inclusion

**Using West** If west is installed and `ZEPHYR_MODULES` is not already set, the build system finds all the modules in your west installation and uses those. It does this by running `west list` to get the paths of all the projects in the installation, then filters the results to just those projects which have the necessary module metadata files.
Each project in the west list output is tested like this:

- If the project contains a file named `zephyr/module.yml`, then the content of that file will be used to determine which files should be added to the build, as described in the previous section.
- Otherwise (i.e. if the project has no `zephyr/module.yml`), the build system looks for `zephyr/CMakeLists.txt` and `zephyr/Kconfig` files in the project. If both are present, the project is considered a module, and those files will be added to the build.
- If neither of those checks succeed, the project is not considered a module, and is not added to `ZEPHYR_MODULES`.

**Without West** If you don't have west installed or don't want the build system to use it to find Zephyr modules, you can set `ZEPHYR_MODULES` yourself using one of the following options. Each of the directories in the list must contain either a `zephyr/module.yml` file or the files `zephyr/CMakeLists.txt` and `Kconfig`, as described in the previous section.

1. At the CMake command line, like this:
   
   ```
cmake -DZEPHYR_MODULES=<path-to-module1>[;<path-to-module2>[...]] ...
   ```

2. At the top of your application's top level CMakeLists.txt, like this:

   ```
set(ZEPHYR_MODULES <path-to-module1> <path-to-module2> [...] )
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

   If you choose this option, make sure to set the variable **before** calling `find_package(Zephyr ...)`, as shown above.

3. In a separate CMake script which is pre-loaded to populate the CMake cache, like this:

   ```
   # Put this in a file with a name like "zephyr-modules.cmake"
   set(ZEPHYR_MODULES <path-to-module1> <path-to-module2>
    CACHE STRING "pre-cached modules")
   ```

   You can tell the build system to use this file by adding `-C zephyr-modules.cmake` to your CMake command line.

**Not using modules** If you don't have west installed and don't specify `ZEPHYR_MODULES` yourself, then no additional modules are added to the build. You will still be able to build any applications that don't require code or Kconfig options defined in an external repository.

### 2.9.9 Submitting changes to modules

When submitting new or making changes to existing modules the main repository Zephyr needs a reference to the changes to be able to verify the changes. In the main tree this is done using revisions. For code that is already merged and part of the tree we use the commit hash, a tag, or a branch name. For pull requests however, we require specifying the pull request number in the revision field to allow building the zephyr main tree with the changes submitted to the module.

To avoid merging changes to master with pull request information, the pull request should be marked as DNM (Do Not Merge) or preferably a draft pull request to make sure it is not merged by mistake and to allow for the module to be merged first and be assigned a permanent commit hash. Once the module is merged, the revision will need to be changed either by the submitter or by the maintainer to the commit hash of the module which reflects the changes.

Note that multiple and dependent changes to different modules can be submitted using exactly the same process. In this case you will change multiple entries of all modules that have a pull request against them.
Process for submitting a new module

Please follow the process in *Submission and review process* and obtain the TSC approval to integrate the external source code as a module.

If the request is approved, a new repository will be created by the project team and initialized with basic information that would allow submitting code to the module project following the project contribution guidelines.

If a module is maintained as a fork of another project on Github, the Zephyr module related files and changes in relation to upstream need to be maintained in a special branch named `zephyr`.

Maintainers from the Zephyr project will create the repository and initialize it. You will be added as a collaborator in the new repository. Submit the module content (code) to the new repository following the guidelines described [here](#), and then add a new entry to the `west.yml` with the following information:

```yaml
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add `my_module` to the manifest:

```yaml
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the `my_module` repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

Process for submitting changes to existing modules

1. Submit the changes using a pull request to an existing repository following the *contribution guidelines*.
2. Submit a pull request changing the entry referencing the module into the `west.yml` of the main Zephyr tree with the following information:

```yaml
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add `my_module` to the manifest:

```yaml
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the `my_module` repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

## 2.10 West (Zephyr’s meta-tool)

The Zephyr project includes a swiss-army knife command line tool named `west`. West is developed in its own repository.

1 Zephyr is an English name for the Latin *Zephyrus*, the ancient Greek god of the west wind.
West's built-in commands provide a multiple repository management system with features inspired by Google's Repo tool and Git submodules. West is also “pluggable”: you can write your own west extension commands which add additional features to west. Zephyr uses this to provide conveniences for building applications, flashing and debugging them, and more.

Like git and docker, the top-level west command takes some common options, a sub-command to run, and then options and arguments for that sub-command:

```
west [common-opts] <command> [opts] <args>
```

Since west v0.8, you can also run west like this:

```
python3 -m west [common-opts] <command> [opts] <args>
```

You can run `west --help` (or `west -h` for short) to get top-level help for available west commands, and `west <command> -h` for detailed help on each command.

The following pages document west's v0.14.x releases, and provide additional context about the tool.

### 2.10.1 Installing west

West is written in Python 3 and distributed through PyPI. Use `pip3` to install or upgrade west:

On Linux:

```
pip3 install --user -U west
```

On Windows and macOS:

```
pip3 install -U west
```

**Note:** See [Python and pip](#) for additional clarification on using the `--user` switch.

Afterwards, you can run `pip3 show -f west` for information on where the west binary and related files were installed.

Once west is installed, you can use it to **clone the Zephyr repositories**.

#### Structure

West's code is distributed via PyPI in a Python package named `west`. This distribution includes a launcher executable, which is also named `west` (or `west.exe` on Windows).

When west is installed, the launcher is placed by `pip3` somewhere in the user's filesystem (exactly where depends on the operating system, but should be in the PATH environment variable). This launcher is the command-line entry point to running both built-in commands like `west init`, `west update`, along with any extensions discovered in the workspace.

In addition to its command-line interface, you can also use west's Python APIs directly. See [west-apis](#) for details.

#### Enabling shell completion

West currently supports shell completion in the following combinations of platform and shell:

- Linux: bash
- macOS: bash
In order to enable shell completion, you will need to obtain the corresponding completion script and have it sourced every time you enter a new shell session.

To obtain the completion script you can use the `west completion` command:

```bash
cd /path/to/zephyr/
west completion bash > ~/.west-completion.bash
```

**Note:** Remember to update your local copy of the completion script using `west completion` when you update Zephyr.

Next, you need to import `west-completion.bash` into your bash shell.

On Linux, you have the following options:

- Copy `west-completion.bash` to `/etc/bash_completion.d/`.
- Copy `west-completion.bash` to `/usr/share/bash-completion/completions/`.
- Copy `west-completion.bash` to a local folder and source it from your `~/.bashrc`.

On macOS, you have the following options:

- Copy `west-completion.bash` to a local folder and source it from your `~/.bash_profile`.
- Install the `bash-completion` package with `brew`:
  ```bash
  brew install bash-completion
  ```
  Then source the main bash completion script in your `~/.bash_profile`:
  ```bash
  source /usr/local/etc/profile.d/bash_completion.sh
  ```
  and finally copy `west-completion.bash` to `/usr/local/etc/bash_completion.d/`.

### 2.10.2 West Release Notes

**v0.14.0**

Bug fixes:

- West commands that were run with a bad local configuration file dumped stack in a confusing way. This has been fixed and west now prints a sensible error message in this case.

- A bug in the way west looks for the zephyr repository was fixed. The bug itself usually appeared when running an extension command like `west build` in a new workspace for the first time; this used to fail (just for the first time, not on subsequent command invocations) unless you ran the command in the workspace's top level directory.

- West now prints sensible error messages when the user lacks permission to open the manifest file instead of dumping stack traces.

API changes:

- The `west.manifest.MalformedConfig` exception type has been moved to the `west.configuration` module

- The `west.manifest.MalformedConfig` exception type has been moved to the `west.configuration` module

- The `west.configuration.Configuration` class now raises `MalformedConfig` instead of `RuntimeError` in some cases
v0.13.1

Bug fix:

- When calling `west.manifest.Manifest.from_file()` when outside of a workspace, west again falls back on the ZEPHYR_BASE environment variable to locate the workspace.

v0.13.0

New features:

- You can now associate arbitrary user data with the manifest repository itself in the `manifest:
  self: userdata: value`, like so:

  ```yaml
  manifest:
    self:
      userdata: <any YAML value can go here>
  ```

Bug fixes:

- The path to the manifest repository reported by west could be incorrect in certain circumstances detailed in [issue #572](https://github.com/zephyrproject-rtos/west/issues/572). This has been fixed as part of a larger overhaul of path handling support in the west.manifest API module.
- The `west.Manifest.ManifestProject.__repr__` return value was fixed

API changes:

- `west.configuration.Configuration`: new object-oriented interface to the current configuration. This reflects the system, global, and workspace-local configuration values, and allows you to read, write, and delete configuration options from any or all of these locations.
- `west.commands.WestCommand`:
  - `config`: new attribute, returns a Configuration object or aborts the program if none is set. This is always usable from within extension command `do_run()` implementations.
  - `has_config`: new boolean attribute, which is True if and only if reading `self.config` will abort the program.
- The path handling in the `west.manifest` package has been overhauled in a backwards-incompatible way. For more details, see commit [56cfe8d1d1f3c9b45de3793c738ac62db52ac](https://github.com/zephyrproject-rtos/west/commit/56cfe8d1d1f3c9b45de3793c738ac62db52ac).
- `west.manifest.Manifest.validate()`: this now returns the validated data as a Python dict. This can be useful if the value passed to this function was a str, and the dict is desired.
- `west.manifest.Manifest: new:
  - path attributes abspath, posixpath, relative_path, yaml_path, repo_path, repo_posixpath
  - userdata attribute, which contains the parsed value from `manifest: self: userdata:`, or is None
  - `from_topdir()` factory method
- `west.manifest.ManifestProject: new userdata attribute, which also contains the parsed value from `manifest: self: userdata:`, or is None
- `west.manifest.ManifestImportFailed`: the constructor can now take any value; this can be used to reflect failed imports from a `map` or other compound value.
- Deprecated configuration APIs:
The following APIs are now deprecated in favor of using a Configuration object. Usually this will be done via `self.config` from a `WestCommand` instance, but this can be done directly by instantiating a Configuration object for other usages.

- `west.configuration.config`
- `west.configuration.read_config`
- `west.configuration.update_config`
- `west.configuration.delete_config`

v0.12.0

New features:

- West now works on the MSYS2 platform.
- West manifest files can now contain arbitrary user data associated with each project. See Repository user data for details.

Bug fixes:

- The `west list` command's `{sha}` format key has been fixed for the manifest repository; it now prints `N/A" ("not applicable") as expected.

API changes:

- The `west.manifest.Project.userdata` attribute was added to support project user data.

v0.11.1

New features:

- `west status` now only prints output for projects which have a nonempty status.

Bug fixes:

- The manifest file parser was incorrectly allowing project names which contain the path separator characters `/` and `.`. These invalid characters are now rejected.

  Note: if you need to place a project within a subdirectory of the workspace `topdir`, use the `path:` key. If you need to customize a project's fetch URL relative to its remote `url-base`, use `repo-path:`. See Projects for examples.

- The changes made in west v0.10.1 to the `west init --manifest-rev` option which selected the default branch name were leaving the manifest repository in a detached HEAD state. This has been fixed by using `git clone` internally instead of `git init` and `git fetch`. See issue #522 for details.

- The `WEST_CONFIG_LOCAL` environment variable now correctly overrides the default location, `<workspace topdir>/.west/config`.

- `west update --fetch=smart` (smart is the default) now correctly skips fetches for project revisions which are lightweight tags (it already worked correctly for annotated tags; only lightweight tags were unnecessarily fetched).

Other changes:

- The fix for issue #522 mentioned above introduces a new restriction. The `west init --manifest-rev` option value, if given, must now be either a branch or a tag. In particular, "pseudo-branches" like GitHub's `pull/1234/head` references which could previously be used to fetch a pull request can no longer be passed to `--manifest-rev`. Users must now fetch and check out such revisions manually after running `west init`.

API changes:
• `west.manifest.Manifest.get_projects()` avoids incorrect results in some edge cases described in issue #523.
• `west.manifest.Project.sha()` now works correctly for tag revisions. (This applies to both lightweight and annotated tags.)

v0.11.0
New features:
• `west update` now supports `--narrow`, `--name-cache`, and `--path-cache` options. These can be influenced by the `update.narrow`, `update.name-cache`, and `update.path-cache` `Configuration` options. These can be used to optimize the speed of the update.
• `west update` now supports a `--fetch-opt` option that will be passed to the `git fetch` command used to fetch remote revisions when updating each project.

Bug fixes:
• `west update` now synchronizes Git submodules in projects by default. This avoids issues if the URL changes in the manifest file from when the submodule was first initialized. This behavior can be disabled by setting the `update.sync-submodules` configuration option to `false`.

Other changes:
• the `west-apis-manifest` module has fixed docstrings for the `Project` class

v0.10.1
New features:
• The `west init` command's `--manifest-rev (--mr)` option no longer defaults to `master`. Instead, the command will query the repository for its default branch name and use that instead. This allows users to move from `master` to `main` without breaking scripts that do not provide this option.

v0.10.0
New features:
• The `name` key in a project's `submodules list` is now optional.

Bug fixes:
• West now checks that the manifest schema version is one of the explicitly allowed values documented in `Version`. The old behavior was just to check that the schema version was newer than the `west` version where the `manifest:` `version:` key was introduced. This incorrectly allowed invalid schema versions, like `0.8.2`.

Other changes:
• A manifest file's `group-filter` is now propagated through an import. This is a change from how `west v0.9.x` handled this. In `west v0.9.x`, only the top level manifest file's `group-filter` had any effect; the group filter lists from any imported manifests were ignored.

Starting with `west v0.10.0`, the group filter lists from imported manifests are also imported. For details, see `Group Filters and Imports`.

The new behavior will take effect if `manifest: version:` is not given or is at least 0.10. The old behavior is still available in the top level manifest file only with an explicit `manifest: version:` 0.9. See `Version` for more information on schema versions.

See `west pull request #482` for the motivation for this change and additional context.
v0.9.1

Bug fixes:
- Commands like `west manifest --resolve` now correctly include group and group filter information.

Other changes:
- West now warns if you combine `import` with `group-filter`. Semantics for this combination have changed starting with v0.10.x. See the v0.10.0 release notes above for more information.

v0.9.0

**Warning:** The `west config` fix described below comes at a cost: any comments or other manual edits in configuration files will be removed when setting a configuration option via that command or the `west.configuration` API.

**Warning:** Combining the `group-filter` feature introduced in this release with manifest imports is discouraged. The resulting behavior has changed in west v0.10.

New features:
- West manifests now support *Git Submodules in Projects*. This allows you to clone Git submodules into a west project repository in addition to the project repository itself.
- West manifests now support *Project Groups and Active Projects*. Project groups can be enabled and disabled to determine what projects are “active”, and therefore will be acted upon by the following commands: `west update`, `west list`, `west diff`, `west status`, `west forall`.
- `west update` no longer updates inactive projects by default. It now supports a `--group-filter` option which allows for one-time modifications to the set of enabled and disabled project groups.
- Running `west list`, `west diff`, `west status`, or `west forall` with no arguments does not print information for inactive projects by default. If the user specifies a list of projects explicitly at the command line, output for them is included regardless of whether they are active. These commands also now support `--all` arguments to include all projects, even inactive ones.
- `west list` now supports a `{groups}` format string key in its `--format` argument.

Bug fixes:
- The `west config` command and `west.configuration` API did not correctly store some configuration values, such as strings which contain commas. This has been fixed; see commit 36f3f91e for details.
- A manifest file with an empty `manifest: self: path: value` is invalid, but west used to let it pass silently. West now rejects such manifests.
- A bug affecting the behavior of the `west init -l` command was fixed; see issue #435.

API changes:
- added `west.manifest.Manifest.is_active()`
- added `west.manifest.Manifest.group_filter`
- added `submodules` attribute to `west.manifest.Project`, which has newly added type `west.manifest.Submodule`

Other changes:
• The Manifest Imports feature now supports the terms allowlist and blocklist instead of whitelist and blacklist, respectively.

The old terms are still supported for compatibility, but the documentation has been updated to use the new ones exclusively.

v0.8.0

This is a feature release which changes the manifest schema by adding support for a path-prefix: key in an import: mapping, along with some other features and fixes.

• Manifest import mappings now support a path-prefix: key, which places the project and its imported repositories in a subdirectory of the workspace. See Example 3.4: Import into a subdirectory for an example.

• The west command line application can now also be run using python3 -m west. This makes it easier to run west under a particular Python interpreter without modifying the PATH environment variable.

• west manifest -path prints the absolute path to west.yml

• west init now supports an --mf foo.yml option, which initializes the workspace using foo.yml instead of west.yml.

• west list now prints the manifest repository's path using the manifest.path configuration option, which may differ from the self: path: value in the manifest data. The old behavior is still available, but requires passing a new --manifest-path-from-yaml option.

• Various Python API changes; see west-apis for details.

v0.7.3

This is a bugfix release.

• Fix an error where a failed import could leave the workspace in an unusable state (see [PR #415](https://github.com/zephyrproject-rtos/west/pull/415) for details)

v0.7.2

This is a bugfix and minor feature release.

• Filter out duplicate extension commands brought in by manifest imports

• Fix west.Manifest.get_projects() when finding the manifest repository by path

v0.7.1

This is a bugfix and minor feature release.

• west update --stats now prints timing for operations which invoke a subprocess, time spent in west's Python process for each project, and total time updating each project.

• west todir always prints a POSIX style path

• minor console output changes
The main user-visible feature in west 0.7 is the Manifest Imports feature. This allows users to load west manifest data from multiple different files, resolving the results into a single logical manifest.

Additional user-visible changes:

- The idea of a “west installation” has been renamed to “west workspace” in this documentation and in the west API documentation. The new term seems to be easier for most people to work with than the old one.
- West manifests now support a schema version.
- The “west config” command can now be run outside of a workspace, e.g. to run `west config --global section.key value` to set a configuration option’s value globally.
- There is a new `west todir` command, which prints the root directory of the current west workspace.
- The `west -vv init` command now prints the git operations being performed, and their results.
- The restriction that no project can be named “manifest” is now enforced; the name “manifest” is reserved for the manifest repository, and is usable as such in commands like `west list manifest`, instead of `west list path-to-manifest-repository` being the only way to say that
- It’s no longer an error if there is no project named “zephyr”. This is part of an effort to make west generally usable for non-Zephyr use cases.
- Various bug fixes.

The developer-visible changes to the west-apis are:

- west.build and west.cmake: deprecated; this is Zephyr-specific functionality and should never have been part of west. Since Zephyr v1.14 LTS relies on it, it will continue to be included in the distribution, but will be removed when that version of Zephyr is obsoleted.
- west.commands:
  - `WestCommand.requires_installation`: deprecated; use `requires_workspace` instead
  - `WestCommand.requires_workspace`: new
  - `WestCommand.has_manifest`: new
  - `WestCommand.manifest`: this is now settable
- west.configuration: callers can now identify the workspace directory when reading and writing configuration files
- west.log:
  - `msg()`: new
- west.manifest:
  - The module now uses the standard logging module instead of `west.log`
  - `QUAL_REFS_WEST`: new
  - `SCHEMA_VERSION`: new
  - Defaults: removed
  - `Manifest.as_dict()`: new
  - `Manifest.as_frozen_yaml()`: new
  - `Manifest.as_yaml()`: new
  - `Manifest.from_file()` and `from_data()`: these factory methods are more flexible to use and less reliant on global state
  - `Manifest.validate()`: new
- ManifestImportFailed: new
- ManifestProject: semi-deprecated and will likely be removed later.
- Project: the constructor now takes a todir argument
- Project.format() and its callers are removed. Use f-strings instead.
- Project.name_and_path: new
- Project.remote_name: new
- Project.sha() now captures stderr
- Remote: removed

West now requires Python 3.6 or later. Additionally, some features may rely on Python dictionaries being insertion-ordered; this is only an implementation detail in CPython 3.6, but is part of the language specification as of Python 3.7.

v0.6.3

This point release fixes an error in the behavior of the deprecated west.cmake module.

v0.6.2

This point release fixes an error in the behavior of west update --fetch=smart, introduced in v0.6.1. All v0.6.1 users must upgrade.

v0.6.1

**Warning:** Do not use this point release. Make sure to use v0.6.2 instead.

The user-visible features in this point release are:

- The `west update` command has a new `--fetch` command line flag and `update.fetch` configuration option. The default value, "smart", skips fetching SHAs and tags which are available locally.
- Better and more consistent error-handling in the `west diff`, `west status`, `west forall`, and `west update` commands. Each of these commands can operate on multiple projects; if a subprocess related to one project fails, these commands now continue to operate on the rest of the projects. All of them also now report a nonzero error code from the west process if any of these subprocesses fails (this was previously not true of `west forall` in particular).
- The `west manifest` command also handles errors better.
- The `west list` command now works even when the projects are not cloned, as long as its format string only requires information which can be read from the manifest file. It still fails if the format string requires data stored in the project repository, e.g. if it includes the `{sha}` format string key.
- Commands and options which operate on git revisions now accept abbreviated SHAs. For example, `west init --mr SHA_PREFIX` now works. Previously, the `--mr` argument needed to be the entire 40 character SHA if it wasn’t a branch or a tag.

The developer-visible changes to the west-apis are:

- `west.log.banner()`: new
- `west.log.small_banner()`: new
- `west.manifest.Manifest.get_projects()`: new
• west.manifest.Project.is_cloned(): new
• west.commands.WestCommand instances can now access the parsed Manifest object via a new
  self.manifest property during the do_run() call. If read, it returns the Manifest object or aborts the
  command if it could not be parsed.
• west.manifest.Project.git() now has a capture_stderr kwarg

v0.6.0

• No separate bootstrapper

In west v0.5.x, the program was split into two components, a bootstrapper and a per-installation
clone. See Multiple Repository Management in the v1.14 documentation for more details.

This is similar to how Google’s Repo tool works, and lets west iterate quickly at first. It caused
confusion, however, and west is now stable enough to be distributed entirely as one piece via PyPI.

From v0.6.x onwards, all of the core west commands and helper classes are part of the west package
distributed via PyPI. This eliminates complexity and makes it possible to import west modules from
anywhere in the system, not just extension commands.

• The selfupdate command still exists for backwards compatibility, but now simply exits after print-
ing an error message.
• Manifest syntax changes
  - A west manifest file's projects elements can now specify their fetch URLs directly, like so:

    ```
    manifest:
      projects:
        - name: example-project-name
          url: https://github.com/example/example-project
    ```

    Project elements with url attributes set in this way may not also have remote attributes.
  - Project names must be unique: this restriction is needed to support future work, but was not
    possible in west v0.5.x because distinct projects may have URLs with the same final pathname
    component, like so:

    ```
    manifest:
      remotes:
        - name: remote-1
          url-base: https://github.com/remote-1
        - name: remote-2
          url-base: https://github.com/remote-2
      projects:
        - name: project
          remote: remote-1
          path: remote-1-project
        - name: project
          remote: remote-2
          path: remote-2-project
    ```

    These manifests can now be written with projects that use url instead of remote, like so:

    ```
    manifest:
      projects:
        - name: remote-1-project
          url: https://github.com/remote-1/project
        - name: remote-2-project
          url: https://github.com/remote-2/project
    ```
• The `west list` command now supports a `{sha}` format string key
• The default format string for `west list` was changed to "{name:12} {path:28} {revision:40} {url}".
• The command `west manifest --validate` can now be run to load and validate the current manifest file, among other error-handling fixes related to manifest parsing.
• Incompatible API changes were made to `west`'s APIs. Further changes are expected until API stability is declared in `west v1.0`.

  – The `west.manifest.Project` constructor's `remote` and `defaults` positional arguments are now kwargs. A new `url` kwarg was also added; if given, the `Project` URL is set to that value, and the `remote` kwarg is ignored.
  – `west.manifest.MANIFEST_SECTIONS` was removed. There is only one section now, namely `manifest`. The `sections` kwarg in the `west.manifest.Manifest` factory methods and constructor were also removed.
  – The `west.manifest.SpecialProject` class was removed. Use `west.manifest.ManifestProject` instead.

v0.5.x

West v0.5.x is the first version used widely by the Zephyr Project as part of its v1.14 Long-Term Support (LTS) release. The `west v0.5.x documentation` is available as part of the Zephyr's v1.14 documentation.

West's main features in v0.5.x are:

• Multiple repository management using Git repositories, including self-update of west itself
• Hierarchical configuration files
• Extension commands

Versions Before v0.5.x

Tags in the `west` repository before v0.5.x are prototypes which are of historical interest only.

2.10.3 Troubleshooting West

This page covers common issues with `west` and how to solve them.

`west update` fetching failures

One good way to troubleshoot fetching issues is to run `west update` in verbose mode, like this:

```sh
west -v update
```

The output includes Git commands run by `west` and their outputs. Look for something like this:

```sh
=== updating your_project (path/to/your/project):
w west.manifest: your_project: checking if cloned
[...other west.manifest logs...]
--- your_project: fetching, need revision SOME_SHA
w west.manifest: running 'git fetch ... https://github.com/your-username/your_project .. --.' in /some/directory
```
The `git fetch` command example in the last line above is what needs to succeed.

One strategy is to go to `/some/directory`, copy/paste and run the entire `git fetch` command, then debug from there using the documentation for your credential storage helper.

If you’re behind a corporate firewall and may have proxy or other issues, `curl -v FETCH_URL` (for HTTPS URLs) or `ssh -v FETCH_URL` (for SSH URLs) may be helpful.

If you can get the `git fetch` command to run successfully without prompting for a password when you run it directly, you will be able to run `west update` without entering your password in that same shell.

"'west' is not recognized as an internal or external command, operable program or batch file.'"

On Windows, this means that either west is not installed, or your `PATH` environment variable does not contain the directory where pip installed `west.exe`.

First, make sure you’ve installed west; see `Installing west`. Then try running `west` from a new `cmd.exe` window. If that still doesn't work, keep reading.

You need to find the directory containing `west.exe`, then add it to your `PATH`. (This `PATH` change should have been done for you when you installed Python and pip, so ordinarily you should not need to follow these steps.)

Run this command in `cmd.exe`:

```
pip3 show west
```

Then:

1. Look for a line in the output that looks like `Location: C:\foo\python\python38\lib\site-packages`. The exact location will be different on your computer.

2. Look for a file named `west.exe` in the `scripts` directory `C:\foo\python\python38\scripts`.

    **Important:** Notice how `lib\site-packages` in the `pip3 show` output was changed to `scripts`!

3. If you see `west.exe` in the `scripts` directory, add the full path to `scripts` to your `PATH` using a command like this:

    ```
    setx PATH "%PATH%;C:\foo\python\python38\scripts"
    ```

4. Close your `cmd.exe` window and open a new one. You should be able to run `west`.

"'Error: unexpected keyword argument 'requires_workspace'"

This error occurs on some Linux distributions after upgrading to west 0.7.0 or later from 0.6.x. For example:

```
$ west update
[... stack trace ...]
TypeError: __init__() got an unexpected keyword argument 'requires_workspace'
```

This appears to be a problem with the distribution's pip; see this comment in west issue 373 for details. Some versions of Ubuntu and Linux Mint are known to have this problem. Some users report issues on Fedora as well.

Neither macOS nor Windows users have reported this issue. There have been no reports of this issue on other Linux distributions, like Arch Linux, either.
Workaround 1: remove the old version, then upgrade:

```
$ pip3 show west | grep Location: | cut -f 2 -d ' ' 
/home/foo/.local/lib/python3.6/site-packages
$ rm -r /home/foo/.local/lib/python3.6/site-packages/west
$ pip3 install --user west==0.7.0
```

Workaround 2: install west in a Python virtual environment

One option is to use the venv module that's part of the Python 3 standard library. Some distributions remove this module from their base Python 3 packages, so you may need to do some additional work to get it installed on your system.

“invalid choice: ‘build’” (or ‘flash’, etc.)

If you see an unexpected error like this when trying to run a Zephyr extension command (like west flash, west build, etc.):

```
$ west build [...]  
west: error: argument <command>: invalid choice: 'build' (choose from 'init', [...] )
```

```
$ west flash [...]  
west: error: argument <command>: invalid choice: 'flash' (choose from 'init', [...] )
```

The most likely cause is that you're running the command outside of a west workspace. West needs to know where your workspace is to find Extensions.

To fix this, you have two choices:

1. Run the command from inside a workspace (e.g. the zephyrproject directory you created when you got started).
   For example, create your build directory inside the workspace, or run west flash --build-dir YOUR_BUILD_DIR from inside the workspace.

2. Set the ZEPHYR_BASE environment variable and re-run the west extension command. If set, west will use ZEPHYR_BASE to find your workspace.

If you're unsure whether a command is built-in or an extension, run west help from inside your workspace. The output prints extension commands separately, and looks like this for mainline Zephyr:

```
$ west help

built-in commands for managing git repositories:
  init: create a west workspace
  [...]  

other built-in commands:
  help: get help for west or a command
  [...]  

extension commands from project manifest (path: zephyr):
  build: compile a Zephyr application
  flash: flash and run a binary on a board
  [...]  
```

“invalid choice: ‘post-init’”

If you see this error when running west init:
west: error: argument <command>: invalid choice: 'post-init'
(choose from 'init', 'update', 'list', 'manifest', 'diff',
'status', 'forall', 'config', 'selfupdate', 'help')

Then you have an old version of west installed, and are trying to use it in a workspace that requires a more recent version.

The easiest way to resolve this issue is to upgrade west and retry as follows:

1. Install the latest west with the -U option for pip3 install as shown in Installing west.
2. Back up any contents of zephyrproject/.west/config that you want to save. (If you don't have any configuration options set, it's safe to skip this step.)
3. Completely remove the zephyrproject/.west directory (if you don't, you will get the “already in a workspace” error message discussed next).
4. Run west init again.

“already in an installation”

You may see this error when running west init with west 0.6:

FATAL ERROR: already in an installation (<some directory>), aborting

If this is unexpected and you're really trying to create a new west workspace, then it's likely that west is using the ZEPHYR_BASE environment variable to locate a workspace elsewhere on your system.

This is intentional; it allows you to put your Zephyr applications in any directory and still use west to build, flash, and debug them, for example.

To resolve this issue, unset ZEPHYR_BASE and try again.

2.10.4 Basics

This page introduces west's basic concepts and provides references to further reading.

West's built-in commands allow you to work with projects (Git repositories) under a common workspace directory.

Example workspace

If you've followed the upstream Zephyr getting started guide, your workspace looks like this:

```
zephyrproject/   # west topdir
    .west/       # marks the location of the topdir
        config  # per-workspace local configuration file

    # The manifest repository, never modified by west after creation:
    zephyr/      # .git/ repo
        west.yml # manifest file
            [... other files ...]

    # Projects managed by west:
    modules/
        lib/
            tinycbor/  # .git/ project
    net-tools/  # .git/ project
            [... other projects ...]
```
Workspace concepts

Here are the basic concepts you should understand about this structure. Additional details are in Workspaces.

topdir

Above, zephyrproject is the name of the workspace’s top level directory, or topdir. (The name zephyrproject is just an example – it could be anything, like z, my-zephyr-workspace, etc.) You’ll typically create the topdir and a few other files and directories using west init.

.west directory

The topdir contains the .west directory. When west needs to find the topdir, it searches for .west, and uses its parent directory. The search starts from the current working directory (and starts again from the location in the ZEPHYR_BASE environment variable as a fallback if that fails).

configuration file

The file .west/config is the workspace’s local configuration file.

manifest repository

Every west workspace contains exactly one manifest repository, which is a Git repository containing a manifest file. The location of the manifest repository is given by the manifest.path configuration option in the local configuration file. For upstream Zephyr, zephyr is the manifest repository, but you can configure west to use any Git repository in the workspace as the manifest repository. The only requirement is that it contains a valid manifest file. See Topologies supported for information on other options, and West Manifests for details on the manifest file format.

manifest file

The manifest file is a YAML file that defines projects, which are the additional Git repositories in the workspace managed by west. The manifest file is named west.yml by default; this can be overridden using the manifest.file local configuration option. You use the west update command to update the workspace’s projects based on the contents of the manifest file.

projects

Projects are Git repositories managed by west. Projects are defined in the manifest file and can be located anywhere inside the workspace. In the above example workspace, tinycbor and net-tools are projects. By default, the Zephyr build system uses west to get the locations of all the projects in the workspace, so any code they contain can be used as Modules (External projects).

extensions

Any repository known to west (either the manifest repository or any project repository) can define Extensions. Extensions are extra west commands you can run when using that workspace. The zephyr repository uses this feature to provide Zephyr-specific commands like west build. Defining these as extensions keeps west’s core agnostic to the specifics of any workspace’s Zephyr version, etc.

ignored files

A workspace can contain additional Git repositories or other files and directories not managed by west. West basically ignores anything in the workspace except .west, the manifest repository, and the projects specified in the manifest file.

west init and west update

The two most important workspace-related commands are west init and west update.
west init basics  This command creates a west workspace.

**Important:** West doesn't change your manifest repository contents after `west init` is run. Use ordinary Git commands to pull new versions, etc.

You will typically run it once, like this:

```shell
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v2.5.0 zephyrproject
```

This will:

1. Create the topdir, `zephyrproject`, along with `.west` and `.west/config` inside it
2. Clone the manifest repository from `https://github.com/zephyrproject-rtos/zephyr`, placing it into `zephyrproject/zephyr`
3. Check out the `v2.5.0` git tag in your local zephyr clone
4. Set `manifest.path` to `zephyr` in `.west/config`
5. Set `manifest.file` to `west.yml`

Your workspace is now almost ready to use; you just need to run `west update` to clone the rest of the projects into the workspace to finish.

For more details, see `west init`.

west update basics  This command makes sure your workspace contains Git repositories matching the projects in the manifest file.

**Important:** Whenever you check out a different revision in your manifest repository, you should run `west update` to make sure your workspace contains the project repositories the new revision expects.

The `west update` command reads the manifest file's contents by:

1. Finding the topdir. In the `west init` example above, that means finding `zephyrproject`.
2. Loading `.west/config` in the topdir to read the `manifest.path` (e.g. `zephyr`) and `manifest.file` (e.g. `west.yml`) options.
3. Loading the manifest file given by these options (e.g. `zephyrproject/zephyr/west.yml`).

It then uses the manifest file to decide where missing projects should be placed within the workspace, what URLs to clone them from, and what Git revisions should be checked out locally. Project repositories which already exist are updated in place by fetching and checking out their respective Git revisions in the manifest file.

For more details, see `west update`.

Other built-in commands

See *[Built-in commands]*.

Zephyr Extensions

See the following pages for information on Zephyr's extension commands:

- *Building, Flashing and Debugging*
- *Signing Binaries*
Additional Zephyr extension commands

Enabling shell completion

Troubleshooting

See Troubleshooting West.

2.10.5 Built-in commands

This page describes west's built-in commands, some of which were introduced in Basics, in more detail. Some commands are related to Git commands with the same name, but operate on the entire workspace. For example, west diff shows local changes in multiple Git repositories in the workspace.

Some commands take projects as arguments. These arguments can be project names as specified in the manifest file, or (as a fallback) paths to them on the local file system. Omitting project arguments to commands which accept them (such as west list, west forall, etc.) usually defaults to using all projects in the manifest file plus the manifest repository itself.

For additional help, run west <command> -h (e.g. west init -h).

west init

This command creates a west workspace. It can be used in two ways:

1. Cloning a new manifest repository from a remote URL
2. Creating a workspace around an existing local manifest repository

**Option 1**: to clone a new manifest repository from a remote URL, use:

```
west init [-m URL] [--mr REVISION] [--mf FILE] [directory]
```

The new workspace is created in the given directory, creating a new .west inside this directory. You can give the manifest URL using the -m switch, the initial revision to check out using --mr, and the location of the manifest file within the repository using --mf.

For example, running:

```
wes init -m https://github.com/zephyrproject-rtos/zephyr --mr v1.14.0 zp
```

would clone the upstream official zephyr repository into zp/zephyr, and check out the v1.14.0 release. This command creates zp/.west, and set the manifest.path configuration option to zephyr to record the location of the manifest repository in the workspace. The default manifest file location is used.

The -m option defaults to https://github.com/zephyrproject-rtos/zephyr. The --mf option defaults to west.yml. Since west v0.10.1, west will use the default branch in the manifest repository unless the --mr option is used to override it. (In prior versions, --mr defaulted to master.)

If no directory is given, the current working directory is used.

**Option 2**: to create a workspace around an existing local manifest repository, use:

```
west init -l [--mf FILE] directory
```

This creates .west next to directory in the file system, and sets manifest.path to directory.

As above, --mf defaults to west.yml.

Reconfiguring the workspace:
If you change your mind later, you are free to change `manifest.path` and `manifest.file` using `west config` after running `west init`. Just be sure to run `west update` afterwards to update your workspace to match the new manifest file.

```bash
west update
```

```bash
west update [-f {always,smart}] [-k] [-r]
            [--group-filter FILTER] [--stats] [PROJECT ...]
```

**Which projects are updated:**

By default, this command parses the manifest file, usually `west.yml`, and updates each project specified there. If your manifest uses `project groups`, then only the active projects are updated.

To operate on a subset of projects only, give `PROJECT` argument(s). Each `PROJECT` is either a project name as given in the manifest file, or a path that points to the project within the workspace. If you specify projects explicitly, they are updated regardless of whether they are active.

**Project update procedure:**

For each project that is updated, this command:

1. Initializes a local Git repository for the project in the workspace, if it does not already exist
2. Inspects the project's `revision` field in the manifest, and fetches it from the remote if it is not already available locally
3. Sets the project's `manifest-rev` branch to the commit specified by the revision in the previous step
4. Checks out `manifest-rev` in the local working copy as a detached HEAD
5. If the manifest file specifies a `submodules` key for the project, recursively updates the project's submodules as described below.

To avoid unnecessary fetches, `west update` will not fetch project `revision` values which are Git SHAs or tags that are already available locally. This is the behavior when the `-f` (`--fetch`) option has its default value, `smart`. To force this command to fetch from project remotes even if the revisions appear to be available locally, either use `-f always` or set the `update.fetch` configuration option to `always`. SHAs may be given as unique prefixes as long as they are acceptable to Git.

If the project `revision` is a Git ref that is neither a tag nor a SHA (i.e. if the project is tracking a branch), `west update` always fetches, regardless of `-f` and `update.fetch`.

Some branch names might look like short SHAs, like `deadbeef`. West treats these like SHAs. You can disambiguate by prefixing the revision value with `refs/heads/`, e.g. `revision: refs/heads/deadbeef`.

For safety, `west update` uses `git checkout --detach` to check out a detached HEAD at the manifest revision for each updated project, leaving behind any branches which were already checked out. This is typically a safe operation that will not modify any of your local branches.

However, if you had added some local commits onto a previously detached HEAD checked out by west, then git will warn you that you've left behind some commits which are no longer referred to by any branch. These may be garbage-collected and lost at some point in the future. To avoid this if you have local commits in the project, make sure you have a local branch checked out before running `west update`.

If you would rather rebase any locally checked out branches instead, use the `-r` (`--rebase`) option.

If you would like `west update` to keep local branches checked out as long as they point to commits that are descendants of the new `manifest-rev`, use the `-k` (`--keep-descendants`) option.

---

1 West may fetch all refs from the Git server when given a SHA as a revision. This is because some Git servers have historically not allowed fetching SHAs directly.
**Note:** `west update --rebase` will fail in projects that have git conflicts between your branch and new commits brought in by the manifest. You should immediately resolve these conflicts as you usually do with git, or you can use `git -C <project_path> rebase --abort` to ignore incoming changes for the moment.

With a clean working tree, a plain `west update` never fails because it does not try to hold on to your commits and simply leaves them aside.

`west update --keep-descendants` offers an intermediate option that never fails either but does not treat all projects the same:

- in projects where your branch diverged from the incoming commits, it does not even try to rebase and leaves your branches behind just like a plain `west update` does;
- in all other projects where no rebase or merge is needed it keeps your branches in place.

**One-time project group manipulation:**

The `--group-filter` option can be used to change which project groups are enabled or disabled for the duration of a single `west update` command. See *Project Groups and Active Projects* for details on the project group feature.

The `west update` command behaves as if the `--group-filter` option's value were appended to the `manifest.group-filter` configuration option.

For example, running `west update --group-filter=+foo,-bar` would behave the same way as if you had temporarily appended the string "+foo,-bar" to the value of `manifest.group-filter`, run `west update`, then restored `manifest.group-filter` to its original value.

Note that using the syntax `--group-filter=VALUE` instead of `--group-filter VALUE` avoids issues parsing command line options if you just want to disable a single group, e.g. `--group-filter=-bar`.

**Submodule update procedure:**

If a project in the manifest has a `submodules` key, the submodules are updated as follows, depending on the value of the submodules key.

If the project has `submodules: true`, west first synchronizes the project's submodules with:

```sh
git submodule sync --recursive
```

West then runs one of the following in the project repository, depending on whether you run `west update` with the `--rebase` option or without it:

```sh
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive
```

Otherwise, the project has `submodules: <list-of-submodules>`. In this case, west synchronizes the project's submodules with:

```sh
git submodule sync --recursive -- <submodule-path>
```

Then it updates each submodule in the list as follows, depending on whether you run `west update` with the `--rebase` option or without it:

```sh
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive <submodule-path>

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive <submodule-path>
```
The `git submodule sync` commands are skipped if the `update.sync-submodules` Configuration option is false.

**Other project commands**

West has a few more commands for managing the projects in the workspace, which are summarized here. Run `west <command> -h` for detailed help.

- `west list`: print a line of information about each project in the manifest, according to a format string
- `west manifest`: manage the manifest file. See *Manifest Command*.
- `west diff`: run `git diff` in local project repositories
- `west status`: run `git status` in local project repositories
- `west forall`: run an arbitrary command in local project repositories

**Other built-in commands**

Finally, here is a summary of other built-in commands.

- `west config`: get or set configuration options
- `west todir`: print the top level directory of the west workspace
- `west help`: get help about a command, or print information about all commands in the workspace, including Extensions

### 2.10.6 Workspaces

This page describes the `west workspace` concept introduced in *Basics* in more detail.

**The manifest-rev branch**

West creates and controls a Git branch named `manifest-rev` in each project. This branch points to the revision that the manifest file specified for the project at the time `west update` was last run. Other workspace management commands may use `manifest-rev` as a reference point for the upstream revision as of this latest update. Among other purposes, the `manifest-rev` branch allows the manifest file to use SHAs as project revisions.

Although `manifest-rev` is a normal Git branch, west will recreate and/or reset it on the next update. For this reason, it is dangerous to check it out or otherwise modify it yourself. For instance, any commits you manually add to this branch may be lost the next time you run `west update`. Instead, check out a local branch with another name, and either rebase it on top of a new `manifest-rev`, or merge `manifest-rev` into it.

**Note:** West does not create a `manifest-rev` branch in the manifest repository, since `west` does not manage the manifest repository’s branches or revisions.

**The refs/west/* Git refs**

West also reserves all Git refs that begin with `refs/west/` (such as `refs/west/foo`) for itself in local project repositories. Unlike `manifest-rev`, these refs are not regular branches. West's behavior here is an implementation detail; users should not rely on these refs' existence or behavior.
Private repositories

You can use west to fetch from private repositories. There is nothing west-specific about this.

The west update command essentially runs `git fetch YOUR_PROJECT_URL` when a project's manifest-rev branch must be updated to a newly fetched commit. It's up to your environment to make sure the fetch succeeds.

You can either enter the password manually or use any of the credential helpers built in to Git. Since Git has credential storage built in, there is no need for a west-specific feature.

The following sections cover common cases for running `west update` without having to enter your password, as well as how to troubleshoot issues.

**Fetching via HTTPS**  On Windows when fetching from GitHub, recent versions of Git prompt you for your GitHub password in a graphical window once, then store it for future use (in a default installation). Passwordless fetching from GitHub should therefore work "out of the box" on Windows after you have done it once.

In general, you can store your credentials on disk using the "store" git credential helper. See the [git-credential-store](https://git-scm.com/docs/git-credential-store) manual page for details.

To use this helper for all the repositories in your workspace, run:

```bash
west forall -c "git config credential.helper store"
```

To use this helper on just the projects `foo` and `bar`, run:

```bash
west forall -c "git config credential.helper store" foo bar
```

To use this helper by default on your computer, run:

```bash
git config --global credential.helper store
```

On GitHub, you can set up a [personal access token](https://github.com/settings/applications/new) to use in place of your account password. (This may be required if your account has two-factor authentication enabled, and may be preferable to storing your account password in plain text even if two-factor authentication is disabled.)

You can use the Git credential store to authenticate with a GitHub PAT (Personal Access Token) like so:

```bash
echo "https://x-access-token:$GH_TOKEN@github.com" >> ~/.git-credentials
```

If you don't want to store any credentials on the file system, you can store them in memory temporarily using [git-credential-cache](https://git-scm.com/docs/git-credential-cache) instead.

If you setup fetching via SSH, you can use Git URL rewrite feature. The following command instructs Git to use SSH URLs for GitHub instead of HTTPS ones:

```bash
git config --global url."git@github.com:".insteadOf "https://github.com/"
```

**Fetching via SSH**  If your SSH key has no password, fetching should just work. If it does have a password, you can avoid entering it manually every time using [ssh-agent](https://manpages.ubuntu.com/manpages/bionic/man1/ssh-agent.1.html).

On GitHub, see [Connecting to GitHub with SSH](https://docs.github.com/en/extending-github/enterprise/set-up-ssh-for-github) for details on configuration and key creation.

**Project locations**

Projects can be located anywhere inside the workspace, but they may not “escape” it.

In other words, project repositories need not be located in subdirectories of the manifest repository or as immediate subdirectories of the topdir. However, projects must have paths inside the workspace.
You may replace a project's repository directory within the workspace with a symbolic link to elsewhere on your computer, but west will not do this for you.

**Topologies supported**

The following are example source code topologies supported by west.

- **T1**: star topology, zephyr is the manifest repository
- **T2**: star topology, a Zephyr application is the manifest repository
- **T3**: forest topology, freestanding manifest repository

**T1: Star topology, zephyr is the manifest repository**

- The zephyr repository acts as the central repository and specifies its *Modules (External projects)* in its `west.yml`
- Analogy with existing mechanisms: Git submodules with zephyr as the super-project

This is the default. See *Workspace concepts* for how mainline Zephyr is an example of this topology.

**T2: Star topology, application is the manifest repository**

- Useful for those focused on a single application
- A repository containing a Zephyr application acts as the central repository and names other projects required to build it in its `west.yml`. This includes the zephyr repository and any modules.
- Analogy with existing mechanisms: Git submodules with the application as the super-project, zephyr and other projects as submodules

A workspace using this topology looks like this:

```
west-workspace/
  application/ # .git/
    CMakeLists.txt
    prj.conf
    src/
      main.c
      west.yml # main manifest with optional import(s) and override(s)
  modules/
    lib/     # .git/ project from either the main manifest or some import.
      tinycbor/ # .git/ project from either the main manifest or some import.
    zephyr/ # .git/ project
      west.yml # This can be partially imported with lower precedence or ignored.

# Only the 'manifest-rev' version can be imported.
```

Here is an example application/west.yml which uses *Manifest Imports*, available since west 0.7, to import Zephyr v2.5.0 and its modules into the application manifest file:

```
# Example T2 west.yml, using manifest imports.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
```

(continues on next page)
projects:
  - name: zephyr
    remote: zephyrproject-rtos
    revision: v2.5.0
    import: true
  self:
    path: application

You can still selectively “override” individual Zephyr modules if you use import: in this way; see Example 1.3: Downstream of a Zephyr release, with module fork for an example.

Another way to do the same thing is to copy/paste zephyr/west.yml to application/west.yml, adding an entry for the zephyr project itself, like this:

```yaml
# Equivalent to the above, but with manually maintained Zephyr modules.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  defaults:
    remote: zephyrproject-rtos
  projects:
    - name: zephyr
      revision: v2.5.0
      west-commands: scripts/west-commands.yml
    - name: net-tools
      revision: some-sha-goes-here
      path: tools/net-tools
    # ... other Zephyr modules go here ...
  self:
    path: application
```

(The west-commands is there for Building, Flashing and Debugging and other Zephyr-specific Extensions. It's not necessary when using import.)

The main advantage to using import is not having to track the revisions of imported projects separately. In the above example, using import means Zephyr's module versions are automatically determined from the zephyr/west.yml revision, instead of having to be copy/pasted (and maintained) on their own.

### T3: Forest topology

- Useful for those supporting multiple independent applications or downstream distributions with no “central” repository
- A dedicated manifest repository which contains no Zephyr source code, and specifies a list of projects all at the same “level”
- Analogy with existing mechanisms: Google repo-based source distribution

A workspace using this topology looks like this:

```
west-workspace/
  app1/     # .git/ project
   |         
   |         
   |         CMakeLists.txt
   |         prj.conf
   |         src/
   |             main.c
  app2/     # .git/ project
   |         
   |         CMakeLists.txt
```

(continues on next page)
Here is an example T3 manifest-repo/west.yml which uses Manifest Imports, available since west 0.7, to import Zephyr v2.5.0 and its modules, then add the app1 and app2 projects:

```yaml
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: your-git-server
      url-base: https://git.example.com/your-company
  defaults:
    remote: your-git-server
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
    - name: app1
      revision: SOME_SHA_OR_BRANCH_OR_TAG
    - name: app2
      revision: ANOTHER_SHA_OR_BRANCH_OR_TAG
  self:
    path: manifest-repo
```

You can also do this “by hand” by copy/pasting zephyr/west.yml as shown above for the T2 topology, with the same caveats.

### 2.10.7 West Manifests

This page contains detailed information about west’s multiple repository model, manifest files, and the west manifest command. For API documentation on the west.manifest module, see west-apis-manifest. For a more general introduction and command overview, see Basics.

#### Multiple Repository Model

West’s view of the repositories in a west workspace, and their history, looks like the following figure (though some parts of this example are specific to upstream Zephyr’s use of west):

The history of the manifest repository is the line of Git commits which is “floating” on top of the gray plane. Parent commits point to child commits using solid arrows. The plane below contains the Git commit history of the repositories in the workspace, with each project repository boxed in by a rectangle. Parent/child commit relationships in each repository are also shown with solid arrows.
The commits in the manifest repository (again, for upstream Zephyr this is the zephyr repository itself) each have a manifest file. The manifest file in each commit specifies the corresponding commits which it expects in each of the project repositories. This relationship is shown using dotted line arrows in the diagram. Each dotted line arrow points from a commit in the manifest repository to a corresponding commit in a project repository.

Notice the following important details:

- Projects can be added (like P1 between manifest repository commits D and E) and removed (P2 between the same manifest repository commits)
- Project and manifest repository histories don’t have to move forwards or backwards together:
  - P2 stays the same from A → B, as do P1 and P3 from F → G.
  - P3 moves forward from A → B.
  - P3 moves backward from C → D.

One use for moving backward in project history is to “revert” a regression by going back to a revision before it was introduced.

- Project repository commits can be “skipped”: P3 moves forward multiple commits in its history from B → C.
- In the above diagram, no project repository has two revisions “at the same time”: every manifest file refers to exactly one commit in the projects it cares about. This can be relaxed by using a branch name as a manifest revision, at the cost of being able to bisect manifest repository history.

**Manifest Files**

West manifests are YAML files. Manifests have a top-level `manifest` section with some subsections, like this:

```yaml
manifest:
  remotes:
```

(continues on next page)
In YAML terms, the manifest file contains a mapping, with a `manifest` key. Any other keys and their contents are ignored (west v0.5 also required a `west` key, but this is ignored starting with v0.6).

The manifest contains subsections, like `defaults`, `remotes`, `projects`, and `self`. In YAML terms, the value of the `manifest` key is also a mapping, with these “subsections” as keys. As of west v0.10, all of these “subsection” keys are optional.

The `projects` value is a list of repositories managed by west and associated metadata. We'll discuss it soon, but first we will describe the `remotes` section, which can be used to save typing in the `projects` list.

### Remotes

The `remotes` subsection contains a sequence which specifies the base URLs where projects can be fetched from.

Each `remotes` element has a name and a “URL base”. These are used to form the complete Git fetch URL for each project. A project's fetch URL can be set by appending a project-specific path onto a remote URL base. (As we'll see below, projects can also specify their complete fetch URLs.)

For example:

```yaml
manifest:
    # ...
remotes:
    - name: remote1
      url-base: https://git.example.com/base1
    - name: remote2
      url-base: https://git.example.com/base2
```

The `remotes` keys and their usage are in the following table.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Mandatory; a unique name for the remote.</td>
</tr>
<tr>
<td>url-base</td>
<td>A prefix that is prepended to the fetch URL for each project with this remote.</td>
</tr>
</tbody>
</table>

Above, two remotes are given, with names `remote1` and `remote2`. Their URL bases are respectively `https://git.example.com/base1` and `https://git.example.com/base2`. You can use SSH URL bases as well; for example, you might use `git@example.com:base1` if `remote1` supported Git over SSH as well. Anything acceptable to Git will work.

### Projects

The `projects` subsection contains a sequence describing the project repositories in the west workspace. Every project has a unique name. You can specify what Git remote URLs to use when cloning and fetching the projects, what revisions to track, and where the project should be stored on the local file system.

Here is an example. We'll assume the `remotes` given above.
manifest:
  # [... same remotes as above...]
projects:
- name: proj1
  remote: remote1
  path: extra/project-1
- name: proj2
  repo-path: my-path
  remote: remote2
  revision: v1.3
- name: proj3
  url: https://github.com/user/project-three
  revision: abcde413a111

In this manifest:

- proj1 has remote remote1, so its Git fetch URL is https://git.example.com/base1/proj1. The remote url-base is appended with a / and the project name to form the URL.

  Locally, this project will be cloned at path extra/project-1 relative to the west workspace's root directory, since it has an explicit path attribute with this value.

  Since the project has no revision specified, master is used by default. The current tip of this branch will be fetched and checked out as a detached HEAD when west next updates this project.

- proj2 has a remote and a repo-path, so its fetch URL is https://git.example.com/base2/my-path. The repo-path attribute, if present, overrides the default name when forming the fetch URL.

  Since the project has no path attribute, its name is used by default. It will be cloned into a directory named proj2. The commit pointed to by the v1.3 tag will be checked out when west updates the project.

- proj3 has an explicit url, so it will be fetched from https://github.com/user/project-three.

  Its local path defaults to its name, proj3. Commit abcde413a111 will be checked out when it is next updated.

The available project keys and their usage are in the following table. Sometimes we'll refer to the defaults subsection; it will be described next.
Table 2.3: projects elements keys

<table>
<thead>
<tr>
<th>Key(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Mandatory; a unique name for the project. The name cannot be one of the reserved values “west” or “manifest”. The name must be unique in the manifest file.</td>
</tr>
<tr>
<td>remote, url</td>
<td>Mandatory (one of the two, but not both). If the project has a remote, that remote’s url-base will be combined with the project’s name (or repo-path, if it has one) to form the fetch URL instead. If the project has a url, that’s the complete fetch URL for the remote Git repository. If the project has neither, the defaults section must specify a remote, which will be used as the the project’s remote. Otherwise, the manifest is invalid.</td>
</tr>
<tr>
<td>repo-path</td>
<td>Optional. If given, this is concatenated on to the remote’s url-base instead of the project’s name to form its fetch URL. Projects may not have both url and repo-path attributes.</td>
</tr>
<tr>
<td>revision</td>
<td>Optional. The Git revision that west update should check out. This will be checked out as a detached HEAD by default, to avoid conflicting with local branch names. If not given, the revision value from the defaults subsection will be used if present. A project revision can be a branch, tag, or SHA. The default revision is master if not otherwise specified. Using HEAD~0(^1) as the revision will cause west to keep the current state of the project.</td>
</tr>
<tr>
<td>path</td>
<td>Optional. Relative path specifying where to clone the repository locally, relative to the top directory in the west workspace. If missing, the project’s name is used as a directory name.</td>
</tr>
<tr>
<td>clone-depth</td>
<td>Optional. If given, a positive integer which creates a shallow history in the cloned repository limited to the given number of commits. This can only be used if the revision is a branch or tag.</td>
</tr>
<tr>
<td>west-commands</td>
<td>Optional. If given, a relative path to a YAML file within the project which describes additional west commands provided by that project. This file is named west-commands.yml by convention. See Extensions for details.</td>
</tr>
<tr>
<td>import</td>
<td>Optional. If true, imports projects from manifest files in the given repository into the current manifest. See Manifest Imports for details.</td>
</tr>
<tr>
<td>groups</td>
<td>Optional, a list of groups the project belongs to. See Project Groups and Active Projects for details.</td>
</tr>
<tr>
<td>submodules</td>
<td>Optional. You can use this to make west update also update Git submodules defined by the project. See Git Submodules in Projects for details.</td>
</tr>
<tr>
<td>userdata</td>
<td>Optional. The value is an arbitrary YAML value. See Repository user data.</td>
</tr>
</tbody>
</table>

**Defaults** The defaults subsection can provide default values for project attributes. In particular, the default remote name and revision can be specified here. Another way to write the same manifest we have been describing so far using defaults is:

```yaml
manifest:
  defaults:
    remote: remote1
    revision: v1.3

remotes:
  - name: remote1
    url-base: https://git.example.com/base1
  - name: remote2
    url-base: https://git.example.com/base2
```

\(^1\) In git, HEAD is a reference, whereas HEAD~\(<n>\) is a valid revision but not a reference. West fetches references, such as refs/heads/main or HEAD, and commits not available locally, but will not fetch commits if they are already available. HEAD~0 is resolved to a specific commit that is locally available, and therefore west will simply checkout the locally available commit, identified by HEAD~0.
The available **defaults** keys and their usage are in the following table.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>remote</td>
<td>Optional. This will be used for a project’s <code>remote</code> if it does not have a <code>url</code> or <code>remote</code> key set.</td>
</tr>
<tr>
<td>revision</td>
<td>Optional. This will be used for a project’s <code>revision</code> if it does not have one set. If not given, the default is <code>master</code>.</td>
</tr>
</tbody>
</table>

**Self**  The **self** subsection can be used to control the manifest repository itself.

As an example, let’s consider this snippet from the zephyr repository’s `west.yml`:

```yaml
manifest:
    # ...
    self:
        path: zephyr
        west-commands: scripts/west-commands.yml
```

This ensures that the zephyr repository is cloned into path `zephyr`, though as explained above that would have happened anyway if cloning from the default manifest URL, `https://github.com/zephyrproject-rtos/zephyr`. Since the zephyr repository does contain extension commands, its `self` entry declares the location of the corresponding `west-commands.yml` relative to the repository root.

The available **self** keys and their usage are in the following table.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Optional. The <code>path west init</code> should clone the manifest repository into, relative to the west workspace <code>topdir</code>. If not given, the basename of the path component in the manifest repository URL will be used by default. For example, if the URL is <code>https://git.example.com/project-repo</code>, the manifest repository would be cloned to the directory <code>project-repo</code>.</td>
</tr>
<tr>
<td>west-commands</td>
<td>Optional. This is analogous to the same key in a project sequence element.</td>
</tr>
<tr>
<td>import</td>
<td>Optional. This is also analogous to the <code>projects</code> key, but allows importing projects from other files in the manifest repository. See <a href="#">Manifest Imports</a>.</td>
</tr>
</tbody>
</table>

**Version**  The `version` subsection can be used to mark the lowest version of the manifest file schema that can parse this file’s data:
The `manifest` schema `manifest-schema.yml` in the west source code repository is used to validate the manifest section. The current manifest version is 0.13, which is supported by west version v0.13.x.

The `version` value may be any one of these values: "0.7", "0.8", "0.9", "0.10", "0.12", "0.13". West v0.11 did not include any new features which broke the previous schema, so "0.11" is not a valid schema version.

West v0.10.x can load manifests with any of these version values, while west v0.9.x can only load versions up to "0.9", and so on.

West halts with an error if you ask it to load a manifest file written in a version it cannot handle.

Quoting the `version` value as shown above forces the YAML parser to treat it as a string. Without quotes, 0.10 in YAML is just the floating point value 0.1. You can omit the quotes if the value is the same when cast to string, but it’s best to include them. Always use quotes if you’re not sure.

**Group-filter** See *Project Groups and Active Projects*.

### Project Groups and Active Projects

You can use the `groups` and `group-filter` keys briefly described *above* to place projects into groups, and filter which groups are enabled. These keys appear in the manifest like this:

```yaml
manifest:
  version: "0.10"
  # marks that this file uses version 0.10 of the west manifest
  # file format.

The pykwalify schema `manifest-schema.yml` in the west source code repository is used to validate the manifest section. The current manifest version is 0.13, which is supported by west version v0.13.x.

The `version` value may be any one of these values: "0.7", "0.8", "0.9", "0.10", "0.12", "0.13". West v0.11 did not include any new features which broke the previous schema, so "0.11" is not a valid schema version.

West v0.10.x can load manifests with any of these version values, while west v0.9.x can only load versions up to "0.9", and so on.

West halts with an error if you ask it to load a manifest file written in a version it cannot handle.

Quoting the `version` value as shown above forces the YAML parser to treat it as a string. Without quotes, 0.10 in YAML is just the floating point value 0.1. You can omit the quotes if the value is the same when cast to string, but it’s best to include them. Always use quotes if you’re not sure.

**Group-filter** See *Project Groups and Active Projects*.

### Project Group Examples

You can enable or disable project groups using `group-filter`. Projects whose groups are all disabled are inactive; west essentially ignores inactive projects unless explicitly requested not to.

The next section introduces project groups; the following sections describe *Enabled and Disabled Project Groups* and *Active and Inactive Projects*. There are some basic examples in *Project Group Examples*.

Finally, *Group Filters and Imports* provides a simplified overview of how `group-filter` interacts with the `Manifest Imports` feature.

**Project Groups** Inside `manifest: projects:`, you can add a project to one or more groups. The `groups` key is a list of group names. Group names are strings.

For example, in this manifest fragment:

```yaml
manifest:
  projects:
    - name: project-1
      groups:
        - groupA
      - name: project-2
        groups:
          - groupB
          - groupC
      - name: project-3
```
The projects are in these groups:

- **project-1**: one group, named `groupA`
- **project-2**: two groups, named `groupB` and `groupC`
- **project-3**: no groups

Project group names must not contain commas (,), colons (:), or whitespace.

Group names must not begin with a dash (-) or the plus sign (+), but they may contain these characters elsewhere in their names. For example, `foo-bar` and `foo+bar` are valid groups, but `-foobar` and `+foobar` are not.

Group names are otherwise arbitrary strings. Group names are case sensitive.

As a restriction, no project may use both `import:` and `groups:`. (This avoids some edge cases whose semantics are difficult to specify.)

---

**Enabled and Disabled Project Groups**  
All project groups are enabled by default. You can enable or disable groups in both your manifest file and *Configuration*.

Within a manifest file, `manifest: group-filter:` is a YAML list of groups to enable and disable.

To enable a group, prefix its name with a plus sign (+). For example, `groupA` is enabled in this manifest fragment:

```yaml
manifest:
  group-filter: [+groupA]
```

Although this is redundant for groups that are already enabled by default, it can be used to override settings in an imported manifest file. See *Group Filters and Imports* for more information.

To disable a group, prefix its name with a dash (-). For example, `groupA` and `groupB` are disabled in this manifest fragment:

```yaml
manifest:
  group-filter: [-groupA,-groupB]
```

---

**Note:** Since `group-filter` is a YAML list, you could have written this fragment as follows:

```yaml
manifest:
  group-filter:
    - -groupA
    - -groupB
```

However, this syntax is harder to read and therefore discouraged.

---

In addition to the manifest file, you can control which groups are enabled and disabled using the `manifest.group-filter` configuration option. This option is a comma-separated list of groups to enable and/or disable.

To enable a group, add its name to the list prefixed with +. To disable a group, add its name prefixed with -. For example, setting `manifest.group-filter` to `+groupA,-groupB` enables `groupA`, and disables `groupB`.

The value of the configuration option overrides any data in the manifest file. You can think of this as if the `manifest.group-filter` configuration option is appended to the `manifest: group-filter:` list from YAML, with "last entry wins" semantics.
Active and Inactive Projects  All projects are active by default. Projects with no groups are always active. A project is inactive if all of its groups are disabled. This is the only way to make a project inactive.

Most west commands that operate on projects will ignore inactive projects by default. For example, west update when run without arguments will not update inactive projects. As another example, running west list without arguments will not print information for inactive projects.

Project Group Examples  This section contains example situations involving project groups and active projects. The examples use both manifest: group-filter: YAML lists and manifest.group-filter configuration lists, to show how they work together.

Note that the defaults and remotes data in the following manifests isn’t relevant except to make the examples complete and self-contained.

Example 1: no disabled groups  The entire manifest file is:

```yaml
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB
    - name: baz
  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The manifest.group-filter configuration option is not set (you can ensure this by running west config -D manifest.group-filter).

No groups are disabled, because all groups are enabled by default. Therefore, all three projects (foo, bar, and baz) are active. Note that there is no way to make project baz inactive, since it has no groups.

Example 2: Disabling one group via manifest  The entire manifest file is:

```yaml
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB
  group-filter: [-groupA]
  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

(continues on next page)
The manifest.group-filter configuration option is not set (you can ensure this by running west config -D manifest.group-filter).

Since groupA is disabled, project foo is inactive. Project bar is active, because groupB is enabled.

**Example 3: Disabling multiple groups via manifest**  The entire manifest file is:

```plaintext
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  group-filter: [-groupA,-groupB]

defaults:
  remote: example-remote

remotes:
  - name: example-remote
    url-base: https://git.example.com
```

The manifest.group-filter configuration option is not set (you can ensure this by running west config -D manifest.group-filter).

Both foo and bar are inactive, because all of their groups are disabled.

**Example 4: Disabling a group via configuration**  The entire manifest file is:

```plaintext
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  defaults:
    remote: example-remote

remotes:
  - name: example-remote
    url-base: https://git.example.com
```

The manifest.group-filter configuration option is set to -groupA (you can ensure this by running west config manifest.group-filter -- -groupA; the extra -- is required so the argument parser does not treat -groupA as a command line option -g with value roupA).

Project foo is inactive because groupA has been disabled by the manifest.group-filter configuration option. Project bar is active because groupB is enabled.
Example 5: Overriding a disabled group via configuration  The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
      groups:
        - name: baz
        groups:
          - groupA
          - groupB
  group-filter: [-groupA]
  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The manifest.group-filter configuration option is set to +groupA (you can ensure this by running west config manifest.group-filter +groupA).

In this case, groupA is enabled: the manifest.group-filter configuration option has higher precedence than the manifest: group-filter: [-groupA] content in the manifest file.

Therefore, projects foo and bar are both active.

Example 6: Overriding multiple disabled groups via configuration  The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
      groups:
        - name: baz
        groups:
          - groupA
          - groupB
  group-filter: [-groupA,-groupB]
  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The manifest.group-filter configuration option is set to +groupA,+groupB (you can ensure this by running west config manifest.group-filter "+groupA,+groupB").

In this case, both groupA and groupB are enabled, because the configuration value overrides the manifest file for both groups.

Therefore, projects foo and bar are both active.

Example 7: Disabling multiple groups via configuration  The entire manifest file is:
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

defaults:
  remote: example-remote
remotes:
  - name: example-remote
    url-base: https://git.example.com

The manifest.group-filter configuration option is set to `-groupA,-groupB` (you can ensure this by running `west config manifest.group-filter -- "-groupA,-groupB"`).

In this case, both groupA and groupB are disabled.

Therefore, projects foo and bar are both inactive.

Group Filters and Imports This section provides a simplified description of how the manifest.group-filter: value behaves when combined with Manifest Imports. For complete details, see Manifest Import Details.

**Warning:** The below semantics apply to west v0.10.0 and later. West v0.9.x semantics are different, and combining group-filter with import in west v0.9.x is discouraged.

In short:

- if you only import one manifest, any groups it disables in its group-filter are also disabled in your manifest
- you can override this in your manifest file's manifest: group-filter: value, your workspace's manifest.group-filter configuration option, or both

Here are some examples.

**Example 1: no overrides** You are using this parent/west.yml manifest:

```yaml
# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
        groups:
          - unstable
```

And child/west.yml contains:
Only child and project-2 are active in the resolved manifest.

The unstable group is disabled in child/west.yml, and that is not overridden in parent/west.yml. Therefore, the final group-filter for the resolved manifest is [-unstable].

Since project-1 and project-3 are in the unstable group and are not in any other group, they are inactive.

**Example 2: overriding an imported group-filter via manifest**

You are using this parent/west.yml manifest:

```yaml
# parent/west.yml:
manifest:
  group-filter: [+unstable,-optional]
projects:
  - name: child
    url: https://git.example.com/child
    import: true
  - name: project-1
    url: https://git.example.com/project-1
    groups:
      - unstable
```

And child/west.yml contains:

```yaml
# child/west.yml:
manifest:
  group-filter: [-unstable]
projects:
  - name: project-2
    url: https://git.example.com/project-2
    groups:
      - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

Only the child, project-1, and project-3 projects are active.

The [-unstable] group filter in child/west.yml is overridden in parent/west.yml, so the unstable group is enabled. Since project-1 and project-3 are in the unstable group, they are active.

The same parent/west.yml file disables the optional group, so project-2 is inactive.

The final group filter specified by parent/west.yml is [+unstable,-optional].
Example 3: overriding an imported group-filter via configuration

You are using this parent/west.yml manifest:

```yaml
# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
      - unstable
```

And child/west.yml contains:

```yaml
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

If you run:

```
west config manifest.group-filter +unstable,-optional
```

Then only the child, project-1, and project-3 projects are active.

The -unstable group filter in child/west.yml is overridden in the manifest.group-filter configuration option, so the unstable group is enabled. Since project-1 and project-3 are in the unstable group, they are active.

The same configuration option disables the optional group, so project-2 is inactive.

The final group filter specified by parent/west.yml and the manifest.group-filter configuration option is [+unstable,-optional].

Git Submodules in Projects

You can use the submodules keys briefly described above to force west update to also handle any Git submodules configured in project's git repository. The submodules key can appear inside projects, like this:

```yaml
manifest:
  projects:
    - name: some-project
      submodules: ...
```

The submodules key can be a boolean or a list of mappings. We’ll describe these in order.

**Option 1: Boolean**  
This is the easiest way to use submodules.
If `submodules` is true as a projects attribute, `west update` will recursively update the project's Git submodules whenever it updates the project itself. If it's false or missing, it has no effect.

For example, let's say you have a source code repository `foo`, which has some submodules, and you want `west update` to keep all of them them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```yaml
manifest:
  projects:
    - name: foo
      submodules: true
    - name: bar
```

Here, `west update` will initialize and update all submodules in `foo`. If `bar` has any submodules, they are ignored, because `bar` does not have a `submodules` value.

**Option 2: List of mappings** The `submodules` key may be a list of mappings, one list element for each desired submodule. Each submodule listed is updated recursively. You can still track and update unlisted submodules with `git` commands manually; present or not they will be completely ignored by `west`.

The `path` key must match exactly the path of one submodule relative to its parent west project, as shown in the output of `git submodule status`. The `name` key is optional and not used by `west` for now; it's not passed to `git submodule` commands either. The `name` key was briefly mandatory in `west` version 0.9.0, but was made optional in 0.9.1.

For example, let's say you have a source code repository `foo`, which has many submodules, and you want `west update` to keep some but not all of them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```yaml
manifest:
  projects:
    - name: foo
      submodules:
        - path: path/to/foo-first-sub
          name: foo-second-sub
        - path: path/to/foo-second-sub
    - name: bar
```

Here, `west update` will recursively initialize and update just the submodules in `foo` with paths `path/to/foo-first-sub` and `path/to/foo-second-sub`. Any submodules in `bar` are still ignored.

**Repository user data**

`west` versions v0.12 and later support an optional `userdata` key in projects.

`west` versions v0.13 and later supports this key in the `manifest: self:` section.

It is meant for consumption by programs that require user-specific project metadata. Beyond parsing it as YAML, `west` itself ignores the value completely.

The key's value is arbitrary YAML. `west` parses the value and makes it accessible to programs using `west-apis` as the `userdata` attribute of the corresponding `west.manifest.Project` object.

Example manifest fragment:
manifest:
  projects:
  - name: foo
  - name: bar
    userdata: a-string
  - name: baz
    userdata:
      key: value
  self:
    userdata: blub

Example Python usage:

manifest = west.manifest.Manifest.from_file()

foo, bar, baz = manifest.get_projects(['foo', 'bar', 'baz'])

foo.userdata # None
bar.userdata # 'a-string'
baz.userdata # {'key': 'value'}
manifest.userdata # 'blub'

**Manifest Imports**

You can use the import key briefly described above to include projects from other manifest files in your west.yml. This key can be either a project or self section attribute:

manifest:
  projects:
  - name: some-project
    import: ...
  self:
    import: ...

You can use a “self: import:” to load additional files from the repository containing your west.yml. You can use a “project: ... import:” to load additional files defined in that project’s Git history.

West resolves the final manifest from individual manifest files in this order:

1. imported files in self
2. your west.yml file
3. imported files in projects

During resolution, west ignores projects which have already been defined in other files. For example, a project named foo in your west.yml makes west ignore other projects named foo imported from your projects list.

The import key can be a boolean, path, mapping, or sequence. We’ll describe these in order, using examples:

- **Boolean**
  - Example 1.1: Downstream of a Zephyr release
  - Example 1.2: “Rolling release” Zephyr downstream
  - Example 1.3: Downstream of a Zephyr release, with module fork

- **Relative path**
  - Example 2.1: Downstream of a Zephyr release with explicit path
– Example 2.2: Downstream with directory of manifest files
– Example 2.3: Continuous Integration overrides

• Mapping with additional configuration
  – Example 3.1: Downstream with name allowlist
  – Example 3.2: Downstream with path allowlist
  – Example 3.3: Downstream with path blocklist
  – Example 3.4: Import into a subdirectory

• Sequence of paths and mappings
  – Example 4.1: Downstream with sequence of manifest files
  – Example 4.2: Import order illustration

A more formal description of how this works is last, after the examples.

Troubleshooting Note If you’re using this feature and find west’s behavior confusing, try resolving your manifest to see the final results after imports are done.

Option 1: Boolean This is the easiest way to use import.

If import is true as a projects attribute, west imports projects from the west.yml file in that project’s root directory. If it’s false or missing, it has no effect. For example, this manifest would import west.yml from the p1 git repository at revision v1.0:

manifest:
  # ...
  projects:
  - name: p1
    revision: v1.0
    import: true  # Import west.yml from p1’s v1.0 git tag
  - name: p2
    import: false  # Nothing is imported from p2.
  - name: p3
    # Nothing is imported from p3 either.

It’s an error to set import to either true or false inside self, like this:

manifest:
  # ...
  self:
  import: true  # Error

Example 1.1: Downstream of a Zephyr release You have a source code repository you want to use with Zephyr v1.14.1 LTS. You want to maintain the whole thing using west. You don’t want to modify any of the mainline repositories.

In other words, the west workspace you want looks like this:
You can do this with the following `my-repo/west.yml`:

```yaml
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: true
```

You can then create the workspace on your computer like this, assuming `my-repo` is hosted at `https://git.example.com/my-repo`:

```bash
west init -m https://git.example.com/my-repo my-downstream
```

```bash
cd my-downstream
west update
```

After `west init`, `my-downstream/my-repo` will be cloned.

After `west update`, all of the projects defined in the zephyr repository's `west.yml` at revision v1.14.1 will be cloned into `my-downstream` as well.

You can add and commit any code to `my-repo` you please at this point, including your own Zephyr applications, drivers, etc. See Application Development.

### Example 1.2: “Rolling release” Zephyr downstream

This is similar to Example 1.1: Downstream of a Zephyr release, except we’ll use `revision: main` for the zephyr repository:

```yaml
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
```

You can create the workspace in the same way:

```bash
west init -m https://git.example.com/my-repo my-downstream
```

```bash
cd my-downstream
west update
```

This time, whenever you run `west update`, the special `manifest-rev` branch in the zephyr repository will be updated to point at a newly fetched main branch tip from the URL `https://github.com/zephyrproject-rtos/zephyr`.

The contents of `zephyr/west.yml` at the new `manifest-rev` will then be used to import projects from Zephyr. This lets you stay up to date with the latest changes in the Zephyr project. The cost is that

2.10. West (Zephyr's meta-tool)
running `west update` will not produce reproducible results, since the remote main branch can change every time you run it.

It’s also important to understand that west ignores your working tree’s `zephyr/west.yml` entirely when resolving imports. West always uses the contents of imported manifests as they were committed to the latest manifest-rev when importing from a project.

You can only import manifest from the file system if they are in your manifest repository’s working tree. See Example 2.2: Downstream with directory of manifest files for an example.

**Example 1.3: Downstream of a Zephyr release, with module fork**  This manifest is similar to the one in Example 1.1: Downstream of a Zephyr release, except it:

- is a downstream of Zephyr 2.0
- includes a downstream fork of the `modules/hal/nordic` module which was included in that release

```yaml
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: hal_nordic
      remote: my-remote
      revision: my-sha
      path: modules/hal/nordic
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.0.0
      import: true

# subset of zephyr/west.yml contents at v2.0.0:
manifest:
  defaults:
    remote: zephyrproject-rtos
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    # ...
    - name: hal_nordic
      path: modules/hal/nordic
      revision: another-sha
```

With this manifest file, the project named `hal_nordic`:

- is cloned from `https://git.example.com/hal_nordic` instead of `https://github.com/zephyrproject-rtos/hal_nordic`.
- is updated to commit `my-sha` by `west update`, instead of the mainline commit `another-sha`

In other words, when your top-level manifest defines a project, like `hal_nordic`, west will ignore any other definition it finds later on while resolving imports.

This does mean you have to copy the path: `modules/hal/nordic` value into `my-repo/west.yml` when defining `hal_nordic` there. The value from `zephyr/west.yml` is ignored entirely. See Resolving Manifests for troubleshooting advice if this gets confusing in practice.

When you run `west update`, west will:
- update zephyr's manifest-rev to point at the v2.0.0 tag
- import zephyr/west.yml at that manifest-rev
- locally check out the v2.0.0 revisions for all zephyr projects except hal_nordic
- update hal_nordic to my-sha instead of another-sha

Option 2: Relative path  The import value can also be a relative path to a manifest file or a directory containing manifest files. The path is relative to the root directory of the projects or self repository the import key appears in.

Here is an example:

```json
manifest:
  projects:
    - name: project-1
      revision: v1.0
      import: west.yml
    - name: project-2
      revision: main
      import: p2-manifests
  self:
    import: submanifests
```

This will import the following:

- the contents of project-1/west.yml at manifest-rev, which points at tag v1.0 after running west update
- any YAML files in the directory tree project-2/p2-manifests at the latest commit in the main branch, as fetched by west update, sorted by file name
- YAML files in submanifests in your manifest repository, as they appear on your file system, sorted by file name

Notice how projects imports get data from Git using manifest-rev, while self imports get data from your file system. This is because as usual, west leaves version control for your manifest repository up to you.

Example 2.1: Downstream of a Zephyr release with explicit path  This is an explicit way to write an equivalent manifest to the one in Example 1.1: Downstream of a Zephyr release.

```json
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: west.yml
```

The setting import: west.yml means to use the file west.yml inside the zephyr project. This example is contrived, but shows the idea.

This can be useful in practice when the name of the manifest file you want to import is not west.yml.

Example 2.2: Downstream with directory of manifest files  Your Zephyr downstream has a lot of additional repositories. So many, in fact, that you want to split them up into multiple manifest files, but keep track of them all in a single manifest repository, like this:
You want to add all the files in `my-repo/submanifests` to the main manifest file, `my-repo/west.yml`, in addition to projects in `zephyr/west.yml`. You want to track the latest development code in the Zephyr repository’s main branch instead of using a fixed revision.

Here’s how:

```yaml
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
  self:
    import: submanifests
```

Manifest files are imported in this order during resolution:

1. `my-repo/submanifests/01-libraries.yml`
2. `my-repo/submanifests/02-vendor-hals.yml`
3. `my-repo/submanifests/03-applications.yml`
4. `my-repo/west.yml`
5. `zephyr/west.yml`

**Note:** The `.yml` file names are prefixed with numbers in this example to make sure they are imported in the specified order.

You can pick arbitrary names. West sorts files in a directory by name before importing.

Notice how the manifests in `submanifests` are imported before `my-repo/west.yml` and `zephyr/west.yml`. In general, an import in the `self` section is processed before the manifest files in `projects` and the main manifest file.

This means projects defined in `my-repo/submanifests` take highest precedence. For example, if `01-libraries.yml` defines `hal_nordic`, the project by the same name in `zephyr/west.yml` is simply ignored. As usual, see Resolving Manifests for troubleshooting advice.

This may seem strange, but it allows you to redefine projects “after the fact”, as we’ll see in the next example.

**Example 2.3: Continuous Integration overrides** Your continuous integration system needs to fetch and test multiple repositories in your west workspace from a developer’s forks instead of your mainline development trees, to see if the changes all work well together.

Starting with Example 2.2: Downstream with directory of manifest files, the CI scripts add a file `00-ci.yml` in `my-repo/submanifests`, with these contents:
# my-repo/submanifests/00-ci.yml:

```yaml
manifest:
  projects:
    - name: a-vendor-hal
      url: https://github.com/a-developer/hal
      revision: a-pull-request-branch
    - name: an-application
      url: https://github.com/a-developer/application
      revision: another-pull-request-branch
```

The CI scripts run `west update` after generating this file in `my-repo/submanifests`. The projects defined in `00-ci.yml` have higher precedence than other definitions in `my-repo/submanifests`, because the name `00-ci.yml` comes before the other file names.

Thus, `west update` always checks out the developer’s branches in the projects named `a-vendor-hal` and `an-application`, even if those same projects are also defined elsewhere.

**Option 3: Mapping**  
The import key can also contain a mapping with the following keys:

- **file**: Optional. The name of the manifest file or directory to import. This defaults to `west.yml` if not present.
- **name-allowlist**: Optional. If present, a name or sequence of project names to include.
- **path-allowlist**: Optional. If present, a path or sequence of project paths to match against. This is a shell-style globbing pattern, currently implemented with `pathlib`. Note that this means case sensitivity is platform specific.
- **name-blocklist**: Optional. Like `name-allowlist`, but contains project names to exclude rather than include.
- **path-blocklist**: Optional. Like `path-allowlist`, but contains project paths to exclude rather than include.
- **path-prefix**: Optional (new in v0.8.0). If given, this will be prepended to the project’s path in the workspace, as well as the paths of any imported projects. This can be used to place these projects in a subdirectory of the workspace.

Allowlists override blocklists if both are given. For example, if a project is blocked by path, then allowed by name, it will still be imported.

**Example 3.1: Downstream with name allowlist**  Here is a pair of manifest files, representing a mainline and a downstream. The downstream doesn’t want to use all the mainline projects, however. We’ll assume the mainline `west.yml` is hosted at `https://git.example.com/mainline/manifest`.

```yaml
# mainline west.yml:
manifest:
  projects:
    - name: mainline-app  # included
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2  # included
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2

# downstream west.yml:
```

(continues on next page)
manifest:
  projects:
  - name: mainline
    url: https://git.example.com/mainline/manifest
    import:
      name-allowlist:
      - mainline-app
      - lib2
  - name: downstream-app
    url: https://git.example.com/downstream/app
  - name: lib3
    path: libraries/lib3
    url: https://git.example.com/downstream/lib3

An equivalent manifest in a single file would be:

manifest:
  projects:
  - name: mainline
    url: https://git.example.com/mainline/manifest
  - name: downstream-app
    url: https://git.example.com/downstream/app
  - name: lib3
    path: libraries/lib3
    url: https://git.example.com/downstream/lib3
  - name: mainline-app
    # imported
    path: examples/app
    url: https://git.example.com/mainline/app
  - name: lib2
    # imported
    path: libraries/lib2
    url: https://git.example.com/mainline/lib2

If an allowlist had not been used, the lib project from the mainline manifest would have been imported.

Example 3.2: Downstream with path allowlist Here is an example showing how to allowlist mainline's libraries only, using path-allowlist.

# mainline west.yml:
manifest:
  projects:
  - name: app
    path: examples/app
    url: https://git.example.com/mainline/app
  - name: lib
    path: libraries/lib
    # included
    url: https://git.example.com/mainline/lib
  - name: lib2
    path: libraries/lib2
    # included
    url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
  - name: mainline
    url: https://git.example.com/mainline/manifest
    import:
(continues on next page)
path-allowlist: libraries/*
- name: app
  url: https://git.example.com/downstream/app
- name: lib3
  path: libraries/lib3
  url: https://git.example.com/downstream/lib3

An equivalent manifest in a single file would be:

```
manifest:
  projects:
    - name: lib  # imported
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2  # imported
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2
    - name: mainline
      url: https://git.example.com/mainline/manifest
    - name: app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

Example 3.3: Downstream with path blocklist  Here's an example showing how to block all vendor HALs from mainline by common path prefix in the workspace, add your own version for the chip you're targeting, and keep everything else.

```
# mainline west.yml:
manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app
    - name: lib
      path: libraries/lib
    - name: lib2
      path: libraries/lib2
    - name: hal_foo
      path: modules/hals/foo  # excluded
    - name: hal_bar
      path: modules/hals/bar  # excluded
    - name: hal_baz
      path: modules/hals/baz  # excluded

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
```

(continues on next page)
An equivalent manifest in a single file would be:

```
manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app            # imported
    - name: lib            # imported
      path: libraries/lib
    - name: lib2           # imported
      path: libraries/lib2
    - name: mainline
      repo-path: https://git.example.com/mainline/manifest
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo
```

**Example 3.4: Import into a subdirectory**  You want to import a manifest and its projects, placing everything into a subdirectory of your west workspace.

For example, suppose you want to import this manifest from project `foo`, adding this project and its projects `bar` and `baz` to your workspace:

```
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
    - name: example
      url-base: https://git.example.com
  projects:
    - name: bar
    - name: baz
```

Instead of importing these into the top level workspace, you want to place all three project repositories in an `external-code` subdirectory, like this:

```
workspace/
  └── external-code/
      └── foo/
      │    └── bar/
      │         └── baz/
```

You can do this using this manifest:

```
manifest:
  projects:
    - name: foo
```

(continues on next page)
An equivalent manifest in a single file would be:

```yaml
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
    - name: example
      url-base: https://git.example.com
  projects:
    - name: foo
      path: external-code/foo
    - name: bar
      path: external-code/bar
    - name: baz
      path: external-code/baz
```

Option 4: Sequence  The import key can also contain a sequence of files, directories, and mappings.

Example 4.1: Downstream with sequence of manifest files  This example manifest is equivalent to the manifest in Example 2.2: Downstream with directory of manifest files, with a sequence of explicitly named files.

```yaml
# my-repo/west.yml:
manifest:
  projects:
    - name: zephyr
      url: https://github.com/zephyrproject-rtos/zephyr
      import: west.yml
  self:
  import:
    - submanifests/01-libraries.yml
    - submanifests/02-vendor-hals.yml
    - submanifests/03-applications.yml
```

Example 4.2: Import order illustration  This more complicated example shows the order that west imports manifest files:

```yaml
# my-repo/west.yml
manifest:
  # ...
  projects:
    - name: my-library
    - name: my-app
    - name: zephyr
      import: true
    - name: another-manifest-repo
      import: submanifests
  self:
  import:
```
For this example, west resolves imports in this order:

1. the listed files in my-repo/submanifests are first, in the order they occur (e.g. libraries.yml comes before applications.yml, since this is a sequence of files), since the self: import: is always imported first
2. my-repo/west.yml is next (with projects my-library etc. as long as they weren't already defined somewhere in submanifests)
3. zephyr/west.yml is after that, since that's the first import key in the projects list in my-repo/west.yml
4. files in another-manifest-repo/submanifests are last (sorted by file name), since that's the final project import

### Manifest Import Details

This section describes how west resolves a manifest file that uses import a bit more formally.

#### Overview

The import key can appear in a west manifest's projects and self sections. The general case looks like this:

```yaml
# Top-level manifest file.
manifest:
  projects:
    - name: foo
      import: import-1
    - name: bar
      import: import-2
    # ...
    - name: baz
      import: import-N
  self:
    import: self-import
```

Import keys are optional. If any of import-1, ..., import-N are missing, west will not import additional manifest data from that project. If self-import is missing, no additional files in the manifest repository (beyond the top-level file) are imported.

The ultimate outcomes of resolving manifest imports are:

- a projects list, which is produced by combining the projects defined in the top-level file with those defined in imported files
- a set of extension commands, which are drawn from the the west-commands keys in in the top-level file and any imported files
- a group-filter list, which is produced by combining the top-level and any imported filters

Importing is done in this order:

1. Manifests from self-import are imported first.
2. The top-level manifest file's definitions are handled next.
3. Manifests from import-1, ..., import-N, are imported in that order.
When an individual `import` key refers to multiple manifest files, they are processed in this order:

- If the value is a relative path naming a directory (or a map whose file is a directory), the manifest files it contains are processed in lexicographic order – i.e., sorted by file name.
- If the value is a sequence, its elements are recursively imported in the order they appear.

This process recurses if necessary. E.g., if `import-1` produces a manifest file that contains an `import` key, it is resolved recursively using the same rules before its contents are processed further.

**Projects** This section describes how the final `projects` list is created.

Projects are identified by name. If the same name occurs in multiple manifests, the first definition is used, and subsequent definitions are ignored. For example, if `import-1` contains a project named `bar`, that is ignored, because the top-level `west.yml` has already defined a project by that name.

The contents of files named by `import-1` through `import-N` are imported from Git at the latest manifest-rev revisions in their projects. These revisions can be updated to the values `rev-1` through `rev-N` by running `west update`. If any manifest-rev reference is missing or out of date, `west update` also fetches project data from the remote fetch URL and updates the reference.

Also note that all imported manifests, from the root manifest to the repository which defines a project P, must be up to date in order for `west to update P` itself. For example, this means `west update P` would update manifest-rev in the baz project if `bash/west.yml` defines P, as well as updating the manifest-rev branch in the local git clone of P. Confusingly, updating baz may result in the removal of P from `bash/west.yml`, which “should” cause `west update P` to fail with an unrecognized project!

For this reason, it’s not possible to run `west update P` if P is defined in an imported manifest; you must update this project along with all the others with a plain `west update`.

By default, west won’t fetch any project data over the network if a project’s revision is a SHA or tag which is already available locally, so updating the extra projects shouldn’t take too much time unless it’s really needed. See the documentation for the `update.fetch` configuration option for more information.

**Extensions** All extension commands defined using `west-commands` keys discovered while handling imports are available in the resolved manifest.

If an imported manifest file has a `west-commands`: definition in its `self:` section, the extension commands defined there are added to the set of available extensions at the time the manifest is imported. They will thus take precedence over any extension commands with the same names added later on.

**Group filters** The resolved manifest has a `group-filter` value which is the result of concatenating the `group-filter` values in the top-level manifest and any imported manifests.

Manifest files which appear earlier in the import order have higher precedence and are therefore concatenated later into the final `group-filter`.

In other words, let:

- the submanifest resolved from `self-import` have group filter `self-filter`
- the top-level manifest file have group filter `top-filter`
- the submanifests resolved from `import-1` through `import-N` have group filters `filter-1` through `filter-N` respectively

The final resolved `group-filter` value is then `filter1 + filter-2 + ... + filter-N + top-filter + self-filter`, where `+` here refers to list concatenation.

**Important:** The order that filters appear in the above list matters.
The last filter element in the final concatenated list “wins” and determines if the group is enabled or
disabled.

For example, in [-foo] + [+foo], group foo is enabled. However, in [+foo] + [-foo], group foo is
disabled.

For simplicity, west and this documentation may elide concatenated group filter elements which are
redundant using these rules. For example, [+foo] + [-foo] could be written more simply as [-foo],
for the reasons given above. As another example, [-foo] + [+foo] could be written as the empty list
[], since all groups are enabled by default.

Manifest Command

The west manifest command can be used to manipulate manifest files. It takes an action, and action-
specific arguments.

The following sections describe each action and provides a basic signature for simple uses. Run west
manifest --help for full details on all options.

Resolving Manifests  The --resolve action outputs a single manifest file equivalent to your current
manifest and all its imported manifests:

west manifest --resolve [-o outfile]

The main use for this action is to see the “final” manifest contents after performing any imports.

To print detailed information about each imported manifest file and how projects are handled during
manifest resolution, set the maximum verbosity level using -v:

west -v manifest --resolve

Freezing Manifests  The --freeze action outputs a frozen manifest:

west manifest --freeze [-o outfile]

A “frozen” manifest is a manifest file where every project’s revision is a SHA. You can use --freeze to
produce a frozen manifest that’s equivalent to your current manifest file. The -o option specifies an
output file; if not given, standard output is used.

Validating Manifests  The --validate action either succeeds if the current manifest file is valid, or
fails with an error:

west manifest --validate

The error message can help diagnose errors.

Get the manifest path  The --path action prints the path to the top level manifest file:

west manifest --path

The output is something like /path/to/workspace/west.yml. The path format depends on your oper-
ating system.
2.10.8  Configuration

This page documents west's configuration file system, the west config command, and configuration options used by built-in commands. For API documentation on the west.configuration module, see west-apis-configuration.

West Configuration Files

West's configuration file syntax is INI-like; here is an example file:

```ini
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

Above, the manifest section has option path set to zephyr. Another way to say the same thing is that manifest.path is zephyr in this file.

There are three types of configuration file:

1. **System**: Settings in this file affect west's behavior for every user logged in to the computer. Its location depends on the platform:
   - Linux: `/etc/westconfig`
   - macOS: `/usr/local/etc/westconfig`
   - Windows: `%PROGRAMDATA%\west\config`

2. **Global** (per user): Settings in this file affect how west behaves when run by a particular user on the computer.
   - All platforms: the default is `.westconfig` in the user's home directory.
   - Linux note: if the environment variable `XDG_CONFIG_HOME` is set, then `$XDG_CONFIG_HOME/west/config` is used.
   - Windows note: the following environment variables are tested to find the home directory: `%HOME%`, then `%USERPROFILE%`, then a combination of `%HOMEDRIVE%` and `%HOMEPATH%`.

3. **Local**: Settings in this file affect west's behavior for the current west workspace. The file is `.west/config`, relative to the workspace's root directory.

A setting in a file which appears lower down on this list overrides an earlier setting. For example, if color.ui is true in the system's configuration file, but false in the workspace's, then the final value is false. Similarly, settings in the user configuration file override system settings, and so on.

west config

The built-in config command can be used to get and set configuration values. You can pass west config the options --system, --global, or --local to specify which configuration file to use. Only one of these can be used at a time. If none is given, then writes default to --local, and reads show the final value after applying overrides.

Some examples for common uses follow; run west config -h for detailed help, and see Built-in Configuration Options for more details on built-in options.

To set manifest.path to some-other-manifest:

```bash
west config manifest.path some-other-manifest
```
Doing the above means that commands like `west update` will look for the west manifest inside the `some-other-manifest` directory (relative to the workspace root directory) instead of the directory given to `west init`, so be careful!

To read `zephyr.base`, the value which will be used as `ZEPHYR_BASE` if it is unset in the calling environment (also relative to the workspace root):

```
west config zephyr.base
```

You can switch to another zephyr repository without changing `manifest.path` – and thus the behavior of commands like `west update` – using:

```
west config zephyr.base some-other-zephyr
```

This can be useful if you use commands like `git worktree` to create your own zephyr directories, and want commands like `west build` to use them instead of the zephyr repository specified in the manifest. (You can go back to using the directory in the upstream manifest by running `west config zephyr.base zephyr`.)

To set `color.ui` to `false` in the global (user-wide) configuration file, so that west will no longer print colored output for that user when run in any workspace:

```
west config --global color.ui false
```

To undo the above change:

```
west config --global color.ui true
```

**Built-in Configuration Options**

The following table documents configuration options supported by west’s built-in commands. Configuration options supported by Zephyr’s extension commands are documented in the pages for those commands.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color.ui</td>
<td>Boolean. If true (the default), then west output is colorized when stdout is a terminal.</td>
</tr>
<tr>
<td>commands.</td>
<td>Boolean, default true, disables Extensions if false</td>
</tr>
<tr>
<td>allow_extensions</td>
<td>String, default west.yml. Relative path from the manifest repository root directory to the manifest file used by west init and other commands which parse the manifest.</td>
</tr>
<tr>
<td>manifest.file</td>
<td>String, default west.yml. Relative path from the manifest repository root directory to the manifest file used by west init and other commands which parse the manifest.</td>
</tr>
<tr>
<td>manifest.group-filter</td>
<td>String, default empty. A comma-separated list of project groups to enable and disable within the workspace. Prefix enabled groups with + and disabled groups with -. For example, the value &quot;+foo,-bar&quot; enables group foo and disables bar. See Project Groups and Active Projects.</td>
</tr>
<tr>
<td>manifest.path</td>
<td>String, relative path from the west workspace root directory to the manifest repository used by west update and other commands which parse the manifest. Set locally by west init.</td>
</tr>
<tr>
<td>update.fetch</td>
<td>String, one of &quot;smart&quot; (the default behavior starting in v0.6.1) or &quot;always&quot; (the previous behavior). If set to &quot;smart&quot;, the west update command will skip fetching from project remotes when those projects' revisions in the manifest file are SHAs or tags which are already available locally. The &quot;always&quot; behavior is to unconditionally fetch from the remote.</td>
</tr>
<tr>
<td>update.name-cache</td>
<td>String. If non-empty, west update will use its value as the --name-cache option's value if not given on the command line.</td>
</tr>
<tr>
<td>update.narrow</td>
<td>Boolean. If true, west update behaves as if --narrow was given on the command line. The default is false.</td>
</tr>
<tr>
<td>update.path-cache</td>
<td>String. If non-empty, west update will use its value as the --path-cache option's value if not given on the command line.</td>
</tr>
<tr>
<td>update.sync-submodules</td>
<td>Boolean. If true (the default), west update will synchronize Git submodules before updating them.</td>
</tr>
<tr>
<td>zephyr.base</td>
<td>String, default value to set for the ZEPHYR_BASE environment variable while the west command is running. By default, this is set to the path to the manifest project with path zephyr (if there is one) during west init. If the variable is already set, then this setting is ignored unless zephyr.base-prefer is &quot;configfile&quot;.</td>
</tr>
<tr>
<td>zephyr.base-prefer</td>
<td>String, one the values &quot;env&quot; and &quot;configfile&quot;. If set to &quot;env&quot; (the default), setting ZEPHYR_BASE in the calling environment overrides the value of the zephyr.base configuration option. If set to &quot;configfile&quot;, the configuration option wins instead.</td>
</tr>
</tbody>
</table>

### 2.10.9 Extensions

West is “pluggable”: you can add your own commands to west without editing its source code. These are called west extension commands, or just “extensions” for short. Extensions show up in the west --help output in a special section for the project which defines them. This page provides general information on west extension commands, and has a tutorial for writing your own.

Some commands you can run when using west with Zephyr, like the ones used to build, flash, and debug and the ones described here, are extensions. That's why help for them shows up like this in west --help:

```
commands from project at "zephyr":
  completion: display shell completion scripts
  boards: display information about supported boards
  build: compile a Zephyr application
  sign: sign a Zephyr binary for bootloader chain-loading
  flash: flash and run a binary on a board
  debug: flash and interactively debug a Zephyr application
```
Disabling Extension Commands

To disable support for extension commands, set the `commands.allow_extensions` configuration option to `false`. To set this globally for whenever you run `west`, use:

```
west config --global commands.allow_extensions false
```

If you want to, you can then re-enable them in a particular `west` workspace with:

```
west config --local commands.allow_extensions true
```

Note that the files containing extension commands are not imported by `west` unless the commands are explicitly run. See below for details.

Adding a West Extension

There are three steps to adding your own extension:

1. Write the code implementing the command.
2. Add information about it to a `west-commands.yml` file.
3. Make sure the `west-commands.yml` file is referenced in the `west` manifest.

Note that `west` ignores extension commands whose names are the same as a built-in command.

**Step 1: Implement Your Command**  
Create a Python file to contain your command implementation (see the “Meta > Requires” information on the `west` PyPI page for details on the currently supported versions of Python). You can put it in anywhere in any project tracked by your `west` manifest, or the manifest repository itself. This file must contain a subclass of the `west.commands.WestCommand` class; this class will be instantiated and used when your extension is run.

Here is a basic skeleton you can use to get started. It contains a subclass of `WestCommand`, with implementations for all the abstract methods. For more details on the `west` APIs you can use, see `west-apis`.

```python
'''my_west_extension.py
Basic example of a west extension.''

from textwrap import dedent  # just for nicer code indentation
from west.commands import WestCommand  # your extension must subclass this
from west import log  # use this for user output

class MyCommand(WestCommand):

    def __init__(self):
        super().__init__(
            'my-command-name',  # gets stored as self.name
            'one-line help for what my-command-name does',  # self.help
            # self.description:
```

(continues on next page)
A multi-line description of my-command.

You can split this up into multiple paragraphs and they'll get reflowed for you. You can also pass
formatter_class=argparse.RawDescriptionHelpFormatter when calling
parser_adder.add_parser() below if you want to keep your line endings.'''

```python
def do_add_parser(self, parser_adder):
    # This is a bit of boilerplate, which allows you full control over the
    # type of argparse handling you want. The "parser_adder" argument is
    # the return value of an argparse.ArgumentParser.add_subparsers() call.
    parser = parser_adder.add_parser(self.name,
                                      help=self.help,
                                      description=self.description)

    # Add some example options using the standard argparse module API.
    parser.add_argument('--optional', help='an optional argument')
    parser.add_argument('required', help='a required argument')

    return parser  # gets stored as self.parser

def do_run(self, args, unknown_args):
    # This gets called when the user runs the command, e.g.:
    # $ west my-command-name -o FOO BAR
    # --optional is FOO
    # required is BAR
    log.inf('--optional is', args.optional)
    log.inf('required is', args.required)
```

You can ignore the second argument to do_run() (unknown_args above), as WestCommand will reject unknown arguments by default. If you want to be passed a list of unknown arguments instead, add accepts_unknown_args=True to the super().__init__() arguments.

### Step 2: Add or Update Your `west-commands.yml`

You now need to add a `west-commands.yml` file to your project which describes your extension to west.

Here is an example for the above class definition, assuming it’s in `my_west_extension.py` at the project root directory:

```yaml
west-commands:
  - file: my_west_extension.py
    commands:
      - name: my-command-name
        class: MyCommand
        help: one-line help for what my-command-name does
```

The top level of this YAML file is a map with a west-commands key. The key's value is a sequence of "command descriptors". Each command descriptor gives the location of a file implementing west extensions, along with the names of those extensions, and optionally the names of the classes which define them (if not given, the class value defaults to the same thing as name).

Some information in this file is redundant with definitions in the Python code. This is because west won’t import `my_west_extension.py` until the user runs `west my-command-name`, since:

- It allows users to run `west update` with a manifest from an untrusted source, then use other west
commands without your code being imported along the way. Since importing a Python module is shell-equivalent, this provides some peace of mind.

- It’s a small optimization, since your code will only be imported if it is needed.

So, unless your command is explicitly run, west will just load the west-commands.yml file to get the basic information it needs to display information about your extension to the user in west --help output, etc.

If you have multiple extensions, or want to split your extensions across multiple files, your west-commands.yml will look something like this:

```yaml
west-commands:
  - file: my_west_extension.py
    commands:
      - name: my-command-name
        class: MyCommand
        help: one-line help for what my-command-name does
    - file: another_file.py
      commands:
        - name: command2
          help: another cool west extension
        - name: a-third-command
          class: ThirdCommand
          help: a third command in the same file as command2
```

Above:

- `my_west_extension.py` defines extension `my-command-name` with class `MyCommand`
- `another_file.py` defines two extensions:
  1. `command2` with class `command2`
  2. `a-third-command` with class `ThirdCommand`

See the file west-commands-schema.yml in the west repository for a schema describing the contents of a west-commands.yml.

**Step 3: Update Your Manifest**

Finally, you need to specify the location of the west-commands.yml you just edited in your west manifest. If your extension is in a project, add it like this:

```yaml
manifest:
  # [... other contents ...]
  projects:
    - name: your-project
      west-commands: path/to/west-commands.yml
  # [... other projects ...]
```

Where `path/to/west-commands.yml` is relative to the root of the project. Note that the name west-commands.yml, while encouraged, is just a convention; you can name the file something else if you need to.

Alternatively, if your extension is in the manifest repository, just do the same thing in the manifest’s self section, like this:

```yaml
manifest:
  # [... other contents ...]
  self:
    west-commands: path/to/west-commands.yml
```

148 Chapter 2. Developing with Zephyr
That’s it; you can now run `west my-command-name`. Your command’s name, help, and the project which contains its code will now also show up in the `west --help` output. If you share the updated repositories with others, they’ll be able to use it, too.

### 2.10.10 Building, Flashing and Debugging

Zephyr provides several `west extension commands` for building, flashing, and interacting with Zephyr programs running on a board: `build`, `flash`, `debug`, `debugserver` and `attach`.

For information on adding board support for the flashing and debugging commands, see Flash and debug support in the board porting guide.

**Building: `west build`**

**Tip:** Run `west build -h` for a quick overview.

The `build` command helps you build Zephyr applications from source. You can use `west config` to configure its behavior.

Its default behavior tries to “do what you mean”:

- If there is a Zephyr build directory named `build` in your current working directory, it is incrementally re-compiled. The same is true if you run `west build` from a Zephyr build directory.
- Otherwise, if you run `west build` from a Zephyr application's source directory and no build directory is found, a new one is created and the application is compiled in it.

**Basics**  The easiest way to use `west build` is to go to an application’s root directory (i.e. the folder containing the application's `CMakeLists.txt`) and then run:

```
west build -b <BOARD>
```

Where `<BOARD>` is the name of the board you want to build for. This is exactly the same name you would supply to CMake if you were to invoke it with: `cmake -DBOARD=<BOARD>`.

**Tip:** You can use the `west boards` command to list all supported boards.

A build directory named `build` will be created, and the application will be compiled there after `west build` runs CMake to create a build system in that directory. If `west build` finds an existing build directory, the application is incrementally re-compiled there without re-running CMake. You can force CMake to run again with `--cmake`.

You don’t need to use the `--board` option if you’ve already got an existing build directory; `west build` can figure out the board from the CMake cache. For new builds, the `--board` option, `BOARD` environment variable, or `build.board` configuration option are checked (in that order).

**Sysbuild (multi-domain builds)**  `Sysbuild (System build)` can be used to create a multi-domain build system combining multiple images for a single or multiple boards.

Use `--sysbuild` to select the `Sysbuild (System build)` build infrastructure with `west build` to build multiple domains.

More detailed information regarding the use of sysbuild can be found in the `Sysbuild (System build)` guide.
Tip: The build.sysbuild configuration option can be enabled to tell west build to default build using sysbuild. --no-sysbuild can be used to disable sysbuild for a specific build.

west build will build all domains through the top-level build folder of the domains specified by sysbuild. A single domain from a multi-domain project can be built by using --domain argument.

Examples Here are some west build usage examples, grouped by area.

Forcing CMake to Run Again To force a CMake re-run, use the --cmake (or -c) option:

```bash
west build -c
```

Setting a Default Board To configure west build to build for the reel_board by default:

```bash
west config build.board reel_board
```

(You can use any other board supported by Zephyr here; it doesn’t have to be reel_board.)

Setting Source and Build Directories To set the application source directory explicitly, give its path as a positional argument:

```bash
west build -b <BOARD> path/to/source/directory
```

To set the build directory explicitly, use --build-dir (or -d):

```bash
west build -b <BOARD> --build-dir path/to/build/directory
```

To change the default build directory from build, use the build.dir-fmt configuration option. This lets you name build directories using format strings, like this:

```bash
west config build.dir-fmt "build/{board}/{app}"
```

With the above, running west build -b reel_board samples/hello_world will use build directory build/reel_board/hello_world. See Configuration Options for more details on this option.

Setting the Build System Target To specify the build system target to run, use --target (or -t).

For example, on host platforms with QEMU, you can use the run target to build and run the hello_world sample for the emulated qemu_x86 board in one command:

```bash
west build -b qemu_x86 -t run samples/hello_world
```

As another example, to use -t to list all build system targets:

```bash
west build -t help
```

As a final example, to use -t to run the pristine target, which deletes all the files in the build directory:

```bash
west build -t pristine
```
**Pristine Builds**  A *pristine* build directory is essentially a new build directory. All byproducts from previous builds have been removed.

To force `west build` make the build directory pristine before re-running CMake to generate a build system, use the `--pristine=always` (or `-p=always`) option.

Giving `--pristine` or `-p` without a value has the same effect as giving it the value `always`. For example, these commands are equivalent:

```
west build -p reel_board samples/hello_world
west build -p=always -b reel_board samples/hello_world
```

By default, `west build` applies a heuristic to detect if the build directory needs to be made pristine. This is the same as using `--pristine=auto`.

**Tip:** You can run `west config build.pristine always` to always do a pristine build, or `west config build.pristine never` to disable the heuristic. See the `west build` Configuration Options for details.

**Verbose Builds**  To print the CMake and compiler commands run by `west build`, use the global `west` verbosity option, `-v`:

```
w west -v build -b reel_board samples/hello_world
```

**One-Time CMake Arguments**  To pass additional arguments to the CMake invocation performed by `west build`, pass them after a `--` at the end of the command line.

**Important:** Passing additional CMake arguments like this forces `west build` to re-run CMake, even if a build system has already been generated.

After using `--` once to generate the build directory, use `west build -d <build-dir>` on subsequent runs to do incremental builds.

For example, to use the Unix Makefiles CMake generator instead of Ninja (which `west build` uses by default), run:

```
w west build -b reel_board -- -G'Unix Makefiles'
```

To use Unix Makefiles and set `CMAKE_VERBOSE_MAKEFILE` to ON:

```
w west build -b reel_board -- -G'Unix Makefiles' -DCMAKE_VERBOSE_MAKEFILE=ON
```

Notice how the `--` only appears once, even though multiple CMake arguments are given. All command-line arguments to `west build` after a `--` are passed to CMake.

To set `DTC_OVERLAY_FILE` to enable-modem.overlay, using that file as a devicetree overlay:

```
w west build -b reel_board -- -DDTC_OVERLAY_FILE=enable-modem.overlay
```

To merge the `file.conf` Kconfig fragment into your build's `.config`:

```
w west build -- -DOVERLAY_CONFIG=file.conf
```

**Permanent CMake Arguments**  The previous section describes how to add CMake arguments for a single `west build` command. If you want to save CMake arguments for `west build` to use every time it generates a new build system instead, you should use the `build.cmake-args` configuration option.
Whenever `west build` runs CMake to generate a build system, it splits this option's value according to shell rules and includes the results in the `cmake` command line.

Remember that, by default, `west build` tries to avoid generating a new build system if one is present in your build directory. Therefore, you need to either delete any existing build directories or do a pristine build after setting `build.cmake-args` to make sure it will take effect.

For example, to always enable `CMAKE_EXPORT_COMPILE_COMMANDS`, you can run:

```bash
west config build.cmake-args -- -DCMAKE_EXPORT_COMPILE_COMMANDS=ON
```

(The extra `--` is used to force the rest of the command to be treated as a positional argument. Without it, `west config` would treat the `-DVAR=VAL` syntax as a use of its `-D` option.)

To enable `CMAKE_VERBOSE_MAKEFILE`, so CMake always produces a verbose build system:

```bash
west config build.cmake-args -- -DCMAKE_VERBOSE_MAKEFILE=ON
```

To save more than one argument in `build.cmake-args`, use a single string whose value can be split into distinct arguments (`west build` uses the Python function `shlex.split()` internally to split the value).

For example, to enable both `CMAKE_EXPORT_COMPILE_COMMANDS` and `CMAKE_VERBOSE_MAKEFILE`:

```bash
west config build.cmake-args -- "-DCMAKE_EXPORT_COMPILE_COMMANDS=ON -DCMAKE_VERBOSE_MAKEFILE=ON"
```

If you want to save your CMake arguments in a separate file instead, you can combine CMake's `-C <initial-cache>` option with `build.cmake-args`. For instance, another way to set the options used in the previous example is to create a file named `~/my-cache.cmake` with the following contents:

```bash
set(CMAKE_EXPORT_COMPILE_COMMANDS ON CACHE BOOL "")
set(CMAKE_VERBOSE_MAKEFILE ON CACHE BOOL "")
```

Then run:

```bash
west config build.cmake-args "-C ~/my-cache.cmake"
```

See the `cmake(1)` manual page and the `set()` command documentation for more details.

**Build tool arguments** Use `-o` to pass options to the underlying build tool.

This works with both `ninja` (the default) and `make` based build systems.

For example, to pass `-dexplain` to `ninja`:

```bash
west build -o=-dexplain
```

As another example, to pass `--keep-going` to `make`:

```bash
west build -o=--keep-going
```

Note that using `-o=--foo` instead of `-o --foo` is required to prevent `--foo` from being treated as a `west build` option.

**Build parallelism** By default, `ninja` uses all of your cores to build, while `make` uses only one. You can control this explicitly with the `-j` option supported by both tools.

For example, to build with 4 cores:

```bash
west build -o=-j4
```

The `-o` option is described further in the previous section.
Build a single domain  In a multi-domain build with hello_world and MCUboot, you can use --domain hello_world to only build this domain:

```sh
west build --sysbuild --domain hello_world
```

The --domain argument can be combined with the --target argument to build the specific target for the target, for example:

```sh
west build --sysbuild --domain hello_world --target help
```

Configuration Options  You can configure west build using these options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>build.board</td>
<td>String. If given, this the board used by west build when --board is not given and BOARD is unset in the environment.</td>
</tr>
<tr>
<td>build.board_warn</td>
<td>Boolean, default true. If false, disables warnings when west build can't figure out the target board.</td>
</tr>
<tr>
<td>build.cmake-args</td>
<td>String. If present, the value will be split according to shell rules and passed to CMake whenever a new build system is generated. See Permanent CMake Arguments.</td>
</tr>
</tbody>
</table>
| build.dir-fmt   | String, default build. The build folder format string, used by west whenever it needs to create or locate a build folder. The currently available arguments are:  
  - `board`: The board name  
  - `source_dir`: The relative path from the current working directory to the source directory. If the current working directory is inside the source directory this will be set to an empty string.  
  - `app`: The name of the source directory. |
| build.generator | String, default Ninja. The CMake Generator to use to create a build system. (To set a generator for a single build, see the above example) |
| build.guess-dir | String, instructs west whether to try to guess what build folder to use when build.dir-fmt is in use and not enough information is available to resolve the build folder name. Can take these values:  
  - `never` (default): Never try to guess, bail out instead and require the user to provide a build folder with -d.  
  - `runners`: Try to guess the folder when using any of the ‘runner’ commands. These are typically all commands that invoke an external tool, such as flash and debug. |
| build.pristine  | String. Controls the way in which west build may clean the build folder before building. Can take the following values:  
  - `never` (default): Never automatically make the build folder pristine.  
  - `auto`: west build will automatically make the build folder pristine before building, if a build system is present and the build would fail otherwise (e.g. the user has specified a different board or application from the one previously used to make the build directory).  
  - `always`: Always make the build folder pristine before building, if a build system is present. |
| build.sysbuild  | Boolean, default false. If true, build application using the sysbuild infrastructure. |
Flashing: `west flash`

**Tip:** Run `west flash -h` for additional help.

**Basics**  From a Zephyr build directory, re-build the binary and flash it to your board:

```bash
west flash
```

Without options, the behavior is the same as `ninja flash` (or `make flash`, etc.).

To specify the build directory, use `--build-dir` (or `-d`):

```bash
west flash --build-dir path/to/build/directory
```

If you don't specify the build directory, `west flash` searches for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see Setting Source and Build Directories), `west flash` searches there instead of `build`.

**Choosing a Runner**  If your board's Zephyr integration supports flashing with multiple programs, you can specify which one to use using the `--runner` (or `--r`) option. For example, if West flashes your board with `nrfjprog` by default, but it also supports JLink, you can override the default with:

```bash
west flash --runner jlink
```

You can override the default flash runner at build time by using the `BOARD_FLASH_RUNNER` CMake variable, and the debug runner with `BOARD_DEBUG_RUNNER`.

For example:

```sh
# Set the default runner to "jlink", overriding the board's usual default.
west build [...] -- -DBOARD_FLASH_RUNNER=jlink
```

See One-Time CMake Arguments and Permanent CMake Arguments for more information on setting CMake arguments.

See Flash and debug runners below for more information on the runner library used by West. The list of runners which support flashing can be obtained with `west flash -H`; if run from a build directory or with `--build-dir`, this will print additional information on available runners for your board.

**Configuration Overrides**  The CMake cache contains default values West uses while flashing, such as where the board directory is on the file system, the path to the zephyr binaries to flash in several formats, and more. You can override any of this configuration at runtime with additional options.

For example, to override the HEX file containing the Zephyr image to flash (assuming your runner expects a HEX file), but keep other flash configuration at default values:

```bash
west flash --hex-file path/to/some/other.hex
```

The `west flash -h` output includes a complete list of overrides supported by all runners.

**Runner-Specific Overrides**  Each runner may support additional options related to flashing. For example, some runners support an `--erase` flag, which mass-erases the flash storage on your board before flashing the Zephyr image.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):
west flash --context

**Important:** Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, `west flash -H` just prints a list of runners. You can use `west flash -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the jlink runner:

```
west flash -H -r jlink
```

**Multi-domain flashing**  When a `Sysbuild (multi-domain builds)` folder is detected, then `west flash` will flash all domains in the order defined by sysbuild.

It is possible to flash the image from a single domain in a multi-domain project by using `--domain`.

For example, in a multi-domain build with hello_world and MCUboot, you can use the `--domain` hello_world domain to only flash only the image from this domain:

```
west flash --domain hello_world
```

**Debugging:** `west debug, west debugserver`

**Tip:** Run `west debug -h` or `west debugserver -h` for additional help.

**Basics**  From a Zephyr build directory, to attach a debugger to your board and open up a debug console (e.g. a GDB session):

```
west debug
```

To attach a debugger to your board and open up a local network port you can connect a debugger to (e.g. an IDE debugger):

```
west debugserver
```

Without options, the behavior is the same as `ninja debug` and `ninja debugserver` (or `make debug`, etc.).

To specify the build directory, use `--build-dir` (or `-d`):

```
west debug --build-dir path/to/build/directory
west debugserver --build-dir path/to/build/directory
```

If you don't specify the build directory, these commands search for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see Setting Source and Build Directories), `west debug` searches there instead of `build`.

**Choosing a Runner**  If your board's Zephyr integration supports debugging with multiple programs, you can specify which one to use using the `--runner` (or `-r`) option. For example, if West debugs your board with `pyocd-gdbserver` by default, but it also supports JLink, you can override the default with:
west debug --runner jlink
west debugserver --runner jlink

See Flash and debug runners below for more information on the runner library used by West. The list of runners which support debugging can be obtained with west debug -H; if run from a build directory or with --build-dir, this will print additional information on available runners for your board.

Configuration Overrides  The CMake cache contains default values West uses for debugging, such as where the board directory is on the file system, the path to the zephyr binaries containing symbol tables, and more. You can override any of this configuration at runtime with additional options.

For example, to override the ELF file containing the Zephyr binary and symbol tables (assuming your runner expects an ELF file), but keep other debug configuration at default values:

west debug --elf-file path/to/some/other.elf
west debugserver --elf-file path/to/some/other.elf

The west debug -h output includes a complete list of overrides supported by all runners.

Runner-Specific Overrides  Each runner may support additional options related to debugging. For example, some runners support flags which allow you to set the network ports used by debug servers.

To view all of the available options for the runners your board supports, as well as their usage information, use --context (or -H):

west debug --context

(The command west debugserver --context will print the same output.)

Important:  Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, west debug -H just prints a list of runners. You can use west debug -H -r <runner-name> to print usage information for options supported by that runner.

For example, to print usage information about the jlink runner:

west debug -H -r jlink

Multi-domain debugging  west debug can only debug a single domain at a time. When a Sysbuild (multi-domain builds) folder is detected, west debug will debug the default domain specified by sysbuild.

The default domain will be the application given as the source directory. See the following example:

west build --sysbuild path/to/source/directory

For example, when building hello_world with MCUboot using sysbuild, hello_world becomes the default domain:

west build --sysbuild samples/hello_world

So to debug hello_world you can do:

west debug

or:
If you wish to debug MCUboot, you must explicitly specify MCUboot as the domain to debug:

west debug --domain mcuboot

Flash and debug runners

The flash and debug commands use Python wrappers around various Flash & Debug Host Tools. These wrappers are all defined in a Python library at scripts/west_commands/runners. Each wrapper is called a runner. Runners can flash and/or debug Zephyr programs.

The central abstraction within this library is ZephyrBinaryRunner, an abstract class which represents runners. The set of available runners is determined by the imported subclasses of ZephyrBinaryRunner. ZephyrBinaryRunner is available in the runners.core module; individual runner implementations are in other submodules, such as runners.nrfjprog, runners.openocd, etc.

Hacking

This section documents the runners.core module used by the flash and debug commands. This is the core abstraction used to implement support for these features.

Warning: These APIs are provided for reference, but they are more “shared code” used to implement multiple extension commands than a stable API.

Developers can add support for new ways to flash and debug Zephyr programs by implementing additional runners. To get this support into upstream Zephyr, the runner should be added into a new or existing runners module, and imported from runners/__init__.py.

Note: The test cases in scripts/west_commands/tests add unit test coverage for the runners package and individual runner classes.

Please try to add tests when adding new runners. Note that if your changes break existing test cases, CI testing on upstream pull requests will fail.

Zephyr binary runner core interfaces

This provides the core ZephyrBinaryRunner class meant for public use, as well as some other helpers for concrete runner classes.

```python
class runners.core.BuildConfiguration(build_dir: str)
    # This helper class provides access to build-time configuration.
    # Configuration options can be read as if the object were a dict, either object['CONFIG_FOO'] or object.get('CONFIG_FOO').
    # Kconfig configuration values are available (parsed from .config).
    def getboolean(option)
        # If a boolean option is explicitly set to y or n, returns its value. Otherwise, falls back to False.
```

2.10. West (Zephyr's meta-tool)
exception runners.core.MissingProgram(program)

    FileNotFoundError subclass for missing program dependencies.

    No significant changes from the parent FileNotFoundError; this is useful for explicitly signaling that
    the file in question is a program that some class requires to proceed.

    The filename attribute contains the missing program.

class runners.core.NetworkPortHelper

    Helper class for dealing with local IP network ports.

get_unused_ports(starting_from)

    Find unused network ports, starting at given values.

    starting_from is an iterable of ports the caller would like to use.

    The return value is an iterable of ports, in the same order, using the given values if they were
    unused, or the next sequentially available unused port otherwise.

    Ports may be bound between this call's check and actual usage, so callers still need to handle
    errors involving returned ports.

class runners.core.RunnerCaps(commands: Set[str] = {'attach', 'debug', 'debugserver', 'flash'},

dev_id: bool = False,
flash_addr: bool = False,
erase: bool = False,
tool_opt: bool = False)

    This class represents a runner class's capabilities.

    Each capability is represented as an attribute with the same name. Flag attributes are True or False.

    Available capabilities:

    • commands: set of supported commands; default is {'flash', 'debug', 'debugserver', 'attach'}.

    • dev_id: whether the runner supports device identifiers, in the form of an -i, –dev-id option.
      This is useful when the user has multiple debuggers connected to a single computer, in order
      to select which one will be used with the command provided.

    • flash_addr: whether the runner supports flashing to an arbitrary address. Default is False. If
      true, the runner must honor the –dt-flash option.

    • erase: whether the runner supports an –erase option, which does a mass-erase of the entire
      addressable flash on the target before flashing. On multi-core SoCs, this may only erase
      portions of flash specific the actual target core. (This option can be useful for things like
      clearing out old settings values or other subsystem state that may affect the behavior of the
      zephyr image. It is also sometimes needed by SoCs which have flash-like areas that can't be
      sector erased by the underlying tool before flashing; UICR on nRF SoCs is one example.)

    • tool_opt: whether the runner supports a –tool-opt (-O) option, which can be given multiple
      times and is passed on to the underlying tool that the runner wraps.

class runners.core.RunnerConfig(build_dir: str,

board_dir: str,
elf_file: Optional[str],
hex_file: Optional[str],
bin_file: Optional[str],
gdb: Optional[str] = None,
openocd: Optional[str] = None,
openocd_search: List[str] = [])

    Runner execution-time configuration.

    This is a common object shared by all runners. Individual runners can register specific configuration
    options using their do_add_parser() hooks.

    bin_file: Optional[str]
        Alias for field number 4

    board_dir: str
        Alias for field number 1

    build_dir: str
        Alias for field number 0
elf_file: Optional[str]
   Alias for field number 2

gdb: Optional[str]
   Alias for field number 5

hex_file: Optional[str]
   Alias for field number 3

openocd: Optional[str]
   Alias for field number 6

openocd_search: List[str]
   Alias for field number 7

class runners.core.ZephyrBinaryRunner(cfg: RunnerConfig)
   Abstract superclass for binary runners (flashers, debuggers).

   Note: this class's API has changed relatively rarely since it as added, but it is not considered a
   stable Zephyr API, and may change without notice.

   With some exceptions, boards supported by Zephyr must provide generic means to be flashed (have
   a Zephyr firmware binary permanently installed on the device for running) and debugged (have a
   breakpoint debugger and program loader on a host workstation attached to a running target).

   This is supported by four top-level commands managed by the Zephyr build system:

   • ‘flash’: flash a previously configured binary to the board, start execution on the target, then
     return.

   • ‘debug’: connect to the board via a debugging protocol, program the flash, then drop the user
     into a debugger interface with symbol tables loaded from the current binary, and block until it
     exits.

   • ‘debugserver’: connect via a board-specific debugging protocol, then reset and halt the target.
     Ensure the user is now able to connect to a debug server with symbol tables loaded from the
     binary.

   • ‘attach’: connect to the board via a debugging protocol, then drop the user into a debugger
     interface with symbol tables loaded from the current binary, and block until it exits. Unlike
     ‘debug’, this command does not program the flash.

   This class provides an API for these commands. Every subclass is called a ‘runner’ for short. Each
   runner has a name (like ‘pyocd’), and declares commands it can handle (like ‘flash’). Boards (like
   ‘nrf52dk_nrf52832’) declare which runner(s) are compatible with them to the Zephyr build system,
   along with information on how to configure the runner to work with the board.

   The build system will then place enough information in the build directory to create and use
   runners with this class's create() method, which provides a command line argument parsing API.
   You can also create runners by instantiating subclasses directly.

   In order to define your own runner, you need to:

   1. Define a ZephyrBinaryRunner subclass, and implement its abstract methods. You may need to
      override capabilities().

   2. Make sure the Python module defining your runner class is imported, e.g. by editing this
      package's __init__.py (otherwise, get_runners() won't work).

   3. Give your runner's name to the Zephyr build system in your board's board.cmake.

   Additional advice:

   • If you need to import any non-standard-library modules, make sure to catch ImportError and
     defer complaints about it to a RuntimeError if one is missing. This avoids affecting users that
     don't require your runner, while still making it clear what went wrong to users that do require
     it that don't have the necessary modules installed.
• If you need to ask the user something (e.g. using input()), do it in your create() classmethod, not do_run(). That ensures your __init__() really has everything it needs to call do_run(), and also avoids calling input() when not instantiating within a command line application.

• Use self.logger to log messages using the standard library's logging API; your logger is named “runner.<your-runner-name()>”

For command-line invocation from the Zephyr build system, runners define their own argparse-based interface through the common add_parser() (and runner-specific do_add_parser() it delegates to), and provide a way to create instances of themselves from a RunnerConfig and parsed runner-specific arguments via create().

Runners use a variety of host tools and configuration values, the user interface to which is abstracted by this class. Each runner subclass should take any values it needs to execute one of these commands in its constructor. The actual command execution is handled in the run() method.

classmethod add_parser(parser)
    Adds a sub-command parser for this runner.

    The given object, parser, is a sub-command parser from the argparse module. For more details, refer to the documentation for argparse.ArgumentParser.add_subparsers().

    The lone common optional argument is:
    • –dt-flash (if the runner capabilities includes flash_addr)

    Runner-specific options are added through the do_add_parser() hook.

property build_conf: BuildConfiguration
    Get a BuildConfiguration for the build directory.

call(cmd: List[str], **kwargs) \rightarrow int
    Subclass subprocess.call() wrapper.

    Subclasses should use this method to run command in a subprocess and get its return code, rather than using subprocess directly, to keep accurate debug logs.

classmethod capabilities() \rightarrow RunnerCaps
    Returns a RunnerCaps representing this runner's capabilities.

    This implementation returns the default capabilities.

    Subclasses should override appropriately if needed.

cfg
    RunnerConfig for this instance.

check_call(cmd: List[str], **kwargs)
    Subclass subprocess.check_call() wrapper.

    Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.

check_output(cmd: List[str], **kwargs) \rightarrow bytes
    Subclass subprocess.check_output() wrapper.

    Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.

classmethod create(cfg: RunnerConfig, args: Namespace) \rightarrow ZephyrBinaryRunner
    Create an instance from command-line arguments.

    • cfg: runner configuration (pass to superclass __init__)
    • args: arguments parsed from execution environment, as specified by add_parser().
classmethod dev_id_help() → str
    Get the ArgParse help text for the --dev-id option.

abstract classmethod do_add_parser(parser)
    Hook for adding runner-specific options.

abstract classmethod do_create(cfg: RunnerConfig, args: Namespace) → ZephyrBinaryRunner
    Hook for instance creation from command line arguments.

abstract do_run(command: str, **kwargs)
    Concrete runner; run() delegates to this. Implement in subclasses.
    In case of an unsupported command, raise a ValueError.

ensure_output(output_type: str) → None
    Ensure self.cfg has a particular output artifact.
    For example, ensure_output('bin') ensures that self.cfg.bin_file refers to an existing file. Errors out if it's missing or undefined.

    Parameters
        output_type -- string naming the output type

static flash_address_from_build_conf(build_conf: BuildConfiguration)
    If CONFIG_HAS_FLASH_LOAD_OFFSET is n in build_conf, return the CONFIG_FLASH_BASE_ADDRESS value. Otherwise, return CONFIG_FLASH_BASE_ADDRESS + CONFIG_FLASH_LOAD_OFFSET.

static get_flash_address(args: Namespace, build_conf: BuildConfiguration, default: int = 0) → int
    Helper method for extracting a flash address.
    If args.dt_flash is true, returns the address obtained from ZephyrBinaryRunner.flash_address_from_build_conf(build_conf).
    Otherwise (when args.dt_flash is False), the default value is returned.

static get_runners() → List[Type[ZephyrBinaryRunner]]
    Get a list of all currently defined runner classes.

logger
    logging.Logger for this instance.

abstract classmethod name() → str
    Return this runner's user-visible name.
    When choosing a name, pick something short and lowercase, based on the name of the tool (like opencld, jlink, etc.) or the target architecture/board (like xtensa etc.).

popen_ignore_int(cmd: List[str], **kwargs) → Popen
    Spawn a child command, ensuring it ignores SIGINT.
    The returned subprocess.Popen object must be manually terminated.

static require(program: str) → str
    Require that a program is installed before proceeding.

    Parameters
        program -- name of the program that is required, or path to a program binary.

    If program is an absolute path to an existing program binary, this call succeeds. Otherwise, try to find the program by name on the system PATH.
    If the program can be found, its path is returned. Otherwise, raises MissingProgram.
run(command: str, **kwargs)
    Runs command (‘flash’, ‘debug’, ‘debugserver’, ‘attach’).
    This is the main entry point to this runner.

run_client(client)
    Run a client that handles SIGINT.

run_server_and_client(server, client)
    Run a server that ignores SIGINT, and a client that handles it.
    This routine portably:
    • creates a Popen object for the server command which ignores SIGINT
    • runs client in a subprocess while temporarily ignoring SIGINT
    • cleans up the server after the client exits.
    It’s useful to e.g. open a GDB server and client.

property thread_info_enabled: bool
    Returns True if self.build_conf has CONFIG_DEBUG_THREAD_INFO enabled.

classmethod tool_opt_help() → str
    Get the ArgParse help text for the –tool-opt option.

Doing it By Hand

If you prefer not to use West to flash or debug your board, simply inspect the build directory for the
binaries output by the build system. These will be named something like zephyr/zephyr.elf, zephyr/
zephyr.hex, etc., depending on your board’s build system integration. These binaries may be flashed
to a board using alternative tools of your choice, or used for debugging as needed, e.g. as a source of
symbol tables.

By default, these West commands rebuild binaries before flashing and debugging. This can of course
also be accomplished using the usual targets provided by Zephyr’s build system (in fact, that’s how these
commands do it).

2.10.11 Signing Binaries

The west sign extension command can be used to sign a Zephyr application binary for consumption by
a bootloader using an external tool. Run west sign -h for command line help.

MCUboot / imgtool

The Zephyr build system has special support for signing binaries for use with the MCUboot bootloader
using the imgtool program provided by its developers. You can both build and sign this type of application
binary in one step by setting some Kconfig options. If you do, west flash will use the signed binaries.
If you use this feature, you don’t need to run west sign yourself; the build system will do it for you.

Here is an example workflow, which builds and flashes MCUboot, as well as the hello_world application
for chain-loading by MCUboot. Run these commands from the zephyrproject workspace you created
in the Getting Started Guide.

west build -b YOUR_BOARD bootloader/mcuboot/boot/zephyr -d build-mcuboot
west build -b YOUR_BOARD zephyr/samples/hello_world -d build-hello-signed -- \
    -DCONFIG_BOOTLOADER_MCUBOOT=y \ 
    -DCONFIG_MCUBOOT_SIGNATURE_KEY_FILE="bootloader/mcuboot/root-rsa-2048.pem"

(continues on next page)
west flash -d build-mcuboot
west flash -d build-hello-signed

Notes on the above commands:

- YOUR_BOARD should be changed to match your board
- The CONFIG_MCUBOOT_SIGNATURE_KEY_FILE value is the insecure default provided and used by by MCUboot for development and testing
- You can change the hello_world application directory to any other application that can be loaded by MCUboot, such as the smp_svr_sample

For more information on these and other related configuration options, see:

- CONFIG_BOOTLOADER_MCUBOOT: build the application for loading by MCUboot
- CONFIG_MCUBOOT_SIGNATURE_KEY_FILE: the key file to use with west sign. If you have your own key, change this appropriately
- CONFIG_MCUBOOT_EXTRA_IMGTOOL_ARGS: optional additional command line arguments for imgtool
- CONFIG_MCUBOOT_GENERATE_CONFIRMED_IMAGE: also generate a confirmed image, which may be more useful for flashing in production environments than the OTA-able default image
- On Windows, if you get “Access denied” issues, the recommended fix is to run pip3 install imgtool, then retry with a pristine build directory.

If your west flash runner uses an image format supported by imgtool, you should see something like this on your device's serial console when you run west flash -d build-mcuboot:

*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1 ***
[00:00:00.469] <inf> mcuboot: Starting bootloader
[00:00:00.116] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1, copy_
→ done=0x3, image_ok=0x3
[00:00:00.213] <inf> mcuboot: Boot source: none
[00:00:00.374] <err> mcuboot: Failed reading image headers; Image=0
[00:00:00.437] <err> mcuboot: Unable to find bootable image

Then, you should see something like this when you run west flash -d build-hello-signed:

*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1 ***
[00:00:00.469] <inf> mcuboot: Starting bootloader
[00:00:00.116] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1, copy_
→ done=0x3, image_ok=0x3
[00:00:00.213] <inf> mcuboot: Boot source: none
[00:00:00.374] <err> mcuboot: Swap type: none
[00:00:00.437] <err> mcuboot: Bootloader chainload address offset: 0xc000
[00:00:00.500] <err> mcuboot: Jumping to the first image slot
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1 ***
Hello World! nrf52840dk_nrf52840

Whether west flash supports this feature depends on your runner. The nrfjprog and pyocd runners work with the above flow. If your runner does not support this flow and you would like it to, please send a patch or file an issue for adding support.

### 2.10.12 Additional Zephyr extension commands

This page documents miscellaneous Zephyr Extensions.
Listing boards: west boards

The `boards` command can be used to list the boards that are supported by Zephyr without having to resort to additional sources of information.

It can be run by typing:

```
w west boards
```

This command lists all supported boards in a default format. If you prefer to specify the display format yourself you can use the `--format` (or `-f`) flag:

```
w west boards -f "\{arch\}:\{name\}"
```

Additional help about the formatting options can be found by running:

```
w west boards -h
```

Shell completion scripts: west completion

The `completion` extension command outputs shell completion scripts that can then be used directly to enable shell completion for the supported shells.

It currently supports the following shells:

- bash
- zsh

Additional instructions are available in the command’s help:

```
w west help completion
```

Installing CMake packages: west zephyr-export

This command registers the current Zephyr installation as a CMake config package in the CMake user package registry.

In Windows, the CMake user package registry is found in `HKEY_CURRENT_USER\Software\Kitware\CMake\Packages`.

In Linux and MacOS, the CMake user package registry is found in `~/.cmake/packages`.

You may run this command when setting up a Zephyr workspace. If you do, application CMakeLists.txt files that are outside of your workspace will be able to find the Zephyr repository with the following:

```
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

See `share/zephyr-package/cmake` for details.

Software bill of materials: west spdx

This command generates SPDX 2.2 tag-value documents, creating relationships from source files to the corresponding generated build files. SPDX-License-Identifier comments in source files are scanned and filled into the SPDX documents.

To use this command:

1. Pre-populate a build directory `BUILD_DIR` like this:
west spdx --init -d BUILD_DIR

This step ensures the build directory contains CMake metadata required for SPDX document generation.

2. Build your application using this pre-created build directory, like so:
   west build -d BUILD_DIR [...]

3. Generate SPDX documents using this build directory:
   west spdx -d BUILD_DIR

This generates the following SPDX bill-of-materials (BOM) documents in BUILD_DIR/spdx/:

- app.spdx: BOM for the application source files used for the build
- zephyr.spdx: BOM for the specific Zephyr source code files used for the build
- build.spdx: BOM for the built output files

Each file in the bill-of-materials is scanned, so that its hashes (SHA256 and SHA1) can be recorded, along with any detected licenses if an `SPDX-License-Identifier` comment appears in the file.

SPDX Relationships are created to indicate dependencies between CMake build targets, build targets that are linked together, and source files that are compiled to generate the built library files.

west spdx accepts these additional options:

- `-n PREFIX`: a prefix for the Document Namespaces that will be included in the generated SPDX documents. See SPDX specification clause 6 for details. If `-n` is omitted, a default namespace will be generated according to the default format described in section 2.5 using a random UUID.
- `-s SPDX_DIR`: specifies an alternate directory where the SPDX documents should be written instead of BUILD_DIR/spdx/.
- `--analyze-includes`: in addition to recording the compiled source code files (e.g. `.c`, `.S`) in the bills-of-materials, also attempt to determine the specific header files that are included for each `.c` file.

   This takes longer, as it performs a dry run using the C compiler for each `.c` file using the same arguments that were passed to it for the actual build.

- `--include-sdk`: with `--analyze-includes`, also create a fourth SPDX document, sdk.spdx, which lists header files included from the SDK.

Working with binary blobs: west blobs

The `blobs` command allows users to interact with binary blobs declared in one or more modules via their module.yml file.

The `blobs` command has three sub-commands, used to list, fetch or clean (i.e. delete) the binary blobs themselves.

You can list binary blobs while specifying the format of the output:

west blobs list -f '{module}: {type} {path}'

For the full set of variables available in `-f/--format` run west blobs -h.

Fetching blobs works in a similar manner:

west blobs fetch
Note that, as described in the modules section, fetched blobs are stored in a `zephyr/blobs/` folder relative to the root of the corresponding module repository.

As does deleting them:

```
west blobs clean
```

Additionally the tool allows you to specify the modules you want to list, fetch or clean blobs for by typing the module names as a command-line parameter.

### 2.10.13 History and Motivation

West was added to the Zephyr project to fulfill two fundamental requirements:

- The ability to work with multiple Git repositories
- The ability to provide an extensible and user-friendly command-line interface for basic Zephyr workflows

During the development of west, a set of Design Constraints were identified to avoid the common pitfalls of tools of this kind.

#### Requirements

Although the motivation behind splitting the Zephyr codebase into multiple repositories is outside of the scope of this page, the fundamental requirements, along with a clear justification of the choice not to use existing tools and instead develop a new one, do belong here.

The basic requirements are:

- **R1**: Keep externally maintained code in separately maintained repositories outside of the main zephyr repository, without requiring users to manually clone each of the external repositories
- **R2**: Provide a tool that both Zephyr users and distributors can make use of to benefit from and extend
- **R3**: Allow users and downstream distributions to override or remove repositories without having to make changes to the zephyr repository
- **R4**: Support both continuous tracking and commit-based (bisectable) project updating

#### Rationale for a custom tool

Some of west’s features are similar to those provided by Git Submodules and Google’s repo.

Existing tools were considered during west’s initial design and development. None were found suitable for Zephyr’s requirements. In particular, these were examined in detail:

- Google repo
  - Does not cleanly support using zephyr as the manifest repository (R4)
  - Python 2 only
  - Does not play well with Windows
  - Assumes Gerrit is used for code review
- Git submodules
  - Does not fully support R1, since the externally maintained repositories would still need to be inside the main zephyr Git tree
  - Does not support R3, since downstream copies would need to either delete or replace submodule definitions
– Does not support continuous tracking of the latest HEAD in external repositories (R4)
– Requires hardcoding of the paths/locations of the external repositories

**Multiple Git Repositories**

Zephyr intends to provide all required building blocks needed to deploy complex IoT applications. This in turn means that the Zephyr project is much more than an RTOS kernel, and is instead a collection of components that work together. In this context, there are a few reasons to work with multiple Git repositories in a standardized manner within the project:

• Clean separation of Zephyr original code and imported projects and libraries
• Avoidance of license incompatibilities between original and imported code
• Reduction in size and scope of the core Zephyr codebase, with additional repositories containing optional components instead of being imported directly into the tree
• Safety and security certifications
• Enforcement of modularization of the components
• Out-of-tree development based on subsets of the supported boards and SoCs

See Basics for information on how west workspaces manage multiple git repositories.

**Design Constraints**

West is:

• **Optional**: it is always possible to drop back to “raw” command-line tools, i.e. use Zephyr without using west (although west itself might need to be installed and accessible to the build system). It may not always be convenient to do so, however. (If all of west’s features were already conveniently available, there would be no reason to develop it.)

• **Compatible with CMake**: building, flashing and debugging, and emulator support will always remain compatible with direct use of CMake.

• **Cross-platform**: West is written in Python 3, and works on all platforms supported by Zephyr.

• **Usable as a Library**: whenever possible, west features are implemented as libraries that can be used standalone in other programs, along with separate command line interfaces that wrap them. West itself is a Python package named west; its libraries are implemented as subpackages.

• **Conservative about features**: no features will be accepted without strong and compelling motivation.

• **Clearly specified**: West’s behavior in cases where it wraps other commands is clearly specified and documented. This enables interoperability with third party tools, and means Zephyr developers can always find out what is happening “under the hood” when using west.

See Zephyr issue #6205 and for more details and discussion.

### 2.10.14 Moving to West

To convert a “pre-west” Zephyr setup on your computer to west, follow these steps. If you are starting from scratch, use the Getting Started Guide instead. See Troubleshooting West for advice on common issues.

1. Install west.
   
   On Linux:
pip3 install --user -U west

On Windows and macOS:

pip3 install -U west

For details, see *Installing west*.

2. Move your zephyr repository to a new zephyrproject parent directory, and change directory there.

On Linux and macOS:

```bash
mkdir zephyrproject
mv zephyr zephyrproject
cd zephyrproject
```

On Windows cmd.exe:

```bash
mkdir zephyrproject
move zephyr zephyrproject
chdir zephyrproject
```

The name `zephyrproject` is recommended, but you can choose any name with no spaces anywhere in the path.

3. Create a west workspace using the zephyr repository as a local manifest repository:

```
west init -l zephyr
```

This creates `zephyrproject/.west`, marking the root of your workspace, and does some other setup. It will not change the contents of the zephyr repository in any way.

4. Clone the rest of the repositories used by zephyr:

```
w west update
```

Make sure to run this command whenever you pull zephyr. Otherwise, your local repositories will get out of sync. (Run west list for current information on these repositories.)

You are done: zephyrproject is now set up to use west.

### 2.10.15 Using Zephyr without west

This page provides information on using Zephyr without west. This is not recommended for beginners due to the extra effort involved. In particular, you will have to do work “by hand” to replace these features:

- cloning the additional source code repositories used by Zephyr in addition to the main zephyr repository, and keeping them up to date
- specifying the locations of these repositories to the Zephyr build system
- flashing and debugging without understanding detailed usage of the relevant host tools

**Note:** If you have previously installed west and want to stop using it, uninstall it first:

```
ip3 uninstall west
```

Otherwise, Zephyr’s build system will find it and may try to use it.
Getting the Source

In addition to downloading the zephyr source code repository itself, you will need to manually clone the additional projects listed in the west manifest file inside that repository.

```
mkdir zephyrproject
cd zephyrproject
git clone https://github.com/zephyrproject-rtos/zephyr
# clone additional repositories listed in zephyr/west.yml,
# and check out the specified revisions as well.
```

As you pull changes in the zephyr repository, you will also need to maintain those additional repositories, adding new ones as necessary and keeping existing ones up to date at the latest revisions.

Building applications

You can build a Zephyr application using CMake and Ninja (or make) directly without west installed if you specify any modules manually.

```
cmake -Bbuild -GNinja -DZEPHYR_MODULES=module1;module2;... samples/hello_world
ninja -Cbuild
```

When building with west installed, the Zephyr build system will use it to set `ZEPHYR_MODULES`.

If you don't have west installed and your application does not need any of these repositories, the build will still work.

If you don't have west installed and your application does need one of these repositories, you must set `ZEPHYR_MODULES` yourself as shown above.

See [Modules (External projects)](https://zephyr-project.org/docs/users/build-system/modules) for more details.

Similarly, if your application requires binary blobs and you are not using west, you will need to download and place those blobs in the right places instead of using `west` blobs. See [Binary Blobs](https://zephyr-project.org/docs/users/build-system/binary-blobs) for more details.

Flashing and Debugging

Running build system targets like `ninja flash`, `ninja debug`, etc. is just a call to the corresponding west command. For example, `ninja flash` calls west `flash`. If you don't have west installed on your system, running those targets will fail. You can of course still flash and debug using any Flash & Debug Host Tools which work for your board (and which those west commands wrap).

If you want to use these build system targets but do not want to install west on your system using `pip`, it is possible to do so by manually creating a west workspace:

```
# cd into zephyrproject if not already there
git clone https://github.com/zephyrproject-rtos/west .west/west
```

Then create a file `.west/config` with the following contents:

```
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

---

1 Note that west `build` invokes ninja, among other tools. There's no recursive invocation of either west or ninja involved by default, however, as west `build` does not invoke `ninja flash`, `debug`, etc. The one exception is if you specifically run one of these build system targets with a command line like `west build -t flash`. In that case, west is run twice: once for `west build`, and in a subprocess, again for `west flash`. Even in this case, `ninja` is only run once, as `ninja flash`. This is because these build system targets depend on an up to date build of the Zephyr application, so it's compiled before `west flash` is run.
After that, and in order for `ninja` to be able to invoke `west` to flash and debug, you must specify the west directory. This can be done by setting the environment variable `WEST_DIR` to point to `zephyrproject/`. Run `west/west` before running CMake to set up a build directory.

For details on west's Python APIs, see `west-apis`.

## 2.11 Testing

### 2.11.1 Test Framework

The Zephyr Test Framework (Ztest) provides a simple testing framework intended to be used during development. It provides basic assertion macros and a generic test structure.

The framework can be used in two ways, either as a generic framework for integration testing, or for unit testing specific modules.

To enable the latest APIs of Ztest simply set `CONFIG_ZTEST_NEW_API=y`. The legacy APIs will soon be deprecated and eventually removed.

### Creating a test suite

Using Ztest to create a test suite is as easy as calling the `ZTEST_SUITE`. The macro accepts the following arguments:

- **suite_name** - The name of the suite. This name must be unique within a single binary.
- **ztest_suite_predicate_t** - An optional predicate function to allow choosing when the test will run. The predicate will get a pointer to the global state passed in through `ztest_run_all()` and should return a boolean to decide if the suite should run.
- **ztest_suite_setup_t** - An optional setup function which returns a test fixture. This will be called and run once per test suite run.
- **ztest_suite_before_t** - An optional before function which will run before every single test in this suite.
- **ztest_suite_after_t** - An optional after function which will run after every single test in this suite.
- **ztest_suite_teardown_t** - An optional teardown function which will run at the end of all the tests in the suite.

Below is an example of a test suite using a predicate:

```c
#include <zephyr/ztest.h>
#include "test_state.h"

static bool predicate(const void *global_state)
{
  return ((const struct test_state*)global_state)->x == 5;
}

ZTEST_SUITE(alternating_suite, predicate, NULL, NULL, NULL, NULL);
```

### Adding tests to a suite

There are 4 macros used to add a test to a suite, they are:

- **`ZTEST` (suite_name, test_name)** - Which can be used to add a test by `test_name` to a given suite by `suite_name`. 
• **ZTEST_USER** (suite_name, test_name) - Which behaves the same as **ZTEST**, only that when **CONFIG_USERSPACE** is enabled, then the test will be run in a userspace thread.

• **ZTEST_F** (suite_name, test_name) - Which behaves the same as **ZTEST**, only that the test function will already include a variable named fixture with the type <suite_name>_fixture.

• **ZTEST_USER_F** (suite_name, test_name) - Which combines the fixture feature of **ZTEST_F** with the userspace threading for the test.

**Test fixtures** Test fixtures can be used to help simplify repeated test setup operations. In many cases, tests in the same suite will require some initial setup followed by some form of reset between each test. This is achieved via fixtures in the following way:

```c
#include <zephyr/ztest.h>

struct my_suite_fixture {
    size_t max_size;
    size_t size;
    uint8_t buff[1];
};

static void *my_suite_setup(void)
{
    /* Allocate the fixture with 256 byte buffer */
    struct my_suite_fixture *fixture = k_malloc(sizeof(struct my_suite_fixture) + 255);
    zassert_not_null(fixture, NULL);
    fixture->max_size = 256;
    return fixture;
}

static void my_suite_before(void *f)
{
    struct my_suite_fixture *fixture = (struct my_suite_fixture *)f;
    memset(fixture->buff, 0, fixture->max_size);
    fixture->size = 0;
}

static void my_suite_teardown(void *f)
{
    k_free(f);
}

ZTEST_SUITE(my_suite, NULL, my_suite_setup, my_suite_before, NULL, my_suite_teardown);

ZTEST_F(my_suite, test_feature_x)
{
    zassert_equal(0, fixture->size);
    zassert_equal(256, fixture->max_size);
}
```

**Advanced features**

**Test result expectations** Some tests were made to be broken. In cases where the test is expected to fail or skip due to the nature of the code, it’s possible to annotate the test as such. For example:
#include <zephyr/ztest.h>

ZTEST_SUITE(my_suite, NULL, NULL, NULL, NULL, NULL);

ZTEST_EXPECT_FAIL(my_suite, test_fail)
ZTEST(my_suite, test_fail)
{
    /** This will fail the test */
    zassert_true(false, NULL);
}

ZTEST_EXPECT_SKIP(my_suite, test_fail)
ZTEST(my_suite, test_skip)
{
    /** This will skip the test */
    zassert_true(false, NULL);
}

In this example, the above tests should be marked as failed and skipped respectively. Instead, Ztest will mark both as passed due to the expectation.

Test rules Test rules are a way to run the same logic for every test and every suite. There are a lot of cases where you might want to reset some state for every test in the binary (regardless of which suite is currently running). As an example, this could be to reset mocks, reset emulators, flush the UART, etc.

#include <zephyr/fff.h>
#include <zephyr/ztest.h>
#include "test_mocks.h"

DEFINE_FFF_GLOBALS;

DEFINE_FAKE_VOID_FUN(my_weak_func);

static void fff_reset_rule_before(const struct ztest_unit_test *test, void __attribute__((unused)) *fixture)
{
    ARG_UNUSED(test);
    ARG_UNUSED(fixture);

    RESET_FAKE(my_weak_func);
}

ZTEST_RULE(fff_reset_rule, fff_reset_rule_before, NULL);

A custom test_main While the Ztest framework provides a default test_main() function, it's possible that some applications will want to provide custom behavior. This is particularly true if there's some global state that the tests depend on and that state either cannot be replicated or is difficult to replicate without starting the process over. For example, one such state could be a power sequence. Assuming there's a board with several steps in the power-on sequence a test suite can be written using the predicate to control when it would run. In that case, the test_main() function can be written as following:

#include <zephyr/ztest.h>

(continues on next page)
```c
#include "my_test.h"

void test_main(void)
{
    struct power_sequence_state state;

    /* Only suites that use a predicate checking for phase == PWR_PHASE_0 will run. */
    state.phase = PWR_PHASE_0;
    ztest_run_all(&state);

    /* Only suites that use a predicate checking for phase == PWR_PHASE_1 will run. */
    state.phase = PWR_PHASE_1;
    ztest_run_all(&state);

    /* Only suites that use a predicate checking for phase == PWR_PHASE_2 will run. */
    state.phase = PWR_PHASE_2;
    ztest_run_all(&state);

    /* Check that all the suites in this binary ran at least once. */
    ztest_verify_all_test_suites_ran();
}
```

**Quick start - Integration testing**

A simple working base is located at `samples/subsys/testsuite/integration`. Just copy the files to `tests/` and edit them for your needs. The test will then be automatically built and run by the twister script. If you are testing the `bar` component of `foo`, you should copy the sample folder to `tests/foo/bar`. It can then be tested with:

```
./scripts/twister -s tests/foo/bar/test-identifier
```

In the example above `tests/foo/bar` signifies the path to the test and the `test-identifier` references a test defined in the `testcase.yaml` file.

To run all tests defined in a test project, run:

```
./scripts/twister -T tests/foo/bar/
```

The sample contains the following files:

CMakeLists.txt

```makefile
# SPDX-License-Identifier: Apache-2.0

cmake_minimum_required(VERSION 3.20.0)
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
project(integration)

FILE(GLOB app_sources src/*.c)
target_sources(app PRIVATE ${app_sources})
```

testcase.yaml

```yaml
tests:
    # section.subsection
    sample.testing.ztest:
        build_only: true
```

(continues on next page)
Listing Tests

Skipping Tests

A test case project may consist of multiple sub-tests or smaller tests that either can be testing functionality or APIs. Functions implementing a test should follow the guidelines below:

- Test cases function names should be prefix with `test_`
- Test cases should be documented using doxygen
- Test function names should be unique within the section or component being tested

An example can be seen below:

```c
/**
 * @brief Test Asserts
 *
 * This test verifies the zassert_true macro.
 */
ZTEST(framework_tests, test_assert)
{
   zassert_true(1, "1 was false");
   zassert_false(0, "0 was true");
   zassert_is_null(NULL, "NULL was not NULL");
   zassert_not_null("foo", "\"foo\" was NULL");
   zassert_equal(1, 1, "1 was not equal to 1");
   zassert_equal_ptr(NULL, NULL, "NULL was not equal to NULL");
}```
Zephyr Project Documentation, Release 3.2.99

(continued from previous page)

*/
ZTEST(my_suite, test_assert)
{
    zassert_true(1, "1 was false");
}

Listing Tests  Tests (test projects) in the Zephyr tree consist of many test cases that run as part of a project and test similar functionality, for example an API or a feature. The twister script can parse the test cases in all test projects or a subset of them, and can generate reports on a granular level, i.e. if cases have passed or failed or if they were blocked or skipped.

Twister parses the source files looking for test case names, so you can list all kernel test cases, for example, by entering:

twister --list-tests -T tests/kernel

Skipping Tests  Special- or architecture-specific tests cannot run on all platforms and architectures, however we still want to count those and report them as being skipped. Because the test inventory and the list of tests is extracted from the code, adding conditionals inside the test suite is sub-optimal. Tests that need to be skipped for a certain platform or feature need to explicitly report a skip using ztest_test_skip() or Z_TEST_SKIP_IFDEF. If the test runs, it needs to report either a pass or fail. For example:

```c
#ifdef CONFIG_TEST1
ZTEST(common, test_test1)
{
    zassert_true(1, "true");
}
#else
ZTEST(common, test_test1)
{
    ztest_test_skip();
}
#endif
ZTEST(common, test_test2)
{
    Z_TEST_SKIP_IFDEF(CONFIG_BUGxxxxx);
    zassert_equal(1, 0, NULL);
}

ZTEST_SUITE(common, NULL, NULL, NULL, NULL, NULL);
```

Quick start - Unit testing

Ztest can be used for unit testing. This means that rather than including the entire Zephyr OS for testing a single function, you can focus the testing efforts into the specific module in question. This will speed up testing since only the module will have to be compiled in, and the tested functions will be called directly.

Since you won’t be including basic kernel data structures that most code depends on, you have to provide function stubs in the test. Ztest provides some helpers for mocking functions, as demonstrated below.
In a unit test, mock objects can simulate the behavior of complex real objects and are used to decide whether a test failed or passed by verifying whether an interaction with an object occurred, and if required, to assert the order of that interaction.

**Best practices for declaring the test suite** `twister` and other validation tools need to obtain the list of subcases that a Zephyr `test` test image will expose.

### Rationale

This all is for the purpose of traceability. It’s not enough to have only a semaphore test project. We also need to show that we have testpoints for all APIs and functionality, and we trace back to documentation of the API, and functional requirements.

The idea is that test reports show results for every sub-testcase as passed, failed, blocked, or skipped. Reporting on only the high-level test project level, particularly when tests do too many things, is too vague.

**Other questions:**

- Why not pre-scan with CPP and then parse? or post scan the ELF file?
  
  If C pre-processing or building fails because of any issue, then we won’t be able to tell the subcases.

- Why not declare them in the YAML testcase description?
  
  A separate testcase description file would be harder to maintain than just keeping the information in the test source files themselves – only one file to update when changes are made eliminates duplication.

### Stress test framework

Zephyr stress test framework (Ztress) provides an environment for executing user functions in multiple priority contexts. It can be used to validate that code is resilient to preemptions. The framework tracks the number of executions and preemptions for each context. Execution can have various completion conditions like timeout, number of executions or number of preemptions.

The framework is setting up the environment by creating the requested number of threads (each on different priority), optionally starting a timer. For each context, a user function (different for each context) is called and then the context sleeps for a randomized amount of system ticks. The framework is tracking CPU load and adjusts sleeping periods to achieve higher CPU load. In order to increase the probability of preemptions, the system clock frequency should be relatively high. The default 100 Hz on QEMU x86 is much too low and it is recommended to increase it to 100 kHz.

The stress test environment is setup and executed using `ZTRESS_EXECUTE` which accepts a variable number of arguments. Each argument is a context that is specified by `ZTRESS_TIMER` or `ZTRESS_THREAD` macros. Contexts are specified in priority descending order. Each context specifies completion conditions by providing the minimum number of executions and preemptions. When all conditions are met and the execution has completed, an execution report is printed and the macro returns. Note that while the test is executing, a progress report is periodically printed.

Execution can be prematurely completed by specifying a test timeout (`ztress_set_timeout()`) or an explicit abort (`ztress_abort()`).

User function parameters contains an execution counter and a flag indicating if it is the last execution.

The example below presents how to setup and run 3 contexts (one of which is `k_timer` interrupt handler context). Completion criteria is set to at least 10000 executions of each context and 1000 preemptions of the lowest priority context. Additionally, the timeout is configured to complete after 10 seconds if those conditions are not met. The last argument of each context is the initial sleep time which will be adjusted throughout the test to achieve the highest CPU load.
Zephyr Project Documentation, Release 3.2.99

ztress_set_timeout(K_MSEC(10000));
ZTRESS_EXECUTE(ZTRESS_TIMER(foo_0, user_data_0, 10000, Z_TIMEOUT_TICKS(20)),
  ZTRESS_THREAD(foo_1, user_data_1, 10000, 0, Z_TIMEOUT_
  →TICKS(20)),
  ZTRESS_THREAD(foo_2, user_data_2, 10000, 1000, Z_TIMEOUT_
  →TICKS(20)));

Configuration  Static configuration of Ztress contains:
  • ZTRESS_MAX_THREADS - number of supported threads.
  • ZTRESS_STACK_SIZE - Stack size of created threads.
  • ZTRESS_REPORT_PROGRESS_MS - Test progress report interval.

API reference

Running tests

group ztest_test
  This module eases the testing process by providing helpful macros and other testing structures.

Defines

ZTEST(suite, fn)
  Create and register a new unit test.
  Calling this macro will create a new unit test and attach it to the declared suite. The suite
does not need to be defined in the same compilation unit.

  Parameters
  • suite – The name of the test suite to attach this test
  • fn – The test function to call.

ZTEST_USER(suite, fn)
  Define a test function that should run as a user thread.
  This macro behaves exactly the same as ZTEST, but calls the test function in user space if
CONFIG_USERSPACE was enabled.

  Parameters
  • suite – The name of the test suite to attach this test
  • fn – The test function to call.

ZTEST_F(suite, fn)
  Define a test function.
  This macro behaves exactly the same as ZTEST(), but the function takes an argument for the
fixture of type struct suite##_fixture* named this.

  Parameters
  • suite – The name of the test suite to attach this test
  • fn – The test function to call.
ZTEST_USER_F(suite, fn)
Define a test function that should run as a user thread.
If CONFIG_USERSPACE is not enabled, this is functionally identical to ZTEST_F(). The test
function takes a single fixture argument of type struct suite##_fixture* named this.

Parameters
• suite – The name of the test suite to attach this test
• fn – The test function to call.

ZTEST_RULE(name, before_each_fn, after_each_fn)
Define a test rule that will run before/after each unit test.
Functions defined here will run before/after each unit test for every test suite. Along with the
callback, the test functions are provided a pointer to the test being run, and the data. This
provides a mechanism for tests to perform custom operations depending on the specific test
or the data (for example logging may use the test's name).
Ordering:
• Test rule's before function will run before the suite's before function. This is done to
  allow the test suite's customization to take precedence over the rule which is applied to
  all suites.
• Test rule's after function is not guaranteed to run in any particular order.

Parameters
• name – The name for the test rule (must be unique within the compilation unit)
• before_each_fn – The callback function (ztest_rule_cb) to call before each test
  (may be NULL)
• after_each_fn – The callback function (ztest_rule_cb) to call after each test
  (may be NULL)

ztest_run_test_suite(suite)
Run the specified test suite.

Parameters
• suite – Test suite to run.

Typedefs

typedef void (*ztest_rule_cb)(const struct ztest_unit_test *test, void *data)
Test rule callback function signature.
The function signature that can be used to register a test rule's before/after callback. This
provides access to the test and the fixture data (if provided).

Param test
  Pointer to the unit test in context

Param data
  Pointer to the test's fixture data (may be NULL)

Functions
void ztest_test_fail(void)
    Fail the currently running test.
    This is the function called from failed assertions and the like. You probably don't need to call
    it yourself.

void ztest_test_pass(void)
    Pass the currently running test.
    Normally a test passes just by returning without an assertion failure. However, if
    the success case for your test involves a fatal fault, you can call this function from
    k_sys_fatal_error_handler to indicate that the test passed before aborting the thread.

void ztest_test_skip(void)
    Skip the current test.

void ztest_skip_failed_assumption(void)

void ztest_simple_1cpu_before(void *data)
    A 'before' function to use in test suites that just need to start 1cpu.
    Ignores data, and calls z_test_1cpu_start()

    Parameters
    • data – The test suite's data

void ztest_simple_1cpu_after(void *data)
    A 'after' function to use in test suites that just need to stop 1cpu.
    Ignores data, and calls z_test_1cpu_stop()

    Parameters
    • data – The test suite's data

struct ztest_test_rule

struct ztest_arch_api
    #include <ztest_test_new.h> Structure for architecture specific APIs.

**Assertions** These macros will instantly fail the test if the related assertion fails. When an assertion
fails, it will print the current file, line and function, alongside a reason for the failure and an optional
message. If the config option: `CONFIG_ZTEST_ASSERT_VERBOSE` is 0, the assertions will only print the
file and line numbers, reducing the binary size of the test.

Example output for a failed macro from `zassert_equal(buf->ref, 2, "Invalid refcount")`:

Assertion failed at main.c:62: test_get_single_buffer: Invalid refcount (buf->ref not
    equal to 2)
Aborted at unit test function

**group ztest_assert**

This module provides assertions when using Ztest.

**Defines**

`zassert(cond, default_msg, ...)`

`zassume(cond, default_msg, ...)`

2.11. Testing
zassert_unreachable(...)  
Assert that this function call won’t be reached.

Parameters
  • ... – Optional message and variables to print if the assertion fails

zassert_true(cond, ...)
Assert that \texttt{cond} is true.

Parameters
  • \texttt{cond} – Condition to check
  • ... – Optional message and variables to print if the assertion fails

zassert_false(cond, ...)
Assert that \texttt{cond} is false.

Parameters
  • \texttt{cond} – Condition to check
  • ... – Optional message and variables to print if the assertion fails

zassert_ok(cond, ...)
Assert that \texttt{cond} is 0 (success)

Parameters
  • \texttt{cond} – Condition to check
  • ... – Optional message and variables to print if the assertion fails

zassert_is_null(ptr, ...)
Assert that \texttt{ptr} is NULL.

Parameters
  • \texttt{ptr} – Pointer to compare
  • ... – Optional message and variables to print if the assertion fails

zassert_not_null(ptr, ...)
Assert that \texttt{ptr} is not NULL.

Parameters
  • \texttt{ptr} – Pointer to compare
  • ... – Optional message and variables to print if the assertion fails

zassert_equal(a, b, ...)
Assert that \texttt{a} equals \texttt{b}.

\texttt{a} and \texttt{b} won’t be converted and will be compared directly.

Parameters
  • \texttt{a} – Value to compare
  • \texttt{b} – Value to compare
  • ... – Optional message and variables to print if the assertion fails

zassert_not_equal(a, b, ...)
Assert that \texttt{a} does not equal \texttt{b}.

\texttt{a} and \texttt{b} won’t be converted and will be compared directly.

Parameters
• a – Value to compare
• b – Value to compare
• ... – Optional message and variables to print if the assertion fails

\texttt{zassert\_equal\_ptr(a, b, ...)}

Assert that \( a \) equals \( b \).

\( a \) and \( b \) will be converted to \texttt{void *} before comparing.

\textbf{Parameters}

• a – Value to compare
• b – Value to compare
• ... – Optional message and variables to print if the assertion fails

\texttt{zassert\_within(a, b, d, ...)}

Assert that \( a \) is within \( b \) with delta \( d \).

\textbf{Parameters}

• a – Value to compare
• b – Value to compare
• d – Delta
• ... – Optional message and variables to print if the assertion fails

\texttt{zassert\_between\_inclusive(a, l, u, ...)}

Assert that \( a \) is greater than or equal to \( l \) and less than or equal to \( u \).

\textbf{Parameters}

• a – Value to compare
• l – Lower limit
• u – Upper limit
• ... – Optional message and variables to print if the assertion fails

\texttt{zassert\_mem\_equal(...)}

Assert that 2 memory buffers have the same contents.

This macro calls the final memory comparison assertion macro. Using double expansion allows providing some arguments by macros that would expand to more than one values (ANSI-C99 defines that all the macro arguments have to be expanded before macro call).

\textbf{Parameters}

• ... – Arguments, see \texttt{zassert\_mem\_equal\_} for real arguments accepted.

\texttt{zassert\_mem\_equal\_}(buf, exp, size, ...)

Internal assert that 2 memory buffers have the same contents.

\textbf{Note:} This is internal macro, to be used as a second expansion. See \texttt{zassert\_mem\_equal}. 

\textbf{Parameters}

• buf – Buffer to compare
• exp – Buffer with expected contents
• size – Size of buffers
• ... – Optional message and variables to print if the assertion fails
**Assumptions**  These macros will instantly skip the test or suite if the related assumption fails. When an assumption fails, it will print the current file, line, and function, alongside a reason for the failure and an optional message. If the config option: \texttt{CONFIG_ZTEST_ASSUME_VERBOSE} is 0, the assumptions will only print the file and line numbers, reducing the binary size of the test.

Example output for a failed macro from \texttt{zassume_equal(buf->ref, 2, "Invalid refcount")}:

```
group ztest_assume
  This module provides assumptions when using Ztest.

Defines

\texttt{zassume_true(cond, ...)}
  Assume that \texttt{cond} is true.
  If the assumption fails, the test will be marked as “skipped”.

  \textbf{Parameters}
  \begin{itemize}
    \item \texttt{cond} – Condition to check
    \item \ldots – Optional message and variables to print if the assumption fails
  \end{itemize}

\texttt{zassume_false(cond, ...)}
  Assume that \texttt{cond} is false.
  If the assumption fails, the test will be marked as “skipped”.

  \textbf{Parameters}
  \begin{itemize}
    \item \texttt{cond} – Condition to check
    \item \ldots – Optional message and variables to print if the assumption fails
  \end{itemize}

\texttt{zassume_ok(cond, ...)}
  Assume that \texttt{cond} is 0 (success)
  If the assumption fails, the test will be marked as “skipped”.

  \textbf{Parameters}
  \begin{itemize}
    \item \texttt{cond} – Condition to check
    \item \ldots – Optional message and variables to print if the assumption fails
  \end{itemize}

\texttt{zassume_is_null(ptr, ...)}
  Assume that \texttt{ptr} is NULL.
  If the assumption fails, the test will be marked as “skipped”.

  \textbf{Parameters}
  \begin{itemize}
    \item \texttt{ptr} – Pointer to compare
    \item \ldots – Optional message and variables to print if the assumption fails
  \end{itemize}

\texttt{zassume_not_null(ptr, ...)}
  Assume that \texttt{ptr} is not NULL.
  If the assumption fails, the test will be marked as “skipped”.

  \textbf{Parameters}
  \begin{itemize}
    \item \texttt{ptr} – Pointer to compare
    \item \ldots – Optional message and variables to print if the assumption fails
  \end{itemize}
```
**zassume_equal(a, b, ...)**  
Assume that \( a \) equals \( b \).  
\( a \) and \( b \) won’t be converted and will be compared directly. If the assumption fails, the test will be marked as “skipped”.  

**Parameters**  
- \( a \) – Value to compare  
- \( b \) – Value to compare  
- \( ... \) – Optional message and variables to print if the assumption fails

**zassume_not_equal(a, b, ...)**  
Assume that \( a \) does not equal \( b \).  
\( a \) and \( b \) won’t be converted and will be compared directly. If the assumption fails, the test will be marked as “skipped”.  

**Parameters**  
- \( a \) – Value to compare  
- \( b \) – Value to compare  
- \( ... \) – Optional message and variables to print if the assumption fails

**zassume_equal_ptr(a, b, ...)**  
Assume that \( a \) equals \( b \).  
\( a \) and \( b \) will be converted to \texttt{void *} before comparing. If the assumption fails, the test will be marked as “skipped”.  

**Parameters**  
- \( a \) – Value to compare  
- \( b \) – Value to compare  
- \( ... \) – Optional message and variables to print if the assumption fails

**zassume_within(a, b, d, ...)**  
Assume that \( a \) is within \( b \) with delta \( d \).  
If the assumption fails, the test will be marked as “skipped”.  

**Parameters**  
- \( a \) – Value to compare  
- \( b \) – Value to compare  
- \( d \) – Delta  
- \( ... \) – Optional message and variables to print if the assumption fails

**zassume_between_inclusive(a, l, u, ...)**  
Assume that \( a \) is greater than or equal to \( l \) and less than or equal to \( u \).  
If the assumption fails, the test will be marked as “skipped”.  

**Parameters**  
- \( a \) – Value to compare  
- \( l \) – Lower limit  
- \( u \) – Upper limit  
- \( ... \) – Optional message and variables to print if the assumption fails
zassume_mem_equal(...)  
Assume that 2 memory buffers have the same contents.

This macro calls the final memory comparison assumption macro. Using double expansion allows providing some arguments by macros that would expand to more than one values (ANSI-C99 defines that all the macro arguments have to be expanded before macro call).

Parameters

• ... – Arguments, see \texttt{zassume\_mem\_equal\_\_} for real arguments accepted.

\texttt{zassume\_mem\_equal\_\_}(buf, exp, size, ...)

Internal assume that 2 memory buffers have the same contents.

If the assumption fails, the test will be marked as “skipped”.

Note: This is internal macro, to be used as a second expansion. See \texttt{zassume\_mem\_equal}.

Parameters

• buf – Buffer to compare
• exp – Buffer with expected contents
• size – Size of buffers
• ... – Optional message and variables to print if the assumption fails

Mocking via FFF  
Zephyr has integrated with FFF for mocking. See \texttt{FFF} for documentation. To use it, use the following in your source:

\texttt{#include <zephyr/fff.h>}

Zephyr provides several FFF-based fake drivers which can be used as either stubs or mocks. Fake driver instances are configured via \textit{Devicetree} and \textit{Configuration System (Kconfig)}. See the following devicetree bindings for more information:

• \texttt{zephyr,\_fake\_can}
• \texttt{zephyr,\_fake\_eeprom}

Customizing Test Output

The way output is presented when running tests can be customized. An example can be found in \texttt{tests/ztest/custom\_output}.

Customization is enabled by setting \texttt{CONFIG\_ZTEST\_TC\_UTIL\_USER\_OVERRIDE} to “y” and adding a file \texttt{tc\_util\_user\_override.h} with your overrides.

Add the line \texttt{zephyr\_include\_directories(my\_folder)} to your project's \texttt{CMakeLists.txt} to let Zephyr find your header file during builds.

See the file \texttt{subsys\_testsuite\_include\_tc\_util.h} to see which macros and/or defines can be overridden. These will be surrounded by blocks such as:

\texttt{#ifndef SOMETHING
#define SOMETHING <default implementation>
#endif /* SOMETHING */}
Shuffling Test Sequence

By default the tests are sorted and run in alphanumerical order. Test cases may be dependent on this sequence. Enable `ZTEST_SHUFFLE` to randomize the order. The output from the test will display the seed for failed tests. For native posix builds you can provide the seed as an argument to twister with `--seed`.

Static configuration of `ZTEST_SHUFFLE` contains:

- `ZTEST_SHUFFLE_SUITE_REPEAT_COUNT` - Number of iterations the test suite will run.
- `ZTEST_SHUFFLE_TEST_REPEAT_COUNT` - Number of iterations the test will run.

Test Selection

For POSIX enabled builds with `ZTEST_NEW_API` use command line arguments to list or select tests to run. The test argument expects a comma separated list of `suite::test`. You can substitute the test name with an `*` to run all tests within a suite.

For example

```
$ zephyr.exe -list
$ zephyr.exe -test="fixture_tests::test_fixture_pointer,framework_tests::test_assert_mem_equal"
$ zephyr.exe -test="framework_tests::*"
```

### 2.11.2 Test Runner (Twister)

This script scans for the set of unit test applications in the git repository and attempts to execute them. By default, it tries to build each test case on boards marked as default in the board definition file.

The default options will build the majority of the tests on a defined set of boards and will run in an emulated environment if available for the architecture or configuration being tested.

In normal use, twister runs a limited set of kernel tests (inside an emulator). Because of its limited test execution coverage, twister cannot guarantee local changes will succeed in the full build environment, but it does sufficient testing by building samples and tests for different boards and different configurations to help keep the complete code tree buildable.

When using (at least) one `--v` option, twister's console output shows for every test how the test is run (qemu, native_posix, etc.) or whether the binary was just built. There are a few reasons why twister only builds a test and doesn’t run it:

- The test is marked as `build_only: true` in its `.yaml` configuration file.
- The test configuration has defined a harness but you don’t have it or haven’t set it up.
- The target device is not connected and not available for flashing.
- You or some higher level automation invoked twister with `--build-only`.

To run the script in the local tree, follow the steps below:

**Linux**

```
$ source zephyr-env.sh
$ ./scripts/twister
```

**Windows**

```
zephyr-env.cmd
python ./scripts\twister
```
If you have a system with a large number of cores and plenty of free storage space, you can build and run all possible tests using the following options:

**Linux**

```
$ ./scripts/twister --all --enable-slow
```

**Windows**

```
python .\scripts\twister --all --enable-slow
```

This will build for all available boards and run all applicable tests in a simulated (for example QEMU) environment.

If you want to run tests on one or more specific platforms, you can use the `--platform` option, it is a platform filter for testing, with this option, test suites will only be built/run on the platforms specified. This option also supports different revisions of one same board, you can use `--platform board@revision` to test on a specific revision.

The list of command line options supported by twister can be viewed using:

**Linux**

```
$ ./scripts/twister --help
```

**Windows**

```
python .\scripts\twister --help
```

### Board Configuration

To build tests for a specific board and to execute some of the tests on real hardware or in an emulation environment such as QEMU a board configuration file is required which is generic enough to be used for other tasks that require a board inventory with details about the board and its configuration that is only available during build time otherwise.

The board metadata file is located in the board directory and is structured using the YAML markup language. The example below shows a board with a data required for best test coverage for this specific board:

```yaml
identifier: frdm_k64f
name: NXP FRDM-K64F
type: mcu
arch: arm
toolchain:
  - zephyr
  - gnuarmemb
  - xtools
supported:
  - arduino_gpio
  - arduino_i2c
  - netif:eth
  - adc
  - i2c
  - nvs
  - spi
  - gpio
  - usb_device
  - watchdog
  - can
```

(continues on next page)
- pwm

**testing:**

default: true

**identifier:**

A string that matches how the board is defined in the build system. This same string is used when building, for example when calling `west build` or `cmake`:

```sh
# with west
west build -b reel_board
# with cmake
cmake -DBOARD=reel_board ..
```

**name:**

The actual name of the board as it appears in marketing material.

**type:**

Type of the board or configuration, currently we support 2 types: mcu, qemu

**arch:**

Architecture of the board

**toolchain:**

The list of supported toolchains that can build this board. This should match one of the values used for 'ZEPHYR_TOOLCHAIN_VARIANT' when building on the command line

**ram:**

Available RAM on the board (specified in KB). This is used to match testcase requirements. If not specified we default to 128KB.

**flash:**

Available FLASH on the board (specified in KB). This is used to match testcase requirements. If not specified we default to 512KB.

**supported:**

A list of features this board supports. This can be specified as a single word feature or as a variant of a feature class. For example:

```sh
supported:
  - pci
```

This indicates the board does support PCI. You can make a testcase build or run only on such boards, or:

```sh
supported:
  - netif:eth
  - sensor:bmi16
```

A testcase can both depend on ‘eth’ to only test ethernet or on ‘netif’ to run on any board with a networking interface.

**testing:**

testing relating keywords to provide best coverage for the features of this board.

**default:** [True|False]:

This is a default board, it will tested with the highest priority and is covered when invoking the simplified twister without any additional arguments.

**ignore_tags:**

Do not attempt to build (and therefore run) tests marked with this list of tags.

**only_tags:**

Only execute tests with this list of tags on a specific platform.
Test Cases

Test cases are detected by the presence of a ‘testcase.yaml’ or a ‘sample.yaml’ files in the application’s project directory. This file may contain one or more entries in the test section each identifying a test scenario.

The name of each testcase needs to be unique in the context of the overall testsuite and has to follow basic rules:

1. The format of the test identifier shall be a string without any spaces or special characters (allowed characters: alphanumeric and [_=]) consisting of multiple sections delimited with a dot (.)
2. Each test identifier shall start with a section followed by a subsection separated by a dot. For example, a test that covers semaphores in the kernel shall start with kernel.semaphore.
3. All test identifiers within a testcase.yaml file need to be unique. For example a testcase.yaml file covering semaphores in the kernel can have:
   - kernel.semaphore: For general semaphore tests
   - kernel.semaphore.stress: Stress testing semaphores in the kernel.
4. Depending on the nature of the test, an identifier can consist of at least two sections:
   - Ztest tests: The individual testcases in the ztest testsuite will be concatenated to identifier in the testcase.yaml file generating unique identifiers for every testcase in the suite.
   - Standalone tests and samples: This type of test should at least have 3 sections in the test identifier in the testcase.yaml (or sample.yaml) file. The last section of the name shall signify the test itself.

Test cases are written using the YAML syntax and share the same structure as samples. The following is an example test with a few options that are explained in this document.

```yaml
tests:
  bluetooth.gatt:
    build_only: true
    platform_allow: qemu_cortex_m3 qemu_x86
    tags: bluetooth
  bluetooth.gatt.br:
    build_only: true
    extra_args: CONF_FILE="prj_br.conf"
    filter: not CONFIG_DEBUG
    platform_exclude: up_squared
    platform_allow: qemu_cortex_m3 qemu_x86
    tags: bluetooth

A sample with tests will have the same structure with additional information related to the sample and what is being demonstrated:

```yaml
sample:
  name: hello world
  description: Hello World sample, the simplest Zephyr application
  tests:
    sample.basic.hello_world:
      build_only: true
      tags: tests
      min_ram: 16
    sample.basic.hello_world.singlethread:
      build_only: true
      extra_args: CONF_FILE=prj_single.conf
      filter: not CONFIG_BT
```
The full canonical name for each test case is:

<path to test case>/<test entry>

Each test block in the testcase meta data can define the following key/value pairs:

**tags: <list of tags>** *(required)*
A set of string tags for the testcase. Usually pertains to functional domains but can be anything. Command line invocations of this script can filter the set of tests to run based on tag.

**skip: <True|False>** *(default False)*
skip testcase unconditionally. This can be used for broken tests.

**slow: <True|False>** *(default False)*
Don't run this test case unless --enable-slow was passed in on the command line. Intended for time-consuming test cases that are only run under certain circumstances, like daily builds. These test cases are still compiled.

**extra_args: <list of extra arguments>*
Extra arguments to pass to Make when building or running the test case.

**extra_configs: <list of extra configurations>*
Extra configuration options to be merged with a master prj.conf when building or running the test case. For example:

```plaintext
common:
  tags: drivers adc
tests:
  test:
    depends_on: adc
test_async:
  extra_configs:
    - CONFIG_ADC_ASYNC=y
```

**build_only: <True|False>** *(default False)*
If true, don’t try to run the test even if the selected platform supports it.

**build_on_all: <True|False>** *(default False)*
If true, attempt to build test on all available platforms.

**depends_on: <list of features>*
A board or platform can announce what features it supports, this option will enable the test only those platforms that provide this feature.

**min_ram: <integer>*
minimum amount of RAM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

**min_flash: <integer>*
minimum amount of ROM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

**timeout: <number of seconds>*
Length of time to run test in QEMU before automatically killing it. Default to 60 seconds.

**arch_allow: <list of arches, such as x86, arm, arc>*
Set of architectures that this test case should only be run for.

**arch_exclude: <list of arches, such as x86, arm, arc>*
Set of architectures that this test case should not run on.
platform_allow: <list of platforms>
Set of platforms that this test case should only be run for. Do not use this option to limit testing or building in CI due to time or resource constraints, this option should only be used if the test or sample can only be run on the allowed platform and nothing else.

integration_platforms: <YML list of platforms/boards>
This option limits the scope to the listed platforms when twister is invoked with the –integration option. Use this instead of platform_allow if the goal is to limit scope due to timing or resource constraints.

platform_exclude: <list of platforms>
Set of platforms that this test case should not run on.

extra_sections: <list of extra binary sections>
When computing sizes, twister will report errors if it finds extra, unexpected sections in the Zephyr binary unless they are named here. They will not be included in the size calculation.

dev_timeout: <positive integer> (default None)
Set a limit on the time that each test case is allowed to run. If the test case takes longer than this amount of time to run, it will be timed out. This is used for device testing cases that may take a long time to run. Setting this value to None will disable the timeout.

device_start: <device start >
Run this before the test case starts. Useful for initializing hardware or setting up environments.

device_stop: <device stop >
Run this after the test case stops. Useful for cleaning up or shutting down hardware.

deviceroot: <deviceroot>
Set the root directory for the test case. Used to determine the location of test case files.

devicename: <devicename>
Set the name of the device for this test case. Used to identify the device in test case output.

devicetype: <devicetype>
Set the type of the device for this test case. Used to identify the device type in test case output.

devicememory: <devicememory>
Set the memory configuration for this test case. Used to identify the device memory in test case output.

devicecheck: <devicecheck>
Set the device check configuration for this test case. Used to identify the device check in test case output.

devicemodule: <devicemodule>
Set the device module configuration for this test case. Used to identify the device module in test case output.

devicemodulecheck: <devicemodulecheck>
Set the device module check configuration for this test case. Used to identify the device module check in test case output.

devicemoduleversion: <devicemoduleversion>
Set the device module version configuration for this test case. Used to identify the device module version in test case output.

devicemodulebuild: <devicemodulebuild>
Set the device module build configuration for this test case. Used to identify the device module build in test case output.

devicemodulecheckbuild: <devicemodulecheckbuild>
Set the device module check build configuration for this test case. Used to identify the device module check build in test case output.

The following options are currently supported:

type: <one_line|multi_line> (required)
Depends on the regex string to be matched

record: <recording options>

regex: <expression> (required)
Any string that the particular test case prints to record test results.

regex: <expression> (required)
Any string that the particular test case prints to confirm test runs as expected.

ordered: <True|False> (default False)
Check the regular expression strings in orderly or randomly fashion

repeat: <integer>
Number of times to validate the repeated regex expression

fixture: <expression>
Specify a test case dependency on an external device(e.g., sensor), and identify setups that fulfill this dependency. It depends on specific test setup and board selection logic to pick the particular board(s) out of multiple boards that fulfill the dependency in an automation setup based on “fixture” keyword. Some sample fixture names are i2c_hts221, i2c_bme280, i2c_FRAM, ble_fw and gpio_loop.

Only one fixture can be defined per testcase.

pytest_root: <pytest directory> (default pytest)
Specify a pytest directory which need to execute when test case begin to running, default pytest directory name is pytest, after pytest finished, twister will check if this case pass or fail according the pytest report.
pytest_args: <list of arguments> (default empty)
  Specify a list of additional arguments to pass to pytest.

The following is an example yaml file with a few harness_config options.

```yaml
sample:
  name: HTS221 Temperature and Humidity Monitor
common:
  tags: sensor
  harness: console
  harness_config:
    type: multi_line
    ordered: false
    regex:
      - "Temperature:(.*)C"
      - "Relative Humidity:(.*)%"
  fixture: i2c_hts221
tests:
  test:
    tags: sensors
    depends_on: i2c
```

The following is an example yaml file with pytest harness_config options, default pytest_root name "pytest" will be used if pytest_root not specified. please refer the example in samples/subsys/testsuite/pytest/.

```yaml
tests:
  pytest.example:
    harness: pytest
    harness_config:
      pytest_root: [pytest directory name]
```

filter: <expression>
  Filter whether the testcase should be run by evaluating an expression against an environment containing the following values:

```yaml
{ ARCH : <architecture>,
  PLATFORM : <platform>,
  <all CONFIG_* key/value pairs in the test's generated defconfig>,
  *<env>: any environment variable available
}
```

The grammar for the expression language is as follows:

expression ::= expression “and” expression

expression “or” expression

“not” expression

“(” expression “)”

symbol “==” constant

symbol “!”=” constant

symbol “<” number

symbol “>” number

symbol “>=” number

symbol “<=” number

symbol “in” list

symbol “:” string

symbol
list ::= "[" list_contents "]"

list_contents ::= constant

list_contents "," constant

constant ::= number

string

For the case where expression ::= symbol, it evaluates to true if the symbol is defined to a non-empty string.

Operator precedence, starting from lowest to highest:

- or (left associative) and (left associative) not (right associative)
- all comparison operators
- (non-associative)

arch_allow, arch_exclude, platform_allow, platform_exclude are all syntactic sugar for these expressions. For instance

arch_exclude = x86 arc

Is the same as:

filter = not ARCH in ["x86", "arc"]

The ‘:’ operator compiles the string argument as a regular expression, and then returns a true value only if the symbol’s value in the environment matches. For example, if CONFIG_SOC="stm32f107xc" then

filter = CONFIG_SOC : "stm.*"

Would match it.

The set of test cases that actually run depends on directives in the testcase filed and options passed in on the command line. If there is any confusion, running with -v or examining the discard report (twister_discard.csv) can help show why particular test cases were skipped.

Metrics (such as pass/fail state and binary size) for the last code release are stored in scripts/release/twister_last_release.csv. To update this, pass the --all --release options.

To load arguments from a file, write ‘+’ before the file name, e.g., +file_name. File content must be one or more valid arguments separated by line break instead of white spaces.

Most everyday users will run with no arguments.

Running in Integration Mode

This mode is used in continuous integration (CI) and other automated environments used to give developers fast feedback on changes. The mode can be activated using the --integration option of twister and narrows down the scope of builds and tests if applicable to platforms defined under the integration keyword in the testcase definition file (testcase.yaml and sample.yaml).

Running Tests on Hardware

Beside being able to run tests in QEMU and other simulated environments, twister supports running most of the tests on real devices and produces reports for each run with detailed FAIL/PASS results.
Executing tests on a single device  To use this feature on a single connected device, run twister with the following new options:

**Linux**

```
scripts/twister --device-testing --device-serial /dev/ttyACM0
--device-serial-baud 115200 -p frdm_k64f -T tests/kernel
```

**Windows**

```
python .\scripts\twister --device-testing --device-serial COM1
--device-serial-baud 115200 -p frdm_k64f -T tests/kernel
```

The `--device-serial` option denotes the serial device the board is connected to. This needs to be accessible by the user running twister. You can run this on only one board at a time, specified using the `--platform` option.

The `--device-serial-baud` option is only needed if your device does not run at 115200 baud.

To support devices without a physical serial port, use the `--device-serial-pty` option. In this cases, log messages are captured for example using a script. In this case you can run twister with the following options:

**Linux**

```
scripts/twister --device-testing --device-serial-pty "script.py"
-p intel_adsp_cavs25 -T tests/kernel
```

**Windows**

**Note:** Not supported on Windows OS

The script is user-defined and handles delivering the messages which can be used by twister to determine the test execution status.

Executing tests on multiple devices  To build and execute tests on multiple devices connected to the host PC, a hardware map needs to be created with all connected devices and their details such as the serial device, baud and their IDs if available. Run the following command to produce the hardware map:

**Linux**

```
./scripts/twister --generate-hardware-map map.yml
```

**Windows**

```
python .\scripts\twister --generate-hardware-map map.yml
```

The generated hardware map file (map.yml) will have the list of connected devices, for example:

**Linux**

```
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: unknown
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem14614202
- connected: true
  id: 000683759358
  platform: unknown
```
(continues on next page)
product: J-Link
runner: unknown
serial: /dev/cu.usbmodem0006837593581

Windows

- connected: true
  id: 000683759358
  platform: unknown
  product: unknown
  runner: unknown
  serial: COM1
- connected: true
  id: 000683759358
  platform: unknown
  product: unknown
  runner: unknown
  serial: COM2

Any options marked as 'unknown' need to be changed and set with the correct values, in the above example the platform names, the products and the runners need to be replaced with the correct values corresponding to the connected hardware. In this example we are using a reel_board and an nrf52840dk_nrf52840:

Linux

- connected: true
  id: 000683759358
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
  baud: 9600
- connected: true
  id: 000683759358
  platform: nrf52840dk_nrf52840
  product: J-Link
  runner: nrfjprog
  serial: /dev/cu.usbmodem0006837593581
  baud: 9600

Windows

- connected: true
  id: 000683759358
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: COM1
  baud: 9600
- connected: true
  id: 000683759358
  platform: nrf52840dk_nrf52840
  product: J-Link
  runner: nrfjprog
  serial: COM2
  baud: 9600
The baud entry is only needed if not running at 115200.

If the map file already exists, then new entries are added and existing entries will be updated. This way you can use one single master hardware map and update it for every run to get the correct serial devices and status of the devices.

With the hardware map ready, you can run any tests by pointing to the map

**Linux**

```
./scripts/twister --device-testing --hardware-map map.yml -T samples/hello_world/
```

**Windows**

```
python ./scripts/twister --device-testing --hardware-map map.yml -T samples\hello_world
```

The above command will result in twister building tests for the platforms defined in the hardware map and subsequently flashing and running the tests on those platforms.

---

**Note:** Currently only boards with support for both pyocd and nrfjprog are supported with the hardware map features. Boards that require other runners to flash the Zephyr binary are still work in progress.

---

Serial PTY support using `--device-serial-pty` can also be used in the hardware map:

```
- connected: true
  id: None
  platform: intel_adsp_cavs18
  product: None
  runner: intel_adsp
  serial_pty: path/to/script.py
  runner_params:
    - --remote-host=remote_host_ip_addr
    - --key=/path/to/key.pem
- connected: true
  id: None
  platform: intel_adsp_cavs25
  product: None
  runner: intel_adsp
  serial_pty: path/to/script.py
  runner_params:
    - --remote-host=remote_host_ip_addr
    - --key=/path/to/key.pem
```

The runner_params field indicates the parameters you want to pass to the west runner. For some boards the west runner needs some extra parameters to work. It is equivalent to following west and twister commands.

**Linux**

```
west flash --remote-host remote_host_ip_addr --key /path/to/key.pem
twister -p intel_adsp_cavs18 --device-testing --device-serial-pty script.py
 --west-flash="--remote-host=remote_host_ip_addr,--key=/path/to/key.pem"
```

**Windows**

**Note:** Not supported on Windows OS
**Note:** For serial PTY, the “--generate-hardware-map” option cannot scan it out and generate a correct hardware map automatically. You have to edit it manually according to above example. This is because the serial port of the PTY is not fixed and being allocated in the system at runtime.

**Fixtures** Some tests require additional setup or special wiring specific to the test. Running the tests without this setup or test fixture may fail. A testcase can specify the fixture it needs which can then be matched with hardware capability of a board and the fixtures it supports via the command line or using the hardware map file.

Fixtures are defined in the hardware map file as a list:

```plaintext
- connected: true
  fixtures:
    - gpio_loopback
      id: 0240000026334e450015400f5e0e00b4eb1000097969900
      platform: frdm_k64f
      product: DAPLink CMSIS-DAP
      runner: pyocd
      serial: /dev/ttyACM9
```

When running `twister` with `--device-testing`, the configured fixture in the hardware map file will be matched to testcases requesting the same fixtures and these test will be executed on the boards that provide this fixture.

Fixtures can also be provided via `twister` command option `--fixture`, this option can be used multiple times and all given fixtures will be appended as a list. And the given fixtures will be assigned to all boards, this means that all boards set by current `twister` command can run those testcases which request the same fixtures.

**Notes** It may be useful to annotate board descriptions in the hardware map file with additional information. Use the “notes” keyword to do this. For example:

```plaintext
- connected: false
  fixtures:
    - gpio_loopback
      id: 000683290670
      notes: An nrf5340dk_nrf5340 is detected as an nrf52840dk_nrf52840 with no serial port, and three serial ports with an unknown platform. The board id of the serial ports is not the same as the board id of the development kit. If you want to regenerate this file you will need to update serial to reference the third port, and platform to nrf5340dk_nrf5340_cpuapp or another supported board target.
      platform: nrf52840dk_nrf52840
      product: J-Link
      runner: jlink
      serial: null
```

**Overriding Board Identifier** When (re-)generated the hardware map file will contain an “id” keyword that serves as the argument to `--board-id` when flashing. In some cases the detected ID is not the correct one to use, for example when using an external J-Link probe. The “probe_id” keyword overrides the “id” keyword for this purpose. For example:

```plaintext
- connected: false
  id: 022900000059ebc6000000000000000000000000000000000000000
```

(continues on next page)
Quarantine Twister allows using user-defined yaml files defining the list of tests to be put under quarantine. Such tests will be skipped and marked accordingly in the output reports. This feature is especially useful when running larger test suits, where a failure of one test can affect the execution of other tests (e.g. putting the physical board in a corrupted state).

To use the quarantine feature one has to add the argument 

```bash
--quarantine-list
(PATH_TO_QUARANTINE_YAML)
```

to a twister call. The current status of tests on the quarantine list can also be verified by adding 

```bash
--quarantine-verify
```

to the above argument. This will make twister skip all tests which are not on the given list.

A quarantine yaml has to be a sequence of dictionaries. Each dictionary has to have “scenarios” and “platforms” entries listing combinations of scenarios and platforms to put under quarantine. In addition, an optional entry “comment” can be used, where some more details can be given (e.g. link to a reported issue). These comments will also be added to the output reports.

An example of entries in a quarantine yaml:

```yaml
- scenarios:
  - sample.basic.helloworld
  platforms:
    - all
  comment: "Link to the issue: https://github.com/zephyrproject-rtos/zephyr/pull/33287"

- scenarios:
  - kernel.common
  - kernel.common.misra
  - kernel.common.nano64
  platforms:
    - qemu_cortex_m3
    - native_posix
```

Running in Tests in Random Order

Enable ZTEST framework’s CONFIG_ZTEST_SHUFFLE config option to run your tests in random order. This can be beneficial for identifying dependencies between test cases. For native_posix platforms, you can provide the seed to the random number generator by providing 

```bash
-seed=value
```

as an argument to twister. See Shuffling Test Sequence for more details.

### 2.11.3 Generating coverage reports

With Zephyr, you can generate code coverage reports to analyze which parts of the code are covered by a given test or application.

You can do this in two ways:

- In a real embedded target or QEMU, using Zephyr’s gcov integration
- Directly in your host computer, by compiling your application targeting the POSIX architecture
Test coverage reports in embedded devices or QEMU

**Overview** GCC GCOV is a test coverage program used together with the GCC compiler to analyze and create test coverage reports for your programs, helping you create more efficient, faster running code and discovering untested code paths.

In Zephyr, gcov collects coverage profiling data in RAM (and not to a file system) while your application is running. Support for gcov collection and reporting is limited by available RAM size and so is currently enabled only for QEMU emulation of embedded targets.

**Details** There are 2 parts to enable this feature. The first is to enable the coverage for the device and the second to enable in the test application. As explained earlier the code coverage with gcov is a function of RAM available. Therefore ensure that the device has enough RAM when enabling the coverage for it. For example a small device like frdm_k64f can run a simple test application but the more complex test cases which consume more RAM will crash when coverage is enabled.

To enable the device for coverage, select `CONFIG_HAS_COVERAGE_SUPPORT` in the Kconfig.board file.

To report the coverage for the particular test application set `CONFIG_COVERAGE`.

**Steps to generate code coverage reports** These steps will produce an HTML coverage report for a single application.

1. Build the code with `CONFIG_COVERAGE=y`.
   ```bash
   west build -b mps2_an385 -- -DCONFIG_COVERAGE=y -DCONFIG_COVERAGE_DUMP=y
   ```
2. Capture the emulator output into a log file. You may need to terminate the emulator with Ctrl-A X for this to complete after the coverage dump has been printed:
   ```bash
   ninja -Cbuild run | tee log.log
   or
   ninja -Cbuild run | tee log.log
   ```
3. Generate the gcov .gcda and .gcno files from the log file that was saved:
   ```bash
   $ python3 scripts/gen_gcov_files.py -i log.log
   ```
4. Find the gcov binary placed in the SDK. You will need to pass the path to the gcov binary for the appropriate architecture when you later invoke gcovr:
   ```bash
   $ find $ZEPHYR_SDK_INSTALL_DIR -iregex ".*gcov"
   ```
5. Create an output directory for the reports:
   ```bash
   $ mkdir -p gcov_report
   ```
6. Run gcovr to get the reports:
   ```bash
   $ gcovr -r $ZEPHYR_BASE . --html --o gcov_report/coverage.html --html-details --gcov-executable <gcov_path_in_SDK>
   ```

**Coverage reports using the POSIX architecture**

When compiling for the POSIX architecture, you utilize your host native tooling to build a native executable which contains your application, the Zephyr OS, and some basic HW emulation.
That means you can use the same tools you would while developing any other desktop application.

To build your application with gcc's gcov, simply set CONFIG_COVERAGE before compiling it. When you run your application, gcov coverage data will be dumped into the respective gcda and gcno files. You may postprocess these with your preferred tools. For example:

```
west build -b native_posix samples/hello_world -- -DCONFIG_COVERAGE=y

$ ./build/zephyr/zephyr.exe
# Press Ctrl+C to exit
lcov --capture --directory ./ --output-file lcov.info -q --rc lcov_branch_coverage=1
genhtml lcov.info --output-directory lcov_html -q --ignore-errors source --branch--coverage --highlight --legend
```

**Note:** You need a recent version of lcov (at least 1.14) with support for intermediate text format. Such packages exist in recent Linux distributions. Alternatively, you can use gcovr (at least version 4.2).

**Coverage reports using Twister**

Zephyr's `twister script` can automatically generate a coverage report from the tests which were executed. You just need to invoke it with the `--coverage` command line option.

For example, you may invoke:

```
$ twister --coverage -p qemu_x86 -T tests/kernel
```

or:

```
$ twister --coverage -p native_posix -T tests/bluetooth
```

which will produce `twister-out/coverage/index.html` with the report.

The process differs for unit tests, which are built with the host toolchain and require a different board:

```
$ twister --coverage -p unit_testing -T tests/unit
```

which produces a report in the same location as non-unit testing.

### 2.11.4 Sparse support

Sparse is a static code analysis tool. Apart from performing common code analysis tasks it also supports an `address_space` attribute, which allows introduction of distinct address spaces in C code with subsequent verification that pointers to different address spaces do not get confused. Additionally it supports a `force` attribute which should be used to cast pointers between different address spaces. At the moment Zephyr introduces a single custom address space `__cache` used to identify pointers from the cached address range on the Xtensa architecture. This helps identify cases where cached and uncached addresses are confused.

**Running with sparse**

To run a sparse verification build `west build` should be called with a `-DSPARSE=y` parameter, e.g.

```
wester build -d hello -b intel_adsp_cavs25 zephyr/samples/hello_world -- -DSPARSE=y
```
2.11.5 ZTest Deprecated APIs

Ztest is currently being migrated to a new API, this documentation provides information about the deprecated APIs which will eventually be removed. See Test Framework for the new API. Similarly, ZTest's mocking framework is also deprecated (see Mocking via FFF).

Quick start - Unit testing

Ztest can be used for unit testing. This means that rather than including the entire Zephyr OS for testing a single function, you can focus the testing efforts into the specific module in question. This will speed up testing since only the module will have to be compiled in, and the tested functions will be called directly.

Since you won't be including basic kernel data structures that most code depends on, you have to provide function stubs in the test. Ztest provides some helpers for mocking functions, as demonstrated below.

In a unit test, mock objects can simulate the behavior of complex real objects and are used to decide whether a test failed or passed by verifying whether an interaction with an object occurred, and if required, to assert the order of that interaction.

Best practices for declaring the test suite  

Twister and other validation tools need to obtain the list of subcases that a Zephyr ztest test image will expose.

Rationale

This all is for the purpose of traceability. It's not enough to have only a semaphore test project. We also need to show that we have testpoints for all APIs and functionality, and we trace back to documentation of the API, and functional requirements.

The idea is that test reports show results for every sub-testcase as passed, failed, blocked, or skipped. Reporting on only the high-level test project level, particularly when tests do too many things, is too vague.

There exist two alternatives to writing tests. The first, and more verbose, approach is to directly declare and run the test suites. Here is a generic template for a test showing the expected use of ztest_test_suite():

```c
#define CONFIG_WHATEVER /* Conditionally skip test_sometest3 */
void test_sometest3(void)
{
    ztest_test_skip();
}
else
void test_sometest4(void);
...

void test_main(void)
{
    ztest_test_suite(common,
                     ztest_unit_test(test_sometest1),
                     ztest_unit_test(test_sometest2),
                     ...
    
(continues on next page)```
ztest_unit_test(test_sometest3),
    ztest_unit_test(test_sometest4)
);  
ztest_run_test_suite(common);
}

Alternatively, it is possible to split tests across multiple files using ztest_register_test_suite() which bypasses the need for extern:

```c
#include <zephyr/ztest.h>

void test_sometest1(void) {
    zassert_true(1, "true");
}

ztest_register_test_suite(common, NULL,
                           ztest_unit_test(test_sometest1)
                          );
```

The above sample simple registers the test suite and uses a NULL pragma function (more on that later). It is important to note that the test suite isn't directly run in this file. Instead two alternatives exist for running the suite. First, if to do nothing. A default test_main function is provided by ztest. This is the preferred approach if the test doesn't involve a state and doesn't require use of the pragma.

In cases of an integration test it is possible that some general state needs to be set between test suites. This can be thought of as a state diagram in which test_main simply goes through various actions that modify the board's state and different test suites need to run. This is achieved in the following:

```c
#include <zephyr/ztest.h>

struct state {
    bool is_hibernating;
    bool is_usb_connected;
}

static bool pragma_always(const void *state) {
    return true;
}

static bool pragma_not_hibernating_not_connected(const void *s) {
    struct state *state = s;
    return !state->is_hibernating && !state->is_usb_connected;
}

static bool pragma_usb_connected(const void *s) {
    return ((struct state *)s)->is_usb_connected;
}

ztest_register_test_suite(baseline, pragma_always,
                         ztest_unit_test(test_case0));
ztest_register_test_suite(before_usb, pragma_not_hibernating_not_connected,
                          ztest_unit_test(test_case1),
                          ztest_unit_test(test_case2));
ztest_register_test_suite(with_usb, pragma_usb_connected,
                          (continues on next page)
ztest_unit_test(test_case3),
ztest_unit_test(test_case4));

void test_main(void)
{
    struct state state;

    /* Should run `baseline` test suite only. */
    ztest_run_registered_test_suites(&state);

    /* Simulate power on and update state. */
    emulate_power_on();
    /* Should run `baseline` and `before_usb` test suites. */
    ztest_run_registered_test_suites(&state);

    /* Simulate plugging in a USB device. */
    emulate_plugging_in_usb();
    /* Should run `baseline` and `with_usb` test suites. */
    ztest_run_registered_test_suites(&state);

    /* Verify that all the registered test suites actually ran. */
    ztest_verify_all_registered_test_suites_ran();
}

For twister to parse source files and create a list of subcases, the declarations of ztest_test_suite() and ztest_register_test_suite() must follow a few rules:

- one declaration per line
- conditional execution by using ztest_test_skip()

What to avoid:

- packing multiple testcases in one source file

void test_main(void)
{
    #ifdef TEST_feature1
    ztest_test_suite(feature1,
    ztest_unit_test(test_1a),
    ztest_unit_test(test_1b),
    ztest_unit_test(test_1c)
    );
    ztest_run_test_suite(feature1);
    #endif

    #ifdef TEST_feature2
    ztest_test_suite(feature2,
    ztest_unit_test(test_2a),
    ztest_unit_test(test_2b)
    );
    ztest_run_test_suite(feature2);
    #endif

    • Do not use #if

    ztest_test_suite(common,
    ztest_unit_test(test_sometest1),

• Do not add comments on lines with a call to ztest_unit_test():

```c
ztest_test_suite(common,
    ztest_unit_test(test_sometest1),
    ztest_unit_test(test_sometest2) /* will fail */,
    /* will fail! */ ztest_unit_test(test_sometest3),
    ztest_unit_test(test_sometest4),
...}
```

• Do not define multiple definitions of unit / user unit test case per line

```c
ztest_test_suite(common,
    ztest_unit_test(test_sometest1), ztest_unit_test(test_sometest2),
    ztest_unit_test(test_sometest3),
    ztest_unit_test(test_sometest4),
...}
```

Other questions:

• Why not pre-scan with CPP and then parse? or post scan the ELF file?
  If C pre-processing or building fails because of any issue, then we won’t be able to tell the subcases.

• Why not declare them in the YAML testcase description?
  A separate testcase description file would be harder to maintain than just keeping the information
  in the test source files themselves – only one file to update when changes are made eliminates
  duplication.

Mocking

These functions allow abstracting callbacks and related functions and controlling them from specific
tests. You can enable the mocking framework by setting CONFIG_ZTEST_MOCKING to “y” in the configu-
ration file of the test. The amount of concurrent return values and expected parameters is limited by
CONFIG_ZTEST_PARAMETER_COUNT.

Here is an example for configuring the function expect_two_parameters to expect the values \(a=2\) and \(b=3\), and telling returns_int to return 5:

```c
#include <zephyr/ztest.h>

static void expect_two_parameters(int a, int b)
{
    ztest_check_expected_value(a);
    ztest_check_expected_value(b);
}

static void parameter_tests(void)
{
    ztest_expect_value(expect_two_parameters, a, 2);
}
group ztest_mock

This module provides simple mocking functions for unit testing. These need CONFIG_ZTEST_MOCKING=y.

**Defines**

ztest_expect_value(func, param, value)

Tell function *func* to expect the value *value* for *param*. When using ztest_check_expected_value(), tell that the value of *param* should be *value*. The value will internally be stored as an uintptr_t.

**Parameters**

- func – Function in question
- param – Parameter for which the value should be set
- value – Value for *param*

ztest_check_expected_value(param)

If *param* doesn’t match the value set by ztest_expect_value(), fail the test.

This will first check that does *param* have a value to be expected, and then checks whether the value of the parameter is equal to the expected value. If either of these checks fail, the current test will fail. This must be called from the called function.

**Parameters**

- param – Parameter to check

ztest_expect_data(func, param, data)

Tell function *func* to expect the data *data* for *param*.  

2.11. Testing
When using `ztest_check_expected_data()`, the data pointed to by `param` should be same `data` in this function. Only data pointer is stored by this function, so it must still be valid when `ztest_check_expected_data` is called.

**Parameters**

- `func` – Function in question
- `param` – Parameter for which the data should be set
- `data` – pointer for the data for parameter `param`

```c
ztest_check_expected_data(param, length)
```

If data pointed by `param` don’t match the data set by `ztest_expect_data()`, fail the test.

This will first check that `param` is expected to be null or non-null and then check whether the data pointed by parameter is equal to expected data. If either of these checks fail, the current test will fail. This must be called from the called function.

**Parameters**

- `param` – Parameter to check
- `length` – Length of the data to compare

```c
ztest_return_data(func, param, data)
```

Tell function `func` to return the data `data` for `param`.

When using `ztest_return_data()`, the data pointed to by `param` should be same `data` in this function. Only data pointer is stored by this function, so it must still be valid when `ztest_copy_return_data` is called.

**Parameters**

- `func` – Function in question
- `param` – Parameter for which the data should be set
- `data` – pointer for the data for parameter `param`

```c
ztest_copy_return_data(param, length)
```

Copy the data set by `ztest_return_data` to the memory pointed by `param`.

This will first check that `param` is not null and then copy the data. This must be called from the called function.

**Parameters**

- `param` – Parameter to return data for
- `length` – Length of the data to return

```c
ztest_returns_value(func, value)
```

Tell `func` that it should return `value`.

**Parameters**

- `func` – Function that should return `value`
- `value` – Value to return from `func`

```c
ztest_get_return_value()
```

Get the return value for current function.

The return value must have been set previously with `ztest_returns_value()`. If no return value exists, the current test will fail.

**Returns**

The value the current function should return
ztest_get_return_value_ptr()

Get the return value as a pointer for current function.

The return value must have been set previously with `ztest_returns_value()`. If no return value exists, the current test will fail.

**Returns**

The value the current function should return as a `void *`

## 2.12 Toolchains

Guides on how to set up toolchains for Zephyr development.

### 2.12.1 Zephyr SDK

The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr's supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).

**Supported architectures**

The Zephyr SDK supports the following target architectures:

- ARC (32-bit and 64-bit; ARCv1, ARCv2, ARCv3)
- ARM (32-bit and 64-bit; ARMv6, ARMv7, ARMv8; A/R/M Profiles)
- MIPS (32-bit and 64-bit)
- Nios II
- RISC-V (32-bit and 64-bit; RV32I, RV32E, RV64I)
- x86 (32-bit and 64-bit)
- Xtensa

**Installation bundle and variables**

The Zephyr SDK bundle supports all major operating systems (Linux, macOS and Windows) and is delivered as a compressed file. The installation consists of extracting the file and running the included setup script. Additional OS-specific instructions are described in the sections below.

If no toolchain is selected, the build system looks for Zephyr SDK and uses the toolchain from there. You can enforce this by setting the environment variable `ZEPHYR_TOOLCHAIN_VARIANT` to `zephyr`.

If you install the Zephyr SDK outside any of the default locations (listed in the operating system specific instructions below) and you want automatic discovery of the Zephyr SDK, then you must register the Zephyr SDK in the CMake package registry by running the setup script. If you decide not to register the Zephyr SDK in the CMake registry, then the `ZEPHYR_SDK_INSTALL_DIR` can be used to point to the Zephyr SDK installation directory.

You can also set `ZEPHYR_SDK_INSTALL_DIR` to point to a directory containing multiple Zephyr SDKs, allowing for automatic toolchain selection. For example, you can set `ZEPHYR_SDK_INSTALL_DIR` to `/company/tools`, where the `company/tools` folder contains the following subfolders:

- `/company/tools/zephyr-sdk-0.13.2`
- `/company/tools/zephyr-sdk-a.b.c`
This allows the Zephyr build system to choose the correct version of the SDK, while allowing multiple Zephyr SDKs to be grouped together at a specific path.

Install Zephyr SDK on Linux

1. Download and verify the latest Zephyr SDK bundle:

```
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/zephyr-sdk-0.15.2_linux-x86_64.tar.gz
wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/SHA-256.sum | sha256sum --check --ignore-missing
```

You can change 0.15.2 to another version if needed; the Zephyr SDK Releases page contains all available SDK releases.

If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace x86_64 with aarch64 in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

```
cd <sdk download directory>
tar xvf zephyr-sdk-0.15.2_linux-x86_64.tar.gz
```

3. Run the Zephyr SDK bundle setup script:

```
./setup.sh
```

If this fails, make sure Zephyr’s dependencies were installed as described in Install Requirements and Dependencies.

If you want to uninstall the SDK, remove the directory where you installed it. If you relocate the SDK directory, you need to re-run the setup script.

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following default locations:

- `$HOME`
- `$HOME/.local`
- `$HOME/.local/opt`
- `$HOME/bin`
- `/opt`
- `/usr/local`

The Zephyr SDK bundle archive contains the zephyr-sdk-0.15.2 directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-0.15.2`.

Install Zephyr SDK on macOS

1. Download and verify the latest Zephyr SDK bundle:

```
cd ~
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/zephyr-sdk-0.15.2_macos-x86_64.tar.gz
```

(continues on next page)
If your host architecture is 64-bit ARM (Apple Silicon, also known as M1), replace x86_64 with aarch64 in order to download the 64-bit ARM macOS SDK.

2. Extract the Zephyr SDK bundle archive:

```
tar xvf zephyr-sdk-0.15.2_macos-x86_64.tar.gz
```

_Note:_ It is recommended to extract the Zephyr SDK bundle at one of the following default locations:

- $HOME
- $HOME/.local
- $HOME/.local/opt
- $HOME/bin
- /opt
- /usr/local

The Zephyr SDK bundle archive contains the `zephyr-sdk-0.15.2` directory and, when extracted under $HOME, the resulting installation path will be $HOME/zephyr-sdk-0.15.2.

3. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-0.15.2
./setup.sh
```

_Note:_ You only need to run the setup script once after extracting the Zephyr SDK bundle.

You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

### Install Zephyr SDK on Windows

1. Open a cmd.exe window by pressing the Windows key typing “cmd.exe”.

2. Download the latest Zephyr SDK bundle:

```
cd %HOMEPATH%
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.15.2/zephyr-sdk-0.15.2_windows-x86_64.zip
```

3. Extract the Zephyr SDK bundle archive:

```
unzip zephyr-sdk-0.15.2_windows-x86_64.zip
```

_Note:_ It is recommended to extract the Zephyr SDK bundle at one of the following default locations:

- %HOMEPATH%
- %PROGRAMFILES%
The Zephyr SDK bundle archive contains the `zephyr-sdk-0.15.2` directory and, when extracted under `%HOMEPATH%`, the resulting installation path will be `%HOMEPATH%\zephyr-sdk-0.15.2`.

4. Run the Zephyr SDK bundle setup script:

```bash
cd zephyr-sdk-0.15.2
setup.cmd
```

**Note:** You only need to run the setup script once after extracting the Zephyr SDK bundle. You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

### 2.12.2 Arm Compiler 6

1. Download and install a development suite containing the Arm Compiler 6 for your operating system.

2. **Set these environment variables:**
   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `armclang`.
   - Set `ARMCLANG_TOOLCHAIN_PATH` to the toolchain installation directory.

3. The Arm Compiler 6 needs the `ARMLMD_LICENSE_FILE` environment variable to point to your license file or server. For example:

   ```bash
   # Linux, macOS, license file:
   export ARMLMD_LICENSE_FILE=/<path>/license_armds.dat
   # Linux, macOS, license server:
   export ARMLMD_LICENSE_FILE=8224@myserver
   
   # Windows, license file:
   set ARMLMD_LICENSE_FILE=c:\<path>\license_armds.dat
   # Windows, license server:
   set ARMLMD_LICENSE_FILE=8224@myserver
   ```

1. If the Arm Compiler 6 was installed as part of an Arm Development Studio, then you must set the `ARM_PRODUCT_DEF` to point to the product definition file: See also: Product and toolkit configuration. For example if the Arm Development Studio is installed in: `/opt/armds-2020-1` with a Gold license, then set `ARM_PRODUCT_DEF` to point to `/opt/armds-2020-1/gold.elmap`.

**Note:** The Arm Compiler 6 uses `armlink` for linking. This is incompatible with Zephyr's linker script template, which works with GNU ld. Zephyr's Arm Compiler 6 support Zephyr's CMake linker script generator, which supports generating scatter files. Basic scatter file support is in place, but there are still areas covered in ld templates which are not fully supported by the CMake linker script generator.

Some Zephyr subsystems or modules may also contain C or assembly code that relies on GNU intrinsics and have not yet been updated to work fully with `armclang`. 

---

Chapter 2. Developing with Zephyr
2.12.3 Cadence Tensilica Xtensa C/C++ Compiler (XCC)

1. Obtain Tensilica Software Development Toolkit targeting the specific SoC on hand. This usually contains two parts:
   - The Xtensa Xplorer which contains the necessary executables and libraries.
   - A SoC-specific add-on to be installed on top of Xtensa Xplorer.
     - This add-on allows the compiler to generate code for the SoC on hand.
2. Install Xtensa Xplorer and then the SoC add-on.
   - Follow the instruction from Cadence on how to install the SDK.
   - Depending on the SDK, there are two set of compilers:
     - GCC-based compiler: xt-xcc and its friends.
     - Clang-based compiler: xt-clang and its friends.
3. Make sure you have obtained a license to use the SDK, or has access to a remote licensing server.
4. Set these environment variables:
   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `xcc` or `xcc-clang`.
   - Set `XTENSA_TOOLCHAIN_PATH` to the toolchain installation directory.
   - Set `XTENSA_CORE` to the SoC ID where application is being targeting.
   - Set `TOOLCHAIN_VER` to the Xtensa SDK version.
5. For example, assuming the SDK is installed in `/opt/xtensa`, and using the SDK for application development on `intel_adsp_cavs15`, setup the environment using:

   ```
   # Linux
   export ZEPHYR_TOOLCHAIN_VARIANT=xcc
   export XTENSA_TOOLCHAIN_PATH=/opt/xtensa/XtDevTools/install/tools/
   export XTENSA_CORE=X6H3SUE_RI_2018_0
   export TOOLCHAIN_VER=RI-2018.0-linux
   ```
6. To use Clang-based compiler:
   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `xcc-clang`.
   - Note that the Clang-based compiler may contain an old LLVM bug which results in the following error:

     ```
     /tmp/file.s: Assembler messages:
     /tmp/file.s:20: Error: file number 1 already allocated
     clang-3.9: error: Xtensa-as command failed with exit code 1
     ```

     If this happens, set `XCC_NO_G_FLAG` to 1.
     - For example:

     ```
     # Linux
     export XCC_NO_G_FLAG=1
     ```
   - Also note that setting `XCC_USE_CLANG` to 1 and `ZEPHYR_TOOLCHAIN_VARIANT` to `xcc` is deprecated. Set `ZEPHYR_TOOLCHAIN_VARIANT` to `xcc-clang` instead.

2.12.4 DesignWare ARC MetaWare Development Toolkit (MWDT)

1. You need to have ARC MWDT installed on your host.
2. *Set these environment variables:*
   - Set `$ZEPHYR_TOOLCHAIN_VARIANT` to `arcmwdr`.
   - Set `$ARCMWDT_TOOLCHAIN_PATH` to the toolchain installation directory. MWDT installation provides $METAWARE_ROOT$ so simply set `$ARCMWDT_TOOLCHAIN_PATH` to `$METAWARE_ROOT/..` (Linux) or `%METAWARE_ROOT%\..` (Windows)

3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `$ARCMWDT_TOOLCHAIN_PATH` values may be different on your system):

   ```bash
   # Linux:
   $ echo $ZEPHYR_TOOLCHAIN_VARIANT
   arcmwdr
   $ echo $ARCMWDT_TOOLCHAIN_PATH
   /home/you/ARC/MWDT_2019.12/
   
   # Windows:
   > echo %ZEPHYR_TOOLCHAIN_VARIANT%
   arcmwdr
   > echo %ARCMWDT_TOOLCHAIN_PATH%
   C:\ARC\MWDT_2019.12\   
   
   2.12.5 GNU Arm Embedded

1. Download and install a GNU Arm Embedded build for your operating system and extract it on your file system.

   **Note:** On Windows, we'll assume for this guide that you install into the directory `C:\gnu_arm_embedded`. You can also choose the default installation path used by the ARM GCC installer, in which case you will need to adjust the path accordingly in the guide below.

   **Warning:** On macOS Catalina or later you might need to change a security policy for the toolchain to be able to run from the terminal.

2. *Set these environment variables:*
   - Set `$ZEPHYR_TOOLCHAIN_VARIANT` to `gnuarmemb`.
   - Set `$GNUARMEMB_TOOLCHAIN_PATH` to the toolchain installation directory.

3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `GNUARMEMB_TOOLCHAIN_PATH` values may be different on your system):

   ```bash
   # Linux, macOS:
   $ echo $ZEPHYR_TOOLCHAIN_VARIANT
   gnuarmemb
   $ echo $GNUARMEMB_TOOLCHAIN_PATH
   /home/you/Downloads/gnu_arm_embedded
   
   # Windows:
   > echo %ZEPHYR_TOOLCHAIN_VARIANT%
   gnuarmemb
   > echo %GNUARMEMB_TOOLCHAIN_PATH%
   C:\gnu_arm_embedded
   ```
2.12.6 Intel oneAPI Toolkit

1. Download Intel oneAPI Base Toolkit

2. Assuming the toolkit is installed in `/opt/intel/oneApi`, set environment using:

   ```
   # Linux, macOS:
   export ONEAPI_TOOLCHAIN_PATH=/opt/intel/oneapi
   source $ONEAPI_TOOLCHAIN_PATH/compiler/latest/env/vars.sh
   
   # Windows:
   > set ONEAPI_TOOLCHAIN_PATH=C:\Users\Intel\oneapi
   ```

   To setup the complete oneApi environment, use:

   ```
   source /opt/intel/oneapi/setvars.sh
   ```

   The above will also change the python environment to the one used by the toolchain and might conflict with what Zephyr uses.

3. Set `ZEPHYR_TOOLCHAIN_VARIANT` to `oneApi`.

2.12.7 Crosstool-NG

You can build toolchains from source code using crosstool-NG.

1. Follow the steps on the crosstool-NG website to prepare your host.

2. Follow the Zephyr SDK with Crosstool NG instructions to build your toolchain. Repeat as necessary to build toolchains for multiple target architectures.

   You will need to clone the `sdk-ng` repo and run the following command:

   ```
   ./go.sh <arch>
   ```

   **Note:** Currently, only i586 and Arm toolchain builds are verified.

3. Set these environment variables:

   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `xtools`.
   - Set `XTOOLSC_TOOLCHAIN_PATH` to the toolchain build directory.

4. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `XTOOLSC_TOOLCHAIN_PATH` values may be different on your system):

   ```
   # Linux, macOS:
   $ echo $ZEPHYR_TOOLCHAIN_VARIANT
   xtools
   ```
2.12.8 Host Toolchains

In some specific configurations, like when building for non-MCU x86 targets on a Linux host, you may be able to re-use the native development tools provided by your operating system.

To use your host gcc, set the ZEPHYR_TOOLCHAIN_VARIANT environment variable to host. To use clang, set ZEPHYR_TOOLCHAIN_VARIANT to llvm.

2.12.9 Other Cross Compilers

This toolchain variant is borrowed from the Linux kernel build system's mechanism of using a CROSS_COMPILE environment variable to set up a GNU-based cross toolchain.

Examples of such “other cross compilers” are cross toolchains that your Linux distribution packaged, that you compiled on your own, or that you downloaded from the net. Unlike toolchains specifically listed in Toolchains, the Zephyr build system may not have been tested with them, and doesn’t officially support them. (Nonetheless, the toolchain set-up mechanism itself is supported.)

Follow these steps to use one of these toolchains.

1. **Install a cross compiler suitable for your host and target systems.**

   For example, you might install the gcc-arm-none-eabi package on Debian-based Linux systems, or arm-none-eabi-newlib on Fedora or Red Hat:

   ```bash
   # On Debian or Ubuntu
   sudo apt-get install gcc-arm-none-eabi
   # On Fedora or Red Hat
   sudo dnf install arm-none-eabi-newlib
   ```

2. **Set these environment variables:**

   - Set ZEPHYR_TOOLCHAIN_VARIANT to cross-compile.
   - Set CROSS_COMPILE to the common path prefix which your toolchain's binaries have, e.g. the path to the directory containing the compiler binaries plus the target triplet and trailing dash.

3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the CROSS_COMPILE value may be different on your system):

   ```bash
   # Linux, macOS:
   $ echo $ZEPHYR_TOOLCHAIN_VARIANT
   cross-compile
   $ echo $CROSS_COMPILE
   /usr/bin/arm-none-eabi-
   ```

   You can also set CROSS_COMPILE as a CMake variable.

When using this option, all of your toolchain binaries must reside in the same directory and have a common file name prefix. The CROSS_COMPILE variable is set to the directory concatenated with the file name prefix. In the Debian example above, the gcc-arm-none-eabi package installs binaries such as arm-none-eabi-gcc and arm-none-eabi-ld in directory /usr/bin/, so the common prefix is /usr/bin/arm-none-eabi- (including the trailing dash, -). If your toolchain is installed in /opt/mytoolchain/bin with binary names based on target triplet myarch-none-elf, CROSS_COMPILE would be set to /opt/mytoolchain/bin/myarch-none-elf-.
2.12.10 Custom CMake Toolchains

To use a custom toolchain defined in an external CMake file, set these environment variables:

- Set ZEPHYR_TOOLCHAIN_VARIANT to your toolchain's name
- Set TOOLCHAIN_ROOT to the path to the directory containing your toolchain's CMake configuration files.

Zephyr will then include the toolchain cmake files located in the TOOLCHAIN_ROOT directory:

- cmake/toolchain/<toolchain name>/generic.cmake: configures the toolchain for "generic" use, which mostly means running the C preprocessor on the generated Devicetree file.
- cmake/toolchain/<toolchain name>/target.cmake: configures the toolchain for "target" use, i.e. building Zephyr and your application's source code.

Here <toolchain name> is the same as the name provided in ZEPHYR_TOOLCHAIN_VARIANT. See the zephyr files cmake/modules/FindHostTools.cmake and cmake/modules/FindTargetTools.cmake for more details on what your generic.cmake and target.cmake files should contain.

You can also set ZEPHYR_TOOLCHAIN_VARIANT and TOOLCHAIN_ROOT as CMake variables when generating a build system for a Zephyr application, like so:

```
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

```
cmake -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

If you do this, -C <initial-cache> cmake option may useful. If you save your ZEPHYR_TOOLCHAIN_VARIANT, TOOLCHAIN_ROOT, and other settings in a file named my-toolchain.cmake, you can then invoke cmake as cmake -C my-toolchain.cmake ... to save typing.

Zephyr includes include/toolchain.h which again includes a toolchain specific header based on the compiler identifier, such as __llvm__ or __GNUC__. Some custom compilers identify themselves as the compiler on which they are based, for example llvm which then gets the toolchain/llvm.h included. This included file may though not be right for the custom toolchain. In order to solve this, and thus to get the include/other.h included instead, add the set(TOOLCHAIN_USE_CUSTOM 1) cmake line to the generic.cmake and/or target.cmake files located under <TOOLCHAIN_ROOT>/cmake/toolchain/<toolchain name>/.

When TOOLCHAIN_USE_CUSTOM is set, the other.h must be available out-of-tree and it must include the correct header for the custom toolchain. A good location for the other.h header file, would be a directory under the directory specified in TOOLCHAIN_ROOT as include/toolchain. To get the toolchain header included in zephyr's build, the USERINCLUDE can be set to point to the include directory, as shown here:

```
west build -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=... -DUSERINCLUDE=...
```

2.13 Tools and IDEs

2.13.1 Coccinelle

Coccinelle is a tool for pattern matching and text transformation that has many uses in kernel development, including the application of complex, tree-wide patches and detection of problematic programming patterns.

**Note:** Linux and macOS development environments are supported, but not Windows.
Getting Coccinelle

The semantic patches included in the kernel use features and options which are provided by Coccinelle version 1.0.0-rc11 and above. Using earlier versions will fail as the option names used by the Coccinelle files and `coccicheck` have been updated.

Coccinelle is available through the package manager of many distributions, e.g.:

- Debian
- Fedora
- Ubuntu
- OpenSUSE
- Arch Linux
- NetBSD
- FreeBSD

Some distribution packages are obsolete and it is recommended to use the latest version released from the Coccinelle homepage at http://coccinelle.lip6.fr/

Or from Github at:
https://github.com/coccinelle/coccinelle

Once you have it, run the following commands:

```
./autogen
./configure
make
```

as a regular user, and install it with:

```
sudo make install
```

More detailed installation instructions to build from source can be found at:

https://github.com/coccinelle/coccinelle/blob/master/install.txt

Supplemental documentation

For Semantic Patch Language (SmPL) grammar documentation refer to:

https://coccinelle.gitlabpages.inria.fr/website/documentation.html

Using Coccinelle on Zephyr

coccicheck checker is the front-end to the Coccinelle infrastructure and has various modes:

Four basic modes are defined: `patch`, `report`, `context`, and `org`. The mode to use is specified by setting `--mode=<mode>` or `-m=<mode>`.

- `patch` proposes a fix, when possible.
- `report` generates a list in the following format: `file:line:column-column: message`
- `context` highlights lines of interest and their context in a diff-like style. Lines of interest are indicated with `-`.
- `org` generates a report in the Org mode format of Emacs.
Note that not all semantic patches implement all modes. For easy use of Coccinelle, the default mode is `report`.

Two other modes provide some common combinations of these modes.

- `chain` tries the previous modes in the order above until one succeeds.
- `rep+ctxt` runs successively the report mode and the context mode. It should be used with the `C` option (described later) which checks the code on a file basis.

### Examples

To make a report for every semantic patch, run the following command:

```
./scripts/coccischeck --mode=report
```

To produce patches, run:

```
./scripts/coccischeck --mode=patch
```

The `coccischeck` target applies every semantic patch available in the sub-directories of `scripts/coccinelle` to the entire source code tree.

For each semantic patch, a commit message is proposed. It gives a description of the problem being checked by the semantic patch, and includes a reference to Coccinelle.

As any static code analyzer, Coccinelle produces false positives. Thus, reports must be carefully checked, and patches reviewed.

**To enable verbose messages set** `--verbose=1` option, for example:

```
./scripts/coccischeck --mode=report --verbose=1
```

### Coccinelle parallelization

By default, `coccischeck` tries to run as parallel as possible. To change the parallelism, set the `--jobs=<number>` option. For example, to run across 4 CPUs:

```
./scripts/coccischeck --mode=report --jobs=4
```

As of Coccinelle 1.0.2 Coccinelle uses Ocaml parmap for parallelization, if support for this is detected you will benefit from parmap parallelization.

When parmap is enabled `coccischeck` will enable dynamic load balancing by using `--chunksize 1` argument, this ensures we keep feeding threads with work one by one, so that we avoid the situation where most work gets done by only a few threads. With dynamic load balancing, if a thread finishes early we keep feeding it more work.

When parmap is enabled, if an error occurs in Coccinelle, this error value is propagated back, the return value of the `coccischeck` command captures this return value.

### Using Coccinelle with a single semantic patch

The option `--cocci` can be used to check a single semantic patch. In that case, the variable must be initialized with the name of the semantic patch to apply.

For instance:

```
./scripts/coccischeck --mode=report --cocci=<example.cocci>
```

or:
Controlling which files are processed by Coccinelle

By default the entire source tree is checked.

To apply Coccinelle to a specific directory, pass the path of specific directory as an argument.

For example, to check `drivers/usb/` one may write:

```
./scripts/coccicheck --mode=patch drivers/usb/
```

The report mode is the default. You can select another one with the `--mode=<mode>` option explained above.

Debugging Coccinelle SmPL patches

Using coccicheck is best as it provides in the spatch command line include options matching the options used when we compile the kernel. You can learn what these options are by using verbose option, you could then manually run Coccinelle with debug options added.

Alternatively you can debug running Coccinelle against SmPL patches by asking for stderr to be redirected to stderr, by default stderr is redirected to /dev/null, if you’d like to capture stderr you can specify the `--debug=file.err` option to coccicheck. For instance:

```
rm -f cocci.err
./scripts/coccicheck --mode=patch --debug=cocci.err
cat cocci.err
```

Debugging support is only supported when using Coccinelle >= 1.0.2.

Additional Flags

Additional flags can be passed to spatch through the SPFLAGS variable. This works as Coccinelle respects the last flags given to it when options are in conflict.

```
./scripts/coccicheck --sp-flag="--use-glimpse"
```

Coccinelle supports idutils as well but requires coccinelle >= 1.0.6. When no ID file is specified coccinelle assumes your ID database file is in the file .id-utils.index on the top level of the kernel, coccinelle carries a script scripts/idutils_index.sh which creates the database with:

```
mkid -i C --output .id-utils.index
```

If you have another database filename you can also just symlink with this name.

```
./scripts/coccicheck --sp-flag="--use-idutils"
```

Alternatively you can specify the database filename explicitly, for instance:

```
./scripts/coccicheck --sp-flag="--use-idutils /full-path/to/ID"
```

Sometimes coccinelle doesn’t recognize or parse complex macro variables due to insufficient definition. Therefore, to make it parsable we explicitly provide the prototype of the complex macro using the `--macro-file-builtins <headerfile.h>` flag.

The `<headerfile.h>` should contain the complete prototype of the complex macro from which spatch engine can extract the type information required during transformation.
For example:

`Z_SYSCALL_HANDLER` is not recognized by coccinelle. Therefore, we put its prototype in a header file, say for example `mymacros.h`.

```bash
$ cat mymacros.h
#define Z_SYSCALL_HANDLER int xxx
```

Now we pass the header file `mymacros.h` during transformation:

```bash
./scripts/coccicheck --sp-flag="---macro-file-builtins mymacros.h"
```

See `spatch --help` to learn more about spatch options.

Note that the `--use-glimpse` and `--use-idutils` options require external tools for indexing the code. None of them is thus active by default. However, by indexing the code with one of these tools, and according to the cocci file used, spatch could proceed the entire code base more quickly.

### SmPL patch specific options

SmPL patches can have their own requirements for options passed to Coccinelle. SmPL patch specific options can be provided by providing them at the top of the SmPL patch, for instance:

```bash
// Options: --no-includes --include-headers
```

### Proposing new semantic patches

New semantic patches can be proposed and submitted by kernel developers. For sake of clarity, they should be organized in the sub-directories of `scripts/coccinelle/`.

The cocci script should have the following properties:

- The script **must** have report mode.
- The first few lines should state the purpose of the script using /// comments. Usually, this message would be used as the commit log when proposing a patch based on the script.

**Example**

```bash
/// Use ARRAY_SIZE instead of dividing sizeof array with sizeof an element
```

- A more detailed information about the script with exceptional cases or false positives (if any) can be listed using //# comments.

**Example**

```bash
//# This makes an effort to find cases where ARRAY_SIZE can be used such as
//# where there is a division of sizeof the array by the sizeof its first
//# element or by any indexed element or the element type. It replaces the
//# division of the two sizeofs by ARRAY_SIZE.
```

- Confidence: It is a property defined to specify the accuracy level of the script. It can be either High, Moderate or Low depending upon the number of false positives observed.

**Example**

```bash
// Confidence: High
```

- Virtual rules: These are required to support the various modes framed in the script. The virtual rule specified in the script should have the corresponding mode handling rule.
Example

virtual context

@depends on context@
type T;
T[] E;
@@
( *
  (sizeof(E)/sizeof(*E))
  |
  (sizeof(E)/sizeof(E[...]))
  |

### 2.13.2 Using with PlatformIO

[PlatormIO logo]

- **What is PlatformIO?**
- **Installation**
- **Configuration**
- **Tutorials**
- **Project Examples**
- **Next Steps**

**What is PlatformIO?**

PlatformIO is a cross-platform embedded development environment with Zephyr support maintained by its developers.
Since Zephyr support within PlatformIO is not maintained by the Zephyr Project, please report any issues with PlatformIO directly to its developers in the official PlatformIO repositories.

A detailed overview of the PlatformIO ecosystem and its philosophy can be found in the official PlatformIO documentation.

Installation

- **PlatformIO IDE** is a toolset for embedded C/C++ development available on Windows, macOS and Linux platforms
- **PlatformIO Core (CLI)** is a command-line tool that consists of multi-platform build system, platform and library managers and other integration components. It can be used with a variety of code development environments and allows integration with cloud platforms and web services

Configuration

Please go through the official PlatformIO configuration guide for Zephyr project.

Tutorials

- Zephyr and Nordic nRF52-DK: debugging, unit testing, project analysis
- Developing Zephyr RTOS embedded applications on PlatformIO and simulating on Antmicro Renode

Project Examples

Please check the official examples for various development platforms

Next Steps

Here are some useful links for exploring the PlatformIO ecosystem:

- Try other platforms that support Zephyr project
- Learn more about integrations with other IDEs/Text Editors
- Get help from PlatformIO community
Chapter 3

Kernel

3.1 Kernel Services

The Zephyr kernel lies at the heart of every Zephyr application. It provides a low footprint, high performance, multi-threaded execution environment with a rich set of available features. The rest of the Zephyr ecosystem, including device drivers, networking stack, and application-specific code, uses the kernel’s features to create a complete application.

The configurable nature of the kernel allows you to incorporate only those features needed by your application, making it ideal for systems with limited amounts of memory (as little as 2 KB!) or with simple multi-threading requirements (such as a set of interrupt handlers and a single background task). Examples of such systems include: embedded sensor hubs, environmental sensors, simple LED wearable, and store inventory tags.

Applications requiring more memory (50 to 900 KB), multiple communication devices (like Wi-Fi and Bluetooth Low Energy), and complex multi-threading, can also be developed using the Zephyr kernel. Examples of such systems include: fitness wearables, smart watches, and IoT wireless gateways.

3.1.1 Scheduling, Interrupts, and Synchronization

These pages cover basic kernel services related to thread scheduling and synchronization.

 Threads

Note: There is also limited support for using Operation without Threads.

- Lifecycle
  - Thread Creation
  - Thread Termination
  - Thread Aborting
  - Thread Suspension
- Thread States
- Thread Stack objects
  - Kernel-only Stacks
This section describes kernel services for creating, scheduling, and deleting independently executable threads of instructions.

A thread is a kernel object that is used for application processing that is too lengthy or too complex to be performed by an ISR.

Any number of threads can be defined by an application (limited only by available RAM). Each thread is referenced by a thread id that is assigned when the thread is spawned.

A thread has the following key properties:

- A stack area, which is a region of memory used for the thread’s stack. The size of the stack area can be tailored to conform to the actual needs of the thread’s processing. Special macros exist to create and work with stack memory regions.
- A thread control block for private kernel bookkeeping of the thread’s metadata. This is an instance of type k_thread.
- An entry point function, which is invoked when the thread is started. Up to 3 argument values can be passed to this function.
- A scheduling priority, which instructs the kernel’s scheduler how to allocate CPU time to the thread. (See Scheduling.)
- A set of thread options, which allow the thread to receive special treatment by the kernel under specific circumstances. (See Thread Options.)
- A start delay, which specifies how long the kernel should wait before starting the thread.
- An execution mode, which can either be supervisor or user mode. By default, threads run in supervisor mode and allow access to privileged CPU instructions, the entire memory address space, and peripherals. User mode threads have a reduced set of privileges. This depends on the CONFIG_USERSPACE option. See User Mode.

Lifecycle

Thread Creation A thread must be created before it can be used. The kernel initializes the thread control block as well as one end of the stack portion. The remainder of the thread’s stack is typically left uninitialized.
Specifying a start delay of \texttt{K\_NO\_WAIT} instructs the kernel to start thread execution immediately. Alternatively, the kernel can be instructed to delay execution of the thread by specifying a timeout value – for example, to allow device hardware used by the thread to become available.

The kernel allows a delayed start to be canceled before the thread begins executing. A cancellation request has no effect if the thread has already started. A thread whose delayed start was successfully canceled must be re-spawned before it can be used.

**Thread Termination**  Once a thread is started it typically executes forever. However, a thread may synchronously end its execution by returning from its entry point function. This is known as \textbf{termination}.

A thread that terminates is responsible for releasing any shared resources it may own (such as mutexes and dynamically allocated memory) prior to returning, since the kernel does not reclaim them automatically.

In some cases a thread may want to sleep until another thread terminates. This can be accomplished with the \texttt{k\_thread\_join()} API. This will block the calling thread until either the timeout expires, the target thread self-exits, or the target thread aborts (either due to a \texttt{k\_thread\_abort()} call or triggering a fatal error).

Once a thread has terminated, the kernel guarantees that no use will be made of the thread struct. The memory of such a struct can then be re-used for any purpose, including spawning a new thread. Note that the thread must be fully terminated, which presents race conditions where a thread’s own logic signals completion which is seen by another thread before the kernel processing is complete. Under normal circumstances, application code should use \texttt{k\_thread\_join()} or \texttt{k\_thread\_abort()} to synchronize on thread termination state and not rely on signaling from within application logic.

**Thread Aborting**  A thread may asynchronously end its execution by \textbf{aborting}. The kernel automatically aborts a thread if the thread triggers a fatal error condition, such as dereferencing a null pointer.

A thread can also be aborted by another thread (or by itself) by calling \texttt{k\_thread\_abort()}. However, it is typically preferable to signal a thread to terminate itself gracefully, rather than aborting it.

As with thread termination, the kernel does not reclaim shared resources owned by an aborted thread.

**Note:** The kernel does not currently make any claims regarding an application’s ability to respawn a thread that aborts.

**Thread Suspension**  A thread can be prevented from executing for an indefinite period of time if it becomes \textbf{suspended}. The function \texttt{k\_thread\_suspend()} can be used to suspend any thread, including the calling thread. Suspending a thread that is already suspended has no additional effect.

Once suspended, a thread cannot be scheduled until another thread calls \texttt{k\_thread\_resume()} to remove the suspension.

**Note:** A thread can prevent itself from executing for a specified period of time using \texttt{k\_sleep()}. However, this is different from suspending a thread since a sleeping thread becomes executable automatically when the time limit is reached.

**Thread States**  A thread that has no factors that prevent its execution is deemed to be \textbf{ready}, and is eligible to be selected as the current thread.

A thread that has one or more factors that prevent its execution is deemed to be \textbf{unready}, and cannot be selected as the current thread.

The following factors make a thread unready:
• The thread has not been started.
• The thread is waiting for a kernel object to complete an operation. (For example, the thread is taking a semaphore that is unavailable.)
• The thread is waiting for a timeout to occur.
• The thread has been suspended.
• The thread has terminated or aborted.

Note: Although the diagram above may appear to suggest that both Ready and Running are distinct thread states, that is not the correct interpretation. Ready is a thread state, and Running is a schedule state that only applies to Ready threads.

Thread Stack objects Every thread requires its own stack buffer for the CPU to push context. Depending on configuration, there are several constraints that must be met:

• There may need to be additional memory reserved for memory management structures
• If guard-based stack overflow detection is enabled, a small write-protected memory management region must immediately precede the stack buffer to catch overflows.
• If userspace is enabled, a separate fixed-size privilege elevation stack must be reserved to serve as a private kernel stack for handling system calls.
• If userspace is enabled, the thread’s stack buffer must be appropriately sized and aligned such that a memory protection region may be programmed to exactly fit.

The alignment constraints can be quite restrictive, for example some MPUs require their regions to be of some power of two in size, and aligned to its own size.

Because of this, portable code can’t simply pass an arbitrary character buffer to k_thread_create(). Special macros exist to instantiate stacks, prefixed with K_KERNEL_STACK and K_THREAD_STACK.

Kernel-only Stacks If it is known that a thread will never run in user mode, or the stack is being used for special contexts like handling interrupts, it is best to define stacks using the K_KERNEL_STACK macros.
These stacks save memory because an MPU region will never need to be programmed to cover the stack buffer itself, and the kernel will not need to reserve additional room for the privilege elevation stack, or memory management data structures which only pertain to user mode threads.

Attempts from user mode to use stacks declared in this way will result in a fatal error for the caller.

If CONFIG_USERSPACE is not enabled, the set of K_THREAD_STACK macros have an identical effect to the K_KERNEL_STACK macros.

Thread stacks If it is known that a stack will need to host user threads, or if this cannot be determined, define the stack with K_THREAD_STACK macros. This may use more memory but the stack object is suitable for hosting user threads.

If CONFIG_USERSPACE is not enabled, the set of K_THREAD_STACK macros have an identical effect to the K_KERNEL_STACK macros.

Thread Priorities A thread’s priority is an integer value, and can be either negative or non-negative. Numerically lower priorities takes precedence over numerically higher values. For example, the scheduler gives thread A of priority 4 higher priority over thread B of priority 7; likewise thread C of priority -2 has higher priority than both thread A and thread B.

The scheduler distinguishes between two classes of threads, based on each thread’s priority.

- A cooperative thread has a negative priority value. Once it becomes the current thread, a cooperative thread remains the current thread until it performs an action that makes it unready.
- A preemptible thread has a non-negative priority value. Once it becomes the current thread, a preemptible thread may be supplanted at any time if a cooperative thread, or a preemptible thread of higher or equal priority, becomes ready.

A thread’s initial priority value can be altered up or down after the thread has been started. Thus it is possible for a preemptible thread to become a cooperative thread, and vice versa, by changing its priority.

Note: The scheduler does not make heuristic decisions to re-prioritize threads. Thread priorities are set and changed only at the application’s request.

The kernel supports a virtually unlimited number of thread priority levels. The configuration options CONFIG_NUM_COOP_PRIORITIES and CONFIG_NUM_PREEMPT_PRIORITIES specify the number of priority levels for each class of thread, resulting in the following usable priority ranges:

- cooperative threads: (-CONFIG_NUM_COOP_PRIORITIES) to -1
- preemptive threads: 0 to (CONFIG_NUM_PREEMPT_PRIORITIES - 1)

For example, configuring 5 cooperative priorities and 10 preemptive priorities results in the ranges -5 to -1 and 0 to 9, respectively.

3.1. Kernel Services
Meta-IRQ Priorities When enabled (see `CONFIG_NUM_METAIRQ_PRIORITIES`), there is a special subclass of cooperative priorities at the highest (numerically lowest) end of the priority space: meta-IRQ threads. These are scheduled according to their normal priority, but also have the special ability to preempt all other threads (and other meta-IRQ threads) at lower priorities, even if those threads are cooperative and/or have taken a scheduler lock. Meta-IRQ threads are still threads, however, and can still be interrupted by any hardware interrupt.

This behavior makes the act of unblocking a meta-IRQ thread (by any means, e.g. creating it, calling `k_sem_give()`, etc.) into the equivalent of a synchronous system call when done by a lower priority thread, or an ARM-like “pended IRQ” when done from true interrupt context. The intent is that this feature will be used to implement interrupt “bottom half” processing and/or “tasklet” features in driver subsystems. The thread, once woken, will be guaranteed to run before the current CPU returns into application code.

Unlike similar features in other OSes, meta-IRQ threads are true threads and run on their own stack (which must be allocated normally), not the per-CPU interrupt stack. Design work to enable the use of the IRQ stack on supported architectures is pending.

Note that because this breaks the promise made to cooperative threads by the Zephyr API (namely that the OS won’t schedule other thread until the current thread deliberately blocks), it should be used only with great care from application code. These are not simply very high priority threads and should not be used as such.

Thread Options The kernel supports a small set of thread options that allow a thread to receive special treatment under specific circumstances. The set of options associated with a thread are specified when the thread is spawned.

A thread that does not require any thread option has an option value of zero. A thread that requires a thread option specifies it by name, using the `|` character as a separator if multiple options are needed (i.e. combine options using the bitwise OR operator).

The following thread options are supported.

**K_ESSENTIAL**
This option tags the thread as an essential thread. This instructs the kernel to treat the termination or aborting of the thread as a fatal system error.

By default, the thread is not considered to be an essential thread.

**K_SSE_REGS**
This x86-specific option indicate that the thread uses the CPU’s SSE registers. Also see K_FP_REGS.

By default, the kernel does not attempt to save and restore the contents of these registers when scheduling the thread.

**K_FP_REGS**
This option indicate that the thread uses the CPU’s floating point registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. (For more information see Floating Point Services.)

By default, the kernel does not attempt to save and restore the contents of this register when scheduling the thread.

**K_USER**
If `CONFIG_USERSPACE` is enabled, this thread will be created in user mode and will have reduced privileges. See User Mode. Otherwise this flag does nothing.

**K_INHERIT_PERMS**
If `CONFIG_USERSPACE` is enabled, this thread will inherit all kernel object permissions that the parent thread had, except the parent thread object. See User Mode.
Thread Custom Data  Every thread has a 32-bit custom data area, accessible only by the thread itself, and may be used by the application for any purpose it chooses. The default custom data value for a thread is zero.

Note: Custom data support is not available to ISRs because they operate within a single shared kernel interrupt handling context.

By default, thread custom data support is disabled. The configuration option CONFIG_THREAD_CUSTOM_DATA can be used to enable support.

The k_thread_custom_data_set() and k_thread_custom_data_get() functions are used to write and read a thread’s custom data, respectively. A thread can only access its own custom data, and not that of another thread.

The following code uses the custom data feature to record the number of times each thread calls a specific routine.

Note: Obviously, only a single routine can use this technique, since it monopolizes the use of the custom data feature.

```c
int call_tracking_routine(void)
{
    uint32_t call_count;

    if (k_is_in_isr()) {
        /* ignore any call made by an ISR */
    } else {
        call_count = (uint32_t)k_thread_custom_data_get();
        call_count++;
        k_thread_custom_data_set((void *)call_count);
    }

    /* do rest of routine's processing */
    ...
}
```

Use thread custom data to allow a routine to access thread-specific information, by using the custom data as a pointer to a data structure owned by the thread.

Implementation

Spawning a Thread  A thread is spawned by defining its stack area and its thread control block, and then calling k_thread_create().

The stack area must be defined using K_THREAD_STACK_DEFINE or K_KERNEL_STACK_DEFINE to ensure it is properly set up in memory.

The size parameter for the stack must be one of three values:

- The original requested stack size passed to K_THREAD_STACK or K_KERNEL_STACK family of stack instantiation macros.
- For a stack object defined with the K_THREAD_STACK family of macros, the return value of K_THREAD_STACK_SIZEOF() for that object.
- For a stack object defined with the K_KERNEL_STACK family of macros, the return value of K_KERNEL_STACK_SIZEOF() for that object.
The thread spawning function returns its thread id, which can be used to reference the thread. The following code spawns a thread that starts immediately.

```c
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);
struct k_thread my_thread_data;

k_tid_t my_tid = k_thread_create(&my_thread_data, my_stack_area, K_THREAD_STACK_SIZEOF(my_stack_area), my_entry_point, NULL, NULL, NULL, MY_PRIORITY, 0, K_NO_WAIT);
```

Alternatively, a thread can be declared at compile time by calling `K_THREAD_DEFINE`. Observe that the macro defines the stack area, control block, and thread id variables automatically. The following code has the same effect as the code segment above.

```c
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_DEFINE(my_tid, MY_STACK_SIZE, my_entry_point, NULL, NULL, NULL, MY_PRIORITY, 0, 0);
```

**Note:** The delay parameter to `k_thread_create()` is a `k_timeout_t` value, so `K_NO_WAIT` means to start the thread immediately. The corresponding parameter to `K_THREAD_DEFINE` is a duration in integral milliseconds, so the equivalent argument is 0.

**User Mode Constraints** This section only applies if `CONFIG_USERSPACE` is enabled, and a user thread tries to create a new thread. The `k_thread_create()` API is still used, but there are additional constraints which must be met or the calling thread will be terminated:

- The calling thread must have permissions granted on both the child thread and stack parameters; both are tracked by the kernel as kernel objects.
- The child thread and stack objects must be in an uninitialized state, i.e. it is not currently running and the stack memory is unused.
- The stack size parameter passed in must be equal to or less than the bounds of the stack object when it was declared.
- The `K_USER` option must be used, as user threads can only create other user threads.
- The `K_ESSENTIAL` option must not be used, user threads may not be considered essential threads.
- The priority of the child thread must be a valid priority value, and equal to or lower than the parent thread.

**Dropping Permissions** If `CONFIG_USERSPACE` is enabled, a thread running in supervisor mode may perform a one-way transition to user mode using the `k_thread_user_mode_enter()` API. This is a one-
way operation which will reset and zero the thread’s stack memory. The thread will be marked as non-essential.

**Terminating a Thread** A thread terminates itself by returning from its entry point function. The following code illustrates the ways a thread can terminate.

```c
void my_entry_point(int unused1, int unused2, int unused3)
{
    while (1) {
        ... 
        if (<some condition>) {
            return; /* thread terminates from mid-entry point function */
        }
        ...
    }
    /* thread terminates at end of entry point function */
}
```

If `CONFIG_USERSPACE` is enabled, aborting a thread will additionally mark the thread and stack objects as uninitialized so that they may be re-used.

**Runtime Statistics** Thread runtime statistics can be gathered and retrieved if `CONFIG_THREAD_RUNTIME_STATS` is enabled, for example, total number of execution cycles of a thread.

By default, the runtime statistics are gathered using the default kernel timer. For some architectures, SoCs or boards, there are timers with higher resolution available via timing functions. Using of these timers can be enabled via `CONFIG_THREAD_RUNTIME_STATS_USE_TIMING_FUNCTIONS`.

Here is an example:

```c
k_thread_runtime_stats_t rt_stats_thread;

k_thread_runtime_stats_get(k_current_get(), &rt_stats_thread);

printk("Cycles:  %llu\n", rt_stats_thread.execution_cycles);
```

**Suggested Uses** Use threads to handle processing that cannot be handled in an ISR. Use separate threads to handle logically distinct processing operations that can execute in parallel.

**Configuration Options** Related configuration options:

- `CONFIG_MAIN_THREAD_PRIORITY`
- `CONFIG_MAIN_STACK_SIZE`
- `CONFIG_IDLE_STACK_SIZE`
- `CONFIG_THREAD_CUSTOM_DATA`
- `CONFIG_NUM_COOP_PRIORITIES`
- `CONFIG_NUM_PREEMPT_PRIORITIES`
- `CONFIG_TIMESLICING`
- `CONFIG_TIMESLICE_SIZE`
• CONFIG_TIMESLICE_PRIORITY
• CONFIG_USERSPACE

API Reference
group thread_apis

Defines

K_ESSENTIAL
    system thread that must not abort

K_FP_REGS
    FPU registers are managed by context switch.
    This option indicates that the thread uses the CPU’s floating point registers. This instructs
    the kernel to take additional steps to save and restore the contents of these registers when
    scheduling the thread. No effect if CONFIG_FPU_SHARING is not enabled.

K_USER
    user mode thread
    This thread has dropped from supervisor mode to user mode and consequently has additional
    restrictions

K_INHERIT_PERMS
    Inherit Permissions.
    Indicates that the thread being created should inherit all kernel object permissions from the
    thread that created it. No effect if CONFIG_USERSPACE is not enabled.

K_CALLBACK_STATE
    Callback item state.
    This is a single bit of state reserved for “callback manager” utilities (p4wq initially) who need
    to track operations invoked from within a user-provided callback they have been invoked.
    Effectively it serves as a tiny bit of zero-overhead TLS data.

k_thread_access_grant(thread, ...)
    Grant a thread access to a set of kernel objects.
    This is a convenience function. For the provided thread, grant access to the remaining argu-
    ments, which must be pointers to kernel objects.
    The thread object must be initialized (i.e. running). The objects don’t need to be. Note that
    NULL shouldn’t be passed as an argument.

Parameters

    • thread – Thread to grant access to objects
    • ... – list of kernel object pointers

K_THREAD_DEFINE(name, stack_size, entry, p1, p2, p3, prio, options, delay)
    Statically define and initialize a thread.
    The thread may be scheduled for immediate execution or a delayed start.
Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using “|” (the logical OR operator).

The ID of the thread can be accessed using:

```c
extern const k_tid_t <name>;
```

**Parameters**

- **name** – Name of the thread.
- **stack_size** – Stack size in bytes.
- **entry** – Thread entry function.
- **p1** – 1st entry point parameter.
- **p2** – 2nd entry point parameter.
- **p3** – 3rd entry point parameter.
- **prio** – Thread priority.
- **options** – Thread options.
- **delay** – Scheduling delay (in milliseconds), zero for no delay.

**Typedefs**

```c
typedef void (*k_thread_user_cb_t)(const struct k_thread *thread, void *user_data)
```

**Functions**

```c
void k_thread_foreach(k_thread_user_cb_t user_cb, void *user_data)
```

Iterate over all the threads in the system.

This routine iterates over all the threads in the system and calls the user_cb function for each thread.

**Note:** CONFIG_THREAD_MONITOR must be set for this function to be effective.

**Note:** This API uses `k_spin_lock` to protect the _kernel.threads list which means creation of new threads and terminations of existing threads are blocked until this API returns.

**Parameters**

- **user_cb** – Pointer to the user callback function.
- **user_data** – Pointer to user data.

```c
void k_thread_foreach_unlocked(k_thread_user_cb_t user_cb, void *user_data)
```

Iterate over all the threads in the system without locking.

This routine works exactly the same like `k_thread_foreach` but unlocks interrupts when `user_cb` is executed.
Note: **CONFIG_THREAD_MONITOR** must be set for this function to be effective.

Note: This API uses *k_spin_lock* only when accessing the _kernel.threads queue elements. It unlocks it during user callback function processing. If a new task is created when this **foreach** function is in progress, the added new task would not be included in the enumeration. If a task is aborted during this enumeration, there would be a race here and there is a possibility that this aborted task would be included in the enumeration.

Note: If the task is aborted and the memory occupied by its *k_thread* structure is reused when this **k_thread_foreach_unlocked** is in progress it might even lead to the system behave unstable. This function may never return, as it would follow some **next** task pointers treating given pointer as a pointer to the **k_thread** structure while it is something different right now. Do not reuse the memory that was occupied by *k_thread* structure of aborted task if it was aborted after this function was called in any context.

### Parameters
- **user_cb** – Pointer to the user callback function.
- **user_data** – Pointer to user data.

```c
k_tid_t k_thread_create(struct k_thread *new_thread, k_thread_stack_t *stack, size_t stack_size, k_thread_entry_t entry, void *p1, void *p2, void *p3, int prio, uint32_t options, k_timeout_t delay)
```

Create a thread.

This routine initializes a thread, then schedules it for execution.

The new thread may be scheduled for immediate execution or a delayed start. If the newly spawned thread does not have a delayed start the kernel scheduler may preempt the current thread to allow the new thread to execute.

Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using “|” (the logical OR operator).

Stack objects passed to this function must be originally defined with either of these macros in order to be portable:

- **K_THREAD_STACK_DEFINE()** - For stacks that may support either user or supervisor threads.
- **K_KERNEL_STACK_DEFINE()** - For stacks that may support supervisor threads only. These stacks use less memory if **CONFIG_USERSPACE** is enabled.

The stack_size parameter has constraints. It must either be:

- The original size value passed to **K_THREAD_STACK_DEFINE()** or **K_KERNEL_STACK_DEFINE()**
- The return value of **K_THREAD_STACK_SIZEOF(stack)** if the stack was defined with **K_THREAD_STACK_DEFINE()**
- The return value of **K_KERNEL_STACK_SIZEOF(stack)** if the stack was defined with **K_KERNEL_STACK_DEFINE()**.
Using other values, or `sizeof(stack)` may produce undefined behavior.

**Parameters**
- `new_thread` – Pointer to uninitialized struct `k_thread`
- `stack` – Pointer to the stack space.
- `stack_size` – Stack size in bytes.
- `entry` – Thread entry function.
- `p1` – 1st entry point parameter.
- `p2` – 2nd entry point parameter.
- `p3` – 3rd entry point parameter.
- `prio` – Thread priority.
- `options` – Thread options.
- `delay` – Scheduling delay, or `K_NO_WAIT` (for no delay).

**Returns**
ID of new thread.

```c
FUNC_NORETURN void k_thread_user_mode_enter(k_thread_entry_t entry, void *p1, void *p2, void *p3)
```

Drop a thread’s privileges permanently to user mode.

This allows a supervisor thread to be re-used as a user thread. This function does not return, but control will transfer to the provided entry point as if this was a new user thread.

The implementation ensures that the stack buffer contents are erased. Any thread-local storage will be reverted to a pristine state.

Memory domain membership, resource pool assignment, kernel object permissions, priority, and thread options are preserved.

A common use of this function is to re-use the main thread as a user thread once all supervisor mode-only tasks have been completed.

**Parameters**
- `entry` – Function to start executing from
- `p1` – 1st entry point parameter
- `p2` – 2nd entry point parameter
- `p3` – 3rd entry point parameter

```c
static inline void k_thread_heap_assign(struct k_thread *thread, struct k_heap *heap)
```

Assign a resource memory pool to a thread.

By default, threads have no resource pool assigned unless their parent thread has a resource pool, in which case it is inherited. Multiple threads may be assigned to the same memory pool.

Changing a thread’s resource pool will not migrate allocations from the previous pool.

**Parameters**
- `thread` – Target thread to assign a memory pool for resource requests.
- `heap` – Heap object to use for resources, or NULL if the thread should no longer have a memory pool.
void k_thread_system_pool_assign(struct k_thread *thread)
    Assign the system heap as a thread’s resource pool.
    Similar to z_thread_heap_assign(), but the thread will use the kernel heap to draw memory.
    Use with caution, as a malicious thread could perform DoS attacks on the kernel heap.

Parameters
    • thread – Target thread to assign the system heap for resource requests

int k_thread_join(struct k_thread *thread, k_timeout_t timeout)
    Sleep until a thread exits.
    The caller will be put to sleep until the target thread exits, either due to being aborted, self-exiting, or taking a fatal error. This API returns immediately if the thread isn’t running.
    This API may only be called from ISRs with a K_NO_WAIT timeout, where it can be useful as a predicate to detect when a thread has aborted.

Parameters
    • thread – Thread to wait to exit
    • timeout – upper bound time to wait for the thread to exit.

Return values
    • 0 – success, target thread has exited or wasn’t running
    • -EBUSY – returned without waiting
    • -EAGAIN – waiting period timed out
    • -EDEADLK – target thread is joining on the caller, or target thread is the caller

int32_t k_sleep(k_timeout_t timeout)
    Put the current thread to sleep.
    This routine puts the current thread to sleep for duration, specified as a k_timeout_t object.

Note: if timeout is set to K_FOREVER then the thread is suspended.

Parameters
    • timeout – Desired duration of sleep.

Returns
    Zero if the requested time has elapsed or the number of milliseconds left to sleep, if thread was woken up by k_wakeup call.

static inline int32_t k_msleep(int32_t ms)
    Put the current thread to sleep.
    This routine puts the current thread to sleep for duration milliseconds.

Parameters
    • ms – Number of milliseconds to sleep.

Returns
    Zero if the requested time has elapsed or the number of milliseconds left to sleep, if thread was woken up by k_wakeup call.
int32_t k_usleep(int32_t us)

Put the current thread to sleep with microsecond resolution.

This function is unlikely to work as expected without kernel tuning. In particular, because the lower bound on the duration of a sleep is the duration of a tick, CONFIG_SYS_CLOCK_TICKS_PER_SEC must be adjusted to achieve the resolution desired. The implications of doing this must be understood before attempting to use k_usleep(). Use with caution.

Parameters

- us – Number of microseconds to sleep.

Returns

Zero if the requested time has elapsed or the number of microseconds left to sleep, if thread was woken up by k_wakeup call.

void k_busy_wait(uint32_t usec_to_wait)

Cause the current thread to busy wait.

This routine causes the current thread to execute a “do nothing” loop for usec_to_wait microseconds.

Note: The clock used for the microsecond-resolution delay here may be skewed relative to the clock used for system timeouts like k_sleep(). For example k_busy_wait(1000) may take slightly more or less time than k_sleep(K_MSEC(1)), with the offset dependent on clock tolerances.

bool k_can_yield(void)

Check whether it is possible to yield in the current context.

This routine checks whether the kernel is in a state where it is possible to yield or call blocking APIs. It should be used by code that needs to yield to perform correctly, but can feasibly be called from contexts where that is not possible. For example in the PRE_KERNEL initialization step, or when being run from the idle thread.

Returns

True if it is possible to yield in the current context, false otherwise.

void k_yield(void)

Yield the current thread.

This routine causes the current thread to yield execution to another thread of the same or higher priority. If there are no other ready threads of the same or higher priority, the routine returns immediately.

void k_wakeup(k_tid_t thread)

Wake up a sleeping thread.

This routine prematurely wakes up thread from sleeping.

If thread is not currently sleeping, the routine has no effect.

Parameters

- thread – ID of thread to wake.

__attribute_const__ static inline k_tid_t k_current_get(void)

Get thread ID of the current thread.

Returns

ID of current thread.
void k_thread_abort(k_tid_t thread)
Abort a thread.

This routine permanently stops execution of thread. The thread is taken off all kernel queues it is part of (i.e. the ready queue, the timeout queue, or a kernel object wait queue). However, any kernel resources the thread might currently own (such as mutexes or memory blocks) are not released. It is the responsibility of the caller of this routine to ensure all necessary cleanup is performed.

After k_thread_abort() returns, the thread is guaranteed not to be running or to become runnable anywhere on the system. Normally this is done via blocking the caller (in the same manner as k_thread_join()), but in interrupt context on SMP systems the implementation is required to spin for threads that are running on other CPUs. Note that as specified, this means that on SMP platforms it is possible for application code to create a deadlock condition by simultaneously aborting a cycle of threads using at least one termination from interrupt context. Zephyr cannot detect all such conditions.

Parameters
• thread – ID of thread to abort.

void k_thread_start(k_tid_t thread)
Start an inactive thread.

If a thread was created with K_FOREVER in the delay parameter, it will not be added to the scheduling queue until this function is called on it.

Parameters
• thread – thread to start

k_ticks_t k_thread_timeout_expires_ticks(const struct k_thread *t)
Get time when a thread wakes up, in system ticks.

This routine computes the system uptime when a waiting thread next executes, in units of system ticks. If the thread is not waiting, it returns current system time.

k_ticks_t k_thread_timeout_remaining_ticks(const struct k_thread *t)
Get time remaining before a thread wakes up, in system ticks.

This routine computes the time remaining before a waiting thread next executes, in units of system ticks. If the thread is not waiting, it returns zero.

int k_thread_priority_get(k_tid_t thread)
Get a thread's priority.

This routine gets the priority of thread.

Parameters
• thread – ID of thread whose priority is needed.

Returns
Priority of thread.

void k_thread_priority_set(k_tid_t thread, int prio)
Set a thread's priority.

This routine immediately changes the priority of thread.

Rescheduling can occur immediately depending on the priority thread is set to:

• If its priority is raised above the priority of the caller of this function, and the caller is preemptible, thread will be scheduled in.
• If the caller operates on itself, it lowers its priority below that of other threads in the system, and the caller is preemptible, the thread of highest priority will be scheduled in.

Priority can be assigned in the range of -CONFIG_NUM_COOP_PRIORITIES to CONFIG_NUM_PREEMPT_PRIORITIES-1, where -CONFIG_NUM_COOP_PRIORITIES is the highest priority.

Warning: Changing the priority of a thread currently involved in mutex priority inheritance may result in undefined behavior.

Parameters

• thread – ID of thread whose priority is to be set.
• prio – New priority.

void k_thread_deadline_set(k_tid_t thread, int deadline)
Set deadline expiration time for scheduler.

This sets the “deadline” expiration as a time delta from the current time, in the same units used by k_cycle_get_32(). The scheduler (when deadline scheduling is enabled) will choose the next expiring thread when selecting between threads at the same static priority. Threads at different priorities will be scheduled according to their static priority.

Note: Deadlines are stored internally using 32 bit unsigned integers. The number of cycles between the “first” deadline in the scheduler queue and the “last” deadline must be less than 2^31 (i.e a signed non-negative quantity). Failure to adhere to this rule may result in scheduled threads running in an incorrect deadline order.

Note: Despite the API naming, the scheduler makes no guarantees the the thread WILL be scheduled within that deadline, nor does it take extra metadata (like e.g. the “runtime” and “period” parameters in Linux sched_setattr()) that allows the kernel to validate the scheduling for achievability. Such features could be implemented above this call, which is simply input to the priority selection logic.

Note: You should enable CONFIG_SCHED_DEADLINE in your project configuration.

Parameters

• thread – A thread on which to set the deadline
• deadline – A time delta, in cycle units

int k_thread_cpu_mask_clear(k_tid_t thread)
Sets all CPU enable masks to zero.

After this returns, the thread will no longer be schedulable on any CPUs. The thread must not be currently runnable.

Note: You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters

• thread – Thread to operate upon
Returns
Zero on success, otherwise error code

int k_thread_cpu_mask_enable_all(k_tid_t thread)
Sets all CPU enable masks to one.
After this returns, the thread will be schedulable on any CPU. The thread must not be currently runnable.

Note: You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters
• thread – Thread to operate upon

Returns
Zero on success, otherwise error code

int k_thread_cpu_mask_enable(k_tid_t thread, int cpu)
Enable thread to run on specified CPU.
The thread must not be currently runnable.

Note: You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters
• thread – Thread to operate upon
• cpu – CPU index

Returns
Zero on success, otherwise error code

int k_thread_cpu_mask_disable(k_tid_t thread, int cpu)
Prevent thread to run on specified CPU.
The thread must not be currently runnable.

Note: You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters
• thread – Thread to operate upon
• cpu – CPU index

Returns
Zero on success, otherwise error code

int k_thread_cpu_pin(k_tid_t thread, int cpu)
Pin a thread to a CPU.
Pin a thread to a CPU by first clearing the cpu mask and then enabling the thread on the selected CPU.

Parameters
• thread – Thread to operate upon
• cpu – CPU index

Returns
Zero on success, otherwise error code

```c
void k_thread_suspend(k_tid_t thread)
```
Suspend a thread.

This routine prevents the kernel scheduler from making `thread` the current thread. All other
internal operations on `thread` are still performed; for example, kernel objects it is waiting on
are still handed to it. Note that any existing timeouts (e.g. `k_sleep()`, or a timeout argument to
`k_sem_take()` et. al.) will be canceled. On resume, the thread will begin running immediately
and return from the blocked call.

If `thread` is already suspended, the routine has no effect.

Parameters
• thread – ID of thread to suspend.

```c
void k_thread_resume(k_tid_t thread)
```
Resume a suspended thread.

This routine allows the kernel scheduler to make `thread` the current thread, when it is next
eligible for that role.

If `thread` is not currently suspended, the routine has no effect.

Parameters
• thread – ID of thread to resume.

```c
void k_sched_time_slice_set(int32_t slice, int prio)
```
Set time-slicing period and scope.

This routine specifies how the scheduler will perform time slicing of preemptible threads.
To enable time slicing, `slice` must be non-zero. The scheduler ensures that no thread runs for
more than the specified time limit before other threads of that priority are given a chance to
execute. Any thread whose priority is higher than `prio` is exempted, and may execute as long
as desired without being preempted due to time slicing.

Time slicing only limits the maximum amount of time a thread may continuously execute.
Once the scheduler selects a thread for execution, there is no minimum guaranteed time the
thread will execute before threads of greater or equal priority are scheduled.

When the current thread is the only one of that priority eligible for execution, this routine has
no effect; the thread is immediately rescheduled after the slice period expires.

To disable timeslicing, set both `slice` and `prio` to zero.

Parameters
• slice – Maximum time slice length (in milliseconds).
• prio – Highest thread priority level eligible for time slicing.

```c
void k_thread_time_slice_set(struct k_thread *th, int32_t slice_ticks, k_thread_timeslice_fn_t expired, void *data)
```
Set thread time slice.

As for `k_sched_time_slice_set`, but (when `CONFIG_TIMESLICE_PER_THREAD=y`) sets the
timeslice for a specific thread. When non-zero, this timeslice will take precedence over the
global value.

When such a thread's timeslice expires, the configured callback will be called before the thread
is removed/re-added to the run queue. This callback will occur in interrupt context, and the
specified thread is guaranteed to have been preempted by the currently-executing ISR. Such
a callback is free to, for example, modify the thread priority or slice time for future execution, suspend the thread, etc.

**Note:** Unlike the older API, the time slice parameter here is specified in ticks, not milliseconds. Ticks have always been the internal unit, and not all platforms have integer conversions between the two.

**Note:** Threads with a non-zero slice time set will be timesliced always, even if they are higher priority than the maximum timeslice priority set via `k_sched_time_slice_set()`.

**Note:** The callback notification for slice expiration happens, as it must, while the thread is still “current”, and thus it happens before any registered timeouts at this tick. This has the somewhat confusing side effect that the tick time (c.f. `k_uptime_get()`) does not yet reflect the expired ticks. Applications wishing to make fine-grained timing decisions within this callback should use the cycle API, or derived facilities like `k_thread_runtime_stats_get()`.

**Parameters**

- `th` – A valid, initialized thread
- `slice_ticks` – Maximum timeslice, in ticks
- `expired` – Callback function called on slice expiration
- `data` – Parameter for the expiration handler

```c
void k_sched_lock(void)
Lock the scheduler.
This routine prevents the current thread from being preempted by another thread by instructing the scheduler to treat it as a cooperative thread. If the thread subsequently performs an operation that makes it unready, it will be context switched out in the normal manner. When the thread again becomes the current thread, its non-preemptible status is maintained.
This routine can be called recursively.

**Note:** `k_sched_lock()` and `k_sched_unlock()` should normally be used when the operation being performed can be safely interrupted by ISRs. However, if the amount of processing involved is very small, better performance may be obtained by using `irq_lock()` and `irq_unlock()`.

```c
void k_sched_unlock(void)
Unlock the scheduler.
This routine reverses the effect of a previous call to `k_sched_lock()`. A thread must call the routine once for each time it called `k_sched_lock()` before the thread becomes preemptible.
```

```c
void k_thread_custom_data_set(void *value)
Set current thread’s custom data.
This routine sets the custom data for the current thread to @value.
Custom data is not used by the kernel itself, and is freely available for a thread to use as it sees fit. It can be used as a framework upon which to build thread-local storage.

**Parameters**

- `value` – New custom data value.
```
void *k_thread_custom_data_get(void)
Get current thread’s custom data.
This routine returns the custom data for the current thread.

**Returns**
Current custom data value.

int k_thread_name_set(k_tid_t thread, const char *str)
Set current thread name.
Set the name of the thread to be used when CONFIG_THREAD_MONITOR is enabled for tracing and debugging.

**Parameters**
- `thread` – Thread to set name, or NULL to set the current thread
- `str` – Name string

**Return values**
- 0 – on success
- -EFAULT – Memory access error with supplied string
- -ENOSYS – Thread name configuration option not enabled
- -EINVAL – Thread name too long

const char *k_thread_name_get(k_tid_t thread)
Get thread name.
Get the name of a thread

**Parameters**
- `thread` – Thread ID

**Return values**
- Thread name, or NULL if configuration not enabled

int k_thread_name_copy(k_tid_t thread, char *buf, size_t size)
Copy the thread name into a supplied buffer.

**Parameters**
- `thread` – Thread to obtain name information
- `buf` – Destination buffer
- `size` – Destination buffer size

**Return values**
- -ENOSPC – Destination buffer too small
- -EFAULT – Memory access error
- -ENOSYS – Thread name feature not enabled
- 0 – Success

const char *k_thread_state_str(k_tid_t thread_id, char *buf, size_t buf_size)
Get thread state string.
This routine generates a human friendly string containing the thread’s state, and copies as much of it as possible into `buf`.

**Parameters**
- `thread_id` – Thread ID
• buf – Buffer into which to copy state strings
• buf_size – Size of the buffer

**Return values**

Pointer – to `buf` if data was copied, else a pointer to “”.

```c
struct k_thread
#include <thread.h> Thread Structure

Public Members

struct _callee_saved callee_saved
    defined by the architecture, but all archs need these

void *init_data
    static thread init data

_wait_q_t join_queue
    threads waiting in `k_thread_join()

struct __thread_entry entry
    thread entry and parameters description

struct k_thread *next_thread
    next item in list of all threads

void *custom_data
    crude thread-local storage

struct _thread_stack_info stack_info
    Stack Info

struct _mem_domain_info mem_domain_info
    memory domain info of the thread

k_thread_stack_t *stack_obj
    Base address of thread stack

void *syscall_frame
    current syscall frame pointer

int swap_retval
    z_swap() return value

void *switch_handle
    Context handle returned via `arch_switch()

struct k_heap *resource_pool
    resource pool
```
struct_thread_arch arch
    arch-specifics: must always be at the end

group thread_stack_api
    Thread Stack APIs.

Defines

K_KERNEL_STACK_DECLARE(sym, size)
    Declare a reference to a thread stack.
    This macro declares the symbol of a thread stack defined elsewhere in the current scope.
    Parameters
    • sym – Thread stack symbol name
    • size – Size of the stack memory region

K_KERNEL_STACK_ARRAY_DECLARE(sym, nmemb, size)
    Declare a reference to a thread stack array.
    This macro declares the symbol of a thread stack array defined elsewhere in the current scope.
    Parameters
    • sym – Thread stack symbol name
    • nmemb – Number of stacks defined
    • size – Size of the stack memory region

K_KERNEL_PINNED_STACK_ARRAY_DECLARE(sym, nmemb, size)
    Declare a reference to a pinned thread stack array.
    This macro declares the symbol of a pinned thread stack array defined elsewhere in the current scope.
    Parameters
    • sym – Thread stack symbol name
    • nmemb – Number of stacks defined
    • size – Size of the stack memory region

K_KERNEL_STACK_EXTERN(sym)
    Obtain an extern reference to a stack.
    This macro properly brings the symbol of a thread stack defined elsewhere into scope.

    Deprecated:
    Use K_KERNEL_STACK_DECLARE() instead.
    Parameters
    • sym – Thread stack symbol name

K_KERNEL_STACK_ARRAY_EXTERN(sym, nmemb, size)
    Obtain an extern reference to a stack array.
    This macro properly brings the symbol of a stack array defined elsewhere into scope.
Deprecation:
Use `K_KERNEL_STACK_ARRAY_DECLARE()` instead.

**Parameters**
- `sym` – Thread stack symbol name
- `nmemb` – Number of stacks defined
- `size` – Size of the stack memory region

**K_KERNEL_PINNED_STACK_ARRAY_EXTERN(sym, nmemb, size)**
Obtain an extern reference to a pinned stack array.
This macro properly brings the symbol of a pinned stack array defined elsewhere into scope.

Deprecation:
Use `K_KERNEL_PINNED_STACK_ARRAY_DECLARE()` instead.

**Parameters**
- `sym` – Thread stack symbol name
- `nmemb` – Number of stacks defined
- `size` – Size of the stack memory region

**K_KERNEL_STACK_DEFINE(sym, size)**
Define a top level kernel stack memory region.
This defines a region of memory for use as a thread stack, for threads that exclusively run in supervisor mode. This is also suitable for declaring special stacks for interrupt or exception handling.
Stacks defined with this macro may not host user mode threads.
It is legal to precede this definition with the 'static' keyword.
It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of `k_thread_create()`, it may not be the same as the 'size' parameter. Use `K_KERNEL_STACK_SIZEOF()` instead.
The total amount of memory allocated may be increased to accommodate fixed-size stack overflow guards.

**Parameters**
- `sym` – Thread stack symbol name
- `size` – Size of the stack memory region

**K_KERNEL_PINNED_STACK_DEFINE(sym, size)**
Define a top level kernel stack memory region in pinned section.
See `K_KERNEL_STACK_DEFINE()` for more information and constraints.
This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as `K_KERNEL_STACK_DEFINE()`.

**Parameters**
- `sym` – Thread stack symbol name
- `size` – Size of the stack memory region
K_KERNEL_STACK_ARRAY_DEFINE(sym, nmemb, size)
Define a toplevel array of kernel stack memory regions.
Stacks defined with this macro may not host user mode threads.

Parameters
• sym – Kernel stack array symbol name
• nmemb – Number of stacks to define
• size – Size of the stack memory region

K_KERNEL_PINNED_STACK_ARRAY_DEFINE(sym, nmemb, size)
Define a toplevel array of kernel stack memory regions in pinned section.
See K_KERNEL_STACK_ARRAY_DEFINE() for more information and constraints.
This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as K_KERNEL_STACK_ARRAY_DEFINE().

Parameters
• sym – Kernel stack array symbol name
• nmemb – Number of stacks to define
• size – Size of the stack memory region

K_KERNEL_STACK_MEMBER(sym, size)
Define an embedded stack memory region.
Used for kernel stacks embedded within other data structures.
Stacks defined with this macro may not host user mode threads.

Parameters
• sym – Thread stack symbol name
• size – Size of the stack memory region

K_KERNEL_STACK_SIZEOF(sym)

K_THREAD_STACK_DECLARE(sym, size)
Declare a reference to a thread stack.
This macro declares the symbol of a thread stack defined elsewhere in the current scope.

Parameters
• sym – Thread stack symbol name
• size – Size of the stack memory region

K_THREAD_STACK_ARRAY_DECLARE(sym, nmemb, size)
Declare a reference to a thread stack array.
This macro declares the symbol of a thread stack array defined elsewhere in the current scope.

Parameters
• sym – Thread stack symbol name
• nmemb – Number of stacks defined
• size – Size of the stack memory region
K_THREAD_STACK_EXTERN(sym)
Obtain an extern reference to a stack.

This macro properly brings the symbol of a thread stack defined elsewhere into scope.

Deprecated:
Use K_THREAD_STACK_DECLARE() instead.

Parameters
- sym – Thread stack symbol name

K_THREAD_STACK_ARRAY_EXTERN(sym, nmemb, size)
Obtain an extern reference to a thread stack array.

This macro properly brings the symbol of a stack array defined elsewhere into scope.

Deprecated:
Use K_THREAD_STACK_ARRAY_DECLARE() instead.

Parameters
- sym – Thread stack symbol name
- nmemb – Number of stacks defined
- size – Size of the stack memory region

K_THREAD_STACK_SIZEOF(sym)
Return the size in bytes of a stack memory region.

Convenience macro for passing the desired stack size to k_thread_create() since the underlying implementation may actually create something larger (for instance a guard area).

The value returned here is not guaranteed to match the 'size' parameter passed to K_THREAD_STACK_DEFINE and may be larger, but is always safe to pass to k_thread_create() for the associated stack object.

Parameters
- sym – Stack memory symbol

Returns
Size of the stack buffer

K_THREAD_STACK_DEFINE(sym, size)
Define a toplevel thread stack memory region.

This defines a region of memory suitable for use as a thread's stack.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in 'noinit' section so that it isn't zeroed at boot

The defined symbol will always be a k_thread_stack_t which can be passed to k_thread_create(), but should otherwise not be manipulated. If the buffer inside needs to be examined, examine thread->stack_info for the associated thread object to obtain the boundaries.

It is legal to precede this definition with the 'static' keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of k_thread_create(), it may not be the same as the 'size' parameter. Use K_THREAD_STACK_SIZEOF() instead.
Some arches may round the size of the usable stack region up to satisfy alignment constraints. 
*K_THREAD_STACK_SIZEOF()* will return the aligned size.

**Parameters**
- `sym` – Thread stack symbol name
- `size` – Size of the stack memory region

*K_THREAD_PINNED_STACK_DEFINE*(sym, size)

Define a toplevel thread stack memory region in pinned section.
This defines a region of memory suitable for use as a thread's stack.
This is the generic, historical definition. Align to Z_THREAD.Stack.Obj_ALIGN and put in 'noinit' section so that it isn’t zeroed at boot

The defined symbol will always be a k_thread_stack_t which can be passed to k_thread_create(), but should otherwise not be manipulated. If the buffer inside needs to be examined, examine thread->stack_info for the associated thread object to obtain the boundaries.

It is legal to precede this definition with the ‘static’ keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of k_thread_create(), it may not be the same as the ‘size’ parameter. Use K_THREAD_STACK_SIZEOF() instead.

Some arches may round the size of the usable stack region up to satisfy alignment constraints. 
*K_THREAD_STACK_SIZEOF()* will return the aligned size.

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as K_THREAD_STACK_DEFINE().

**Parameters**
- `sym` – Thread stack symbol name
- `size` – Size of the stack memory region

*K_THREAD_STACK_LEN*(size)

Calculate size of stacks to be allocated in a stack array.

This macro calculates the size to be allocated for the stacks inside a stack array. It accepts the indicated "size" as a parameter and if required, pads some extra bytes (e.g. for MPU scenarios). Refer K_THREAD_STACK_ARRAY_DEFINE definition to see how this is used. The returned size ensures each array member will be aligned to the required stack base alignment.

**Parameters**
- `size` – Size of the stack memory region

**Returns**
Appropriate size for an array member

*K_THREAD_STACK_ARRAY_DEFINE*(sym, nmemb, size)

Define a toplevel array of thread stack memory regions.

Create an array of equally sized stacks. See K_THREAD_STACK_DEFINE definition for additional details and constraints.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in 'noinit' section so that it isn’t zeroed at boot

**Parameters**
- `sym` – Thread stack symbol name
- `nmemb` – Number of stacks to define
• size – Size of the stack memory region

K_THREAD_PINNED_STACK_ARRAY_DEFINE(sym, nmemb, size)
Define a toplevel array of thread stack memory regions in pinned section.

Create an array of equally sized stacks. See K_THREAD_STACK_DEFINE definition for additional details and constraints.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in 'noinit' section so that it isn't zeroed at boot.

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as K_THREAD_STACK_DEFINE().

Parameters
• sym – Thread stack symbol name
• nmemb – Number of stacks to define
• size – Size of the stack memory region

K_THREAD_STACK_MEMBER(sym, size)
Define an embedded stack memory region.

Used for stacks embedded within other data structures. Use is highly discouraged but in some cases necessary. For memory protection scenarios, it is very important that any RAM preceding this member not be writable by threads else a stack overflow will lead to silent corruption. In other words, the containing data structure should live in RAM owned by the kernel.

A user thread can only be started with a stack defined in this way if the thread starting it is in supervisor mode.

This is now deprecated, as stacks defined in this way are not usable from user mode. Use K_KERNEL_STACK_MEMBER.

Parameters
• sym – Thread stack symbol name
• size – Size of the stack memory region

Scheduling

The kernel's priority-based scheduler allows an application's threads to share the CPU.

Concepts  The scheduler determines which thread is allowed to execute at any point in time; this thread is known as the current thread.

There are various points in time when the scheduler is given an opportunity to change the identity of the current thread. These points are called reschedule points. Some potential reschedule points are:

• transition of a thread from running state to a suspended or waiting state, for example by k_sem_take() or k_sleep().
• transition of a thread to the ready state, for example by k_sem_give() or k_thread_start()
• return to thread context after processing an interrupt
• when a running thread invokes k_yield()

A thread sleeps when it voluntarily initiates an operation that transitions itself to a suspended or waiting state.
Whenever the scheduler changes the identity of the current thread, or when execution of the current thread is replaced by an ISR, the kernel first saves the current thread’s CPU register values. These register values get restored when the thread later resumes execution.

**Scheduling Algorithm**  The kernel's scheduler selects the highest priority ready thread to be the current thread. When multiple ready threads of the same priority exist, the scheduler chooses the one that has been waiting longest.

A thread's relative priority is primarily determined by its static priority. However, when both earliest-deadline-first scheduling is enabled (CONFIG_SCHED_DEADLINE) and a choice of threads have equal static priority, then the thread with the earlier deadline is considered to have the higher priority. Thus, when earliest-deadline-first scheduling is enabled, two threads are only considered to have the same priority when both their static priorities and deadlines are equal. The routine `k_thread_deadline_set()` is used to set a thread’s deadline.

**Note:** Execution of ISRs takes precedence over thread execution, so the execution of the current thread may be replaced by an ISR at any time unless interrupts have been masked. This applies to both cooperative threads and preemptive threads.

The kernel can be built with one of several choices for the ready queue implementation, offering different choices between code size, constant factor runtime overhead and performance scaling when many threads are added.

- **Simple linked-list ready queue (CONFIG_SCHED_DUMB)**

   The scheduler ready queue will be implemented as a simple unordered list, with very fast constant time performance for single threads and very low code size. This implementation should be selected on systems with constrained code size that will never see more than a small number (3, maybe) of runnable threads in the queue at any given time. On most platforms (that are not otherwise using the red/black tree) this results in a savings of ~2k of code size.

- **Red/black tree ready queue (CONFIG_SCHED_SCALABLE)**

   The scheduler ready queue will be implemented as a red/black tree. This has rather slower constant-time insertion and removal overhead, and on most platforms (that are not otherwise using the red/black tree somewhere) requires an extra ~2kb of code. The resulting behavior will scale cleanly and quickly into the many thousands of threads.

   Use this for applications needing many concurrent runnable threads (> 20 or so). Most applications won’t need this ready queue implementation.

- **Traditional multi-queue ready queue (CONFIG_SCHED_MULTIQ)**

   When selected, the scheduler ready queue will be implemented as the classic/textbook array of lists, one per priority (max 32 priorities).

   This corresponds to the scheduler algorithm used in Zephyr versions prior to 1.12.

   It incurs only a tiny code size overhead vs. the “dumb” scheduler and runs in O(1) time in almost all circumstances with very low constant factor. But it requires a fairly large RAM budget to store those list heads, and the limited features make it incompatible with features like deadline scheduling that need to sort threads more finely, and SMP affinity which need to traverse the list of threads.

   Typical applications with small numbers of runnable threads probably want the DUMB scheduler.

The wait_q abstraction used in IPC primitives to pend threads for later wakeup shares the same backend data structure choices as the scheduler, and can use the same options.

- **Scalable wait_q implementation (CONFIG_WAITQ_SCALABLE)**

   When selected, the wait_q will be implemented with a balanced tree. Choose this if you expect to have many threads waiting on individual primitives. There is a ~2kb code size increase over CONFIG_WAITQ_DUMB (which may be shared with CONFIG_SCHED_SCALABLE) if the red/black tree
is not used elsewhere in the application, and pend/unpend operations on “small” queues will be somewhat slower (though this is not generally a performance path).

- Simple linked-list wait_q (CONFIG_WAITQ_DUMB)
  When selected, the wait_q will be implemented with a doubly-linked list. Choose this if you expect to have only a few threads blocked on any single IPC primitive.

**Cooperative Time Slicing**  Once a cooperative thread becomes the current thread, it remains the current thread until it performs an action that makes it unready. Consequently, if a cooperative thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of higher priority and equal priority.

To overcome such problems, a cooperative thread can voluntarily relinquish the CPU from time to time to permit other threads to execute. A thread can relinquish the CPU in two ways:

- Calling `k_yield()` puts the thread at the back of the scheduler’s prioritized list of ready threads, and then invokes the scheduler. All ready threads whose priority is higher or equal to that of the yielding thread are then allowed to execute before the yielding thread is rescheduled. If no such ready threads exist, the scheduler immediately reschedules the yielding thread without context switching.

- Calling `k_sleep()` makes the thread unready for a specified time period. Ready threads of *all* priorities are then allowed to execute; however, there is no guarantee that threads whose priority is lower than that of the sleeping thread will actually be scheduled before the sleeping thread becomes ready once again.

**Preemptive Time Slicing**  Once a preemptive thread becomes the current thread, it remains the current thread until a higher priority thread becomes ready, or until the thread performs an action that makes it unready. Consequently, if a preemptive thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of equal priority.
To overcome such problems, a preemptive thread can perform cooperative time slicing (as described above), or the scheduler's time slicing capability can be used to allow other threads of the same priority to execute.

The scheduler divides time into a series of **time slices**, where slices are measured in system clock ticks. The time slice size is configurable, but this size can be changed while the application is running.

At the end of every time slice, the scheduler checks to see if the current thread is preemptible and, if so, implicitly invokes `k_yield()` on behalf of the thread. This gives other ready threads of the same priority the opportunity to execute before the current thread is scheduled again. If no threads of equal priority are ready, the current thread remains the current thread.

Threads with a priority higher than specified limit are exempt from preemptive time slicing, and are never preempted by a thread of equal priority. This allows an application to use preemptive time slicing only when dealing with lower priority threads that are less time-sensitive.

**Note:** The kernel's time slicing algorithm does not ensure that a set of equal-priority threads receive an
equitable amount of CPU time, since it does not measure the amount of time a thread actually gets to execute. However, the algorithm does ensure that a thread never executes for longer than a single time slice without being required to yield.

**Scheduler Locking** A preemptible thread that does not wish to be preempted while performing a critical operation can instruct the scheduler to temporarily treat it as a cooperative thread by calling `k_sched_lock()`. This prevents other threads from interfering while the critical operation is being performed.

Once the critical operation is complete the preemptible thread must call `k_sched_unlock()` to restore its normal, preemptible status.

If a thread calls `k_sched_lock()` and subsequently performs an action that makes it unready, the scheduler will switch the locking thread out and allow other threads to execute. When the locking thread again becomes the current thread, its non-preemptible status is maintained.

**Note:** Locking out the scheduler is a more efficient way for a preemptible thread to prevent preemption than changing its priority level to a negative value.

**Thread Sleeping** A thread can call `k_sleep()` to delay its processing for a specified time period. During the time the thread is sleeping the CPU is relinquished to allow other ready threads to execute. Once the specified delay has elapsed the thread becomes ready and is eligible to be scheduled once again.

A sleeping thread can be woken up prematurely by another thread using `k_wakeup()`. This technique can sometimes be used to permit the secondary thread to signal the sleeping thread that something has occurred without requiring the threads to define a kernel synchronization object, such as a semaphore. Waking up a thread that is not sleeping is allowed, but has no effect.

**Busy Waiting** A thread can call `k_busy_wait()` to perform a busy wait that delays its processing for a specified time period without relinquishing the CPU to another ready thread.

A busy wait is typically used instead of thread sleeping when the required delay is too short to warrant having the scheduler context switch from the current thread to another thread and then back again.

**Suggested Uses** Use cooperative threads for device drivers and other performance-critical work.

Use cooperative threads to implement mutually exclusion without the need for a kernel object, such as a mutex.

Use preemptive threads to give priority to time-sensitive processing over less time-sensitive processing.

**CPU Idling**

Although normally reserved for the idle thread, in certain special applications, a thread might want to make the CPU idle.
Concepts  Making the CPU idle causes the kernel to pause all operations until an event, normally an interrupt, wakes up the CPU. In a regular system, the idle thread is responsible for this. However, in some constrained systems, it is possible that another thread takes this duty.

Implementation

Making the CPU idle  Making the CPU idle is simple: call the \texttt{k_cpu_idle()} API. The CPU will stop executing instructions until an event occurs. Most likely, the function will be called within a loop. Note that in certain architectures, upon return, \texttt{k_cpu_idle()} unconditionally unmasks interrupts.

\begin{verbatim}
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}

void main(void)
{
    k_sem_init(&my_sem, 0, 1);
    /* wait for semaphore from ISR, then do related work */
    for (;;) {
        /* wait for ISR to trigger work to perform */
        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {
            /* ... do processing */
        }
        /* put CPU to sleep to save power */
        k_cpu_idle();
    }
}
\end{verbatim}

Making the CPU idle in an atomic fashion  It is possible that there is a need to do some work atomically before making the CPU idle. In such a case, \texttt{k_cpu_atomic_idle()} should be used instead.

In fact, there is a race condition in the previous example: the interrupt could occur between the time the semaphore is taken, finding out it is not available and making the CPU idle again. In some systems, this can cause the CPU to idle until another interrupt occurs, which might be never, thus hanging the system completely. To prevent this, \texttt{k_cpu_atomic_idle()} should have been used, like in this example.

\begin{verbatim}
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}
\end{verbatim}
void main(void)
{
    k_sem_init(&my_sem, 0, 1);
    for (;;)
    {
        unsigned int key = irq_lock();

        /*
         * Wait for semaphore from ISR; if acquired, do related work, then
         * go to next loop iteration (the semaphore might have been given
         * again); else, make the CPU idle.
         */

        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {
            irq_unlock(key);
            /* ... do processing */

        } else {
            /* put CPU to sleep to save power */
            k_cpu_atomic_idle(key);
        }
    }
}

Suggested Uses Use k_cpu_atomic_idle() when a thread has to do some real work in addition to idling
the CPU to wait for an event. See example above.

Use k_cpu_idle() only when a thread is only responsible for idling the CPU, i.e. not doing any real work,
like in this example below.

void main(void)
{
    /* ... do some system/application initialization */

    /* thread is only used for CPU idling from this point on */
    for (;;)
    {
        k_cpu_idle();
    }
}

Note: Do not use these APIs unless absolutely necessary. In a normal system, the idle thread takes
care of power management, including CPU idling.

API Reference
group cpu_idle_apis
Functions

static inline void k_cpu_idle(void)
    Make the CPU idle.
    This function makes the CPU idle until an event wakes it up.
    In a regular system, the idle thread should be the only thread responsible for making the
    CPU idle and triggering any type of power management. However, in some more constrained
    systems, such as a single-threaded system, the only thread would be responsible for this if
    needed.

    **Note:** In some architectures, before returning, the function un masks interrupts uncondi-
    tionally.

static inline void k_cpu_atomic_idle(unsigned int key)
    Make the CPU idle in an atomic fashion.
    Similar to `k_cpu_idle()`, but must be called with interrupts locked.
    Enabling interrupts and entering a low-power mode will be atomic, i.e. there will be no period
    of time where interrupts are enabled before the processor enters a low-power mode.
    After waking up from the low-power mode, the interrupt lockout state will be restored as if
    by `irq_unlock(key)`.

    **Parameters**
    - key – Interrupt locking key obtained from `irq_lock()`.

System Threads

- **Implementation**
  - Writing a `main()` function
- **Suggested Uses**

A *system thread* is a thread that the kernel spawns automatically during system initialization.
The kernel spawns the following system threads:

**Main thread**
This thread performs kernel initialization, then calls the application's `main()` function (if one is
defined).
By default, the main thread uses the highest configured preemptible thread priority (i.e. 0). If the
kernel is not configured to support preemptible threads, the main thread uses the lowest configured
cooperative thread priority (i.e. -1).
The main thread is an essential thread while it is performing kernel initialization or executing the
application's `main()` function; this means a fatal system error is raised if the thread aborts. If
`main()` is not defined, or if it executes and then does a normal return, the main thread terminates
normally and no error is raised.

**Idle thread**
This thread executes when there is no other work for the system to do. If possible, the idle thread
activates the board's power management support to save power; otherwise, the idle thread simply
performs a "do nothing" loop. The idle thread remains in existence as long as the system is running
and never terminates.
The idle thread always uses the lowest configured thread priority. If this makes it a cooperative thread, the idle thread repeatedly yields the CPU to allow the application’s other threads to run when they need to.

The idle thread is an essential thread, which means a fatal system error is raised if the thread aborts.

Additional system threads may also be spawned, depending on the kernel and board configuration options specified by the application. For example, enabling the system workqueue spawns a system thread that services the work items submitted to it. (See Workqueue Threads.)

Implementation

**Writing a main() function** An application-supplied main() function begins executing once kernel initialization is complete. The kernel does not pass any arguments to the function.

The following code outlines a trivial main() function. The function used by a real application can be as complex as needed.

```c
void main(void)
{
    /* initialize a semaphore */
    ...
    /* register an ISR that gives the semaphore */
    ...
    /* monitor the semaphore forever */
    while (1) {
        /* wait for the semaphore to be given by the ISR */
        ...
        /* do whatever processing is now needed */
        ...
    }
}
```

**Suggested Uses** Use the main thread to perform thread-based processing in an application that only requires a single thread, rather than defining an additional application-specific thread.

Workqueue Threads

- Work Item Lifecycle
- Delayable Work
- Triggered Work
- System Workqueue
- How to Use Workqueues
- Workqueue Best Practices
- Suggested Uses
- Configuration Options
- API Reference
A workqueue is a kernel object that uses a dedicated thread to process work items in a first in, first out manner. Each work item is processed by calling the function specified by the work item. A workqueue is typically used by an ISR or a high-priority thread to offload non-urgent processing to a lower-priority thread so it does not impact time-sensitive processing.

Any number of workqueues can be defined (limited only by available RAM). Each workqueue is referenced by its memory address.

A workqueue has the following key properties:

- A queue of work items that have been added, but not yet processed.
- A thread that processes the work items in the queue. The priority of the thread is configurable, allowing it to be either cooperative or preemptive as required.

Regardless of workqueue thread priority the workqueue thread will yield between each submitted work item, to prevent a cooperative workqueue from starving other threads.

A workqueue must be initialized before it can be used. This sets its queue to empty and spawns the workqueue's thread. The thread runs forever, but sleeps when no work items are available.

Note: The behavior described here is changed from the Zephyr workqueue implementation used prior to release 2.6. Among the changes are:

- Precise tracking of the status of cancelled work items, so that the caller need not be concerned that an item may be processing when the cancellation returns. Checking of return values on cancellation is still required.
- Direct submission of delayable work items to the queue with \texttt{K\_NO\_WAIT} rather than always going through the timeout API, which could introduce delays.
- The ability to wait until a work item has completed or a queue has been drained.
- Finer control of behavior when scheduling a delayable work item, specifically allowing a previous deadline to remain unchanged when a work item is scheduled again.
- Safe handling of work item resubmission when the item is being processed on another workqueue.

Using the return values of \texttt{k\_work\_busy\_get()} or \texttt{k\_work\_is\_pending()}, or measurements of remaining time until delayable work is scheduled, should be avoided to prevent race conditions of the type observed with the previous implementation. See also Workqueue Best Practices.

Work Item Lifecycle

Any number of work items can be defined. Each work item is referenced by its memory address.

A work item is assigned a handler function, which is the function executed by the workqueue's thread when the work item is processed. This function accepts a single argument, which is the address of the work item itself. The work item also maintains information about its status.

A work item must be initialized before it can be used. This records the work item's handler function and marks it as not pending.

A work item may be queued (\texttt{K\_WORK\_QUEUED}) by submitting it to a workqueue by an ISR or a thread. Submitting a work item appends the work item to the workqueue's queue. Once the workqueue's thread has processed all of the preceding work items in its queue the thread will remove the next work item from the queue and invoke the work item's handler function. Depending on the scheduling priority of the workqueue's thread, and the work required by other items in the queue, a queued work item may be processed quickly or it may remain in the queue for an extended period of time.

A delayable work item may be scheduled (\texttt{K\_WORK\_DELAYED}) to a workqueue; see Delayable Work.

A work item will be running (\texttt{K\_WORK\_RUNNING}) when it is running on a work queue, and may also be canceling (\texttt{K\_WORK\_CANCELING}) if it started running before a thread has requested that it be cancelled.

A work item can be in multiple states; for example it can be:
• running on a queue;
• marked canceling (because a thread used `k_work_cancel_sync()` to wait until the work item completed);
• queued to run again on the same queue;
• scheduled to be submitted to a (possibly different) queue

_all simultaneously_. A work item that is in any of these states is pending (`k_work_is_pending()`) or busy (`k_work_busy_get()`).

A handler function can use any kernel API available to threads. However, operations that are potentially blocking (e.g. taking a semaphore) must be used with care, since the workqueue cannot process subsequent work items in its queue until the handler function finishes executing.

The single argument that is passed to a handler function can be ignored if it is not required. If the handler function requires additional information about the work it is to perform, the work item can be embedded in a larger data structure. The handler function can then use the argument value to compute the address of the enclosing data structure with `CONTAINER_OF`, and thereby obtain access to the additional information it needs.

A work item is typically initialized once and then submitted to a specific workqueue whenever work needs to be performed. If an ISR or a thread attempts to submit a work item that is already queued the work item is not affected; the work item remains in its current place in the workqueue's queue, and the work is only performed once.

A handler function is permitted to re-submit its work item argument to the workqueue, since the work item is no longer queued at that time. This allows the handler to execute work in stages, without unduly delaying the processing of other work items in the workqueue's queue.

**Important:** A pending work item _must not_ be altered until the item has been processed by the workqueue thread. This means a work item must not be re-initialized while it is busy. Furthermore, any additional information the work item's handler function needs to perform its work must not be altered until the handler function has finished executing.

**Delayable Work** An ISR or a thread may need to schedule a work item that is to be processed only after a specified period of time, rather than immediately. This can be done by scheduling a delayable work item to be submitted to a workqueue at a future time.

A delayable work item contains a standard work item but adds fields that record when and where the item should be submitted.

A delayable work item is initialized and scheduled to a workqueue in a similar manner to a standard work item, although different kernel APIs are used. When the schedule request is made the kernel initiates a timeout mechanism that is triggered after the specified delay has elapsed. Once the timeout occurs the kernel submits the work item to the specified workqueue, where it remains queued until it is processed in the standard manner.

Note that work handler used for delayable still receives a pointer to the underlying non-delayable work structure, which is not publicly accessible from `k_work_delayable`. To get access to an object that contains the delayable work object use this idiom:

```c
static void work_handler(struct k_work *work)
{
    struct k_work_delayable *dwork = k_work_delayable_from_work(work);
    struct work_context *ctx = CONTAINER_OF(dwork, struct work_context, timed_work);
    ...
}
```
Triggered Work  The \texttt{k\_work\_poll\_submit()} interface schedules a triggered work item in response to a poll event (see Polling API), that will call a user-defined function when a monitored resource becomes available or poll signal is raised, or a timeout occurs. In contrast to \texttt{k\_poll()}, the triggered work does not require a dedicated thread waiting or actively polling for a poll event.

A triggered work item is a standard work item that has the following added properties:

- A pointer to an array of poll events that will trigger work item submissions to the workqueue
- A size of the array containing poll events.

A triggered work item is initialized and submitted to a workqueue in a similar manner to a standard work item, although dedicated kernel APIs are used. When a submit request is made, the kernel begins observing kernel objects specified by the poll events. Once at least one of the observed kernel object’s changes state, the work item is submitted to the specified workqueue, where it remains queued until it is processed in the standard manner.

\textbf{Important:} The triggered work item as well as the referenced array of poll events have to be valid and cannot be modified for a complete triggered work item lifecycle, from submission to work item execution or cancellation.

An ISR or a thread may cancel a triggered work item it has submitted as long as it is still waiting for a poll event. In such case, the kernel stops waiting for attached poll events and the specified work is not executed. Otherwise the cancellation cannot be performed.

System Workqueue  The kernel defines a workqueue known as the system workqueue, which is available to any application or kernel code that requires workqueue support. The system workqueue is optional, and only exists if the application makes use of it.

\textbf{Important:} Additional workqueues should only be defined when it is not possible to submit new work items to the system workqueue, since each new workqueue incurs a significant cost in memory footprint. A new workqueue can be justified if it is not possible for its work items to co-exist with existing system workqueue work items without an unacceptable impact; for example, if the new work items perform blocking operations that would delay other system workqueue processing to an unacceptable degree.

How to Use Workqueues

Defining and Controlling a Workqueue  A workqueue is defined using a variable of type \texttt{k\_work\_q}. The workqueue is initialized by defining the stack area used by its thread, initializing the \texttt{k\_work\_q}, either zeroing its memory or calling \texttt{k\_work\_queue\_init()}, and then calling \texttt{k\_work\_queue\_start()}. The stack area must be defined using \texttt{K\_THREAD\_STACK\_DEFINE} to ensure it is properly set up in memory.

The following code defines and initializes a workqueue:

\begin{verbatim}
#define MY_STACK_SIZE 512
#define MY_PRIORITY 5

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);

struct k_work_q my_work_q;

k_work_queue_init(&my_work_q);

k_work_queue_start(&my_work_q, my_stack_area, 
K_THREAD_STACK_SIZEOF(my_stack_area), MY_PRIORITY, 
NULL);
\end{verbatim}
In addition the queue identity and certain behavior related to thread rescheduling can be controlled by the optional final parameter; see \texttt{k_work_queue_start()} for details.

The following API can be used to interact with a workqueue:

- \texttt{k_work_queue_drain()} can be used to block the caller until the work queue has no items left. Work items resubmitted from the workqueue thread are accepted while a queue is draining, but work items from any other thread or ISR are rejected. The restriction on submitting more work can be extended past the completion of the drain operation in order to allow the blocking thread to perform additional work while the queue is “plugged”. Note that draining a queue has no effect on scheduling or processing delayable items, but if the queue is plugged and the deadline expires the item will silently fail to be submitted.

- \texttt{k_work_queue_unplug()} removes any previous block on submission to the queue due to a previous drain operation.

**Submitting a Work Item** A work item is defined using a variable of type \texttt{k_work}. It must be initialized by calling \texttt{k_work_init()}, unless it is defined using \texttt{K_WORK_DEFINE} in which case initialization is performed at compile-time.

An initialized work item can be submitted to the system workqueue by calling \texttt{k_work_submit()}, or to a specified workqueue by calling \texttt{k_work_submit_to_queue()}.

The following code demonstrates how an ISR can offload the printing of error messages to the system workqueue. Note that if the ISR attempts to resubmit the work item while it is still queued, the work item is left unchanged and the associated error message will not be printed.

```c
struct device_info {
    struct k_work work;
    char name[16]
} my_device;

void my_isr(void *arg) {
    ... 
    if (error detected) {
        k_work_submit(&my_device.work);
    }
    ...
}

void print_error(struct k_work *item) {
    struct device_info *the_device = CONTAINER_OF(item, struct device_info, work);
    printk("Got error on device %s\n", the_device->name);
}

/* initialize name info for a device */
strcpy(my_device.name, "FOO_dev");

/* initialize work item for printing device's error messages */
k_work_init(&my_device.work, print_error);

/* install my_isr() as interrupt handler for the device (not shown) */
...
```

The following API can be used to check the status of or synchronize with the work item:

- \texttt{k_work_busy_get()} returns a snapshot of flags indicating work item state. A zero value indicates the work is not scheduled, submitted, being executed, or otherwise still being referenced by the
workqueue infrastructure.

- `k_work_is_pending()` is a helper that indicates `true` if and only if the work is scheduled, queued, or running.
- `k_work_flush()` may be invoked from threads to block until the work item has completed. It returns immediately if the work is not pending.
- `k_work_cancel()` attempts to prevent the work item from being executed. This may or may not be successful. This is safe to invoke from ISRs.
- `k_work_cancel_sync()` may be invoked from threads to block until the work completes; it will return immediately if the cancellation was successful or not necessary (the work wasn’t submitted or running). This can be used after `k_work_cancel()` is invoked (from an ISR) to confirm completion of an ISR-initiated cancellation.

Scheduling a Delayable Work Item  A delayable work item is defined using a variable of type `k_work_delayable`. It must be initialized by calling `k_work_init_delayable()`. For delayed work there are two common use cases, depending on whether a deadline should be extended if a new event occurs. An example is collecting data that comes in asynchronously, e.g. characters from a UART associated with a keyboard. There are two APIs that submit work after a delay:

- `k_work_schedule()` (or `k_work_schedule_for_queue()` ) schedules work to be executed at a specific time or after a delay. Further attempts to schedule the same item with this API before the delay completes will not change the time at which the item will be submitted to its queue. Use this if the policy is to keep collecting data until a specified delay since the first unprocessed data was received;
- `k_work_reschedule()` (or `k_work_reschedule_for_queue()` ) unconditionally sets the deadline for the work, replacing any previous incomplete delay and changing the destination queue if necessary. Use this if the policy is to keep collecting data until a specified delay since the last unprocessed data was received.

If the work item is not scheduled both APIs behave the same. If `K_NO_WAIT` is specified as the delay the behavior is as if the item was immediately submitted directly to the target queue, without waiting for a minimal timeout (unless `k_work_schedule()` is used and a previous delay has not completed).

Both also have variants that allow control of the queue used for submission.

The helper function `k_work_delayable_from_work()` can be used to get a pointer to the containing `k_work_delayable` from a pointer to `k_work` that is passed to a work handler function.

The following additional API can be used to check the status of or synchronize with the work item:

- `k_work_delayable_busy_get()` is the analog to `k_work_busy_get()` for delayable work.
- `k_work_delayable_is_pending()` is the analog to `k_work_is_pending()` for delayable work.
- `k_work_flush_delayable()` is the analog to `k_work_flush()` for delayable work.
- `k_work_cancel_delayable()` is the analog to `k_work_cancel()` for delayable work; similarly with `k_work_cancel_delayable_sync()`.

Synchronizing with Work Items  While the state of both regular and delayable work items can be determined from any context using `k_work_busy_get()` and `k_work_delayable_busy_get()` some use cases require synchronizing with work items after they’ve been submitted. `k_work_flush()`, `k_work_cancel_sync()`, and `k_work_cancel_delayable_sync()` can be invoked from thread context to wait until the requested state has been reached.

These APIs must be provided with a `k_work_sync` object that has no application-inspectable components but is needed to provide the synchronization objects. These objects should not be allocated on a stack if the code is expected to work on architectures with `CONFIG_KERNEL_COHERENCE`.

3.1. Kernel Services  265
Workqueue Best Practices

Avoid Race Conditions  Sometimes the data a work item must process is naturally thread-safe, for example when it's put into a `k_queue` by some thread and processed in the work thread. More often external synchronization is required to avoid data races: cases where the work thread might inspect or manipulate shared state that's being accessed by another thread or interrupt. Such state might be a flag indicating that work needs to be done, or a shared object that is filled by an ISR or thread and read by the work handler.

For simple flags [Atomic Services](#) may be sufficient. In other cases spin locks (`k_spinlock_t`) or thread-aware locks (`k_sem`, `k_mutex`, ...) may be used to ensure data races don't occur.

If the selected lock mechanism can `sleep` then allowing the work thread to sleep will starve other work queue items, which may need to make progress in order to get the lock released. Work handlers should try to take the lock with its no-wait path. For example:

```c
static void work_handler(struct work *work)
{
    struct work_context *parent = CONTAINER_OF(work, struct work_context, work_item);

    if (k_mutex_lock(&parent->lock, K_NO_WAIT) != 0) {
        /* NB: Submit will fail if the work item is being cancelled. */
        (void)k_work_submit(work);
        return;
    }

    /* do stuff under lock */
    k_mutex_unlock(&parent->lock);
    /* do stuff without lock */
}
```

Be aware that if the lock is held by a thread with a lower priority than the work queue the resubmission may starve the thread that would release the lock, causing the application to fail. Where the idiom above is required a delayable work item is preferred, and the work should be (re-)scheduled with a non-zero delay to allow the thread holding the lock to make progress.

Note that submitting from the work handler can fail if the work item had been cancelled. Generally this is acceptable, since the cancellation will complete once the handler finishes. If it is not, the code above must take other steps to notify the application that the work could not be performed.

Work items in isolation are self-locking, so you don't need to hold an external lock just to submit or schedule them. Even if you use external state protected by such a lock to prevent further resubmission, it's safe to do the resubmit as long as you're sure that eventually the item will take its lock and check that state to determine whether it should do anything. Where a delayable work item is being rescheduled in its handler due to inability to take the lock some other self-locking state, such as an atomic flag set by the application/driver when the cancel is initiated, would be required to detect the cancellation and avoid the cancelled work item being submitted again after the deadline.

Check Return Values  All work API functions return status of the underlying operation, and in many cases it is important to verify that the intended result was obtained.

- Submitting a work item (`k_work_submit_to_queue()`) can fail if the work is being cancelled or the queue is not accepting new items. If this happens the work will not be executed, which could cause a subsystem that is animated by work handler activity to become non-responsive.
- Asynchronous cancellation (`k_work_cancel()` or `k_work_cancel_delayable()`) can complete while the work item is still being run by a handler. Proceeding to manipulate state shared with the work handler will result in data races that can cause failures.
Many race conditions have been present in Zephyr code because the results of an operation were not checked.

There may be good reason to believe that a return value indicating that the operation did not complete as expected is not a problem. In those cases the code should clearly document this, by (1) casting the return value to void to indicate that the result is intentionally ignored, and (2) documenting what happens in the unexpected case. For example:

```c
/* If this fails, the work handler will check pub->active and * exit without transmitting. */
(void)k_work_cancel_delayable(&pub->timer);
```

However in such a case the following code must still avoid data races, as it cannot guarantee that the work thread is not accessing work-related state.

**Don’t Optimize Prematurely**  The workqueue API is designed to be safe when invoked from multiple threads and interrupts. Attempts to externally inspect a work item’s state and make decisions based on the result are likely to create new problems.

So when new work comes in, just submit it. Don’t attempt to “optimize” by checking whether the work item is already submitted by inspecting snapshot state with `k_work_is_pending()` or `k_work_busy_get()`, or checking for a non-zero delay from `k_work_delayable_remaining_get()`. Those checks are fragile: a “busy” indication can be obsolete by the time the test is returned, and a “not-busy” indication can also be wrong if work is submitted from multiple contexts, or (for delayable work) if the deadline has completed but the work is still in queued or running state.

A general best practice is to always maintain in shared state some condition that can be checked by the handler to confirm whether there is work to be done. This way you can use the work handler as the standard cleanup path: rather than having to deal with cancellation and cleanup at points where items are submitted, you may be able to have everything done in the work handler itself.

A rare case where you could safely use `k_work_is_pending()` is as a check to avoid invoking `k_work_flush()` or `k_work_cancel_sync()`, if you are certain that nothing else might submit the work while you’re checking (generally because you’re holding a lock that prevents access to state used for submission).

**Suggested Uses**  Use the system workqueue to defer complex interrupt-related processing from an ISR to a shared thread. This allows the interrupt-related processing to be done promptly without compromising the system’s ability to respond to subsequent interrupts, and does not require the application to define and manage an additional thread to do the processing.

**Configuration Options**  Related configuration options:

- `CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE`
- `CONFIG_SYSTEM_WORKQUEUE_PRIORITY`
- `CONFIG_SYSTEM_WORKQUEUE_NO_YIELD`

**API Reference**

group workqueue_apis

*Defines*
K_WORK_DELAYABLE_DEFINE(work, work_handler)
Initialize a statically-defined delayable work item.
This macro can be used to initialize a statically-defined delayable work item, prior to its first use. For example,

```
static K_WORK_DELAYABLE_DEFINE(<dwork>, <work_handler>);
```

Note that if the runtime dependencies support initialization with `k_work_init_delayable()` using that will eliminate the initialized object in ROM that is produced by this macro and copied in at system startup.

**Parameters**
- `work` – Symbol name for delayable work item object
- `work_handler` – Function to invoke each time work item is processed.

K_WORK_USER_DEFINE(work, work_handler)
Initialize a statically-defined user work item.
This macro can be used to initialize a statically-defined user work item, prior to its first use. For example,

```
static K_WORK_USER_DEFINE(<work>, <work_handler>);
```

**Parameters**
- `work` – Symbol name for work item object
- `work_handler` – Function to invoke each time work item is processed.

K_WORK_DEFINE(work, work_handler)
Initialize a statically-defined work item.
This macro can be used to initialize a statically-defined workqueue work item, prior to its first use. For example,

```
static K_WORK_DEFINE(<work>, <work_handler>);
```

**Parameters**
- `work` – Symbol name for work item object
- `work_handler` – Function to invoke each time work item is processed.

**Typedefs**

typedef void (*k_work_handler_t)(struct k_work *work)
The signature for a work item handler function.
The function will be invoked by the thread animating a work queue.

**Param work**
the work item that provided the handler.
typedef void (*k_work_user_handler_t)(struct k_work_user *work)

Work item handler function type for user work queues.

A work item’s handler function is executed by a user workqueue’s thread when the work item
is processed by the workqueue.

**Param work**
Address of the work item.

**Enums**

eenum [anonymous]

**Values:**

enumerator K_WORK_RUNNING = BIT(K_WORK_RUNNING_BIT)
Flag indicating a work item that is running under a work queue thread.
Accessed via k_work_busy_get(). May co-occur with other flags.

enumerator K_WORK_CANCELING = BIT(K_WORK_CANCELING_BIT)
Flag indicating a work item that is being canceled.
Accessed via k_work_busy_get(). May co-occur with other flags.

enumerator K_WORK_QUEUED = BIT(K_WORK_QUEUED_BIT)
Flag indicating a work item that has been submitted to a queue but has not started run-
ning.
Accessed via k_work_busy_get(). May co-occur with other flags.

enumerator K_WORK_DELAYED = BIT(K_WORK_DELAYED_BIT)
Flag indicating a delayed work item that is scheduled for submission to a queue.
Accessed via k_work_busy_get(). May co-occur with other flags.

**Functions**

void k_work_init(struct k_work *work, k_work_handler_t handler)
Initialize a (non-delayable) work structure.

This must be invoked before submitting a work structure for the first time. It need not be
invoked again on the same work structure. It can be re-invoked to change the associated
handler, but this must be done when the work item is idle.

**Function properties (list may not be complete)**

* isr-ok

**Parameters**

- work – the work structure to be initialized.
- handler – the handler to be invoked by the work item.
int k_work_busy_get(const struct k_work *work)
Busy state flags from the work item.
A zero return value indicates the work item appears to be idle.

**Function properties (list may not be complete)**

**isr-ok**

**Note:** This is a live snapshot of state, which may change before the result is checked. Use locks where appropriate.

**Parameters**

- **work** – pointer to the work item.

**Returns**

a mask of flags K_WORK_DELAYED, K_WORK_QUEUED, K_WORK_RUNNING, and K_WORK_CANCELING.

static inline bool k_work_is_pending(const struct k_work *work)
Test whether a work item is currently pending.
Wrapper to determine whether a work item is in a non-idle dstate.

**Function properties (list may not be complete)**

**isr-ok**

**Note:** This is a live snapshot of state, which may change before the result is checked. Use locks where appropriate.

**Parameters**

- **work** – pointer to the work item.

**Returns**

true if and only if `k_work_busy_get()` returns a non-zero value.

int k_work_submit_to_queue(struct k_work *queue, struct k_work *work)
Submit a work item to a queue.

**Function properties (list may not be complete)**

**isr-ok**

**Parameters**

- **queue** – pointer to the work queue on which the item should run. If NULL the queue from the most recent submission will be used.
- **work** – pointer to the work item.

**Return values**

- 0 – if work was already submitted to a queue
- 1 – if work was not submitted and has been queued to queue
- 2 – if work was running and has been queued to the queue that was running it
int k_work_submit(struct k_work *work)
Submit a work item to the system queue.

Function properties (list may not be complete)
isr-ok

Parameters
• work – pointer to the work item.

Returns
as with k_work_submit_to_queue().

bool k_work_flush(struct k_work *work, struct k_work_sync *sync)
Wait for last-submitted instance to complete.
Resubmissions may occur while waiting, including chained submissions (from within the han-
dler).

Note:  Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

Note:  Behavior is undefined if this function is invoked on work from a work queue running work.

Parameters
• work – pointer to the work item.
• sync – pointer to an opaque item containing state related to the pending can-
cellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

Return values
• true – if call had to wait for completion
• false – if work was already idle

int k_work_cancel(struct k_work *work)
Cancel a work item.
This attempts to prevent a pending (non-delayable) work item from being processed by removing it from the work queue. If the item is being processed, the work item will continue to be processed, but resubmissions are rejected until cancellation completes.

If this returns zero cancellation is complete, otherwise something (probably a work queue thread) is still referencing the item.

See also \texttt{k_work_cancel\_sync()}.

**Function properties (list may not be complete)**

\texttt{isr-ok}

**Parameters**

- \texttt{work} – pointer to the work item.

**Returns**

the \texttt{k_work\_busy\_get()} status indicating the state of the item after all cancellation steps performed by this call are completed.

\begin{verbatim}
bool k_work_cancel\_sync(struct k_work *work, struct k_work\_sync *sync)

Cancel a work item and wait for it to complete.
Same as \texttt{k_work\_cancel()} but does not return until cancellation is complete. This can be invoked by a thread after \texttt{k_work\_cancel()} to synchronize with a previous cancellation.

On return the work structure will be idle unless something submits it after the cancellation was complete.

\textbf{Note:} Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

\textbf{Note:} Behavior is undefined if this function is invoked on \texttt{work} from a work queue running \texttt{work}.

\end{verbatim}

**Parameters**

- \texttt{work} – pointer to the work item.
- \texttt{sync} – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

**Return values**

- \texttt{true} – if work was pending (call had to wait for cancellation of a running handler to complete, or scheduled or submitted operations were cancelled);
- \texttt{false} – otherwise

\begin{verbatim}
void k_work\_queue\_init(struct k_work\_q *queue)

Initialize a work queue structure.
This must be invoked before starting a work queue structure for the first time. It need not be invoked again on the same work queue structure.
\end{verbatim}
Function properties (list may not be complete)

**isr-ok**

Parameters

- `queue` – the queue structure to be initialized.

```c
void k_work_queue_start(struct k_work_q *queue, k_thread_stack_t *stack, size_t stack_size, int prio, const struct k_work_queue_config *cfg)
```

Initialize a work queue.

This configures the work queue thread and starts it running. The function should not be re-invoked on a queue.

Parameters

- `queue` – pointer to the queue structure. It must be initialized in zeroed/bss memory or with `k_work_queue_init` before use.
- `stack` – pointer to the work thread stack area.
- `stack_size` – size of the the work thread stack area, in bytes.
- `prio` – initial thread priority
- `cfg` – optional additional configuration parameters. Pass `NULL` if not required, to use the defaults documented in `k_work_queue_config`.

```c
static inline k_tid_t k_work_queue_thread_get(struct k_work_q *queue)
```

Access the thread that animates a work queue.

This is necessary to grant a work queue thread access to things the work items it will process are expected to use.

Parameters

- `queue` – pointer to the queue structure.

Returns

the thread associated with the work queue.

```c
int k_work_queue_drain(struct k_work_q *queue, bool plug)
```

Wait until the work queue has drained, optionally plugging it.

This blocks submission to the work queue except when coming from queue thread, and blocks the caller until no more work items are available in the queue.

If `plug` is true then submission will continue to be blocked after the drain operation completes until `k_work_queue_unplug()` is invoked.

Note that work items that are delayed are not yet associated with their work queue. They must be cancelled externally if a goal is to ensure the work queue remains empty. The `plug` feature can be used to prevent delayed items from being submitted after the drain completes.

Parameters

- `queue` – pointer to the queue structure.
- `plug` – if true the work queue will continue to block new submissions after all items have drained.

Return values

- `1` – if call had to wait for the drain to complete
- `0` – if call did not have to wait
- `negative` – if wait was interrupted or failed
int k_work_queue_unplug(struct k_work_q *queue)
Release a work queue to accept new submissions.
This releases the block on new submissions placed when k_work_queue_drain() is invoked with the plug option enabled. If this is invoked before the drain completes new items may be submitted as soon as the drain completes.

**Function properties (list may not be complete)**

*isr-ok*

**Parameters**
- queue – pointer to the queue structure.

**Return values**
- 0 – if successfully unplugged
- -EALREADY – if the work queue was not plugged.

void k_work_init_delayable(struct k_work_delayable *dwork, k_work_handler_t handler)
Initialize a delayable work structure.
This must be invoked before scheduling a delayable work structure for the first time. It need not be invoked again on the same work structure. It can be re-invoked to change the associated handler, but this must be done when the work item is idle.

**Function properties (list may not be complete)**

*isr-ok*

**Parameters**
- dwork – the delayable work structure to be initialized.
- handler – the handler to be invoked by the work item.

static inline struct k_work_delayable *k_work_delayable_from_work(struct k_work *work)
Get the parent delayable work structure from a work pointer.
This function is necessary when a k_work_handler_t function is passed to k_work_schedule_for_queue() and the handler needs to access data from the container of the containing k_work_delayable.

**Parameters**
- work – Address passed to the work handler

**Returns**
Address of the containing k_work_delayable structure.

int k_work_delayable_busy_get(const struct k_work_delayable *dwork)
Busy state flags from the delayable work item.

**Function properties (list may not be complete)**

*isr-ok*

**Note:** This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.
Parameters
  • dwork – pointer to the delayable work item.

Returns
  a mask of flags K_WORK_DELAYED, K_WORK_QUEUED, K_WORK_RUNNING, and K_WORK_CANCELING. A zero return value indicates the work item appears to be idle.

static inline bool k_work_delayable_is_pending(const struct k_work_delayable *dwork)
Test whether a delayed work item is currently pending.
Wrapper to determine whether a delayed work item is in a non-idle state.

Function properties (list may not be complete)
  isr-ok

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters
  • dwork – pointer to the delayable work item.

Returns
  true if and only if k_work_delayable_busy_get() returns a non-zero value.

static inline k_ticks_t k_work_delayable_expires_get(const struct k_work_delayable *dwork)
Get the absolute tick count at which a scheduled delayable work will be submitted.

Function properties (list may not be complete)
  isr-ok

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters
  • dwork – pointer to the delayable work item.

Returns
  the tick count when the timer that will schedule the work item will expire, or the current tick count if the work is not scheduled.

static inline k_ticks_t k_work_delayable_remaining_get(const struct k_work_delayable *dwork)
Get the number of ticks until a scheduled delayable work will be submitted.

Function properties (list may not be complete)
  isr-ok

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.
Parameters

- dwork – pointer to the delayable work item.

Returns

the number of ticks until the timer that will schedule the work item will expire, or zero if the item is not scheduled.

#include <k_work.h>

int k_work_schedule_for_queue(struct k_work_q *queue, struct k_work_delayable *dwork, k_timeout_t delay)

Submit an idle work item to a queue after a delay.

Unlike k_work_reschedule_for_queue() this is a no-op if the work item is already scheduled or submitted, even if delay is K_NO_WAIT.

Function properties (list may not be complete)

isr-ok

Parameters

- queue – the queue on which the work item should be submitted after the delay.
- dwork – pointer to the delayable work item.
- delay – the time to wait before submitting the work item. If K_NO_WAIT and the work is not pending this is equivalent to k_work_submit_to_queue().

Return values

- 0 – if work was already scheduled or submitted.
- 1 – if work has been scheduled.
- -EBUSY – if delay is K_NO_WAIT and k_work_submit_to_queue() fails with this code.
- -EINVAL – if delay is K_NO_WAIT and k_work_submit_to_queue() fails with this code.
- -ENODEV – if delay is K_NO_WAIT and k_work_submit_to_queue() fails with this code.

#include <k_work.h>

int k_work_schedule(struct k_work_delayable *dwork, k_timeout_t delay)

Submit an idle work item to the system work queue after a delay.

This is a thin wrapper around k_work_schedule_for_queue(), with all the API characteristics of that function.

Parameters

- dwork – pointer to the delayable work item.
- delay – the time to wait before submitting the work item. If K_NO_WAIT this is equivalent to k_work_submit_to_queue().

Returns

as with k_work_schedule_for_queue().

#include <k_work.h>

int k_work_reschedule_for_queue(struct k_work_q *queue, struct k_work_delayable *dwork, k_timeout_t delay)

Reschedule a work item to a queue after a delay.

Unlike k_work_schedule_for_queue() this function can change the deadline of a scheduled work item, and will schedule a work item that isn't idle (e.g. is submitted or running). This function does not affect ("unsubmit") a work item that has been submitted to a queue.
Function properties (list may not be complete)

\textbullet{} \textit{isr-ok}

\underline{Note:} If \texttt{delay} is \texttt{K\_NO\_WAIT} ("no delay") the return values are as with \texttt{k\_work\_submit\_to\_queue()}. 

\textbf{Parameters}

- \texttt{queue} – the queue on which the work item should be submitted after the delay.
- \texttt{dwork} – pointer to the delayable work item.
- \texttt{delay} – the time to wait before submitting the work item. If \texttt{K\_NO\_WAIT} this is equivalent to \texttt{k\_work\_submit\_to\_queue()} after canceling any previous scheduled submission.

\textbf{Return values}

- \texttt{0} – if \texttt{delay} is \texttt{K\_NO\_WAIT} and work was already on a queue
- \texttt{1} – if
  - delay is \texttt{K\_NO\_WAIT} and work was not submitted but has now been queued to queue; or
  - delay not \texttt{K\_NO\_WAIT} and work has been scheduled
- \texttt{2} – if delay is \texttt{K\_NO\_WAIT} and work was running and has been queued to the queue that was running it
- \texttt{-EBUSY} – if delay is \texttt{K\_NO\_WAIT} and \texttt{k\_work\_submit\_to\_queue()} fails with this code.
- \texttt{-EINVAL} – if delay is \texttt{K\_NO\_WAIT} and \texttt{k\_work\_submit\_to\_queue()} fails with this code.
- \texttt{-ENODEV} – if delay is \texttt{K\_NO\_WAIT} and \texttt{k\_work\_submit\_to\_queue()} fails with this code.

\begin{verbatim}
int k_work_reschedule(struct k_work_delayable *dwork, k_timeout_t delay)

Reschedule a work item to the system work queue after a delay.

This is a thin wrapper around \texttt{k\_work\_reschedule\_for\_queue()}, with all the API characteristics of that function.

\textbf{Parameters}

- \texttt{dwork} – pointer to the delayable work item.
- \texttt{delay} – the time to wait before submitting the work item.

\textbf{Returns}

as with \texttt{k\_work\_reschedule\_for\_queue()}. 
\end{verbatim}

\begin{verbatim}
bool k_work_flush_delayable(struct k_work_delayable *dwork, struct k_work_sync *sync)

Flush delayable work.

If the work is scheduled, it is immediately submitted. Then the caller blocks until the work completes, as with \texttt{k\_work\_flush()}. 

\underline{Note:} Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume. 
\end{verbatim}
**Note:** Behavior is undefined if this function is invoked on `dwork` from a work queue running `dwork`.

**Parameters**

- `dwork` – pointer to the delayable work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

**Return values**

- `true` – if call had to wait for completion
- `false` – if work was already idle

```c
int k_work_cancel_delayable(struct k_work_delayable *dwork)
```

Cancel delayable work.

Similar to `k_work_cancel()` but for delayable work. If the work is scheduled or submitted it is canceled. This function does not wait for the cancellation to complete.

**Function properties (list may not be complete)**

- `isr-ok`

**Note:** The work may still be running when this returns. Use `k_work_flush_delayable()` or `k_work_cancel_delayable_sync()` to ensure it is not running.

**Note:** Canceling delayable work does not prevent rescheduling it. It does prevent submitting it until the cancellation completes.

**Parameters**

- `dwork` – pointer to the delayable work item.

**Returns**

the `k_work_delayable_busy_get()` status indicating the state of the item after all cancellation steps performed by this call are completed.

```c
bool k_work_cancel_delayable_sync(struct k_work_delayable *dwork, struct k_work_sync *sync)
```

Cancel delayable work and wait.

Like `k_work_cancel_delayable()` but waits until the work becomes idle.

**Note:** Canceling delayable work does not prevent rescheduling it. It does prevent submitting it until the cancellation completes.
Note: Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

Note: Behavior is undefined if this function is invoked on dwork from a work queue running dwork.

Parameters

- dwork – pointer to the delayable work item.
- sync – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

Return values

- true – if work was not idle (call had to wait for cancellation of a running handler to complete, or scheduled or submitted operations were cancelled);
- false – otherwise

static inline void k_work_user_init(struct k_work_user *work, k_work_user_handler_t handler)

Initialize a userspace work item.

This routine initializes a user workqueue work item, prior to its first use.

Parameters

- work – Address of work item.
- handler – Function to invoke each time work item is processed.

static inline bool k_work_user_is_pending(struct k_work_user *work)

Check if a userspace work item is pending.

This routine indicates if user work item work is pending in a workqueue’s queue.

Function properties (list may not be complete)

- isr-ok

Note: Checking if the work is pending gives no guarantee that the work will still be pending when this information is used. It is up to the caller to make sure that this information is used in a safe manner.

Parameters

- work – Address of work item.

Returns

true if work item is pending, or false if it is not pending.
static inline int k_work_user_submit_to_queue(struct k_work_user_q *work_q, struct k_work_user *work)

Submit a work item to a user mode workqueue.
Submits a work item to a workqueue that runs in user mode. A temporary memory allocation is made from the caller's resource pool which is freed once the worker thread consumes the k_work item. The workqueue thread must have memory access to the k_work item being submitted. The caller must have permission granted on the work_q parameter's queue object.

Function properties (list may not be complete)

  isr-ok

Parameters

  • work_q – Address of workqueue.
  • work – Address of work item.

Return values

  • -EBUSY – if the work item was already in some workqueue
  • -ENOMEM – if no memory for thread resource pool allocation
  • 0 – Success

void k_work_user_queue_start(struct k_work_user_q *work_q, k_thread_stack_t *stack, size_t stack_size, int prio, const char *name)

Start a workqueue in user mode.
This works identically to k_work_queue_start() except it is callable from user mode, and the worker thread created will run in user mode. The caller must have permissions granted on both the work_q parameter's thread and queue objects, and the same restrictions on priority apply as k_thread_create().

Parameters

  • work_q – Address of workqueue.
  • stack – Pointer to work queue thread's stack space, as defined by K_THREAD_STACK_DEFINE()
  • stack_size – Size of the work queue thread's stack (in bytes), which should either be the same constant passed to K_THREAD_STACK_DEFINE() or the value of K_THREAD_STACK_SIZEOF().
  • prio – Priority of the work queue's thread.
  • name – optional thread name. If not null a copy is made into the thread's name buffer.

static inline k_tid_t k_work_user_queue_thread_get(struct k_work_user_q *work_q)

Access the user mode thread that animates a work queue.
This is necessary to grant a user mode work queue thread access to things the work items it will process are expected to use.

Parameters

  • work_q – pointer to the user mode queue structure.

Returns

  the user mode thread associated with the work queue.
void k_work_poll_init(struct k_work_poll *work, k_work_handler_t handler)

Initialize a triggered work item.

This routine initializes a workqueue triggered work item, prior to its first use.

Parameters

• work – Address of triggered work item.
• handler – Function to invoke each time work item is processed.

int k_work_poll_submit_to_queue(struct k_work_q *work_q, struct k_work_poll *work, struct k_poll_event *events, int num_events, k_timeout_t timeout)

Submit a triggered work item.

This routine schedules work item work to be processed by workqueue work_q when one of the given events is signaled. The routine initiates internal poller for the work item and then returns to the caller. Only when one of the watched events happen the work item is actually submitted to the workqueue and becomes pending.

Submitting a previously submitted triggered work item that is still waiting for the event cancels the existing submission and reschedules it the using the new event list. Note that this behavior is inherently subject to race conditions with the pre-existing triggered work item and work queue, so care must be taken to synchronize such resubmissions externally.

Function properties (list may not be complete)

isr-ok

Warning: Provided array of events as well as a triggered work item must be placed in persistent memory (valid until work handler execution or work cancellation) and cannot be modified after submission.

Parameters

• work_q – Address of workqueue.
• work – Address of delayed work item.
• events – An array of events which trigger the work.
• num_events – The number of events in the array.
• timeout – Timeout after which the work will be scheduled for execution even if not triggered.

Return values

• 0 – Work item started watching for events.
• -EINVAL – Work item is being processed or has completed its work.
• -EADDRINUSE – Work item is pending on a different workqueue.

int k_work_poll_submit(struct k_work_poll *work, struct k_poll_event *events, int num_events, k_timeout_t timeout)

Submit a triggered work item to the system workqueue.

This routine schedules work item work to be processed by system workqueue when one of the given events is signaled. The routine initiates internal poller for the work item and then returns to the caller. Only when one of the watched events happen the work item is actually submitted to the workqueue and becomes pending.

Submitting a previously submitted triggered work item that is still waiting for the event cancels the existing submission and reschedules it the using the new event list. Note that this
behavior is inherently subject to race conditions with the pre-existing triggered work item and work queue, so care must be taken to synchronize such resubmissions externally.

**Function properties (list may not be complete)**

`isr-ok`

**Warning:** Provided array of events as well as a triggered work item must not be modified until the item has been processed by the workqueue.

**Parameters**

- `work` – Address of delayed work item.
- `events` – An array of events which trigger the work.
- `num_events` – The number of events in the array.
- `timeout` – Timeout after which the work will be scheduled for execution even if not triggered.

**Return values**

- `0` – Work item started watching for events.
- `-EINVAL` – Work item is being processed or has completed its work.
- `-EADDRINUSE` – Work item is pending on a different workqueue.

```c
int k_work_poll_cancel(struct k_work_poll *work)
```

Cancel a triggered work item.

This routine cancels the submission of triggered work item `work`. A triggered work item can only be canceled if no event triggered work submission.

**Function properties (list may not be complete)**

`isr-ok`

**Parameters**

- `work` – Address of delayed work item.

**Return values**

- `0` – Work item canceled.
- `-EINVAL` – Work item is being processed or has completed its work.

```c
struct k_work_poll
#include <kernel.h> A structure used to submit work.
```

```c
struct k_work_delayable
#include <kernel.h> A structure used to submit work after a delay.
```

```c
struct k_work_sync
#include <kernel.h> A structure holding internal state for a pending synchronous operation on a work item or queue.
```
Instances of this type are provided by the caller for invocation of `k_work_flush()`, `k_work_cancel_sync()` and sibling flush and cancel APIs. A referenced object must persist until the call returns, and be accessible from both the caller thread and the work queue thread.

**Note:** If CONFIG_KERNEL_COHERENCE is enabled the object must be allocated in coherent memory; see `arch_mem_coherent()`. The stack on these architectures is generally not coherent. be stack-allocated. Violations are detected by runtime assertion.

```
struct k_work_queue_config
#include <kernel.h> A structure holding optional configuration items for a work queue.
This structure, and values it references, are not retained by `k_work_queue_start()`.

Public Members

const char *name
The name to be given to the work queue thread.
If left null the thread will not have a name.

bool no_yield
Control whether the work queue thread should yield between items.
Yielding between items helps guarantee the work queue thread does not starve other
threads, including cooperative ones released by a work item. This is the default behavior.
Set this to `true` to prevent the work queue thread from yielding between items. This may
be appropriate when a sequence of items should complete without yielding control.

struct k_work_q
#include <kernel.h> A structure used to hold work until it can be processed.
```

### Operation without Threads

Thread support is not necessary in some applications:

- Bootloaders
- Simple event-driven applications
- Examples intended to demonstrate core functionality

Thread support can be disabled by setting `CONFIG_MULTITHREADING` to `n`. Since this configuration has a significant impact on Zephyr's functionality and testing of it has been limited, there are conditions on what can be expected to work in this configuration.

**What Can be Expected to Work** These core capabilities shall function correctly when `CONFIG_MULTITHREADING` is disabled:

- The **build system**
- The ability to boot the application to `main()`
- **Interrupt management**
- The system clock including `k_uptime_get()`
- Timers, i.e. `k_timer()`

---

3.1. Kernel Services  283
• Non-sleeping delays e.g. `k_busy_wait()`.
• Sleeping `k_cpu_idle()`.
• Pre `main()` drivers and subsystems initialization e.g. `SYS_INIT`.

**Memory Management**

• Specifically identified drivers in certain subsystems, listed below.

The expectations above affect selection of other features; for example `CONFIG_SYS_CLOCK_EXISTS` cannot be set to `n`.

**What Cannot be Expected to Work** Functionality that will not work with `CONFIG_MULTITHREADING` includes majority of the kernel API:

• **Threads**
• **Scheduling**
• **Workqueue Threads**
• **Polling API**
• **Semaphores**
• **Mutexes**
• **Condition Variables**
• **Data Passing**

**Subsystem Behavior Without Thread Support** The sections below list driver and functional subsystems that are expected to work to some degree when `CONFIG_MULTITHREADING` is disabled. Subsystems that are not listed here should not be expected to work.

Some existing drivers within the listed subsystems do not work when threading is disabled, but are within scope based on their subsystem, or may be sufficiently isolated that supporting them on a particular platform is low-impact. Enhancements to add support to existing capabilities that were not originally implemented to work with threads disabled will be considered.

**Flash** The Flash is expected to work for all SoC flash peripheral drivers. Bus-accessed devices like serial memories may not be supported.

*List/table of supported drivers to go here*

**GPIO** The GPIO is expected to work for all SoC GPIO peripheral drivers. Bus-accessed devices like GPIO extenders may not be supported.

*List/table of supported drivers to go here*

**UART** A subset of the UART is expected to work for all SoC UART peripheral drivers.

• Applications that select `CONFIG_UART_INTERRUPT_DRIVEN` may work, depending on driver implementation.
• Applications that select `CONFIG_UART_ASYNC_API` may work, depending on driver implementation.
• Applications that do not select either `CONFIG_UART_ASYNC_API` or `CONFIG_UART_INTERRUPT_DRIVEN` are expected to work.

*List/table of supported drivers to go here, including which API options are supported*
Interrupts

An interrupt service routine (ISR) is a function that executes asynchronously in response to a hardware or software interrupt. An ISR normally preempts the execution of the current thread, allowing the response to occur with very low overhead. Thread execution resumes only once all ISR work has been completed.

- Concepts
  - Multi-level Interrupt handling
  - Preventing Interruptions
  - Offloading ISR Work
- Implementation
  - Defining a regular ISR
  - Defining a ‘direct’ ISR
  - Implementation Details
- Suggested Uses
- Configuration Options
- API Reference

Concepts  Any number of ISRs can be defined (limited only by available RAM), subject to the constraints imposed by underlying hardware.

An ISR has the following key properties:

- An interrupt request (IRQ) signal that triggers the ISR.
- A priority level associated with the IRQ.
- An interrupt handler function that is invoked to handle the interrupt.
- An argument value that is passed to that function.

An IDT (Interrupt Descriptor Table) or a vector table is used to associate a given interrupt source with a given ISR. Only a single ISR can be associated with a specific IRQ at any given time.

Multiple ISRs can utilize the same function to process interrupts, allowing a single function to service a device that generates multiple types of interrupts or to service multiple devices (usually of the same type). The argument value passed to an ISR's function allows the function to determine which interrupt has been signaled.

The kernel provides a default ISR for all unused IDT entries. This ISR generates a fatal system error if an unexpected interrupt is signaled.

The kernel supports interrupt nesting. This allows an ISR to be preempted in mid-execution if a higher priority interrupt is signaled. The lower priority ISR resumes execution once the higher priority ISR has completed its processing.

An ISR's interrupt handler function executes in the kernel's interrupt context. This context has its own dedicated stack area (or, on some architectures, stack areas). The size of the interrupt context stack must be capable of handling the execution of multiple concurrent ISRs if interrupt nesting support is enabled.

Important: Many kernel APIs can be used only by threads, and not by ISRs. In cases where a routine may be invoked by both threads and ISRs the kernel provides the `k_ts_in_isr()` API to allow the routine to alter its behavior depending on whether it is executing as part of a thread or as part of an ISR.
Multi-level Interrupt handling  A hardware platform can support more interrupt lines than natively-provided through the use of one or more nested interrupt controllers. Sources of hardware interrupts are combined into one line that is then routed to the parent controller.

If nested interrupt controllers are supported, `CONFIG_MULTI_LEVEL_INTERRUPTS` should be set to 1, and `CONFIG_2ND_LEVEL_INTERRUPTS` and `CONFIG_3RD_LEVEL_INTERRUPTS` configured as well, based on the hardware architecture.

A unique 32-bit interrupt number is assigned with information embedded in it to select and invoke the correct Interrupt Service Routine (ISR). Each interrupt level is given a byte within this 32-bit number, providing support for up to four interrupt levels using this arch, as illustrated and explained below:

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 9 | 2 | 0 |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 5 |   | A |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   | C | B |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

There are three interrupt levels shown here.

- ‘-’ means interrupt line and is numbered from 0 (right most).
- LEVEL 1 has 12 interrupt lines, with two lines (2 and 9) connected to nested controllers and one device ‘A’ on line 4.
- One of the LEVEL 2 controllers has interrupt line 5 connected to a LEVEL 3 nested controller and one device ‘C’ on line 3.
- The other LEVEL 2 controller has no nested controllers but has one device ‘B’ on line 2.
- The LEVEL 3 controller has one device ‘D’ on line 2.

Here’s how unique interrupt numbers are generated for each hardware interrupt. Let’s consider four interrupts shown above as A, B, C, and D:

- A -> 0x00000004
- B -> 0x00000002
- C -> 0x00000049
- D -> 0x00003069

**Note:** The bit positions for LEVEL 2 and onward are offset by 1, as 0 means that interrupt number is not present for that level. For our example, the LEVEL 3 controller has device D on line 2, connected to the LEVEL 2 controller’s line 5, that is connected to the LEVEL 1 controller’s line 9 (2 -> 5 -> 9). Because of the encoding offset for LEVEL 2 and onward, device D is given the number 0x00030609.

Preventing Interruptions  In certain situations it may be necessary for the current thread to prevent ISRs from executing while it is performing time-sensitive or critical section operations.

A thread may temporarily prevent all IRQ handling in the system using an **IRQ lock**. This lock can be applied even when it is already in effect, so routines can use it without having to know if it is already in effect. The thread must unlock its IRQ lock the same number of times it was locked before interrupts can be once again processed by the kernel while the thread is running.

**Important:** The IRQ lock is thread-specific. If thread A locks out interrupts then performs an operation that puts itself to sleep (e.g. sleeping for N milliseconds), the thread’s IRQ lock no longer applies once thread A is swapped out and the next ready thread B starts to run.
This means that interrupts can be processed while thread B is running unless thread B has also locked out interrupts using its own IRQ lock. (Whether interrupts can be processed while the kernel is switching between two threads that are using the IRQ lock is architecture-specific.)

When thread A eventually becomes the current thread once again, the kernel re-establishes thread A’s IRQ lock. This ensures thread A won’t be interrupted until it has explicitly unlocked its IRQ lock.

If thread A does not sleep but does make a higher-priority thread B ready, the IRQ lock will inhibit any preemption that would otherwise occur. Thread B will not run until the next reschedule point reached after releasing the IRQ lock.

Alternatively, a thread may temporarily disable a specified IRQ so its associated ISR does not execute when the IRQ is signaled. The IRQ must be subsequently enabled to permit the ISR to execute.

**Important:** Disabling an IRQ prevents all threads in the system from being preempted by the associated ISR, not just the thread that disabled the IRQ.

---

**Zero Latency Interrupts** Preventing interruptions by applying an IRQ lock may increase the observed interrupt latency. A high interrupt latency, however, may not be acceptable for certain low-latency use-cases.

The kernel addresses such use-cases by allowing interrupts with critical latency constraints to execute at a priority level that cannot be blocked by interrupt locking. These interrupts are defined as zero-latency interrupts. The support for zero-latency interrupts requires `CONFIG_ZERO_LATENCY_IRQS` to be enabled. In addition to that, the flag `IRQ_ZERO_LATENCY` must be passed to `IRQ_CONNECT` or `IRQ_DIRECT_CONNECT` macros to configure the particular interrupt with zero latency.

Zero-latency interrupts are expected to be used to manage hardware events directly, and not to interoperate with the kernel code at all. They should treat all kernel APIs as undefined behavior (i.e. an application that uses the APIs inside a zero-latency interrupt context is responsible for directly verifying correct behavior). Zero-latency interrupts may not modify any data inspected by kernel APIs invoked from normal Zephyr contexts and shall not generate exceptions that need to be handled synchronously (e.g. kernel panic).

**Important:** Zero-latency interrupts are supported on an architecture-specific basis. The feature is currently implemented in the ARM Cortex-M architecture variant.

---

**Offloading ISR Work** An ISR should execute quickly to ensure predictable system operation. If time consuming processing is required the ISR should offload some or all processing to a thread, thereby restoring the kernel’s ability to respond to other interrupts.

The kernel supports several mechanisms for offloading interrupt-related processing to a thread.

- An ISR can signal a helper thread to do interrupt-related processing using a kernel object, such as a FIFO, LIFO, or semaphore.
- An ISR can instruct the system workqueue thread to execute a work item. (See Workqueue Threads.)

When an ISR offloads work to a thread, there is typically a single context switch to that thread when the ISR completes, allowing interrupt-related processing to continue almost immediately. However, depending on the priority of the thread handling the offload, it is possible that the currently executing cooperative thread or other higher-priority threads may execute before the thread handling the offload is scheduled.

---

3.1. Kernel Services
Defining a regular ISR  

An ISR is defined at runtime by calling `IRQ_CONNECT`. It must then be enabled by calling `irq_enable()`.

**Important:** `IRQ_CONNECT()` is not a C function and does some inline assembly magic behind the scenes. All its arguments must be known at build time. Drivers that have multiple instances may need to define per-instance config functions to configure each instance of the interrupt.

The following code defines and enables an ISR.

```c
#define MY_DEV_IRQ 24 /* device uses IRQ 24 */
#define MY_DEV_PRIO 2 /* device uses interrupt priority 2 */
/* argument passed to my_isr(), in this case a pointer to the device */
#define MY_ISR_ARG DEVICE_GET(my_device)
#define MY_IRQ_FLAGS 0 /* IRQ flags */

void my_isr(void *arg)
{
    /* ISR code */
}

void my_isr_installer(void)
{
    ... irq_connect(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG, MY_IRQ_FLAGS);
    irq_enable(MY_DEV_IRQ);
    ...
}
```

Since the `IRQ_CONNECT` macro requires that all its parameters be known at build time, in some cases this may not be acceptable. It is also possible to install interrupts at runtime with `irq_connect_dynamic()`.

It is used in exactly the same way as `IRQ_CONNECT`:

```c
void my_isr_installer(void)
{
    ... irq_connect_dynamic(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG, MY_IRQ_FLAGS);
    irq_enable(MY_DEV_IRQ);
    ...
}
```

Dynamic interrupts require the `CONFIG_DYNAMIC_INTERRUPTS` option to be enabled. Removing or re-configuring a dynamic interrupt is currently unsupported.

**Defining a ‘direct’ ISR**  

Regular Zephyr interrupts introduce some overhead which may be unacceptable for some low-latency use-cases. Specifically:

- The argument to the ISR is retrieved and passed to the ISR
- If power management is enabled and the system was idle, all the hardware will be resumed from low-power state before the ISR is executed, which can be very time-consuming
- Although some architectures will do this in hardware, other architectures need to switch to the interrupt stack in code
- After the interrupt is serviced, the OS then performs some logic to potentially make a scheduling decision.
Zephyr supports so-called ‘direct’ interrupts, which are installed via `IRQ_DIRECT_CONNECT`. These direct interrupts have some special implementation requirements and a reduced feature set; see the definition of `IRQ_DIRECT_CONNECT` for details.

The following code demonstrates a direct ISR:

```c
#define MY_DEV_IRQ 24 /* device uses IRQ 24 */
#define MY_DEV_PRIO 2 /* device uses interrupt priority 2 */
/* argument passed to my_isr(), in this case a pointer to the device */
#define MY_IRQ_FLAGS 0 /* IRQ flags */

ISR_DIRECT_DECLARE(my_isr)
{
    do_stuff();
    ISR_DIRECT_PM(); /* PM done after servicing interrupt for best latency */
    return 1; /* We should check if scheduling decision should be made */
}

void my_isr_installer(void)
{
    ...
    IRQ_DIRECT_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_IRQ_FLAGS);
    irq_enable(MY_DEV_IRQ);
    ...
}
```

Installation of dynamic direct interrupts is supported on an architecture-specific basis. (The feature is currently implemented in ARM Cortex-M architecture variant. Dynamic direct interrupts feature is exposed to the user via an ARM-only API.)

**Implementation Details** Interrupt tables are set up at build time using some special build tools. The details laid out here apply to all architectures except x86, which are covered in the x86 Details section below.

Any invocation of `IRQ_CONNECT` will declare an instance of struct `_isr_list` which is placed in a special .intList section:

```c
struct _isr_list {
    /** IRQ line number */
    int32_t irq;
    /** Flags for this IRQ, see ISR_FLAG_* definitions */
    int32_t flags;
    /** ISR to call */
    void *func;
    /** Parameter for non-direct IRQs */
    void *param;
};
```

Zephyr is built in two phases; the first phase of the build produces `${ZEPHYR_PREBUILT_EXECUTABLE}.elf` which contains all the entries in the .intList section preceded by a header:

```c
struct {
    void *spurious_irq_handler;
    void *sw_irq_handler;
    uint32_t num_isr;
    uint32_t num_vectors;
    struct _isr_list isrs[]; /* of size num_isr */
};
```
This data consisting of the header and instances of struct _isr_list inside 
${ZEPHYR_PREBUILT_EXECUTABLE}.elf is then used by the gen_isr_tables.py script to generate a C file defining a vector table and software ISR table that are then compiled and linked into the final application.

The priority level of any interrupt is not encoded in these tables, instead IRQ_CONNECT also has a runtime component which programs the desired priority level of the interrupt to the interrupt controller. Some architectures do not support the notion of interrupt priority, in which case the priority argument is ignored.

Vector Table  A vector table is generated when CONFIG_GEN_IRQ_VECTOR_TABLE is enabled. This data structure is used natively by the CPU and is simply an array of function pointers, where each element n corresponds to the IRQ handler for IRQ line n, and the function pointers are:

1. For 'direct' interrupts declared with IRQ_DIRECT_CONNECT, the handler function will be placed here.

2. For regular interrupts declared with IRQ_CONNECT, the address of the common software IRQ handler is placed here. This code does common kernel interrupt bookkeeping and looks up the ISR and parameter from the software ISR table.

3. For interrupt lines that are not configured at all, the address of the spurious IRQ handler will be placed here. The spurious IRQ handler causes a system fatal error if encountered.

Some architectures (such as the Nios II internal interrupt controller) have a common entry point for all interrupts and do not support a vector table, in which case the CONFIG_GEN_IRQ_VECTOR_TABLE option should be disabled.

Some architectures may reserve some initial vectors for system exceptions and declare this in a table elsewhere, in which case CONFIG_GEN_IRQ_START_VECTOR needs to be set to properly offset the indices in the table.

SW ISR Table  This is an array of struct _isr_table_entry:

```
struct _isr_table_entry {
    void *arg;
    void (*isr)(void *);
};
```

This is used by the common software IRQ handler to look up the ISR and its argument and execute it. The active IRQ line is looked up in an interrupt controller register and used to index this table.

x86 Details  The x86 architecture has a special type of vector table called the Interrupt Descriptor Table (IDT) which must be laid out in a certain way per the x86 processor documentation. It is still fundamentally a vector table, and the arch/x86/gen_idt.py tool uses the .intList section to create it. However, on APIC-based systems the indexes in the vector table do not correspond to the IRQ line. The first 32 vectors are reserved for CPU exceptions, and all remaining vectors (up to index 255) correspond to the priority level, in groups of 16. In this scheme, interrupts of priority level 0 will be placed in vectors 32-47, level 1 48-63, and so forth. When the arch/x86/gen_idt.py tool is constructing the IDT, when it configures an interrupt it will look for a free vector in the appropriate range for the requested priority level and set the handler there.

On x86 when an interrupt or exception vector is executed by the CPU, there is no foolproof way to determine which vector was fired, so a software ISR table indexed by IRQ line is not used. Instead, the IRQ_CONNECT call creates a small assembly language function which calls the common interrupt code in _interrupt_enter() with the ISR and parameter as arguments. It is the address of this assembly interrupt stub which gets placed in the IDT. For interrupts declared with IRQ_DIRECT_CONNECT the parameterless ISR is placed directly in the IDT.
On systems where the position in the vector table corresponds to the interrupt’s priority level, the interrupt controller needs to know at runtime what vector is associated with an IRQ line. `arch/x86/gen_idt.py` additionally creates an `_irq_to_interrupt_vector` array which maps an IRQ line to its configured vector in the IDT. This is used at runtime by `IRQ_CONNECT` to program the IRQ-to-vector association in the interrupt controller.

For dynamic interrupts, the build must generate some 4-byte dynamic interrupt stubs, one stub per dynamic interrupt in use. The number of stubs is controlled by the `CONFIG_X86_DYNAMIC_IRQ_STUBS` option. Each stub pushes an unique identifier which is then used to fetch the appropriate handler function and parameter out of a table populated when the dynamic interrupt was connected.

**Suggested Uses** Use a regular or direct ISR to perform interrupt processing that requires a very rapid response, and can be done quickly without blocking.

**Note:** Interrupt processing that is time consuming, or involves blocking, should be handed off to a thread. See [Offloading ISR Work](#) for a description of various techniques that can be used in an application.

**Configuration Options** Related configuration options:

- `CONFIG_ISR_STACK_SIZE`

Additional architecture-specific and device-specific configuration options also exist.

**API Reference**

`group isr_apis`

**Defines**

`IRQ_CONNECT(irq_p, priority_p, isr_p, isr_param_p, flags_p)`

Initialize an interrupt handler.

This routine initializes an interrupt handler for an IRQ. The IRQ must be subsequently enabled before the interrupt handler begins servicing interrupts.

**Warning:** Although this routine is invoked at run-time, all of its arguments must be computable by the compiler at build time.

**Parameters**

- `irq_p` – IRQ line number.
- `priority_p` – Interrupt priority.
- `isr_p` – Address of interrupt service routine.
- `isr_param_p` – Parameter passed to interrupt service routine.
- `flags_p` – Architecture-specific IRQ configuration flags.

`IRQ_DIRECT_CONNECT(irq_p, priority_p, isr_p, flags_p)`

Initialize a ‘direct’ interrupt handler.

This routine initializes an interrupt handler for an IRQ. The IRQ must be subsequently enabled via `irq_enable()` before the interrupt handler begins servicing interrupts.
These ISRs are designed for performance-critical interrupt handling and do not go through common interrupt handling code. They must be implemented in such a way that it is safe to put them directly in the vector table. For ISRs written in C, the `ISR_DIRECT_DECLARE()` macro will do this automatically. For ISRs written in assembly it is entirely up to the developer to ensure that the right steps are taken.

This type of interrupt currently has a few limitations compared to normal Zephyr interrupts:

- No parameters are passed to the ISR.
- No stack switch is done, the ISR will run on the interrupted context's stack, unless the architecture automatically does the stack switch in HW.
- Interrupt locking state is unchanged from how the HW sets it when the ISR runs. On arches that enter ISRs with interrupts locked, they will remain locked.
- Scheduling decisions are now optional, controlled by the return value of ISRs implemented with the `ISR_DIRECT_DECLARE()` macro
- The call into the OS to exit power management idle state is now optional. Normal interrupts always do this before the ISR is run, but when it runs is now controlled by the placement of a `ISR_DIRECT_PM()` macro, or omitted entirely.

**Warning:** Although this routine is invoked at run-time, all of its arguments must be computable by the compiler at build time.

**Parameters**

- `irq_p` – IRQ line number.
- `priority_p` – Interrupt priority.
- `isr_p` – Address of interrupt service routine.
- `flags_p` – Architecture-specific IRQ configuration flags.

**ISR_DIRECT_HEADER()**

Common tasks before executing the body of an ISR.

This macro must be at the beginning of all direct interrupts and performs minimal architecture-specific tasks before the ISR itself can run. It takes no arguments and has no return value.

**ISR_DIRECT_FOOTER(check_reschedule)**

Common tasks before exiting the body of an ISR.

This macro must be at the end of all direct interrupts and performs minimal architecture-specific tasks like EOI. It has no return value.

In a normal interrupt, a check is done at end of interrupt to invoke z_swap() logic if the current thread is preemptible and there is another thread ready to run in the kernel's ready queue cache. This is now optional and controlled by the check_reschedule argument. If unsure, set to nonzero. On systems that do stack switching and nested interrupt tracking in software, z_swap() should only be called if this was a non-nested interrupt.

**Parameters**

- `check_reschedule` – If nonzero, additionally invoke scheduling logic

**ISR_DIRECT_PM()**

Perform power management idle exit logic.

This macro may optionally be invoked somewhere in between `IRQ_DIRECT_HEADER()` and `IRQ_DIRECT_FOOTER()` invocations. It performs tasks necessary to exit power management idle state. It takes no parameters and returns no arguments. It may be omitted, but be careful!
ISR_DIRECT_DECLARE(name)

Helper macro to declare a direct interrupt service routine.

This will declare the function in a proper way and automatically include the ISR_DIRECT_FOOTER() and ISR_DIRECT_HEADER() macros. The function should return nonzero status if a scheduling decision should potentially be made. See ISR_DIRECT_FOOTER() for more details on the scheduling decision.

For architectures that support 'regular' and 'fast' interrupt types, where these interrupt types require different assembly language handling of registers by the ISR, this will always generate code for the 'fast' interrupt type.

Example usage:

ISR_DIRECT_DECLARE(my_isr)
{
  bool done = do_stuff();
  ISR_DIRECT_PM(); // done after do_stuff() due to latency concerns
  if (!done) {
    return 0; // don't bother checking if we have to z_swap()
  }

  k_sem_give(some_sem);
  return 1;
}

Parameters

- name – symbol name of the ISR

irq_lock()

Lock interrupts.

This routine disables all interrupts on the CPU. It returns an unsigned integer “lock-out key”, which is an architecture-dependent indicator of whether interrupts were locked prior to the call. The lock-out key must be passed to irq_unlock() to re-enable interrupts.

This routine can be called recursively, as long as the caller keeps track of each lock-out key that is generated. Interrupts are re-enabled by passing each of the keys to irq_unlock() in the reverse order they were acquired. (That is, each call to irq_lock() must be balanced by a corresponding call to irq_unlock().)

This routine can only be invoked from supervisor mode. Some architectures (for example, ARM) will fail silently if invoked from user mode instead of generating an exception.

Note: This routine must also serve as a memory barrier to ensure the uniprocessor implementation of k_spinlock_t is correct.

Note: This routine can be called by ISRs or by threads. If it is called by a thread, the interrupt lock is thread-specific; this means that interrupts remain disabled only while the thread is running. If the thread performs an operation that allows another thread to run (for example, giving a semaphore or sleeping for N milliseconds), the interrupt lock no longer applies and interrupts may be re-enabled while other processing occurs. When the thread once again becomes the current thread, the kernel re-establishes its interrupt lock; this ensures the thread won’t be interrupted until it has explicitly released the interrupt lock it established.
Warning: The lock-out key should never be used to manually re-enable interrupts or to inspect or manipulate the contents of the CPU’s interrupt bits.

Returns
An architecture-dependent lock-out key representing the “interrupt disable state” prior to the call.

irq_unlock(key)
Unlock interrupts.
This routine reverses the effect of a previous call to irq_lock() using the associated lock-out key. The caller must call the routine once for each time it called irq_lock(), supplying the keys in the reverse order they were acquired, before interrupts are enabled.

This routine can only be invoked from supervisor mode. Some architectures (for example, ARM) will fail silently if invoked from user mode instead of generating an exception.

Note: This routine must also serve as a memory barrier to ensure the uniprocessor implementation of k_spinlock_t is correct.

Note: Can be called by ISRs.

Parameters
• key – Lock-out key generated by irq_lock().

irq_enable(irq)
Enable an IRQ.
This routine enables interrupts from source irq.

Parameters
• irq – IRQ line.

irq_disable(irq)
Disable an IRQ.
This routine disables interrupts from source irq.

Parameters
• irq – IRQ line.

irq_is_enabled(irq)
Get IRQ enable state.
This routine indicates if interrupts from source irq are enabled.

Parameters
• irq – IRQ line.

Returns
interrupt enable state, true or false
Functions

static inline int irq_connect_dynamic(unsigned int irq, unsigned int priority, void (*routine)(const void *parameter), const void *parameter, uint32_t flags)

Configure a dynamic interrupt.
Use this instead of IRQ_CONNECT() if arguments cannot be known at build time.

Parameters
• irq – IRQ line number
• priority – Interrupt priority
• routine – Interrupt service routine
• parameter – ISR parameter
• flags – Arch-specific IRQ configuration flags

Returns
The vector assigned to this interrupt

static inline unsigned int irq_get_level(unsigned int irq)

Return IRQ level This routine returns the interrupt level number of the provided interrupt.

Parameters
• irq – IRQ number in its zephyr format

Returns
1 if IRQ level 1, 2 if IRQ level 2, 3 if IRQ level 3

bool k_is_in_isr(void)

Determine if code is running at interrupt level.
This routine allows the caller to customize its actions, depending on whether it is a thread or an ISR.

Function properties (list may not be complete)

isr-ok

Returns
false if invoked by a thread.

Returns
true if invoked by an ISR.

int k_is_preempt_thread(void)

Determine if code is running in a preemptible thread.
This routine allows the caller to customize its actions, depending on whether it can be pre-empted by another thread. The routine returns a ‘true’ value if all of the following conditions are met:

• The code is running in a thread, not at ISR.
• The thread’s priority is in the preemptible range.
• The thread has not locked the scheduler.
Function properties (list may not be complete)

*isr-ok*

**Returns**
- 0 if invoked by an ISR or by a cooperative thread.
- Non-zero if invoked by a preemptible thread.

static inline bool k_is_pre_kernel(void)

Test whether startup is in the before-main-task phase.

This routine allows the caller to customize its actions, depending on whether it being invoked before the kernel is fully active.

Function properties (list may not be complete)

*isr-ok*

**Returns**
- true if invoked before post-kernel initialization
- false if invoked during/after post-kernel initialization

Polling API

The polling API is used to wait concurrently for any one of multiple conditions to be fulfilled.

- **Concepts**
- **Implementation**
  - Using `k_poll()`
  - Using `k_poll_signal_raise()`
- **Suggested Uses**
- **Configuration Options**
- **API Reference**

**Concepts**  The polling API's main function is `k_poll()`, which is very similar in concept to the POSIX `poll()` function, except that it operates on kernel objects rather than on file descriptors.

The polling API allows a single thread to wait concurrently for one or more conditions to be fulfilled without actively looking at each one individually.

There is a limited set of such conditions:

- a semaphore becomes available
- a kernel FIFO contains data ready to be retrieved
- a poll signal is raised

A thread that wants to wait on multiple conditions must define an array of **poll events**, one for each condition.

All events in the array must be initialized before the array can be polled on.
Each event must specify which **type** of condition must be satisfied so that its state is changed to signal the requested condition has been met.

Each event must specify what **kernel object** it wants the condition to be satisfied.

Each event can optionally specify what **mode** of operation is used when the condition is satisfied.

Apart from the kernel objects, there is also a **poll signal** pseudo-object type that be directly signaled.

The **k_poll()** function returns as soon as one of the conditions it is waiting for is fulfilled. It is possible for more than one to be fulfilled when **k_poll()** returns, if they were fulfilled before **k_poll()** was called, or due to the preemptive multi-threading nature of the kernel. The caller must look at the state of all the poll events in the array to figure out which ones were fulfilled and what actions to take.

Currently, there is only one mode of operation available: the object is not acquired. As an example, this means that when **k_poll()** returns and the poll event states that the semaphore is available, the caller of **k_poll()** must then invoke **k_sem_take()** to take ownership of the semaphore. If the semaphore is contested, there is no guarantee that it will be still available when **k_sem_take()** is called.

### Implementation

**Using k_poll()**  The main API is **k_poll()**, which operates on an array of poll events of type **k_poll_event**. Each entry in the array represents one event a call to **k_poll()** will wait for its condition to be fulfilled.

Poll events can be initialized using either the runtime initializers **K_POLL_EVENT_INITIALIZER()** or **k_poll_event_init()**, or the static initializer **K_POLL_EVENT_STATIC_INITIALIZER()**. An object that matches the **type** specified must be passed to the initializers. The **mode** must be set to **K_POLL_MODE_NOTIFY_ONLY**. The state must be set to **K_POLL_STATE_NOT_READY** (the initializers take care of this). The user **tag** is optional and completely opaque to the API: it is there to help a user to group similar events together. Being optional, it is passed to the static initializer, but not the runtime ones for performance reasons. If using runtime initializers, the user must set it separately in the **k_poll_event** data structure. If an event in the array is to be ignored, most likely temporarily, its type can be set to **K_POLL_TYPE_IGNORE**.

```c
struct k_poll_event events[2] = {
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_SEM_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_sem, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_FIFO_DATA_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_fifo, 0),
};
```

or at runtime

```c
struct k_poll_event events[2];
void some_init(void)
{
    k_poll_event_init(&events[0],
        K_POLL_TYPE_SEM_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_sem);

    k_poll_event_init(&events[1],
        K_POLL_TYPE_FIFO_DATA_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_fifo);
```

(continues on next page)
After the events are initialized, the array can be passed to `k_poll()`. A timeout can be specified to wait only for a specified amount of time, or the special values `K_NO_WAIT` and `K_FOREVER` to either not wait or wait until an event condition is satisfied and not sooner.

A list of pollers is offered on each semaphore or FIFO and as many events can wait in it as the app wants. Notice that the waiters will be served in first-come-first-serve order, not in priority order.

In case of success, `k_poll()` returns 0. If it times out, it returns `-EAGAIN`

```c
// assume there is no contention on this semaphore and FIFO
// -EADDRINUSE will not occur; the semaphore and/or data will be available

void do_stuff(void)
{
    rc = k_poll(events, 2, 1000);
    if (rc == 0) {
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
        } else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        }
    } else {
        // handle timeout
    }
}
```

When `k_poll()` is called in a loop, the events state must be reset to `K_POLL_STATE_NOT_READY` by the user.

```c
void do_stuff(void)
{
    for(;;) {
        rc = k_poll(events, 2, K_FOREVER);
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
        } else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        }
        events[0].state = K_POLL_STATE_NOT_READY;
        events[1].state = K_POLL_STATE_NOT_READY;
    }
}
```

**Using k_poll_signal_raise()** One of the types of events is `K_POLL_TYPE_SIGNAL`: this is a “direct” signal to a poll event. This can be seen as a lightweight binary semaphore only one thread can wait for.

A poll signal is a separate object of type `k_poll_signal` that must be attached to a `k_poll_event`, similar to a semaphore or FIFO. It must first be initialized either via `K_POLL_SIGNAL_INITIALIZER()` or `k_poll_signal_init()`.
It is signaled via the \texttt{k_poll_signal_raise()} function. This function takes a user \texttt{result} parameter that is opaque to the API and can be used to pass extra information to the thread waiting on the event.

If the signal is to be polled in a loop, \textit{both} its event state and its \texttt{signaled} field \texttt{must} be reset on each iteration if it has been signaled.
Note that poll signals are not internally synchronized. A `k_poll()` call that is passed a signal will return after any code in the system calls `k_poll_signal_raise()`. But if the signal is being externally managed and reset via `k_poll_signal_init()`, it is possible that by the time the application checks, the event state may no longer be equal to `K_POLL_STATE_SIGNALED`, and a (naive) application will miss events. Best practice is always to reset the signal only from within the thread invoking the `k_poll()` loop, or else to use some other event type which tracks event counts: semaphores and FIFOs are more error-proof in this sense because they can’t “miss” events, architecturally.

**Suggested Uses** Use `k_poll()` to consolidate multiple threads that would be pending on one object each, saving possibly large amounts of stack space.

Use a poll signal as a lightweight binary semaphore if only one thread pends on it.

**Note:** Because objects are only signaled if no other thread is waiting for them to become available and only one thread can poll on a specific object, polling is best used when objects are not subject of contention between multiple threads, basically when a single thread operates as a main “server” or “dispatcher” for multiple objects and is the only one trying to acquire these objects.

Enums

enum k_poll_modes

Values:

enumerator K_POLL_MODE_NOTIFY_ONLY = 0

enumerator K_POLL_NUM_MODES

Functions

void k_poll_event_init(struct k_poll_event *event, uint32_t type, int mode, void *obj)

Initialize one struct k_poll_event instance.

After this routine is called on a poll event, the event it ready to be placed in an event array to be passed to k_poll().

Parameters

• event – The event to initialize.
• type – A bitfield of the types of event, from the K_POLL_TYPE_xxx values. Only values that apply to the same object being polled can be used together. Choosing K_POLL_TYPE_IGNORE disables the event.
• mode – Future. Use K_POLL_MODE_NOTIFY_ONLY.
• obj – Kernel object or poll signal.
int k_poll(struct k_poll_event *events, int num_events, k_timeout_t timeout)

Wait for one or many of multiple poll events to occur.

This routine allows a thread to wait concurrently for one or many of multiple poll events to have occurred. Such events can be a kernel object being available, like a semaphore, or a poll signal event.

When an event notifies that a kernel object is available, the kernel object is not “given” to the thread calling k_poll(): it merely signals the fact that the object was available when the k_poll() call was in effect. Also, all threads trying to acquire an object the regular way, i.e. by pending on the object, have precedence over the thread polling on the object. This means that the polling thread will never get the poll event on an object until the object becomes available and its pend queue is empty. For this reason, the k_poll() call is more effective when the objects being polled only have one thread, the polling thread, trying to acquire them.

When k_poll() returns 0, the caller should loop on all the events that were passed to k_poll() and check the state field for the values that were expected and take the associated actions.

Before being reused for another call to k_poll(), the user has to reset the state field to K_POLL_STATE_NOT_READY.

When called from user mode, a temporary memory allocation is required from the caller’s resource pool.

Parameters

- **events** – An array of events to be polled for.
- **num_events** – The number of events in the array.
- **timeout** – Waiting period for an event to be ready, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- **0** – One or more events are ready.
- **-EAGAIN** – Waiting period timed out.
- **-EINTR** – Polling has been interrupted, e.g. with k_queue_cancel_wait(). All output events are still set and valid, cancelled event(s) will be set to K_POLL_STATE_CANCELLED. In other words, -EINTR status means that at least one of output events is K_POLL_STATE_CANCELLED.
- **-ENOMEM** – Thread resource pool insufficient memory (user mode only)
- **-EINVAL** – Bad parameters (user mode only)

void k_poll_signal_init(struct k_poll_signal *sig)

Initialize a poll signal object.

Ready a poll signal object to be signaled via k_poll_signal_raise().

Parameters

- **sig** – A poll signal.

void k_poll_signal_reset(struct k_poll_signal *sig)

void k_poll_signal_check(struct k_poll_signal *sig, unsigned int *signaled, int *result)

Fetch the signaled state and result value of a poll signal.

Parameters

- **sig** – A poll signal object
- **signaled** – An integer buffer which will be written nonzero if the object was signaled
int k_poll_signal_raise(struct k_poll_signal *sig, int result)

Signal a poll signal object.

This routine makes ready a poll signal, which is basically a poll event of type K_POLL_TYPE_SIGNAL. If a thread was polling on that event, it will be made ready to run. A result value can be specified.

The poll signal contains a ‘signaled’ field that, when set by k_poll_signal_raise(), stays set until the user sets it back to 0 with k_poll_signal_reset(). It thus has to be reset by the user before being passed again to k_poll() or k_poll() will consider it being signaled, and will return immediately.

Note: The result is stored and the ‘signaled’ field is set even if this function returns an error indicating that an expiring poll was not notified. The next k_poll() will detect the missed raise.

Parameters

- sig – A poll signal.
- result – The value to store in the result field of the signal.

Return values

- 0 – The signal was delivered successfully.
- -EAGAIN – The polling thread’s timeout is in the process of expiring.

struct k_poll_signal

#include <kernel.h>

Public Members

Semaphores

A semaphore is a kernel object that implements a traditional counting semaphore.

Concepts

Any number of semaphores can be defined (limited only by available RAM). Each semaphore is referenced by its memory address.

A semaphore has the following key properties:

- A **count** that indicates the number of times the semaphore can be taken. A count of zero indicates that the semaphore is unavailable.
- A **limit** that indicates the maximum value the semaphore's count can reach.

A semaphore must be initialized before it can be used. Its count must be set to a non-negative value that is less than or equal to its limit.

A semaphore may be **given** by a thread or an ISR. Giving the semaphore increments its count, unless the count is already equal to the limit.

A semaphore may be **taken** by a thread. Taking the semaphore decrements its count, unless the semaphore is unavailable (i.e. at zero). When a semaphore is unavailable a thread may choose to
wait for it to be given. Any number of threads may wait on an unavailable semaphore simultaneously. When the semaphore is given, it is taken by the highest priority thread that has waited longest.

**Note:** You may initialize a “full” semaphore (count equal to limit) to limit the number of threads able to execute the critical section at the same time. You may also initialize an empty semaphore (count equal to 0, with a limit greater than 0) to create a gate through which no waiting thread may pass until the semaphore is incremented. All standard use cases of the common semaphore are supported.

**Note:** The kernel does allow an ISR to take a semaphore, however the ISR must not attempt to wait if the semaphore is unavailable.

### Implementation

#### Defining a Semaphore
A semaphore is defined using a variable of type `k_sem`. It must then be initialized by calling `k_sem_init()`.

The following code defines a semaphore, then configures it as a binary semaphore by setting its count to 0 and its limit to 1.

```c
struct k_sem my_sem;

k_sem_init(&my_sem, 0, 1);
```

Alternatively, a semaphore can be defined and initialized at compile time by calling `K_SEM_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_SEM_DEFINE(my_sem, 0, 1);
```

#### Giving a Semaphore
A semaphore is given by calling `k_sem_give()`.

The following code builds on the example above, and gives the semaphore to indicate that a unit of data is available for processing by a consumer thread.

```c
void input_data_interrupt_handler(void *arg)
{
    /* notify thread that data is available */
    k_sem_give(&my_sem);

    ...
}
```

#### Taking a Semaphore
A semaphore is taken by calling `k_sem_take()`.

The following code builds on the example above, and waits up to 50 milliseconds for the semaphore to be given. A warning is issued if the semaphore is not obtained in time.

```c
void consumer_thread(void)
{
    ...

    if (k_sem_take(&my_sem, K_MSEC(50)) != 0) {
        printk("Input data not available!");
    }
    ...
}
```
Suggested Uses

Use a semaphore to control access to a set of resources by multiple threads.
Use a semaphore to synchronize processing between a producing and consuming threads or ISRs.

Configuration Options

Related configuration options:

- None.

API Reference

group semaphore_apis

Defines

K_SEM_MAX_LIMIT

Maximum limit value allowed for a semaphore.
This is intended for use when a semaphore does not have an explicit maximum limit, and instead is just used for counting purposes.

K_SEM_DEFINE(name, initial_count, count_limit)

Statically define and initialize a semaphore.
The semaphore can be accessed outside the module where it is defined using:

```c
extern struct k_sem <name>;
```

Parameters

- name – Name of the semaphore.
- initial_count – Initial semaphore count.
- count_limit – Maximum permitted semaphore count.

Functions

int k_sem_init(struct k_sem *sem, unsigned int initial_count, unsigned int limit)

Initialize a semaphore.
This routine initializes a semaphore object, prior to its first use.

See also:

K_SEM_MAX_LIMIT
Parameters

- sem – Address of the semaphore.
- initial_count – Initial semaphore count.
- limit – Maximum permitted semaphore count.

Return values

- 0 – Semaphore created successfully
- EINVAL – Invalid values

```c
int k_sem_take(struct k_sem *sem, k_timeout_t timeout)
```

Take a semaphore.

This routine takes sem.

Function properties (list may not be complete)

```
isr-ok
```

**Note:** timeout must be set to K_NO_WAIT if called from ISR.

Parameters

- sem – Address of the semaphore.
- timeout – Waiting period to take the semaphore, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- 0 – Semaphore taken.
- EBUSY – Returned without waiting.
- EAGAIN – Waiting period timed out, or the semaphore was reset during the waiting period.

```c
void k_sem_give(struct k_sem *sem)
```

Give a semaphore.

This routine gives sem, unless the semaphore is already at its maximum permitted count.

Function properties (list may not be complete)

```
isr-ok
```

Parameters

- sem – Address of the semaphore.

```c
void k_sem_reset(struct k_sem *sem)
```

Resets a semaphore's count to zero.

This routine sets the count of sem to zero. Any outstanding semaphore takes will be aborted with -EAGAIN.

Parameters

- sem – Address of the semaphore.
unsigned int k_sem_count_get(struct k_sem *sem)
    Get a semaphore's count.

This routine returns the current count of sem.

    Parameters
    • sem – Address of the semaphore.

    Returns
    Current semaphore count.

User Mode Semaphore API Reference The sys_sem exists in user memory working as counter
semaphore for user mode thread when user mode enabled. When user mode isn't enabled, sys_sem
behaves like k_sem.

group user_semaphore_apis

Defines

SYS_SEM_DEFINE(_name, _initial_count, _count_limit)
    Statically define and initialize a sys_sem.

The semaphore can be accessed outside the module where it is defined using:

    extern struct sys_sem <name>;

Route this to memory domains using K_APP_DMEM().

    Parameters
    • _name – Name of the semaphore.
    • _initial_count – Initial semaphore count.
    • _count_limit – Maximum permitted semaphore count.

Functions

int sys_sem_init(struct sys_sem *sem, unsigned int initial_count, unsigned int limit)
    Initialize a semaphore.

This routine initializes a semaphore instance, prior to its first use.

    Parameters
    • sem – Address of the semaphore.
    • initial_count – Initial semaphore count.
    • limit – Maximum permitted semaphore count.

    Return values
    • 0 – Initial success.
    • -EINVAL – Bad parameters, the value of limit should be located in (0, INT_MAX] and initial_count shouldn't be greater than limit.
int sys_sem_give(struct sys_sem *sem)

Give a semaphore.

This routine gives `sem`, unless the semaphore is already at its maximum permitted count.

**Parameters**
- `sem` – Address of the semaphore.

**Return values**
- 0 – Semaphore given.
- -EINVAL – Parameter address not recognized.
- -EAGAIN – Count reached Maximum permitted count and try again.

int sys_sem_take(struct sys_sem *sem, k_timeout_t timeout)

Take a sys_sem.

This routine takes `sem`.

**Parameters**
- `sem` – Address of the sys_sem.
- `timeout` – Waiting period to take the sys_sem, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**
- 0 – sys_sem taken.
- -EINVAL – Parameter address not recognized.
- -ETIMEOUT – Waiting period timed out.
- -EAGAIN – Count reached Maximum permitted count and try again.

unsigned int sys_sem_count_get(struct sys_sem *sem)

Get sys_sem's value.

This routine returns the current value of `sem`.

**Parameters**
- `sem` – Address of the sys_sem.

**Returns**
Current value of sys_sem.

**Mutexes**

A mutex is a kernel object that implements a traditional reentrant mutex. A mutex allows multiple threads to safely share an associated hardware or software resource by ensuring mutually exclusive access to the resource.

- **Concepts**
  - Reentrant Locking
  - Priority Inheritance
- **Implementation**
  - Defining a Mutex
Any number of mutexes can be defined (limited only by available RAM). Each mutex is referenced by its memory address.

A mutex has the following key properties:

- A **lock count** that indicates the number of times the mutex has been locked by the thread that has locked it. A count of zero indicates that the mutex is unlocked.

- An **owning thread** that identifies the thread that has locked the mutex, when it is locked.

A mutex must be initialized before it can be used. This sets its lock count to zero.

A thread that needs to use a shared resource must first gain exclusive rights to access it by **locking** the associated mutex. If the mutex is already locked by another thread, the requesting thread may choose to wait for the mutex to be unlocked.

After locking a mutex, the thread may safely use the associated resource for as long as needed; however, it is considered good practice to hold the lock for as short a time as possible to avoid negatively impacting other threads that want to use the resource. When the thread no longer needs the resource it must **unlock** the mutex to allow other threads to use the resource.

Any number of threads may wait on a locked mutex simultaneously. When the mutex becomes unlocked it is then locked by the highest-priority thread that has waited the longest.

**Note:** Mutex objects are *not* designed for use by ISRs.

**Reentrant Locking** A thread is permitted to lock a mutex it has already locked. This allows the thread to access the associated resource at a point in its execution when the mutex may or may not already be locked.

A mutex that is repeatedly locked by a thread must be unlocked an equal number of times before the mutex becomes fully unlocked so it can be claimed by another thread.

**Priority Inheritance** The thread that has locked a mutex is eligible for **priority inheritance**. This means the kernel will *temporarily* elevate the thread's priority if a higher priority thread begins waiting on the mutex. This allows the owning thread to complete its work and release the mutex more rapidly by executing at the same priority as the waiting thread. Once the mutex has been unlocked, the unlocking thread resets its priority to the level it had before locking that mutex.

**Note:** The `CONFIG_PRIORITY_CEILING` configuration option limits how high the kernel can raise a thread's priority due to priority inheritance. The default value of 0 permits unlimited elevation.

The owning thread's base priority is saved in the mutex when it obtains the lock. Each time a higher priority thread waits on a mutex, the kernel adjusts the owning thread's priority. When the owning
thread releases the lock (or if the high priority waiting thread times out), the kernel restores the thread’s base priority from the value saved in the mutex.

This works well for priority inheritance as long as only one locked mutex is involved. However, if multiple mutexes are involved, sub-optimal behavior will be observed if the mutexes are not unlocked in the reverse order to which the owning thread’s priority was previously raised. Consequently it is recommended that a thread lock only a single mutex at a time when multiple mutexes are shared between threads of different priorities.

### Implementation

**Defining a Mutex**  A mutex is defined using a variable of type `k_mutex`. It must then be initialized by calling `k_mutex_init()`.

The following code defines and initializes a mutex.

```c
struct k_mutex my_mutex;
k_mutex_init(&my_mutex);
```

Alternatively, a mutex can be defined and initialized at compile time by calling `K_MUTEX_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_MUTEX_DEFINE(my_mutex);
```

**Locking a Mutex**  A mutex is locked by calling `k_mutex_lock()`.

The following code builds on the example above, and waits indefinitely for the mutex to become available if it is already locked by another thread.

```c
k_mutex_lock(&my_mutex, K_FOREVER);
```

The following code waits up to 100 milliseconds for the mutex to become available, and gives a warning if the mutex does not become available.

```c
if (k_mutex_lock(&my_mutex, K_MSEC(100)) == 0) {
    /* mutex successfully locked */
} else {
    printf("Cannot lock XYZ display\n");
}
```

**Unlocking a Mutex**  A mutex is unlocked by calling `k_mutex_unlock()`.

The following code builds on the example above, and unlocks the mutex that was previously locked by the thread.

```c
k_mutex_unlock(&my_mutex);
```

**Suggested Uses**  Use a mutex to provide exclusive access to a resource, such as a physical device.

**Configuration Options**  Related configuration options:

- `CONFIG_PRIORITY_CEILING`
API Reference

group mutex_apis

Defines

K_MUTEX_DEFINE(name)

Statically define and initialize a mutex.

The mutex can be accessed outside the module where it is defined using:

```c
extern struct k_mutex <name>;
```

Parameters

- name – Name of the mutex.

Functions

int k_mutex_init(struct k_mutex *mutex)

Initialize a mutex.

This routine initializes a mutex object, prior to its first use.

Upon completion, the mutex is available and does not have an owner.

Parameters

- mutex – Address of the mutex.

Return values

- 0 – Mutex object created

int k_mutex_lock(struct k_mutex *mutex, k_timeout_t timeout)

Lock a mutex.

This routine locks mutex. If the mutex is locked by another thread, the calling thread waits until the mutex becomes available or until a timeout occurs.

A thread is permitted to lock a mutex it has already locked. The operation completes immediately and the lock count is increased by 1.

Mutexes may not be locked in ISRs.

Parameters

- mutex – Address of the mutex.
- timeout – Waiting period to lock the mutex, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

- 0 – Mutex locked.
- -EBUSY – Returned without waiting.
- -EAGAIN – Waiting period timed out.
int k_mutex_unlock(struct k_mutex *mutex)

Unlock a mutex.

This routine unlocks mutex. The mutex must already be locked by the calling thread.

The mutex cannot be claimed by another thread until it has been unlocked by the calling thread as many times as it was previously locked by that thread.

Mutexes may not be unlocked in ISRs, as mutexes must only be manipulated in thread context due to ownership and priority inheritance semantics.

Parameters

- Mutual – Address of the mutex.

Return values

- 0 – Mutex unlocked.
- -EPERM – The current thread does not own the mutex
- -EINVAL – The mutex is not locked

struct k_mutex

#include <kernel.h> Mutex Structure

Public Members

_wait_q_t wait_q
Mutex wait queue

struct k_thread *owner
Mutex owner

uint32_t lock_count
Current lock count

int owner_orig_prio
Original thread priority

Futex API Reference
k_futex is a lightweight mutual exclusion primitive designed to minimize kernel involvement. Uncontended operation relies only on atomic access to shared memory. k_futex are tracked as kernel objects and can live in user memory so that any access bypasses the kernel object permission management mechanism.

Futex APIs

Functions

int k_futex_wait(struct k_futex *futex, int expected, k_timeout_t timeout)
Pend the current thread on a futex.
Tests that the supplied futex contains the expected value, and if so, goes to sleep until some other thread calls k_futex_wake() on it.

Parameters
• **futex** – Address of the futex.
• **expected** – Expected value of the futex, if it is different the caller will not wait on it.
• **timeout** – Non-negative waiting period on the futex, or one of the special values K_NO_WAIT or K_FOREVER.

**Return values**
• -EACCES – Caller does not have read access to futex address.
• -EAGAIN – If the futex value did not match the expected parameter.
• -EINVAL – Futex parameter address not recognized by the kernel.
• -ETIMEDOUT – Thread woke up due to timeout and not a futex wakeup.
• 0 – if the caller went to sleep and was woken up. The caller should check the futex’s value on wakeup to determine if it needs to block again.

```c
int k_futex_wake(struct k_futex *futex, bool wake_all)
```

Wake one/all threads pending on a futex.

Wake up the highest priority thread pending on the supplied futex, or wakeup all the threads pending on the supplied futex, and the behavior depends on `wake_all`.

**Parameters**
• **futex** – Futex to wake up pending threads.
• **wake_all** – If true, wake up all pending threads; If false, wakeup the highest priority thread.

**Return values**
• -EACCES – Caller does not have access to the futex address.
• -EINVAL – Futex parameter address not recognized by the kernel.
• Number – of threads that were woken up.

**User Mode Mutex API Reference**  
`sys_mutex` behaves almost exactly like `k_mutex`, with the added advantage that a `sys_mutex` instance can reside in user memory. When user mode isn’t enabled, `sys_mutex` behaves like `k_mutex`.

```c
SYS_MUTEX_DEFINE(name)
```

Statically define and initialize a `sys_mutex`.

The mutex can be accessed outside the module where it is defined using:

```c
extern struct sys_mutex <name>;
```

Route this to memory domains using `K_APP_DMEM()`.

**Parameters**
• **name** – Name of the mutex.
Functions

static inline void sys_mutex_init(struct sys_mutex *mutex)
    Initialize a mutex.

This routine initializes a mutex object, prior to its first use.

Upon completion, the mutex is available and does not have an owner.

This routine is only necessary to call when userspace is disabled and the mutex was not created
with SYS_MUTEX_DEFINE().

Parameters
• mutex – Address of the mutex.

static inline int sys_mutex_lock(struct sys_mutex *mutex, k_timeout_t timeout)
    Lock a mutex.

This routine locks mutex. If the mutex is locked by another thread, the calling thread waits
until the mutex becomes available or until a timeout occurs.

A thread is permitted to lock a mutex it has already locked. The operation completes imme-
diately and the lock count is increased by 1.

Parameters
• mutex – Address of the mutex, which may reside in user memory
• timeout – Waiting period to lock the mutex, or one of the special values
  K_NO_WAIT and K_FOREVER.

Return values
• 0 – Mutex locked.
• -EBUSY – Returned without waiting.
• -EAGAIN – Waiting period timed out.
• -EACCES – Caller has no access to provided mutex address
• -EINVAL – Provided mutex not recognized by the kernel

static inline int sys_mutex_unlock(struct sys_mutex *mutex)
    Unlock a mutex.

This routine unlocks mutex. The mutex must already be locked by the calling thread.

The mutex cannot be claimed by another thread until it has been unlocked by the calling
thread as many times as it was previously locked by that thread.

Parameters
• mutex – Address of the mutex, which may reside in user memory

Return values
• 0 – Mutex unlocked
• -EACCES – Caller has no access to provided mutex address
• -EINVAL – Provided mutex not recognized by the kernel or mutex wasn’t locked
• -EPERM – Caller does not own the mutex
Condition Variables

A condition variable is a synchronization primitive that enables threads to wait until a particular condition occurs.

- Concepts
- Implementation
  - Defining a Condition Variable
  - Waiting on a Condition Variable
  - Signaling a Condition Variable
- Suggested Uses
- Configuration Options
- API Reference

Concepts

Any number of condition variables can be defined (limited only by available RAM). Each condition variable is referenced by its memory address.

To wait for a condition to become true, a thread can make use of a condition variable.

A condition variable is basically a queue of threads that threads can put themselves on when some state of execution (i.e., some condition) is not as desired (by waiting on the condition). The function `k_condvar_wait()` performs atomically the following steps:

1. Releases the last acquired mutex.
2. Puts the current thread in the condition variable queue.

Some other thread, when it changes said state, can then wake one (or more) of those waiting threads and thus allow them to continue by signaling on the condition using `k_condvar_signal()` or `k_condvar_broadcast()` then it:

1. Re-acquires the mutex previously released.
2. Returns from `k_condvar_wait()`.

A condition variable must be initialized before it can be used.

Implementation

Defining a Condition Variable

A condition variable is defined using a variable of type `k_condvar`. It must then be initialized by calling `k_condvar_init()`.

The following code defines a condition variable:

```c
struct k_condvar my_condvar;
k_condvar_init(&my_condvar);
```

Alternatively, a condition variable can be defined and initialized at compile time by calling `K_CONDVAR_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_CONDVAR_DEFINE(my_condvar);
```
Waiting on a Condition Variable  A thread can wait on a condition by calling `k_condvar_wait()`. The following code waits on the condition variable.

```c
K_MUTEX_DEFINE(mutex);
K_CONDVAR_DEFINE(condvar)

void main(void)
{
    k_mutex_lock(&mutex, K_FOREVER);
    /* block this thread until another thread signals cond. While
     * blocked, the mutex is released, then re-acquired before this
     * thread is woken up and the call returns.
     */
    k_condvar_wait(&condvar, &mutex, K_FOREVER);
    ...
    k_mutex_unlock(&mutex);
}
```

Signaling a Condition Variable  A condition variable is signaled on by calling `k_condvar_signal()` for one thread or by calling `k_condvar_broadcast()` for multiple threads. The following code builds on the example above.

```c
void worker_thread(void)
{
    k_mutex_lock(&mutex, K_FOREVER);
    /*
     * Do some work and fulfill the condition
     */
    ...
    k_condvar_signal(&condvar);
    k_mutex_unlock(&mutex);
}
```

Suggested Uses  Use condition variables with a mutex to signal changing states (conditions) from one thread to another thread. Condition variables are not the condition itself and they are not events. The condition is contained in the surrounding programming logic.

Mutexes alone are not designed for use as a notification/synchronization mechanism. They are meant to provide mutually exclusive access to a shared resource only.

Configuration Options  Related configuration options:

- None.

API Reference

group condvar_apis

Defines

3.1. Kernel Services
K_CONDVAR_DEFINE(name)
    Statically define and initialize a condition variable.

    The condition variable can be accessed outside the module where it is defined using:

    extern struct k_condvar <name>;

Parameters
    • name – Name of the condition variable.

Functions

int k_condvar_init(struct k_condvar *condvar)
    Initialize a condition variable.

    Parameters
    • condvar – pointer to a k_condvar structure

    Return values
    0 – Condition variable created successfully

int k_condvar_signal(struct k_condvar *condvar)
    Signals one thread that is pending on the condition variable.

    Parameters
    • condvar – pointer to a k_condvar structure

    Return values
    0 – On success

int k_condvar_broadcast(struct k_condvar *condvar)
    Unblock all threads that are pending on the condition variable.

    Parameters
    • condvar – pointer to a k_condvar structure

    Returns
    An integer with number of woken threads on success

int k_condvar_wait(struct k_condvar *condvar, struct k_mutex *mutex, k_timeout_t timeout)
    Waits on the condition variable releasing the mutex lock.

    Atomically releases the currently owned mutex, blocks the current thread waiting on the condition variable specified by condvar, and finally acquires the mutex again.

    The waiting thread unblocks only after another thread calls k_condvar_signal, or k_condvar_broadcast with the same condition variable.

    Parameters
    • condvar – pointer to a k_condvar structure
    • mutex – Address of the mutex.
    • timeout – Waiting period for the condition variable or one of the special values K_NO_WAIT and K_FOREVER.

    Return values
    • 0 – On success
    • -EAGAIN – Waiting period timed out.
Events

An event object is a kernel object that implements traditional events.

Concepts  Any number of event objects can be defined (limited only by available RAM). Each event object is referenced by its memory address. One or more threads may wait on an event object until the desired set of events has been delivered to the event object. When new events are delivered to the event object, all threads whose wait conditions have been satisfied become ready simultaneously.

An event object has the following key properties:

- A 32-bit value that tracks which events have been delivered to it.

An event object must be initialized before it can be used.

Events may be delivered by a thread or an ISR. When delivering events, the events may either overwrite the existing set of events or add to them in a bitwise fashion. When overwriting the existing set of events, this is referred to as setting. When adding to them in a bitwise fashion, this is referred to as posting. Both posting and setting events have the potential to fulfill match conditions of multiple threads waiting on the event object. All threads whose match conditions have been met are made active at the same time.

Threads may wait on one or more events. They may either wait for all of the requested events, or for any of them. Furthermore, threads making a wait request have the option of resetting the current set of events tracked by the event object prior to waiting. Care must be taken with this option when multiple threads wait on the same event object.

Note: The kernel does allow an ISR to query an event object, however the ISR must not attempt to wait for the events.

Implementation

Defining an Event Object  An event object is defined using a variable of type k_event. It must then be initialized by calling k_event_init().

The following code defines an event object.

```c
struct k_event my_event;

k_event_init(&my_event);
```
Alternatively, an event object can be defined and initialized at compile time by calling `K_EVENT_DEFINE`. The following code has the same effect as the code segment above.

```c
K_EVENT_DEFINE(my_event);
```

### Setting Events
Events in an event object are set by calling `k_event_set()`.
The following code builds on the example above, and sets the events tracked by the event object to 0x001.

```c
void input_available_interrupt_handler(void *arg)
{
    /* notify threads that data is available */
    k_event_set(&my_event, 0x001);
    ...
}
```

### Posting Events
Events are posted to an event object by calling `k_event_post()`.
The following code builds on the example above, and posts a set of events to the event object.

```c
void input_available_interrupt_handler(void *arg)
{
    ...
    /* notify threads that more data is available */
    k_event_post(&my_event, 0x120);
    ...
}
```

### Waiting for Events
Threads wait for events by calling `k_event_wait()`.
The following code builds on the example above, and waits up to 50 milliseconds for any of the specified events to be posted. A warning is issued if none of the events are posted in time.

```c
void consumer_thread(void)
{
    uint32_t events;

    events = k_event_wait(&my_event, 0xFFF, false, K_MSEC(50));
    if (events == 0) {
        printk("No input devices are available!");
    } else {
        /* Access the desired input device(s) */
        ...
    }
    ...
}
```

Alternatively, the consumer thread may desire to wait for all the events before continuing.
```c
void consumer_thread(void)
{
    uint32_t events;

    events = k_event_wait_all(&my_event, 0x121, false, K_MSEC(50));
    if (events == 0) {
        printk("At least one input device is not available!");
    } else {
        /* Access the desired input devices */
        ...
    }
    ...
}
```

**Suggested Uses**  Use events to indicate that a set of conditions have occurred. Use events to pass small amounts of data to multiple threads at once.

**Configuration Options**  Related configuration options:

- CONFIG_EVENTS

**API Reference**

`group event_apis`

**Defines**

`K_EVENT_DEFINE(name)`

Statically define and initialize an event object. The event can be accessed outside the module where it is defined using:

```c
extern struct k_event <name>;
```

**Parameters**

- name – Name of the event object.

**Functions**

`void k_event_init(struct k_event *event)`

Initialize an event object. This routine initializes an event object, prior to its first use.

**Parameters**

- event – Address of the event object.
void k_event_post(struct k_event *event, uint32_t events)
Post one or more events to an event object.

This routine posts one or more events to an event object. All tasks waiting on the event object event whose waiting conditions become met by this posting immediately unpend.

Posting differs from setting in that posted events are merged together with the current set of events tracked by the event object.

**Parameters**
- `event` – Address of the event object
- `events` – Set of events to post to event

void k_event_set(struct k_event *event, uint32_t events)
Set the events in an event object.

This routine sets the events stored in event object to the specified value. All tasks waiting on the event object event whose waiting conditions become met by this immediately unpend.

Setting differs from posting in that set events replace the current set of events tracked by the event object.

**Parameters**
- `event` – Address of the event object
- `events` – Set of events to post to event

void k_event_set_masked(struct k_event *event, uint32_t events, uint32_t events_mask)
Set or clear the events in an event object.

This routine sets the events stored in event object to the specified value. All tasks waiting on the event object event whose waiting conditions become met by this immediately unpend. Unlike k_event_set, this routine allows specific event bits to be set and cleared as determined by the mask.

**Parameters**
- `event` – Address of the event object
- `events` – Set of events to post to event
- `events_mask` – Mask to be applied to events

uint32_t k_event_wait(struct k_event *event, uint32_t events, bool reset, k_timeout_t timeout)
Wait for any of the specified events.

This routine waits on event object event until any of the specified events have been delivered to the event object, or the maximum wait time timeout has expired. A thread may wait on up to 32 distinctly numbered events that are expressed as bits in a single 32-bit word.

**Note:** The caller must be careful when resetting if there are multiple threads waiting for the event object event.

**Parameters**
- `event` – Address of the event object
- `events` – Set of desired events on which to wait
- `reset` – If true, clear the set of events tracked by the event object before waiting. If false, do not clear the events.
- `timeout` – Waiting period for the desired set of events or one of the special values K_NO_WAIT and K_FOREVER.
Return values

- set – of matching events upon success
- 0 – if matching events were not received within the specified time

```c
uint32_t k_event_wait_all(struct k_event *event, uint32_t events, bool reset, k_timeout_t timeout)
```

Wait for any of the specified events.

This routine waits on event object `event` until all of the specified events have been delivered to the event object, or the maximum wait time `timeout` has expired. A thread may wait on up to 32 distinctly numbered events that are expressed as bits in a single 32-bit word.

**Note:** The caller must be careful when resetting if there are multiple threads waiting for the event object `event`.

Parameters

- `event` – Address of the event object
- `events` – Set of desired events on which to wait
- `reset` – If true, clear the set of events tracked by the event object before waiting. If false, do not clear the events.
- `timeout` – Waiting period for the desired set of events or one of the special values `K_NO_WAIT` and `K_FOREVER`.

Return values

- set – of matching events upon success
- 0 – if matching events were not received within the specified time

```c
struct k_event
```

```
#include <kernel.h> Event Structure
```

Symmetric Multiprocessing

On multiprocessor architectures, Zephyr supports the use of multiple physical CPUs running Zephyr application code. This support is “symmetric” in the sense that no specific CPU is treated specially by default. Any processor is capable of running any Zephyr thread, with access to all standard Zephyr APIs supported.

No special application code needs to be written to take advantage of this feature. If there are two Zephyr application threads runnable on a supported dual processor device, they will both run simultaneously.

SMP configuration is controlled under the `CONFIG_SMP` kconfig variable. This must be set to “y” to enable SMP features, otherwise a uniprocessor kernel will be built. In general the platform default will have enabled this anywhere it’s supported. When enabled, the number of physical CPUs available is visible at build time as `CONFIG_MP_NUM_CPUS`. Likewise, the default for this will be the number of available CPUs on the platform and it is not expected that typical apps will change it. But it is legal and supported to set this to a smaller (but obviously not larger) number for special purposes (e.g. for testing, or to reserve a physical CPU for running non-Zephyr code).
Synchronization  At the application level, core Zephyr IPC and synchronization primitives all behave identically under an SMP kernel. For example semaphores used to implement blocking mutual exclusion continue to be a proper application choice.

At the lowest level, however, Zephyr code has often used the `irq_lock()`/`irq_unlock()` primitives to implement fine grained critical sections using interrupt masking. These APIs continue to work via an emulation layer (see below), but the masking technique does not: the fact that your CPU will not be interrupted while you are in your critical section says nothing about whether a different CPU will be running simultaneously and be inspecting or modifying the same data!

Spinlocks  SMP systems provide a more constrained `k_spin_lock()` primitive that not only masks interrupts locally, as done by `irq_lock()`, but also atomically validates that a shared lock variable has been modified before returning to the caller, “spinning” on the check if needed to wait for the other CPU to exit the lock. The default Zephyr implementation of `k_spin_lock()` and `k_spin_unlock()` is built on top of the pre-existing atomic layer (itself usually implemented using compiler intrinsics), though facilities exist for architectures to define their own for performance reasons.

One important difference between IRQ locks and spinlocks is that the earlier API was naturally recursive: the lock was global, so it was legal to acquire a nested lock inside of a critical section. Spinlocks are separable: you can have many locks for separate subsystems or data structures, preventing CPUs from contending on a single global resource. But that means that spinlocks must not be used recursively. Code that holds a specific lock must not try to re-acquire it or it will deadlock (it is perfectly legal to nest distinct spinlocks, however). A validation layer is available to detect and report bugs like this.

When used on a uniprocessor system, the data component of the spinlock (the atomic lock variable) is unnecessary and elided. Except for the recursive semantics above, spinlocks in single-CPU contexts produce identical code to legacy IRQ locks. In fact the entirety of the Zephyr core kernel has now been ported to use spinlocks exclusively.

Legacy irq_lock() emulation  For the benefit of applications written to the uniprocessor locking API, `irq_lock()` and `irq_unlock()` continue to work compatibly on SMP systems with identical semantics to their legacy versions. They are implemented as a single global spinlock, with a nesting count and the ability to be atomically reacquired on context switch into locked threads. The kernel will ensure that only one thread across all CPUs can hold the lock at any time, that it is released on context switch, and that it is re-acquired when necessary to restore the lock state when a thread is switched in. Other CPUs will spin waiting for the release to happen.

The overhead involved in this process has measurable performance impact, however. Unlike uniprocessor apps, SMP apps using `irq_lock()` are not simply invoking a very short (often ~1 instruction) interrupt masking operation. That, and the fact that the IRQ lock is global, means that code expecting to be run in an SMP context should be using the spinlock API wherever possible.

CPU Mask  It is often desirable for real time applications to deliberately partition work across physical CPUs instead of relying solely on the kernel scheduler to decide on which threads to execute. Zephyr provides an API, controlled by the `CONFIG_SCHED_CPU_MASK` kconfig variable, which can associate a specific set of CPUs with each thread, indicating on which CPUs it can run.

By default, new threads can run on any CPU. Calling `k_thread_cpu_mask_disable()` with a particular CPU ID will prevent that thread from running on that CPU in the future. Likewise `k_thread_cpu_mask_enable()` will re-enable execution. There are also `k_thread_cpu_mask_clear()` and `k_thread_cpu_mask_enable_all()` APIs available for convenience. For obvious reasons, these APIs are illegal if called on a runnable thread. The thread must be blocked or suspended, otherwise an `EINVAL` will be returned.

Note that when this feature is enabled, the scheduler algorithm involved in doing the per-CPU mask test requires that the list be traversed in full. The kernel does not keep a per-CPU run queue. That means that the performance benefits from the `CONFIG_SCHED_SCALABLE` and `CONFIG_SCHED_MULTIQ` scheduler backends cannot be realized. CPU mask processing is available only when `CONFIG_SCHED_DUMB` is the selected backend. This requirement is enforced in the configuration layer.
SMP Boot Process  A Zephyr SMP kernel begins boot identically to a uniprocessor kernel. Auxiliary CPUs begin in a disabled state in the architecture layer. All standard kernel initialization, including device initialization, happens on a single CPU before other CPUs are brought online.

Just before entering the application main() function, the kernel calls z_smp_init() to launch the SMP initialization process. This enumerates over the configured CPUs, calling into the architecture layer using arch_start_cpu() for each one. This function is passed a memory region to use as a stack on the foreign CPU (in practice it uses the area that will become that CPU’s interrupt stack), the address of a local smp_init_top() callback function to run on that CPU, and a pointer to a “start flag” address which will be used as an atomic signal.

The local SMP initialization (smp_init_top()) on each CPU is then invoked by the architecture layer. Note that interrupts are still masked at this point. This routine is responsible for calling smp_timer_init() to set up any needed stat in the timer driver. On many architectures the timer is a per-CPU device and needs to be configured specially on auxiliary CPUs. Then it waits (spinning) for the atomic “start flag” to be released in the main thread, to guarantee that all SMP initialization is complete before any Zephyr application code runs, and finally calls z_swap() to transfer control to the appropriate runnable thread via the standard scheduler API.

![SMP Initialization Diagram](image)

**Fig. 3.1:** Example SMP initialization process, showing a configuration with two CPUs and two app threads which begin operating simultaneously.

Interprocessor Interrupts  When running in multiprocessor environments, it is occasionally the case that state modified on the local CPU needs to be synchronously handled on a different processor.

One example is the Zephyr k_thread_abort() API, which cannot return until the thread that had been aborted is no longer runnable. If it is currently running on another CPU, that becomes difficult to implement.

3.1. Kernel Services
Another is low power idle. It is a firm requirement on many devices that system idle be implemented using a low-power mode with as many interrupts (including periodic timer interrupts) disabled or deferred as is possible. If a CPU is in such a state, and on another CPU a thread becomes runnable, the idle CPU has no way to “wake up” to handle the newly-runnable load.

So where possible, Zephyr SMP architectures should implement an interprocessor interrupt. The current framework is very simple: the architecture provides a `arch_sched_ipi()` call, which when invoked will flag an interrupt on all CPUs (except the current one, though that is allowed behavior) which will then invoke the `z_sched_ipi()` function implemented in the scheduler. The expectation is that these APIs will evolve over time to encompass more functionality (e.g. cross-CPU calls), and that the scheduler-specific calls here will be implemented in terms of a more general framework.

Note that not all SMP architectures will have a usable IPI mechanism (either missing, or just undocumented/unimplemented). In those cases Zephyr provides fallback behavior that is correct, but perhaps suboptimal.

Using this, `k_thread_abort()` becomes only slightly more complicated in SMP: for the case where a thread is actually running on another CPU (we can detect this atomically inside the scheduler), we broadcast an IPI and spin, waiting for the thread to either become “DEAD” or for it to re-enter the queue (in which case we terminate it the same way we would have in uniprocessor mode). Note that the “aborted” check happens on any interrupt exit, so there is no special handling needed in the IPI per se. This allows us to implement a reasonable fallback when IPI is not available: we can simply spin, waiting until the foreign CPU receives any interrupt, though this may be a much longer time!

Likewise idle wakeups are trivially implementable with an empty IPI handler. If a thread is added to an empty run queue (i.e. there may have been idle CPUs), we broadcast an IPI. A foreign CPU will then be able to see the new thread when exiting from the interrupt and will switch to it if available.

Without an IPI, however, a low power idle that requires an interrupt will not work to synchronously run new threads. The workaround in that case is more invasive: Zephyr will not enter the system idle handler and will instead spin in its idle loop, testing the scheduler state at high frequency (not spinning on it though, as that would involve severe lock contention) for new threads. The expectation is that power constrained SMP applications are always going to provide an IPI, and this code will only be used for testing purposes or on systems without power consumption requirements.

**SMP Kernel Internals** In general, Zephyr kernel code is SMP-agnostic and, like application code, will work correctly regardless of the number of CPUs available. But in a few areas there are notable changes in structure or behavior.

**Per-CPU data** Many elements of the core kernel data need to be implemented for each CPU in SMP mode. For example, the `_current` thread pointer obviously needs to reflect what is running locally, there are many threads running concurrently. Likewise a kernel-provided interrupt stack needs to be created and assigned for each physical CPU, as does the interrupt nesting count used to detect ISR state.

These fields are now moved into a separate struct `_cpu` instance within the `_kernel` struct, which has a `cpus[]` array indexed by ID. Compatibility fields are provided for legacy uniprocessor code trying to access the fields of `cpus[0]` using the older syntax and assembly offsets.

Note that an important requirement on the architecture layer is that the pointer to this CPU struct be available rapidly when in kernel context. The expectation is that `arch_curr_cpu()` will be implemented using a CPU-provided register or addressing mode that can store this value across arbitrary context switches or interrupts and make it available to any kernel-mode code.

Similarly, where on a uniprocessor system Zephyr could simply create a global “idle thread” at the lowest priority, in SMP we may need one for each CPU. This makes the internal predicate test for “`is_idle()`” in the scheduler, which is a hot path performance environment, more complicated than simply testing the thread pointer for equality with a known static variable. In SMP mode, idle threads are distinguished by a separate field in the thread struct.
Switch-based context switching  The traditional Zephyr context switch primitive has been `z_swap()`. Unfortunately, this function takes no argument specifying a thread to switch to. The expectation has always been that the scheduler has already made its preemption decision when its state was last modified and cached the resulting “next thread” pointer in a location where architecture context switch primitives can find it via a simple struct offset. That technique will not work in SMP, because the other CPU may have modified scheduler state since the current CPU last exited the scheduler (for example: it might already be running that cached thread!).

Instead, the SMP “switch to” decision needs to be made synchronously with the swap call, and as we don’t want per-architecture assembly code to be handling scheduler internal state, Zephyr requires a somewhat lower-level context switch primitives for SMP systems: `arch_switch()` is always called with interrupts masked, and takes exactly two arguments. The first is an opaque (architecture defined) handle to the context to which it should switch, and the second is a pointer to such a handle into which it should store the handle resulting from the thread that is being switched out. The kernel then implements a portable `z_swap()` implementation on top of this primitive which includes the relevant scheduler logic in a location where the architecture doesn’t need to understand it.

Similarly, on interrupt exit, switch-based architectures are expected to call `z_get_next_switch_handle()` to retrieve the next thread to run from the scheduler. The argument to `z_get_next_switch_handle()` is either the interrupted thread’s “handle” reflecting the same opaque type used by `arch_switch()`, or NULL if that thread cannot be released to the scheduler just yet. The choice between a handle value or NULL depends on the way CPU interrupt mode is implemented.

Architectures with a large CPU register file would typically preserve only the caller-saved registers on the current thread’s stack when interrupted in order to minimize interrupt latency, and preserve the callee-saved registers only when `arch_switch()` is called to minimize context switching latency. Such architectures must use NULL as the argument to `z_get_next_switch_handle()` to determine if there is a new thread to schedule, and follow through with their own `arch_switch()` or derivative if so, or directly leave interrupt mode otherwise. In the former case it is up to that switch code to store the handle resulting from the thread that is being switched out in that thread’s “switch_handle” field after its context has fully been saved.

Architectures whose entry in interrupt mode already preserves the entire thread state may pass that thread’s handle directly to `z_get_next_switch_handle()` and be done in one step.

Note that while SMP requires CONFIG_USE_SWITCH, the reverse is not true. A uniprocessor architecture built with CONFIG_SMP set to No might still decide to implement its context switching using `arch_switch()`.

API Reference

`group spinlock_apis`

Spinlock APIs.

`Typedefs`

typedef struct `z_spinlock_key` `k_spinlock_key_t`

Spinlock key type.

This type defines a “key” value used by a spinlock implementation to store the system interrupt state at the time of a call to `k_spin_lock()`. It is expected to be passed to a matching `k_spin_unlock()`.

This type is opaque and should not be inspected by application code.

`Functions`
ALWAYS_INLINE static k_spinlock_key_t k_spin_lock(struct k_spinlock *l)

Lock a spinlock.

This routine locks the specified spinlock, returning a key handle representing interrupt state needed at unlock time. Upon returning, the calling thread is guaranteed not to be suspended or interrupted on its current CPU until it calls k_spin_unlock(). The implementation guarantees mutual exclusion: exactly one thread on one CPU will return from k_spin_lock() at a time. Other CPUs trying to acquire a lock already held by another CPU will enter an implementation-defined busy loop (“spinning”) until the lock is released.

Separate spin locks may be nested. It is legal to lock an (unlocked) spin lock while holding a different lock. Spin locks are not recursive, however: an attempt to acquire a spin lock that the CPU already holds will deadlock.

In circumstances where only one CPU exists, the behavior of k_spin_lock() remains as specified above, though obviously no spinning will take place. Implementations may be free to optimize in uniprocessor contexts such that the locking reduces to an interrupt mask operation.

Parameters

• l – A pointer to the spinlock to lock

Returns

A key value that must be passed to k_spin_unlock() when the lock is released.

ALWAYS_INLINE static void k_spin_unlock(struct k_spinlock *l, k_spinlock_key_t key)

Unlock a spin lock.

This releases a lock acquired by k_spin_lock(). After this function is called, any CPU will be able to acquire the lock. If other CPUs are currently spinning inside k_spin_lock() waiting for this lock, exactly one of them will return synchronously with the lock held.

Spin locks must be properly nested. A call to k_spin_unlock() must be made on the lock object most recently locked using k_spin_lock(), using the key value that it returned. Attempts to unlock mis-nested locks, or to unlock locks that are not held, or to passing a key parameter other than the one returned from k_spin_lock(), are illegal. When CONFIG_SPIN_VALIDATE is set, some of these errors can be detected by the framework.

Parameters

• l – A pointer to the spinlock to release

• key – The value returned from k_spin_lock() when this lock was acquired

ALWAYS_INLINE static void k_spin_release(struct k_spinlock *l)

struct k_spinlock

#include <spinlock.h> Kernel Spin Lock.

This struct defines a spin lock record on which CPUs can wait with k_spin_lock(). Any number of spinlocks may be defined in application code.

3.1.2 Data Passing

These pages cover kernel objects which can be used to pass data between threads and ISRs.

The following table summarizes their high-level features.
<table>

[1] Callers allocate space for queue overhead in the data elements themselves.
[2] Objects added with \texttt{k_fifo\_alloc\_put()} and \texttt{k_lifo\_alloc\_put()} do not have alignment constraints, but use temporary memory from the calling thread\'s resource pool.
[3] ISRs can receive only when passing \texttt{K\_NO\_WAIT} as the timeout argument.
[5] ISRs can send and/or receive only when passing \texttt{K\_NO\_WAIT} as the timeout argument.

### Queues

A Queue in Zephyr is a kernel object that implements a traditional queue, allowing threads and ISRs to add and remove data items of any size. The queue is similar to a FIFO and serves as the underlying implementation for both \texttt{k\_fifo} and \texttt{k\_lifo}. For more information on usage see \texttt{k\_fifo}.

### Configuration Options

### API Reference

\texttt{group queue\_apis}

**Defines**

\texttt{K\_QUEUE\_DEFINE(name)}

Statically define and initialize a queue.

The queue can be accessed outside the module where it is defined using:

\begin{verbatim}
extern struct k_queue <name>;
\end{verbatim}
Functions

void k_queue_init(struct k_queue *queue)
Initialize a queue.
This routine initializes a queue object, prior to its first use.

Parameters
• queue – Address of the queue.

void k_queue_cancel_wait(struct k_queue *queue)
Cancel waiting on a queue.
This routine causes first thread pending on queue, if any, to return from k_queue_get() call with NULL value (as if timeout expired). If the queue is being waited on by k_poll(), it will return with -EINTR and K_POLL_STATE_CANCELLED state (and per above, subsequent k_queue_get() will return NULL).

Function properties (list may not be complete)
  isr-ok

Parameters
• queue – Address of the queue.

void k_queue_append(struct k_queue *queue, void *data)
Append an element to the end of a queue.
This routine appends a data item to queue. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

Function properties (list may not be complete)
  isr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

int32_t k_queue_alloc_append(struct k_queue *queue, void *data)
Append an element to a queue.
This routine appends a data item to queue. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete)
  isr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

Return values
• 0 – on success
• -ENOMEM – if there isn’t sufficient RAM in the caller’s resource pool

void k_queue_prepend(struct k_queue *queue, void *data)
Prepend an element to a queue.
This routine prepends a data item to queue. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel’s use.

Function properties (list may not be complete)
irr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

int32_t k_queue_alloc_prepend(struct k_queue *queue, void *data)
Prepend an element to a queue.
This routine prepends a data item to queue. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread’s resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete)
irr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

Return values
• 0 – on success
• -ENOMEM – if there isn’t sufficient RAM in the caller’s resource pool

void k_queue_insert(struct k_queue *queue, void *prev, void *data)
Inserts an element to a queue.
This routine inserts a data item to queue after previous item. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel’s use.

Function properties (list may not be complete)
irr-ok

Parameters
• queue – Address of the queue.
• prev – Address of the previous data item.
• data – Address of the data item.
int k_queue_append_list(struct k_queue *queue, void *head, void *tail)
  Atomically append a list of elements to a queue.

  This routine adds a list of data items to queue in one operation. The data items must be in a singly-linked list, with the first word in each data item pointing to the next data item; the list must be NULL-terminated.

  Function properties (list may not be complete)
  isr-ok

  Parameters
  • queue – Address of the queue.
  • head – Pointer to first node in singly-linked list.
  • tail – Pointer to last node in singly-linked list.

  Return values
  • 0 – on success
  • -EINVAL – on invalid supplied data

int k_queue_merge_slist(struct k_queue *queue, sys_slist_t *list)
  Atomically add a list of elements to a queue.

  This routine adds a list of data items to queue in one operation. The data items must be in a singly-linked list implemented using a sys_slist_t object. Upon completion, the original list is empty.

  Function properties (list may not be complete)
  isr-ok

  Parameters
  • queue – Address of the queue.
  • list – Pointer to sys_slist_t object.

  Return values
  • 0 – on success
  • -EINVAL – on invalid data

void *k_queue_get(struct k_queue *queue, k_timeout_t timeout)
  Get an element from a queue.

  This routine removes first data item from queue. The first word of the data item is reserved for the kernel's use.

  Function properties (list may not be complete)
  isr-ok

  Note: timeout must be set to K_NO_WAIT if called from ISR.

  Parameters
  • queue – Address of the queue.
• timeout – Non-negative waiting period to obtain a data item or one of the special values K_NO_WAIT and K_FOREVER.

**Returns**
Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

```c
bool k_queue_remove(struct k_queue *queue, void *data)
```

Remove an element from a queue.
This routine removes data item from `queue`. The first word of the data item is reserved for the kernel's use. Removing elements from `k_queue` rely on `sys_slist_find_and_remove` which is not a constant time operation.

**Function properties (list may not be complete)**
*isr-ok*

**Note:** `timeout` must be set to K_NO_WAIT if called from ISR.

**Parameters**
- `queue` – Address of the queue.
- `data` – Address of the data item.

**Returns**
true if data item was removed

```c
bool k_queue_unique_append(struct k_queue *queue, void *data)
```

Append an element to a queue only if it’s not present already.
This routine appends data item to `queue`. The first word of the data item is reserved for the kernel's use. Appending elements to `k_queue` relies on `sys_slist_is_node_in_list` which is not a constant time operation.

**Function properties (list may not be complete)**
*isr-ok*

**Parameters**
- `queue` – Address of the queue.
- `data` – Address of the data item.

**Returns**
true if data item was added, false if not

```c
int k_queue_is_empty(struct k_queue *queue)
```

Query a queue to see if it has data available.
Note that the data might be already gone by the time this function returns if other threads are also trying to read from the queue.

**Function properties (list may not be complete)**
*isr-ok*

**Parameters**
FIFOs

A FIFO is a kernel object that implements a traditional first in, first out (FIFO) queue, allowing threads and ISRs to add and remove data items of any size.

- Concepts
  - Implementation
    - Defining a FIFO
    - Writing to a FIFO
    - Reading from a FIFO
- Suggested Uses
- Configuration Options
- API Reference

Concepts  Any number of FIFOs can be defined (limited only by available RAM). Each FIFO is referenced by its memory address.

A FIFO has the following key properties:

- A queue of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A FIFO must be initialized before it can be used. This sets its queue to empty.

FIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes
of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_fifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread's resource pool.

A data item may be **added** to a FIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the FIFO's queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a FIFO by a thread. If the FIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty FIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

**Note:** The kernel does allow an ISR to remove an item from a FIFO, however the ISR must not attempt to wait if the FIFO is empty.

If desired, **multiple data items** can be added to a FIFO in a single operation if they are chained together into a singly-linked list. This capability can be useful if multiple writers are adding sets of related data items to the FIFO, as it ensures the data items in each set are not interleaved with other data items. Adding multiple data items to a FIFO is also more efficient than adding them one at a time, and can be used to guarantee that anyone who removes the first data item in a set will be able to remove the remaining data items without waiting.

### Implementation

**Defining a FIFO** A FIFO is defined using a variable of type `k_fifo`. It must then be initialized by calling `k_fifo_init()`.

The following code defines and initializes an empty FIFO.

```c
struct k_fifo my_fifo;
k_fifo_init(&my_fifo);
```

Alternatively, an empty FIFO can be defined and initialized at compile time by calling `K_FIFO_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_FIFO_DEFINE(my_fifo);
```

**Writing to a FIFO** A data item is added to a FIFO by calling `k_fifo_put()`.

The following code builds on the example above, and uses the FIFO to send data to one or more consumer threads.

```c
struct data_item_t {
    void *fifo_reserved; /* 1st word reserved for use by FIFO */
    ...
};

struct data_item_t tx_data;

void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...
```
Additionally, a singly-linked list of data items can be added to a FIFO by calling `k_fifo_put_list()` or `k_fifo_put_slist()`.

Finally, a data item can be added to a FIFO with `k_fifo_alloc_put()`. With this API, there is no need to reserve space for the kernel’s use in the data item, instead additional memory will be allocated from the calling thread’s resource pool until the item is read.

Reading from a FIFO  A data item is removed from a FIFO by calling `k_fifo_get()`.

The following code builds on the example above, and uses the FIFO to obtain data items from a producer thread, which are then processed in some manner.

```c
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t *rx_data;

    while (1) {
        rx_data = k_fifo_get(&my_fifo, K_FOREVER);

        /* process FIFO data item */
        ...
    }
}
```

Suggested Uses  Use a FIFO to asynchronously transfer data items of arbitrary size in a “first in, first out” manner.

Configuration Options  Related configuration options:

- None

API Reference

group fifo_apis

Defines

`k_fifo_init(fifo)`

Initialize a FIFO queue.

This routine initializes a FIFO queue, prior to its first use.

Parameters

- `fifo` – Address of the FIFO queue.
k_fifo_cancel_wait(fifo)

Cancel waiting on a FIFO queue.

This routine causes first thread pending on fifo, if any, to return from \texttt{k_fifo_get()} call with NULL value (as if timeout expired).

\textbf{Function properties (list may not be complete)}
\textit{isr-ok}

\textbf{Parameters}
- \texttt{fifo} – Address of the FIFO queue.

\noindent k_fifo_put(fifo, data)

Add an element to a FIFO queue.

This routine adds a data item to \texttt{fifo}. A FIFO data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

\textbf{Function properties (list may not be complete)}
\textit{isr-ok}

\textbf{Parameters}
- \texttt{fifo} – Address of the FIFO.
- \texttt{data} – Address of the data item.

\noindent k_fifo_alloc_put(fifo, data)

Add an element to a FIFO queue.

This routine adds a data item to \texttt{fifo}. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

\textbf{Function properties (list may not be complete)}
\textit{isr-ok}

\textbf{Parameters}
- \texttt{fifo} – Address of the FIFO.
- \texttt{data} – Address of the data item.

\textbf{Return values}
- \texttt{0} – on success
- \texttt{-ENOMEM} – if there isn't sufficient RAM in the caller's resource pool

\noindent k_fifo_put_list(fifo, head, tail)

Atomically add a list of elements to a FIFO.

This routine adds a list of data items to \texttt{fifo} in one operation. The data items must be in a singly-linked list, with the first word of each data item pointing to the next data item; the list must be NULL-terminated.

\textbf{Function properties (list may not be complete)}
\textit{isr-ok}
Parameters

• fifo – Address of the FIFO queue.
• head – Pointer to first node in singly-linked list.
• tail – Pointer to last node in singly-linked list.

\texttt{k_fifo_put_slist(fifo, list)}

Atomically add a list of elements to a FIFO queue.

This routine adds a list of data items to \texttt{fifo} in one operation. The data items must be in a singly-linked list implemented using a \texttt{sys\_slist\_t} object. Upon completion, the \texttt{sys\_slist\_t} object is invalid and must be re-initialized via \texttt{sys\_slist\_init()}.  

\textbf{Function properties (list may not be complete)}
\textit{isr-ok}

Parameters

• fifo – Address of the FIFO queue.
• list – Pointer to \texttt{sys\_slist\_t} object.

\texttt{k_fifo_get(fifo, timeout)}

Get an element from a FIFO queue.

This routine removes a data item from \texttt{fifo} in a “first in, first out” manner. The first word of the data item is reserved for the kernel’s use.

\textbf{Function properties (list may not be complete)}
\textit{isr-ok}

\textbf{Note:} \textit{timeout} must be set to \texttt{K\_NO\_WAIT} if called from ISR.

Parameters

• fifo – Address of the FIFO queue.
• timeout – Waiting period to obtain a data item, or one of the special values \texttt{K\_NO\_WAIT} and \texttt{K\_FOREVER}.

\textbf{Returns}

Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

\texttt{k_fifo_is_empty(fifo)}

Query a FIFO queue to see if it has data available.

Note that the data might be already gone by the time this function returns if other threads is also trying to read from the FIFO.

\textbf{Function properties (list may not be complete)}
\textit{isr-ok}

Parameters

• fifo – Address of the FIFO queue.
**Returns**
Non-zero if the FIFO queue is empty.

**Returns**
0 if data is available.

`k_fifo_peek_head(fifo)`
Peek element at the head of a FIFO queue.
Return element from the head of FIFO queue without removing it. A usecase for this is if elements of the FIFO object are themselves containers. Then on each iteration of processing, a head container will be peeked, and some data processed out of it, and only if the container is empty, it will be completely remove from the FIFO queue.

**Parameters**
- fifo – Address of the FIFO queue.

**Returns**
Head element, or NULL if the FIFO queue is empty.

`k_fifo_peek_tail(fifo)`
Peek element at the tail of FIFO queue.
Return element from the tail of FIFO queue (without removing it). A usecase for this is if elements of the FIFO queue are themselves containers. Then it may be useful to add more data to the last container in a FIFO queue.

**Parameters**
- fifo – Address of the FIFO queue.

**Returns**
Tail element, or NULL if a FIFO queue is empty.

`K_FIFO_DEFINE(name)`
Statically define and initialize a FIFO queue.
The FIFO queue can be accessed outside the module where it is defined using:

```c
extern struct k_fifo <name>;
```

**Parameters**
- name – Name of the FIFO queue.

**LIFOs**

A **LIFO** is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove data items of any size.

- **Concepts**
- **Implementation**
  - **Defining a LIFO**
  - **Writing to a LIFO**
  - **Reading from a LIFO**
- **Suggested Uses**
Any number of LIFOs can be defined (limited only by available RAM). Each LIFO is referenced by its memory address.

A LIFO has the following key properties:

- A queue of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A LIFO must be initialized before it can be used. This sets its queue to empty.

LIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds \(N\) bytes of application data requires \(N+4\) (or \(N+8\)) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_lifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread’s resource pool.

A data item may be **added** to a LIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the LIFO’s queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a LIFO by a thread. If the LIFO’s queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty LIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

**Note:** The kernel does allow an ISR to remove an item from a LIFO, however the ISR must not attempt to wait if the LIFO is empty.

### Implementation

#### Defining a LIFO

A LIFO is defined using a variable of type `k_lifo`. It must then be initialized by calling `k_lifo_init()`.

The following defines and initializes an empty LIFO.

```c
struct k_lifo my_lifo;
k_lifo_init(&my_lifo);
```

Alternatively, an empty LIFO can be defined and initialized at compile time by calling `K_LIFO_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_LIFO_DEFINE(my_lifo);
```

#### Writing to a LIFO

A data item is added to a LIFO by calling `k_lifo_put()`.

The following code builds on the example above, and uses the LIFO to send data to one or more consumer threads.

```c
struct data_item_t {
    void *LIFO_reserved;       /* 1st word reserved for use by LIFO */
    ...
};
```
struct data_item_t tx_data;

void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...;
        /* send data to consumers */
        k_lifo_put(&my_lifo, &tx_data);
        ...
    }
}

A data item can be added to a LIFO with `k_lifo_alloc_put()`. With this API, there is no need to reserve space for the kernel's use in the data item, instead additional memory will be allocated from the calling thread's resource pool until the item is read.

Reading from a LIFO  A data item is removed from a LIFO by calling `k_lifo_get()`.

The following code builds on the example above, and uses the LIFO to obtain data items from a producer thread, which are then processed in some manner.

```c
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t *rx_data;
    while (1) {
        rx_data = k_lifo_get(&my_lifo, K_FOREVER);
        /* process LIFO data item */
        ...
    }
}
```

Suggested Uses  Use a LIFO to asynchronously transfer data items of arbitrary size in a “last in, first out” manner.

Configuration Options  Related configuration options:

- None.

API Reference

`group lifo_apis`

Defines

- `k_lifo_init(lifo)`
  
  Initialize a LIFO queue.

  This routine initializes a LIFO queue object, prior to its first use.
Parameters

- lifo – Address of the LIFO queue.

\texttt{k\_lifo\_put( lifo, data )}

Add an element to a LIFO queue.

This routine adds a data item to \texttt{lifo}. A LIFO queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

**Function properties (list may not be complete)**

\texttt{isr-ok}

Parameters

- lifo – Address of the LIFO queue.
- data – Address of the data item.

\texttt{k\_lifo\_alloc\_put( lifo, data )}

Add an element to a LIFO queue.

This routine adds a data item to \texttt{lifo}. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

**Function properties (list may not be complete)**

\texttt{isr-ok}

Parameters

- lifo – Address of the LIFO queue.
- data – Address of the data item.

Return values

- 0 – on success
- -ENOMEM – if there isn’t sufficient RAM in the caller’s resource pool

\texttt{k\_lifo\_get( lifo, timeout )}

Get an element from a LIFO queue.

This routine removes a data item from \texttt{LIFO} in a “last in, first out” manner. The first word of the data item is reserved for the kernel's use.

**Function properties (list may not be complete)**

\texttt{isr-ok}

\textbf{Note: } \texttt{timeout} must be set to \texttt{K\_NO\_WAIT} if called from ISR.

Parameters

- lifo – Address of the LIFO queue.
- timeout – Waiting period to obtain a data item, or one of the special values \texttt{K\_NO\_WAIT} and \texttt{K\_FOREVER}. 
Returns
Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

K_LIFO_DEFINE(name)
Statically define and initialize a LIFO queue.
The LIFO queue can be accessed outside the module where it is defined using:

extern struct k_lifo <name>;

Parameters

- name – Name of the fifo.

Stacks
A stack is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove a limited number of integer data values.

- Concepts
- Implementation
  - Defining a Stack
  - Pushing to a Stack
  - Popping from a Stack
- Suggested Uses
- Configuration Options
- API Reference

Concepts Any number of stacks can be defined (limited only by available RAM). Each stack is referenced by its memory address.

A stack has the following key properties:

- A queue of integer data values that have been added but not yet removed. The queue is implemented using an array of stack_data_t values and must be aligned on a native word boundary. The stack_data_t type corresponds to the native word size i.e. 32 bits or 64 bits depending on the CPU architecture and compilation mode.

- A maximum quantity of data values that can be queued in the array.

A stack must be initialized before it can be used. This sets its queue to empty.

A data value can be added to a stack by a thread or an ISR. The value is given directly to a waiting thread, if one exists; otherwise the value is added to the LIFO’s queue.

Note: If CONFIG_NO_RUNTIME_CHECKS is enabled, the kernel will not detect and prevent attempts to add a data value to a stack that has already reached its maximum quantity of queued values. Adding a data value to a stack that is already full will result in array overflow, and lead to unpredictable behavior.
A data value may be removed from a stack by a thread. If the stack's queue is empty a thread may choose to wait for it to be given. Any number of threads may wait on an empty stack simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

**Note:** The kernel does allow an ISR to remove an item from a stack, however the ISR must not attempt to wait if the stack is empty.

### Implementation

**Defining a Stack** A stack is defined using a variable of type `k_stack`. It must then be initialized by calling `k_stack_init()` or `k_stack_alloc_init()`. In the latter case, a buffer is not provided and it is instead allocated from the calling thread's resource pool.

The following code defines and initializes an empty stack capable of holding up to ten word-sized data values.

```c
#define MAX_ITEMS 10

stack_data_t my_stack_array[MAX_ITEMS];
struct k_stack my_stack;

k_stack_init(&my_stack, my_stack_array, MAX_ITEMS);
```

Alternatively, a stack can be defined and initialized at compile time by calling `K_STACK_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the stack and its array of data values.

```c
K_STACK_DEFINE(my_stack, MAX_ITEMS);
```

**Pushing to a Stack** A data item is added to a stack by calling `k_stack_push()`.

The following code builds on the example above, and shows how a thread can create a pool of data structures by saving their memory addresses in a stack.

```c
/* define array of data structures */
struct my_buffer_type {
    int field1;
    ...
};
struct my_buffer_type my_buffers[MAX_ITEMS];

/* save address of each data structure in a stack */
for (int i = 0; i < MAX_ITEMS; i++) {
    k_stack_push(&my_stack, (stack_data_t)&my_buffers[i]);
}
```

**Popping from a Stack** A data item is taken from a stack by calling `k_stack_pop()`.

The following code builds on the example above, and shows how a thread can dynamically allocate an unused data structure. When the data structure is no longer required, the thread must push its address back on the stack to allow the data structure to be reused.
struct my_buffer_type *new_buffer;

k_stack_pop(&buffer_stack, (stack_data_t *)&new_buffer, K_FOREVER);
new_buffer->field1 = ...  

Suggested Uses  Use a stack to store and retrieve integer data values in a “last in, first out” manner, when the maximum number of stored items is known.

Configuration Options  Related configuration options:
  • None.

API Reference

group stack_apis

Defines

K_STACK_DEFINE(name, stack_num_entries)
  Statically define and initialize a stack.
  The stack can be accessed outside the module where it is defined using:

  extern struct k_stack <name>;

Parameters
  • name – Name of the stack.
  • stack_num_entries – Maximum number of values that can be stacked.

Functions

void k_stack_init(struct k_stack *stack, stack_data_t *buffer, uint32_t num_entries)
  Initialize a stack.
  This routine initializes a stack object, prior to its first use.

  Parameters
    • stack – Address of the stack.
    • buffer – Address of array used to hold stacked values.
    • num_entries – Maximum number of values that can be stacked.

int32_t k_stack_alloc_init(struct k_stack *stack, uint32_t num_entries)
  Initialize a stack.
  This routine initializes a stack object, prior to its first use. Internal buffers will be allocated from the calling thread's resource pool. This memory will be released if k_stack_cleanup() is called, or userspace is enabled and the stack object loses all references to it.

  Parameters
    • stack – Address of the stack.
• `num_entries` – Maximum number of values that can be stacked.

**Returns**
- `ENOMEM` if memory couldn’t be allocated

```c
int k_stack_cleanup(struct k_stack *stack)
```
Release a stack’s allocated buffer.
If a stack object was given a dynamically allocated buffer via `k_stack_alloc_init()`, this will free it. This function does nothing if the buffer wasn’t dynamically allocated.

**Parameters**
- `stack` – Address of the stack.

**Return values**
- `0` – on success
- `-EAGAIN` – when object is still in use

```c
int k_stack_push(struct k_stack *stack, stack_data_t data)
```
Push an element onto a stack.
This routine adds a stack_data_t value `data` to `stack`.

**Function properties (list may not be complete)**

*`isr-ok`*

**Parameters**
- `stack` – Address of the stack.
- `data` – Value to push onto the stack.

**Return values**
- `0` – on success
- `-ENOMEM` – if stack is full

```c
int k_stack_pop(struct k_stack *stack, stack_data_t *data, k_timeout_t timeout)
```
Pop an element from a stack.
This routine removes a stack_data_t value from `stack` in a “last in, first out” manner and stores the value in `data`.

**Function properties (list may not be complete)**

*`isr-ok`*

**Parameters**
- `stack` – Address of the stack.
- `data` – Address of area to hold the value popped from the stack.
- `timeout` – Waiting period to obtain a value, or one of the special values `K_NO_WAIT` and `K_FOREVER`.

**Return values**
- `0` – Element popped from stack.

---

**Note:** `timeout` must be set to `K_NO_WAIT` if called from ISR.
Message Queues

A *message queue* is a kernel object that implements a simple message queue, allowing threads and ISRs to asynchronously send and receive fixed-size data items.

**Concepts**

Any number of message queues can be defined (limited only by available RAM). Each message queue is referenced by its memory address.

A message queue has the following key properties:

- A *ring buffer* of data items that have been sent but not yet received.
- A *data item size*, measured in bytes.
- A *maximum quantity* of data items that can be queued in the ring buffer.

The message queue's ring buffer must be aligned to an N-byte boundary, where N is a power of 2 (i.e. 1, 2, 4, 8, \ldots). To ensure that the messages stored in the ring buffer are similarly aligned to this boundary, the data item size must also be a multiple of N.

A message queue must be initialized before it can be used. This sets its ring buffer to empty.

A data item can be **sent** to a message queue by a thread or an ISR. The data item pointed at by the sending thread is copied to a waiting thread, if one exists; otherwise the item is copied to the message queue's ring buffer, if space is available. In either case, the size of the data area being sent must equal the message queue's data item size.

If a thread attempts to send a data item when the ring buffer is full, the sending thread may choose to wait for space to become available. Any number of sending threads may wait simultaneously when the ring buffer is full; when space becomes available it is given to the highest priority sending thread that has waited the longest.

A data item can be **received** from a message queue by a thread. The data item is copied to the area specified by the receiving thread; the size of the receiving area must equal the message queue's data item size.

If a thread attempts to receive a data item when the ring buffer is empty, the receiving thread may choose to wait for a data item to be sent. Any number of receiving threads may wait simultaneously when the ring buffer is empty; when a data item becomes available it is given to the highest priority receiving thread that has waited the longest.
A thread can also **peek** at the message on the head of a message queue without removing it from the queue. The data item is copied to the area specified by the receiving thread; the size of the receiving area **must** equal the message queue's data item size.

**Note:** The kernel does allow an ISR to receive an item from a message queue, however the ISR must not attempt to wait if the message queue is empty.

---

### Implementation

#### Defining a Message Queue

A message queue is defined using a variable of type `k_msgq`. It must then be initialized by calling `k_msgq_init()`.

The following code defines and initializes an empty message queue that is capable of holding 10 items, each of which is 12 bytes long.

```c
struct data_item_type {
    uint32_t field1;
    uint32_t field2;
    uint32_t field3;
};

char __aligned(4) my_msgq_buffer[10 * sizeof(struct data_item_type)];
struct k_msgq my_msgq;

k_msgq_init(&my_msgq, my_msgq_buffer, sizeof(struct data_item_type), 10);
```

Alternatively, a message queue can be defined and initialized at compile time by calling `K_MSGQ_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the message queue and its buffer.

```c
K_MSGQ_DEFINE(my_msgq, sizeof(struct data_item_type), 10, 4);
```

The following code demonstrates an alignment implementation for the structure defined in the previous example code. `aligned` means each `data_item_type` will begin on the specified byte boundary. `aligned(4)` means that the structure is aligned to an address that is divisible by 4.

```c
typedef struct {
    uint32_t field1;
    uint32_t field2;
    uint32_t field3;
}__attribute__((aligned(4))) data_item_type;
```

#### Writing to a Message Queue

A data item is added to a message queue by calling `k_msgq_put()`.

The following code builds on the example above, and uses the message queue to pass data items from a producing thread to one or more consuming threads. If the message queue fills up because the consumers can't keep up, the producing thread throws away all existing data so the newer data can be saved.

```c
void producer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* create data item to send (e.g. measurement, timestamp, ...) */
        // (continues on next page)
    }
}
```
Reading from a Message Queue
A data item is taken from a message queue by calling `k_msgq_get()`. The following code builds on the example above, and uses the message queue to process data items generated by one or more producing threads. Note that the return value of `k_msgq_get()` should be tested as `-ENOMEM` can be returned due to `k_msgq_purge()`.

```c
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* get a data item */
        k_msgq_get(&my_msgq, &data, K_FOREVER);

        /* process data item */
        ...
    }
}
```

Peeking into a Message Queue
A data item is read from a message queue by calling `k_msgq_peek()`. The following code peeks into the message queue to read the data item at the head of the queue that is generated by one or more producing threads.

```c
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* read a data item by peeking into the queue */
        k_msgq_peek(&my_msgq, &data);

        /* process data item */
        ...
    }
}
```

Suggested Uses
Use a message queue to transfer small data items between threads in an asynchronous manner.

Note: A message queue can be used to transfer large data items, if desired. However, this can increase interrupt latency as interrupts are locked while a data item is written or read. The time to write or read
A data item increases linearly with its size since the item is copied in its entirety to or from the buffer in memory. For this reason, it is usually preferable to transfer large data items by exchanging a pointer to the data item, rather than the data item itself.

A synchronous transfer can be achieved by using the kernel’s mailbox object type.

**Configuration Options**  Related configuration options:
- None.

**API Reference**

*group msgq_apis*

**Defines**

K_MSGQ_FLAG_ALLOC  
K_MSGQ_DEFINE(q_name, q_msg_size, q_max_msgs, q_align)

Synchronously define and initialize a message queue.

The message queue’s ring buffer contains space for q_max_msgs messages, each of which is q_msg_size bytes long. The buffer is aligned to a q_align-byte boundary, which must be a power of 2. To ensure that each message is similarly aligned to this boundary, q_msg_size must also be a multiple of q_align.

The message queue can be accessed outside the module where it is defined using:

```c
extern struct k_msgq <name>;
```

**Parameters**

- q_name – Name of the message queue.
- q_msg_size – Message size (in bytes).
- q_max_msgs – Maximum number of messages that can be queued.
- q_align – Alignment of the message queue’s ring buffer.

**Functions**

void k_msgq_init(struct k_msgq *msgq, char *buffer, size_t msg_size, uint32_t max_msgs)

Initialize a message queue.

This routine initializes a message queue object, prior to its first use.

The message queue’s ring buffer must contain space for max_msgs messages, each of which is msg_size bytes long. The buffer must be aligned to an N-byte boundary, where N is a power of 2 (i.e., 1, 2, 4, ...). To ensure that each message is similarly aligned to this boundary, q_msg_size must also be a multiple of N.

**Parameters**

- msgq – Address of the message queue.
- buffer – Pointer to ring buffer that holds queued messages.
- **msg_size** – Message size (in bytes).
- **max_msgs** – Maximum number of messages that can be queued.

```c
int k_msgq_alloc_init(struct k_msgq *msgq, size_t msg_size, uint32_t max_msgs)
```

Initialize a message queue.

This routine initializes a message queue object, prior to its first use, allocating its internal ring buffer from the calling thread’s resource pool.

Memory allocated for the ring buffer object can be released by calling `k_msgq_cleanup()`, or if userspace is enabled and the msgq object loses all of its references.

**Parameters**

- **msgq** – Address of the message queue.
- **msg_size** – Message size (in bytes).
- **max_msgs** – Maximum number of messages that can be queued.

**Returns**

0 on success, -ENOMEM if there was insufficient memory in the thread’s resource pool, or -EINVAL if the size parameters cause an integer overflow.

```c
int k_msgq_cleanup(struct k_msgq *msgq)
```

Release allocated buffer for a queue.

Releases memory allocated for the ring buffer.

**Parameters**

- **msgq** – message queue to cleanup

**Return values**

- 0 – on success
- -EBUSY – Queue not empty

```c
int k_msgq_put(struct k_msgq *msgq, const void *data, k_timeout_t timeout)
```

Send a message to a message queue.

This routine sends a message to message queue q.

**Function properties (list may not be complete)**

- `isr-ok`

**Note:** The message content is copied from `data` into `msgq` and the `data` pointer is not retained, so the message content will not be modified by this function.

**Parameters**

- **msgq** – Address of the message queue.
- **data** – Pointer to the message.
- **timeout** – Non-negative waiting period to add the message, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**

- 0 – Message sent.
- -ENOMEM – Returned without waiting or queue purged.
- -EAGAIN – Waiting period timed out.
int k_msgq_get(struct k_msgq *msgq, void *data, k_timeout_t timeout)

Receive a message from a message queue.
This routine receives a message from message queue q in a “first in, first out” manner.

Function properties (list may not be complete)

isr-ok

Note: timeout must be set to K_NO_WAIT if called from ISR.

Parameters
- msgq – Address of the message queue.
- data – Address of area to hold the received message.
- timeout – Waiting period to receive the message, or one of the special values K_NO_WAIT and K_FOREVER.

Return values
- 0 – Message received.
- -ENOMEM – Returned without waiting.
- -EAGAIN – Waiting period timed out.

int k_msgq_peek(struct k_msgq *msgq, void *data)

Peek/read a message from a message queue.
This routine reads a message from message queue q in a “first in, first out” manner and leaves the message in the queue.

Function properties (list may not be complete)

isr-ok

Parameters
- msgq – Address of the message queue.
- data – Address of area to hold the message read from the queue.

Return values
- 0 – Message read.
- -ENOMEM – Returned when the queue has no message.

void k_msgq_purge(struct k_msgq *msgq)

Purge a message queue.
This routine discards all unreceived messages in a message queue's ring buffer. Any threads that are blocked waiting to send a message to the message queue are unblocked and see an -ENOMEM error code.

Parameters
- msgq – Address of the message queue.

```c
uint32_t k_msgq_num_free_get(struct k_msgq *msgq)
Get the amount of free space in a message queue.

This routine returns the number of unused entries in a message queue's ring buffer.

Parameters
• msgq – Address of the message queue.

Returns
Number of unused ring buffer entries.
```

```c
void k_msgq_get_attrs(struct k_msgq *msgq, struct k_msgq_attrs *attrs)
Get basic attributes of a message queue.

This routine fetches basic attributes of message queue into attr argument.

Parameters
• msgq – Address of the message queue.
• attrs – pointer to message queue attribute structure.
```

```c
uint32_t k_msgq_num_used_get(struct k_msgq *msgq)
Get the number of messages in a message queue.

This routine returns the number of messages in a message queue's ring buffer.

Parameters
• msgq – Address of the message queue.

Returns
Number of messages.
```

```c
struct k_msgq
#include <kernel.h> Message Queue Structure.
```

**Public Members**

```c
_wait_q_t wait_q
Message queue wait queue

Mailboxes

A mailbox is a kernel object that provides enhanced message queue capabilities that go beyond the capabilities of a message queue object. A mailbox allows threads to send and receive messages of any size synchronously or asynchronously.

- **Concepts**
  - Message Format
  - Message Lifecycle
  - Thread Compatibility
  - Message Flow Control

- **Implementation**
  - Defining a Mailbox
  - Message Descriptors
  - Sending a Message
  - Receiving a Message

- **Suggested Uses**
- **Configuration Options**
Concepts  Any number of mailboxes can be defined (limited only by available RAM). Each mailbox is referenced by its memory address.

A mailbox has the following key properties:

- A **send queue** of messages that have been sent but not yet received.
- A **receive queue** of threads that are waiting to receive a message.

A mailbox must be initialized before it can be used. This sets both of its queues to empty.

A mailbox allows threads, but not ISRs, to exchange messages. A thread that sends a message is known as the **sending thread**, while a thread that receives the message is known as the **receiving thread**. Each message may be received by only one thread (i.e. point-to-multipoint and broadcast messaging is not supported).

Messages exchanged using a mailbox are handled non-anonymously, allowing both threads participating in an exchange to know (and even specify) the identity of the other thread.

**Message Format**  A **message descriptor** is a data structure that specifies where a message's data is located, and how the message is to be handled by the mailbox. Both the sending thread and the receiving thread supply a message descriptor when accessing a mailbox. The mailbox uses the message descriptors to perform a message exchange between compatible sending and receiving threads. The mailbox also updates certain message descriptor fields during the exchange, allowing both threads to know what has occurred.

A mailbox message contains zero or more bytes of **message data**. The size and format of the message data is application-defined, and can vary from one message to the next.

A **message buffer** is an area of memory provided by the thread that sends or receives the message data. An array or structure variable can often be used for this purpose.

A message that has neither form of message data is called an **empty message**.

**Note:**  A message whose message buffer exists, but contains zero bytes of actual data, is *not* an empty message.

**Message Lifecycle**  The life cycle of a message is straightforward. A message is created when it is given to a mailbox by the sending thread. The message is then owned by the mailbox until it is given to a receiving thread. The receiving thread may retrieve the message data when it receives the message from the mailbox, or it may perform data retrieval during a second, subsequent mailbox operation. Only when data retrieval has occurred is the message deleted by the mailbox.

**Thread Compatibility**  A sending thread can specify the address of the thread to which the message is sent, or send it to any thread by specifying `K_ANY`. Likewise, a receiving thread can specify the address of the thread from which it wishes to receive a message, or it can receive a message from any thread by specifying `K_ANY`. A message is exchanged only when the requirements of both the sending thread and receiving thread are satisfied; such threads are said to be **compatible**.

For example, if thread A sends a message to thread B (and only thread B) it will be received by thread B if thread B tries to receive a message from thread A or if thread B tries to receive from any thread. The exchange will not occur if thread B tries to receive a message from thread C. The message can never be received by thread C, even if it tries to receive a message from thread A (or from any thread).
Message Flow Control Mailbox messages can be exchanged synchronously or asynchronously. In a synchronous exchange, the sending thread blocks until the message has been fully processed by the receiving thread. In an asynchronous exchange, the sending thread does not wait until the message has been received by another thread before continuing; this allows the sending thread to do other work (such as gather data that will be used in the next message) before the message is given to a receiving thread and fully processed. The technique used for a given message exchange is determined by the sending thread.

The synchronous exchange technique provides an implicit form of flow control, preventing a sending thread from generating messages faster than they can be consumed by receiving threads. The asynchronous exchange technique provides an explicit form of flow control, which allows a sending thread to determine if a previously sent message still exists before sending a subsequent message.

Implementation

Defining a Mailbox A mailbox is defined using a variable of type \texttt{k_mbox}. It must then be initialized by calling \texttt{k_mbox_init()}. The following code defines and initializes an empty mailbox.

```c
struct k_mbox my_mailbox;
k_mbox_init(&my_mailbox);
```

Alternatively, a mailbox can be defined and initialized at compile time by calling \texttt{K_MBOX_DEFINE}. The following code has the same effect as the code segment above.

```c
K_MBOX_DEFINE(my_mailbox);
```

Message Descriptors A message descriptor is a structure of type \texttt{k_mbox_msg}. Only the fields listed below should be used; any other fields are for internal mailbox use only.

\textbf{info} A 32-bit value that is exchanged by the message sender and receiver, and whose meaning is defined by the application. This exchange is bi-directional, allowing the sender to pass a value to the receiver during any message exchange, and allowing the receiver to pass a value to the sender during a synchronous message exchange.

\textbf{size} The message data size, in bytes. Set it to zero when sending an empty message, or when sending a message buffer with no actual data. When receiving a message, set it to the maximum amount of data desired, or to zero if the message data is not wanted. The mailbox updates this field with the actual number of data bytes exchanged once the message is received.

\textbf{tx_data} A pointer to the sending thread's message buffer. Set it to \texttt{NULL} when sending an empty message. Leave this field uninitialized when receiving a message.

\textbf{tx_target_thread} The address of the desired receiving thread. Set it to \texttt{K_ANY} to allow any thread to receive the message. Leave this field uninitialized when receiving a message. The mailbox updates this field with the actual receiver's address once the message is received.

\textbf{rx_source_thread} The address of the desired sending thread. Set it to \texttt{K_ANY} to receive a message sent by any thread. Leave this field uninitialized when sending a message. The mailbox updates this field with the actual sender's address when the message is put into the mailbox.
Sending a Message  A thread sends a message by first creating its message data, if any. Next, the sending thread creates a message descriptor that characterizes the message to be sent, as described in the previous section. Finally, the sending thread calls a mailbox send API to initiate the message exchange. The message is immediately given to a compatible receiving thread, if one is currently waiting. Otherwise, the message is added to the mailbox's send queue. Any number of messages may exist simultaneously on a send queue. The messages in the send queue are sorted according to the priority of the sending thread. Messages of equal priority are sorted so that the oldest message can be received first. For a synchronous send operation, the operation normally completes when a receiving thread has both received the message and retrieved the message data. If the message is not received before the waiting period specified by the sending thread is reached, the message is removed from the mailbox's send queue and the send operation fails. When a send operation completes successfully the sending thread can examine the message descriptor to determine which thread received the message, how much data was exchanged, and the application-defined info value supplied by the receiving thread.

Note: A synchronous send operation may block the sending thread indefinitely, even when the thread specifies a maximum waiting period. The waiting period only limits how long the mailbox waits before the message is received by another thread. Once a message is received there is no limit to the time the receiving thread may take to retrieve the message data and unblock the sending thread.

For an asynchronous send operation, the operation always completes immediately. This allows the sending thread to continue processing regardless of whether the message is given to a receiving thread immediately or added to the send queue. The sending thread may optionally specify a semaphore that the mailbox gives when the message is deleted by the mailbox, for example, when the message has been received and its data retrieved by a receiving thread. The use of a semaphore allows the sending thread to easily implement a flow control mechanism that ensures that the mailbox holds no more than an application-specified number of messages from a sending thread (or set of sending threads) at any point in time.

Note: A thread that sends a message asynchronously has no way to determine which thread received the message, how much data was exchanged, or the application-defined info value supplied by the receiving thread.

Sending an Empty Message  This code uses a mailbox to synchronously pass 4 byte random values to any consuming thread that wants one. The message “info” field is large enough to carry the information being exchanged, so the data portion of the message isn’t used.

```c
void producer_thread(void)
{
    struct k_mbox_msg send_msg;

    while (1) {
        /* generate random value to send */
        uint32_t random_value = sys_rand32_get();

        /* prepare to send empty message */
        send_msg.info = random_value;
        send_msg.size = 0;
        send_msg.tx_data = NULL;
        send_msg.tx_block.data = NULL;
    }
}
```
Sending Data Using a Message Buffer  This code uses a mailbox to synchronously pass variable-sized requests from a producing thread to any consuming thread that wants it. The message “info” field is used to exchange information about the maximum size message buffer that each thread can handle.

```c
void producer_thread(void)
{
    char buffer[100];
    int buffer_bytes_used;

    struct k_mbox_msg send_msg;

    while (1) {
        /* generate data to send */
        ...
        buffer_bytes_used = ... ;
        memcpy(buffer, source, buffer_bytes_used);

        /* prepare to send message */
        send_msg.info = buffer_bytes_used;
        send_msg.size = buffer_bytes_used;
        send_msg.tx_data = buffer;
        send_msg.tx_block.data = NULL;
        send_msg.tx_target_thread = K_ANY;

        /* send message and wait until a consumer receives it */
        k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);

        /* info, size, and tx_target_thread fields have been updated */

        /* verify that message data was fully received */
        if (send_msg.size < buffer_bytes_used) {
            printf("some message data dropped during transfer!");
            printf("receiver only had room for %d bytes", send_msg.info);
        }
    }
}
```

Receiving a Message  A thread receives a message by first creating a message descriptor that characterizes the message it wants to receive. It then calls one of the mailbox receive APIs. The mailbox searches its send queue and takes the message from the first compatible thread it finds. If no compatible thread exists, the receiving thread may choose to wait for one. If no compatible thread appears before the waiting period specified by the receiving thread is reached, the receive operation fails. Once a receive operation completes successfully the receiving thread can examine the message descriptor to determine which thread sent the message, how much data was exchanged, and the application-defined info value supplied by the sending thread.

Any number of receiving threads may wait simultaneously on a mailboxes' receive queue. The threads
are sorted according to their priority; threads of equal priority are sorted so that the one that started
waiting first can receive a message first.

**Note:** Receiving threads do not always receive messages in a first in, first out (FIFO) order, due to the
thread compatibility constraints specified by the message descriptors. For example, if thread A waits to
receive a message only from thread X and then thread B waits to receive a message from thread Y, an
incoming message from thread Y to any thread will be given to thread B and thread A will continue to
wait.

The receiving thread controls both the quantity of data it retrieves from an incoming message and where
the data ends up. The thread may choose to take all of the data in the message, to take only the initial
part of the data, or to take no data at all. Similarly, the thread may choose to have the data copied into
a message buffer of its choice.

The following sections outline various approaches a receiving thread may use when retrieving message
data.

**Retrieving Data at Receive Time** The most straightforward way for a thread to retrieve message data
is to specify a message buffer when the message is received. The thread indicates both the location of
the message buffer (which must not be NULL) and its size.

The mailbox copies the message's data to the message buffer as part of the receive operation. If the
message buffer is not big enough to contain all of the message's data, any uncopied data is lost. If the
message is not big enough to fill all of the buffer with data, the unused portion of the message buffer
is left unchanged. In all cases the mailbox updates the receiving thread's message descriptor to indicate
how many data bytes were copied (if any).

The immediate data retrieval technique is best suited for small messages where the maximum size of a
message is known in advance.

The following code uses a mailbox to process variable-sized requests from any producing thread, using
the immediate data retrieval technique. The message "info" field is used to exchange information about
the maximum size message buffer that each thread can handle.

```c
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[100];
    int i;
    int total;

    while (1) {
        /* prepare to receive message */
        recv_msg.info = 100;
        recv_msg.size = 100;
        recv_msg.rx_source_thread = K_ANY;

        /* get a data item, waiting as long as needed */
        k_mbox_get(&my_mailbox, &recv_msg, buffer, K_FOREVER);

        /* info, size, and rx_source_thread fields have been updated */

        /* verify that message data was fully received */
        if (recv_msg.info != recv_msg.size) {
            printf("some message data dropped during transfer!");
            printf("sender tried to send %d bytes", recv_msg.info);
        }
    }
}
```

(continues on next page)
compute sum of all message bytes (from 0 to 100 of them) */
    total = 0;
    for (i = 0; i < recv_msg.size; i++) {
        total += buffer[i];
    }
}

Retrieving Data Later Using a Message Buffer

A receiving thread may choose to defer message data retrieval at the time the message is received, so that it can retrieve the data into a message buffer at a later time. The thread does this by specifying a message buffer location of NULL and a size indicating the maximum amount of data it is willing to retrieve later.

The mailbox does not copy any message data as part of the receive operation. However, the mailbox still updates the receiving thread’s message descriptor to indicate how many data bytes are available for retrieval.

The receiving thread must then respond as follows:

- If the message descriptor size is zero, then either the sender's message contained no data or the receiving thread did not want to receive any data. The receiving thread does not need to take any further action, since the mailbox has already completed data retrieval and deleted the message.
- If the message descriptor size is non-zero and the receiving thread still wants to retrieve the data, the thread must call k_mbox_data_get() and supply a message buffer large enough to hold the data. The mailbox copies the data into the message buffer and deletes the message.
- If the message descriptor size is non-zero and the receiving thread does not want to retrieve the data, the thread must call k_mbox_data_get() and specify a message buffer of NULL. The mailbox deletes the message without copying the data.

The subsequent data retrieval technique is suitable for applications where immediate retrieval of message data is undesirable. For example, it can be used when memory limitations make it impractical for the receiving thread to always supply a message buffer capable of holding the largest possible incoming message.

The following code uses a mailbox’s deferred data retrieval mechanism to get message data from a producing thread only if the message meets certain criteria, thereby eliminating unneeded data copying. The message “info” field supplied by the sender is used to classify the message.

```c
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[10000];

    while (1) {
        /* prepare to receive message */
        recv_msg.size = 10000;
        recv_msg.rx_source_thread = K_ANY;

        /* get message, but not its data */
        k_mbox_get(&my_mailbox, &recv_msg, NULL, K_FOREVER);

        /* get message data for only certain types of messages */
        if (is_message_type_ok(recv_msg.info)) {
            /* retrieve message data and delete the message */
            k_mbox_data_get(&recv_msg, buffer);
```

(continues on next page)
Suggested Uses  Use a mailbox to transfer data items between threads whenever the capabilities of a message queue are insufficient.

Configuration Options  Related configuration options:

• CONFIG_NUM_MBOX_ASYNC_MSGS

API Reference

group mailbox_apis

Defines

K_MBOX_DEFINE(name)

Statically define and initialize a mailbox.

The mailbox is to be accessed outside the module where it is defined using:

extern struct k_mbox <name>;

Parameters

• name – Name of the mailbox.

Functions

void k_mbox_init(struct k mbox *mbox)

Initialize a mailbox.

This routine initializes a mailbox object, prior to its first use.

Parameters

• mbox – Address of the mailbox.

int k_mbox_put(struct k mbox *mbox, struct k mbox_msg *tx_msg, k_timeout_t timeout)

Send a mailbox message in a synchronous manner.

This routine sends a message to mbox and waits for a receiver to both receive and process it.

The message data may be in a buffer, in a memory pool block, or non-existent (i.e. an empty message).

Parameters

• mbox – Address of the mailbox.
• tx_msg – Address of the transmit message descriptor.

• timeout – Waiting period for the message to be received, or one of the special values K_NO_WAIT and K_FOREVER. Once the message has been received, this routine waits as long as necessary for the message to be completely processed.

Return values

• 0 – Message sent.

• -ENOMSG – Returned without waiting.

• -EAGAIN – Waiting period timed out.

void k_mbox_async_put (struct k_mbox *mbox, struct k_mbox_msg *tx_msg, struct k_sem *sem)

Send a mailbox message in an asynchronous manner.

This routine sends a message to mbox without waiting for a receiver to process it. The message data may be in a buffer, in a memory pool block, or non-existent (i.e. an empty message). Optionally, the semaphore sem will be given when the message has been both received and completely processed by the receiver.

Parameters

• mbox – Address of the mailbox.

• tx_msg – Address of the transmit message descriptor.

• sem – Address of a semaphore, or NULL if none is needed.

int k_mbox_get (struct k_mbox *mbox, struct k_mbox_msg *rx_msg, void *buffer, k_timeout_t timeout)

Receive a mailbox message.

This routine receives a message from mbox, then optionally retrieves its data and disposes of the message.

Parameters

• mbox – Address of the mailbox.

• rx_msg – Address of the receive message descriptor.

• buffer – Address of the buffer to receive data, or NULL to defer data retrieval and message disposal until later.

• timeout – Waiting period for a message to be received, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

• 0 – Message received.

• -ENOMSG – Returned without waiting.

• -EAGAIN – Waiting period timed out.

void k_mbox_data_get (struct k_mbox_msg *rx_msg, void *buffer)

Retrieve mailbox message data into a buffer.

This routine completes the processing of a received message by retrieving its data into a buffer, then disposing of the message.

Alternatively, this routine can be used to dispose of a received message without retrieving its data.

Parameters

• rx_msg – Address of the receive message descriptor.

• buffer – Address of the buffer to receive data, or NULL to discard the data.
struct k_mbox_msg
    
    include <kernel.h> Mailbox Message Structure.

    Receive message queue

Pipes

A pipe is a kernel object that allows a thread to send a byte stream to another thread. Pipes can be used to synchronously transfer chunks of data in whole or in part.

- Concepts
- Implementation
  - Writing to a Pipe
  - Reading from a Pipe
  - Flushing a Pipe's Buffer
  - Flushing a Pipe
The pipe can be configured with a ring buffer which holds data that has been sent but not yet received; alternatively, the pipe may have no ring buffer.

Any number of pipes can be defined (limited only by available RAM). Each pipe is referenced by its memory address.

A pipe has the following key property:

- A size that indicates the size of the pipe's ring buffer. Note that a size of zero defines a pipe with no ring buffer.

A pipe must be initialized before it can be used. The pipe is initially empty.

Data is synchronously sent either in whole or in part to a pipe by a thread. If the specified minimum number of bytes can not be immediately satisfied, then the operation will either fail immediately or attempt to send as many bytes as possible and then pend in the hope that the send can be completed later. Accepted data is either copied to the pipe's ring buffer or directly to the waiting reader(s).

Data is synchronously received from a pipe by a thread. If the specified minimum number of bytes can not be immediately satisfied, then the operation will either fail immediately or attempt to receive as many bytes as possible and then pend in the hope that the receive can be completed later. Accepted data is either copied from the pipe's ring buffer or directly from the waiting sender(s).

Data may also be flushed from a pipe by a thread. Flushing can be performed either on the entire pipe or on only its ring buffer. Flushing the entire pipe is equivalent to reading all the information in the ring buffer and waiting to be written into a giant temporary buffer which is then discarded. Flushing the ring buffer is equivalent to reading only the data in the ring buffer into a temporary buffer which is then discarded. Flushing the ring buffer does not guarantee that the ring buffer will stay empty; flushing it may allow a pended writer to fill the ring buffer.

**Note:** Flushing does not in practice allocate or use additional buffers.

**Note:** The kernel does allow for an ISR to flush a pipe from an ISR. It also allows it to send/receive data to/from one provided it does not attempt to wait for space/data.

### Implementation

A pipe is defined using a variable of type `k_pipe` and an optional character buffer of type `unsigned char`. It must then be initialized by calling `k_pipe_init()`.

The following code defines and initializes an empty pipe that has a ring buffer capable of holding 100 bytes and is aligned to a 4-byte boundary.

```c
unsigned char __aligned(4) my_ring_buffer[100];
struct k_pipe my_pipe;

k_pipe_init(&my_pipe, my_ring_buffer, sizeof(my_ring_buffer));
```

Alternatively, a pipe can be defined and initialized at compile time by calling `K_PIPE_DEFINE`.

The following code has the same effect as the code segment above. Observe that that macro defines both the pipe and its ring buffer.
K_PIPE_DEFINE(my_pipe, 100, 4);

**Writing to a Pipe**  Data is added to a pipe by calling `k.pipe_put()`.
The following code builds on the example above, and uses the pipe to pass data from a producing thread
to one or more consuming threads. If the pipe's ring buffer fills up because the consumers can't keep up,
the producing thread waits for a specified amount of time.

```c
struct message_header {
  ...
};

void producer_thread(void)
{
  unsigned char *data;
  size_t total_size;
  size_t bytes_written;
  int    rc;
  ...

  while (1) {
    /* Craft message to send in the pipe */
    data = ...;
    total_size = ...;

    /* send data to the consumers */
    rc = k.pipe_put(&my_pipe, data, total_size, &bytes_written,
                    sizeof(struct message_header), K_NO_WAIT);

    if (rc < 0) {
      /* Incomplete message header sent */
      ...
    } else if (bytes_written < total_size) {
      /* Some of the data was sent */
      ...
    } else {
      /* All data sent */
      ...
    }
  }
}
```

**Reading from a Pipe**  Data is read from the pipe by calling `k.pipe_get()`.
The following code builds on the example above, and uses the pipe to process data items generated by
one or more producing threads.

```c
void consumer_thread(void)
{
  unsigned char buffer[120];
  size_t  bytes_read;
  struct message_header *header = (struct message_header *)buffer;

  while (1) {
    rc = k.pipe_get(&my_pipe, buffer, sizeof(buffer), &bytes_read,
                    sizeof(header), K_MSEC(100));

    (continues on next page)
```
if ((rc < 0) || (bytes_read < sizeof (header))) {
    /* Incomplete message header received */
    ...
} else if (header->num_data_bytes + sizeof(header) > bytes_read) {
    /* Only some data was received */
    ...
} else {
    /* All data was received */
    ...
}
}

Use a pipe to send streams of data between threads.

**Note:** A pipe can be used to transfer long streams of data if desired. However it is often preferable to send pointers to large data items to avoid copying the data.

### Flushing a Pipe’s Buffer
Data is flushed from the pipe’s ring buffer by calling `k_pipe_buffer_flush()`.

The following code builds on the examples above, and flushes the pipe’s buffer.

```c
void monitor_thread(void)
{
    while (1) {
        /* Pipe buffer contains stale data. Flush it. */
        k_pipe_buffer_flush(&my_pipe);
        ...
    }
}
```

### Flushing a Pipe
All data in the pipe is flushed by calling `k_pipe_flush()`.

The following code builds on the examples above, and flushes all the data in the pipe.

```c
void monitor_thread(void)
{
    while (1) {
        /* Critical error detected. Flush the entire pipe to reset it. */
        k_pipe_flush(&my_pipe);
        ...
    }
}
```

**Suggested uses** Use a pipe to send streams of data between threads.

**Note:** A pipe can be used to transfer long streams of data if desired. However it is often preferable to send pointers to large data items to avoid copying the data. Copying large data items will negatively
impact interrupt latency as a spinlock is held while copying that data.

**Configuration Options**  Related configuration options:

- CONFIG_PIPES

**API Reference**

**group** pipe_apis

**Defines**

```c
K_PIPE_DEFINE(name, pipe_buffer_size, pipe_align)
```

Statically define and initialize a pipe.

The pipe can be accessed outside the module where it is defined using:

```c
extern struct k_pipe <name>;
```

**Parameters**

- **name** – Name of the pipe.
- **pipe_buffer_size** – Size of the pipe's ring buffer (in bytes), or zero if no ring buffer is used.
- **pipe_align** – Alignment of the pipe's ring buffer (power of 2).

**Functions**

```c
void k_pipe_init(struct k_pipe *pipe, unsigned char *buffer, size_t size)
```

Initialize a pipe.

This routine initializes a pipe object, prior to its first use.

**Parameters**

- **pipe** – Address of the pipe.
- **buffer** – Address of the pipe's ring buffer, or NULL if no ring buffer is used.
- **size** – Size of the pipe's ring buffer (in bytes), or zero if no ring buffer is used.

```c
int k_pipe_cleanup(struct k_pipe *pipe)
```

Release a pipe's allocated buffer.

If a pipe object was given a dynamically allocated buffer via `k_pipe_alloc_init()`, this will free it. This function does nothing if the buffer wasn't dynamically allocated.

**Parameters**

- **pipe** – Address of the pipe.

**Return values**

- **0** – on success
- **-EAGAIN** – nothing to cleanup
int k_pipe_alloc_init(struct k_pipe *pipe, size_t size)
  Initialize a pipe and allocate a buffer for it.

  Storage for the buffer region will be allocated from the calling thread’s resource pool. This
  memory will be released if k_pipe_cleanup() is called, or userspace is enabled and the pipe
  object loses all references to it.

  This function should only be called on uninitialized pipe objects.

  Parameters
  • pipe – Address of the pipe.
  • size – Size of the pipe’s ring buffer (in bytes), or zero if no ring buffer is used.

  Return values
  • 0 – on success
  • -ENOMEM – if memory couldn’t be allocated

int k_pipe_put(struct k_pipe *pipe, void *data, size_t bytes_to_write, size_t *bytes_written,
                 size_t min_xfer, k_timeout_t timeout)

  Write data to a pipe.

  This routine writes up to bytes_to_write bytes of data to pipe.

  Parameters
  • pipe – Address of the pipe.
  • data – Address of data to write.
  • bytes_to_write – Size of data (in bytes).
  • bytes_written – Address of area to hold the number of bytes written.
  • min_xfer – Minimum number of bytes to write.
  • timeout – Waiting period to wait for the data to be written, or one of the
    special values K_NO_WAIT and K_FOREVER.

  Return values
  • 0 – At least min_xfer bytes of data were written.
  • -EIO – Returned without waiting; zero data bytes were written.
  • -EAGAIN – Waiting period timed out; between zero and min_xfer minus one
    data bytes were written.

int k_pipe_get(struct k_pipe *pipe, void *data, size_t bytes_to_read, size_t *bytes_read, size_t
                 min_xfer, k_timeout_t timeout)

  Read data from a pipe.

  This routine reads up to bytes_to_read bytes of data from pipe.

  Parameters
  • pipe – Address of the pipe.
  • data – Address to place the data read from pipe.
  • bytes_to_read – Maximum number of data bytes to read.
  • bytes_read – Address of area to hold the number of bytes read.
  • min_xfer – Minimum number of data bytes to read.
  • timeout – Waiting period to wait for the data to be read, or one of the special
    values K_NO_WAIT and K_FOREVER.

  Return values
• 0 – At least \( \min_xfer \) bytes of data were read.
• -EINVAL – invalid parameters supplied
• -EIO – Returned without waiting; zero data bytes were read.
• -EAGAIN – Waiting period timed out; between zero and \( \min_xfer \) minus one data bytes were read.

\texttt{size_t k\_pipe\_read\_avail(\texttt{struct k\_pipe *pipe})}

Query the number of bytes that may be read from \texttt{pipe}.

**Parameters**

• \texttt{pipe} – Address of the pipe.

**Return values**

\( a \) – number \( n \) such that \( 0 \leq n \leq \texttt{k\_pipe\_size} \); the result is zero for unbuffered pipes.

\texttt{size_t k\_pipe\_write\_avail(\texttt{struct k\_pipe *pipe})}

Query the number of bytes that may be written to \texttt{pipe}.

**Parameters**

• \texttt{pipe} – Address of the pipe.

**Return values**

\( a \) – number \( n \) such that \( 0 \leq n \leq \texttt{k\_pipe\_size} \); the result is zero for unbuffered pipes.

\texttt{void k\_pipe\_flush(\texttt{struct k\_pipe *pipe})}

Flush the pipe of write data.

This routine flushes the pipe. flushing the pipe is equivalent to reading both all the data in the pipe's buffer and all the data waiting to go into that pipe into a large temporary buffer and discarding the buffer. Any writers that were previously pended become unpended.

**Parameters**

• \texttt{pipe} – Address of the pipe.

\texttt{void k\_pipe\_buffer\_flush(\texttt{struct k\_pipe *pipe})}

Flush the pipe's internal buffer.

This routine flushes the pipe's internal buffer. This is equivalent to reading up to \( N \) bytes from the pipe (where \( N \) is the size of the pipe's buffer) into a temporary buffer and then discarding that buffer. If there were writers previously pending, then some may unpend as they try to fill up the pipe's emptied buffer.

**Parameters**

• \texttt{pipe} – Address of the pipe.

\texttt{struct k\_pipe}

\#include <kernel.h> Pipe Structure

**Public Members**

\texttt{unsigned char *buffer}

Pipe buffer: may be NULL

3.1.4 Timing

These pages cover timing related services.

Kernel Timing

Zephyr provides a robust and scalable timing framework to enable reporting and tracking of timed events from hardware timing sources of arbitrary precision.
Time Units  Kernel time is tracked in several units which are used for different purposes.

Real time values, typically specified in milliseconds or microseconds, are the default presentation of time to application code. They have the advantages of being universally portable and pervasively understood, though they may not match the precision of the underlying hardware perfectly.

The kernel presents a “cycle” count via the `k_cycle_get_32()` and `k_cycle_get_64()` APIs. The intent is that this counter represents the fastest cycle counter that the operating system is able to present to the user (for example, a CPU cycle counter) and that the read operation is very fast. The expectation is that very sensitive application code might use this in a polling manner to achieve maximal precision. The frequency of this counter is required to be steady over time, and is available from `sys_clock_hw_cycles_per_sec()` (which on almost all platforms is a runtime constant that evaluates to `CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC`).

For asynchronous timekeeping, the kernel defines a “ticks” concept. A “tick” is the internal count in which the kernel does all its internal uptime and timeout bookkeeping. Interrupts are expected to be delivered on tick boundaries to the extent practical, and no fractional ticks are tracked. The choice of tick rate is configurable via `CONFIG_SYS_CLOCK_TICKS_PER_SEC`. Defaults on most hardware platforms (ones that support setting arbitrary interrupt timeouts) are expected to be in the range of 10 kHz, with software emulation platforms and legacy drivers using a more traditional 100 Hz value.

Conversion  Zephyr provides an extensively enumerated conversion library with rounding control for all time units. Any unit of “ms” (milliseconds), “us” (microseconds), “tick”, or “cyc” can be converted to any other. Control of rounding is provided, and each conversion is available in “floor” (round down to nearest output unit), “ceil” (round up) and “near” (round to nearest). Finally the output precision can be specified as either 32 or 64 bits.

For example: `k_ms_to_ticksceil32()` will convert a millisecond input value to the next higher number of ticks, returning a result truncated to 32 bits of precision; and `k_cyc_to_usfloor64()` will convert a measured cycle count to an elapsed number of microseconds in a full 64 bits of precision. See the reference documentation for the full enumeration of conversion routines.

On most platforms, where the various counter rates are integral multiples of each other and where the output fits within a single word, these conversions expand to a 2-4 operation sequence, requiring full precision only where actually required and requested.

Uptime  The kernel tracks a system uptime count on behalf of the application. This is available at all times via `k_uptime_get()`, which provides an uptime value in milliseconds since system boot. This is expected to be the utility used by most portable application code.

The internal tracking, however, is as a 64 bit integer count of ticks. Apps with precise timing requirements (that are willing to do their own conversions to portable real time units) may access this with `k_uptime_ticks()`.

Timeouts  The Zephyr kernel provides many APIs with a “timeout” parameter. Conceptually, this indicates the time at which an event will occur. For example:

- Kernel blocking operations like `k_sem_take()` or `k_queue_get()` may provide a timeout after which the routine will return with an error code if no data is available.
- Kernel `k_timer` objects must specify delays for their duration and period.
- The kernel `k_work_delayable` API provides a timeout parameter indicating when a work queue item will be added to the system queue.

All these values are specified using a `k_timeout_t` value. This is an opaque struct type that must be initialized using one of a family of kernel timeout macros. The most common, `K_MSEC`, defines a time in milliseconds after the current time (strictly: the time at which the kernel receives the timeout value).
Other options for timeout initialization follow the unit conventions described above: \( K_{\text{NSEC}}() \), \( K_{\text{USEC}} \), \( K_{\text{TICKS}} \) and \( K_{\text{CYC}}() \) specify timeout values that will expire after specified numbers of nanoseconds, microseconds, ticks and cycles, respectively.

Precision of \( k_{\text{timeout}} \) values is configurable, with the default being 32 bits. Large uptime counts in non-tick units will experience complicated rollover semantics, so it is expected that timing-sensitive applications with long uptimes will be configured to use a 64 bit timeout type.

Finally, it is possible to specify timeouts as absolute times since system boot. A timeout initialized with \( K_{\text{TIMEOUT\_ABS\_MS}} \) indicates a timeout that will expire after the system uptime reaches the specified value. There are likewise nanosecond, microsecond, cycles and ticks variants of this API.

### Timing Internals

#### Timeout Queue

All Zephyr \( k_{\text{timeout}} \) events specified using the API above are managed in a single, global queue of events. Each event is stored in a double-linked list, with an attendant delta count in ticks from the previous event. The action to take on an event is specified as a callback function pointer provided by the subsystem requesting the event, along with a \_timeout tracking struct that is expected to be embedded within subsystem-defined data structures (for example: a wait_q struct, or a k_tid_t thread struct).

Note that all variant units passed via a \( k_{\text{timeout}} \) are converted to ticks once on insertion into the list. There no multiple-conversion steps internal to the kernel, so precision is guaranteed at the tick level no matter how many events exist or how long a timeout might be.

Note that the list structure means that the CPU work involved in managing large numbers of timeouts is quadratic in the number of active timeouts. The API design of the timeout queue was intended to permit a more scalable backend data structure, but no such implementation exists currently.

#### Timer Drivers

Kernel timing at the tick level is driven by a timer driver with a comparatively simple API.

- The driver is expected to be able to “announce” new ticks to the kernel via the \texttt{sys\_clock\_announce()} call, which passes an integer number of ticks that have elapsed since the last announce call (or system boot). These calls can occur at any time, but the driver is expected to attempt to ensure (to the extent practical given interrupt latency interactions) that they occur near tick boundaries (i.e. not “halfway through” a tick), and most importantly that they be correct over time and subject to minimal skew vs. other counters and real world time.

- The driver is expected to provide a \texttt{sys\_clock\_set\_timeout()} call to the kernel which indicates how many ticks may elapse before the kernel must receive an announce call to trigger registered timeouts. It is legal to announce new ticks before that moment (though they must be correct) but delay after that will cause events to be missed. Note that the timeout value passed here is in a delta from current time, but that does not absolve the driver of the requirement to provide ticks at a steady rate over time. Naive implementations of this function are subject to bugs where the fractional tick gets “reset” incorrectly and causes clock skew.

- The driver is expected to provide a \texttt{sys\_clock\_elapsed()} call which provides a current indication of how many ticks have elapsed (as compared to a real world clock) since the last call to \texttt{sys\_clock\_announce()}, which the kernel needs to test newly arriving timeouts for expiration.

Note that a natural implementation of this API results in a “tickless” kernel, which receives and processes timer interrupts only for registered events, relying on programmable hardware counters to provide irregular interrupts. But a traditional, “ticked” or “dumb” counter driver can be trivially implemented also:

- The driver can receive interrupts at a regular rate corresponding to the OS tick rate, calling \texttt{sys\_clock\_announce()} with an argument of one each time.

- The driver can ignore calls to \texttt{sys\_clock\_set\_timeout()}, as every tick will be announced regardless of timeout status.
• The driver can return zero for every call to `sys_clock_elapsed()` as no more than one tick can be detected as having elapsed (because otherwise an interrupt would have been received).

SMP Details In general, the timer API described above does not change when run in a multiprocessor context. The kernel will internally synchronize all access appropriately, and ensure that all critical sections are small and minimal. But some notes are important to detail:

• Zephyr is agnostic about which CPU services timer interrupts. It is not illegal (though probably undesirable in some circumstances) to have every timer interrupt handled on a single processor. Existing SMP architectures implement symmetric timer drivers.

• The `sys_clock_announce()` call is expected to be globally synchronized at the driver level. The kernel does not do any per-CPU tracking, and expects that if two timer interrupts fire near simultaneously, that only one will provide the current tick count to the timing subsystem. The other may legally provide a tick count of zero if no ticks have elapsed. It should not “skip” the announce call because of timeslicing requirements (see below).

• Some SMP hardware uses a single, global timer device, others use a per-CPU counter. The complexity here (for example: ensuring counter synchronization between CPUs) is expected to be managed by the driver, not the kernel.

• The next timeout value passed back to the driver via `sys_clock_set_timeout()` is done identically for every CPU. So by default, every CPU will see simultaneous timer interrupts for every event, even though by definition only one of them should see a non-zero ticks argument to `sys_clock_announce()`. This is probably a correct default for timing sensitive applications (because it minimizes the chance that an errant ISR or interrupt lock will delay a timeout), but may be a performance problem in some cases. The current design expects that any such optimization is the responsibility of the timer driver.

Time Slicing An auxiliary job of the timing subsystem is to provide tick counters to the scheduler that allow implementation of time slicing of threads. A thread time-slice cannot be a timeout value, as it does not reflect a global expiration but instead a per-CPU value that needs to be tracked independently on each CPU in an SMP context.

Because there may be no other hardware available to drive timeslicing, Zephyr multiplexes the existing timer driver. This means that the value passed to `sys_clock_set_timeout()` may be clamped to a smaller value than the current next timeout when a time sliced thread is currently scheduled.

Subsystems that keep millisecond APIs In general, code like this will port just like applications code will. Millisecond values from the user may be treated any way the subsystem likes, and then converted into kernel timeouts using `K_MSEC()` at the point where they are presented to the kernel.

Obviously this comes at the cost of not being able to use new features, like the higher precision timeout constructors or absolute timeouts. But for many subsystems with simple needs, this may be acceptable.

One complexity is `K_FOREVER`. Subsystems that might have been able to accept this value to their millisecond API in the past no longer can, because it is no longer an integral type. Such code will need to use a different, integer-valued token to represent “forever”. `K_NO_WAIT` has the same typesafety concern too, of course, but as it is (and has always been) simply a numerical zero, it has a natural porting path.

Subsystems using `k_timeout_t` Ideally, code that takes a “timeout” parameter specifying a time to wait should be using the kernel native abstraction where possible. But `k_timeout_t` is opaque, and needs to be converted before it can be inspected by an application.

Some conversions are simple. Code that needs to test for `K_FOREVER` can simply use the `K_TIMEOUT_EQ()` macro to test the opaque struct for equality and take special action.

The more complicated case is when the subsystem needs to take a timeout and loop, waiting for it to finish while doing some processing that may require multiple blocking operations on underlying kernel code. For example, consider this design:
```c
void my_wait_for_event(struct my_subsys *obj, int32_t timeout_in_ms)
{
    while (true) {
        uint32_t start = k_uptime_get_32();

        if (is_event_complete(obj)) {
            return;
        }

        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout_in_ms);

        /* Subtract elapsed time */
        timeout_in_ms -= (k_uptime_get_32() - start);
    }
}
```

This code requires that the timeout value be inspected, which is no longer possible. For situations like this, the new API provides an internal `sys_clock_timeout_end_calc()` routine that converts an arbitrary timeout to the uptime value in ticks at which it will expire. So such a loop might look like:

```c
void my_wait_for_event(struct my_subsys *obj, k_timeout_t timeout_in_ms)
{
    /* Compute the end time from the timeout */
    uint64_t end = sys_clock_timeout_end_calc(timeout_in_ms);

    while (end > k_uptime_ticks()) {
        if (is_event_complete(obj)) {
            return;
        }

        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout_in_ms);
    }
}
```

Note that `sys_clock_timeout_end_calc()` returns values in units of ticks, to prevent conversion aliasing, is always presented at 64 bit uptime precision to prevent rollover bugs, handles special `K_FOREVER` naturally (as UINT64_MAX), and works identically for absolute timeouts as well as conventional ones.

But some care is still required for subsystems that use it. Note that delta timeouts need to be interpreted relative to a “current time”, and obviously that time is the time of the call to `sys_clock_timeout_end_calc()`. But the user expects that the time is the time they passed the timeout to you. Care must be taken to call this function just once, as synchronously as possible to the timeout creation in user code. It should not be used on a “stored” timeout value, and should never be called iteratively in a loop.

**API Reference**

**group clock_apis**

Clock APIs.

**Defines**

`K_NO_WAIT`

Generate null timeout delay.
This macro generates a timeout delay that instructs a kernel API not to wait if the requested operation cannot be performed immediately.

**Returns**
Timeout delay value.

\( K\_\text{NSEC}(t) \)
Generate timeout delay from nanoseconds.

This macro generates a timeout delay that instructs a kernel API to wait up to \( t \) nanoseconds to perform the requested operation. Note that timer precision is limited to the tick rate, not the requested value.

**Parameters**
- \( t \) – Duration in nanoseconds.

**Returns**
Timeout delay value.

\( K\_\text{USEC}(t) \)
Generate timeout delay from microseconds.

This macro generates a timeout delay that instructs a kernel API to wait up to \( t \) microseconds to perform the requested operation. Note that timer precision is limited to the tick rate, not the requested value.

**Parameters**
- \( t \) – Duration in microseconds.

**Returns**
Timeout delay value.

\( K\_\text{CYC}(t) \)
Generate timeout delay from cycles.

This macro generates a timeout delay that instructs a kernel API to wait up to \( t \) cycles to perform the requested operation.

**Parameters**
- \( t \) – Duration in cycles.

**Returns**
Timeout delay value.

\( K\_\text{TICKS}(t) \)
Generate timeout delay from system ticks.

This macro generates a timeout delay that instructs a kernel API to wait up to \( t \) ticks to perform the requested operation.

**Parameters**
- \( t \) – Duration in system ticks.

**Returns**
Timeout delay value.

\( K\_\text{MSEC}(ms) \)
Generate timeout delay from milliseconds.

This macro generates a timeout delay that instructs a kernel API to wait up to \( ms \) milliseconds to perform the requested operation.

**Parameters**
- \( ms \) – Duration in milliseconds.
Returns
Timeout delay value.

\texttt{K\_SECONDS(s)}

Generate timeout delay from seconds.

This macro generates a timeout delay that instructs a kernel API to wait up to \( s \) seconds to perform the requested operation.

Parameters
- \( s \) – Duration in seconds.

Returns
Timeout delay value.

\texttt{K\_MINUTES(m)}

Generate timeout delay from minutes.

This macro generates a timeout delay that instructs a kernel API to wait up to \( m \) minutes to perform the requested operation.

Parameters
- \( m \) – Duration in minutes.

Returns
Timeout delay value.

\texttt{K\_HOURS(h)}

Generate timeout delay from hours.

This macro generates a timeout delay that instructs a kernel API to wait up to \( h \) hours to perform the requested operation.

Parameters
- \( h \) – Duration in hours.

Returns
Timeout delay value.

\texttt{K\_FOREVER}

Generate infinite timeout delay.

This macro generates a timeout delay that instructs a kernel API to wait as long as necessary to perform the requested operation.

Returns
Timeout delay value.

\texttt{K\_TICKS\_FOREVER}

\texttt{K\_TIMEOUT\_EQ(a, b)}

Compare timeouts for equality.

The \texttt{k\_timeout\_t} object is an opaque struct that should not be inspected by application code. This macro exists so that users can test timeout objects for equality with known constants (e.g. \texttt{K\_NO\_WAIT} and \texttt{K\_FOREVER}) when implementing their own APIs in terms of Zephyr timeout constants.

Returns
True if the timeout objects are identical
typedef uint32_t k_ticks_t

Tick precision used in timeout APIs.

This type defines the word size of the timeout values used in k_timeout_t objects, and thus defines an upper bound on maximum timeout length (or equivalently minimum tick duration). Note that this does not affect the size of the system uptime counter, which is always a 64 bit count of ticks.

Functions

void sys_clock_set_timeout(int32_t ticks, bool idle)

Set system clock timeout.

Informs the system clock driver that the next needed call to sys_clock_announce() will not be until the specified number of ticks from the current time have elapsed. Note that spurious calls to sys_clock_announce() are allowed (i.e. it's legal to announce every tick and implement this function as a noop), the requirement is that one tick announcement should occur within one tick before the specified expiration (that is, passing ticks==1 means "announce the next tick", this convention was chosen to match legacy usage). Similarly a ticks value of zero (or even negative) is legal and treated identically: it simply indicates the kernel would like the next tick announcement as soon as possible.

Note that ticks can also be passed the special value K_TICKS_FOREVER, indicating that no future timer interrupts are expected or required and that the system is permitted to enter an indefinite sleep even if this could cause rollover of the internal counter (i.e. the system uptime counter is allowed to be wrong).

Note also that it is conventional for the kernel to pass INT_MAX for ticks if it wants to preserve the uptime tick count but doesn't have a specific event to await. The intent here is that the driver will schedule any needed timeout as far into the future as possible. For the specific case of INT_MAX, the next call to sys_clock_announce() may occur at any point in the future, not just at INT_MAX ticks. But the correspondence between the announced ticks and real-world time must be correct.

A final note about SMP: note that the call to sys_clock_set_timeout() is made on any CPU, and reflects the next timeout desired globally. The resulting calls(s) to sys_clock_announce() must be properly serialized by the driver such that a given tick is announced exactly once across the system. The kernel does not (cannot, really) attempt to serialize things by “assigning” timeouts to specific CPUs.

Parameters

- ticks – Timeout in tick units
- idle – Hint to the driver that the system is about to enter the idle state immediately after setting the timeout

void sys_clock_idle_exit(void)

Timer idle exit notification.

This notifies the timer driver that the system is exiting the idle and allows it to do whatever bookkeeping is needed to restore timer operation and compute elapsed ticks.

Note: Legacy timer drivers also use this opportunity to call back into sys_clock_announce() to notify the kernel of expired ticks. This is allowed for compatibility, but not recommended. The kernel will figure that out on its own.
void sys_clock_announce(int32_t ticks)
    Announce time progress to the kernel.
    Informs the kernel that the specified number of ticks have elapsed since the last call to
    sys_clock_announce() (or system startup for the first call). The timer driver is expected to
delivery these announcements as close as practical (subject to hardware and latency limitations)
to tick boundaries.

Parameters

- ticks – Elapsed time, in ticks

uint32_t sys_clock_elapsed(void)
    Ticks elapsed since last sys_clock_announce() call.
    Queries the clock driver for the current time elapsed since the last call to sys_clock_announce() was made. The kernel will call this with appropriate locking, the driver needs only provide an
instantaneous answer.

void sys_clock_disable(void)
    Disable system timer.
    This function is a no-op if the system timer does not have the capability of being disabled.

int64_t k_uptime_ticks(void)
    Get system uptime, in system ticks.
    This routine returns the elapsed time since the system booted, in ticks (c.f. CONFIG_SYS_CLOCK_TICKS_PER_SEC), which is the fundamental unit of resolution of kernel
timekeeping.

Returns

- Current uptime in ticks.

static inline int64_t k_uptime_get(void)
    Get system uptime.
    This routine returns the elapsed time since the system booted, in milliseconds.

Note: While this function returns time in milliseconds, it does not mean it has millisecond resolution. The actual resolution depends on CONFIG_SYS_CLOCK_TICKS_PER_SEC config
option.

Calling

- Current uptime in milliseconds.

static inline uint32_t k_uptime_get_32(void)
    Get system uptime (32-bit version).
    This routine returns the lower 32 bits of the system uptime in milliseconds.

Because correct conversion requires full precision of the system clock there is no benefit to
using this over k_uptime_get() unless you know the application will never run long enough for the system clock to approach 2^32 ticks. Calls to this function may involve interrupt
blocking and 64-bit math.

Note: While this function returns time in milliseconds, it does not mean it has millisecond resolution. The actual resolution depends on CONFIG_SYS_CLOCK_TICKS_PER_SEC config
option.
Returns
The low 32 bits of the current uptime, in milliseconds.

static inline int64_t k_uptime_delta(int64_t *reftime)
Get elapsed time.
This routine computes the elapsed time between the current system uptime and an earlier
reference time, in milliseconds.

Parameters
• reftime – Pointer to a reference time, which is updated to the current uptime
upon return.

Returns
Elapsed time.

static inline uint32_t k_cycle_get_32(void)
Read the hardware clock.
This routine returns the current time, as measured by the system's hardware clock.

Returns
Current hardware clock up-counter (in cycles).

static inline uint64_t k_cycle_get_64(void)
Read the 64-bit hardware clock.
This routine returns the current time in 64-bits, as measured by the system's hardware clock,
if available.

See also:
CONFIG_TIMER_HAS_64BIT_CYCLE_COUNTER

Returns
Current hardware clock up-counter (in cycles).

struct k_timeout_t
#include <sys_clock.h> Kernel timeout type.
Timeout arguments presented to kernel APIs are stored in this opaque type, which is capable of representing times in various formats and units. It should be constructed from application data using one of the macros defined for this purpose (e.g. K_MSEC(), K_TIMEOUT_ABS_TICKS(), etc...), or be one of the two constants K_NO_WAIT or K_FOREVER. Applications should not inspect the internal data once constructed. Timeout values may be compared for equality with the K_TIMEOUT_EQ() macro.

Timers
A timer is a kernel object that measures the passage of time using the kernel's system clock. When
a timer's specified time limit is reached it can perform an application-defined action, or it can simply
record the expiration and wait for the application to read its status.

• Concepts
• Implementation
  – Defining a Timer
Concepts  Any number of timers can be defined (limited only by available RAM). Each timer is referenced by its memory address.

A timer has the following key properties:

- A **duration** specifying the time interval before the timer expires for the first time. This is a \texttt{k_timeout_t} value that may be initialized via different units.

- A **period** specifying the time interval between all timer expirations after the first one, also a \texttt{k_timeout_t}. It must be non-negative. A period of \texttt{K_NO_WAIT} (i.e. zero) or \texttt{K_FOREVER} means that the timer is a one shot timer that stops after a single expiration. (For example then, if a timer is started with a duration of 200 and a period of 75, it will first expire after 200ms and then every 75ms after that.)

- An **expiry function** that is executed each time the timer expires. The function is executed by the system clock interrupt handler. If no expiry function is required a \texttt{NULL} function can be specified.

- A **stop function** that is executed if the timer is stopped prematurely while running. The function is executed by the thread that stops the timer. If no stop function is required a \texttt{NULL} function can be specified.

- A **status** value that indicates how many times the timer has expired since the status value was last read.

A timer must be initialized before it can be used. This specifies its expiry function and stop function values, sets the timer's status to zero, and puts the timer into the **stopped** state.

A timer is **started** by specifying a duration and a period. The timer's status is reset to zero, then the timer enters the **running** state and begins counting down towards expiry.

Note that the timer's duration and period parameters specify **minimum** delays that will elapse. Because of internal system timer precision (and potentially runtime interactions like interrupt delay) it is possible that more time may have passed as measured by reads from the relevant system time APIs. But at least this much time is guaranteed to have elapsed.

When a running timer expires its status is incremented and the timer executes its expiry function, if one exists; If a thread is waiting on the timer, it is unblocked. If the timer's period is zero the timer enters the stopped state; otherwise the timer restarts with a new duration equal to its period.

A running timer can be stopped in mid-countdown, if desired. The timer's status is left unchanged, then the timer enters the stopped state and executes its stop function, if one exists. If a thread is waiting on the timer, it is unblocked. Attempting to stop a non-running timer is permitted, but has no effect on the timer since it is already stopped.

A running timer can be restarted in mid-countdown, if desired. The timer's status is reset to zero, then the timer begins counting down using the new duration and period values specified by the caller. If a thread is waiting on the timer, it continues waiting.

A timer's status can be read directly at any time to determine how many times the timer has expired since its status was last read. Reading a timer's status resets its value to zero. The amount of time remaining before the timer expires can also be read; a value of zero indicates that the timer is stopped.

A thread may read a timer's status indirectly by **synchronizing** with the timer. This blocks the thread until the timer's status is non-zero (indicating that it has expired at least once) or the timer is stopped; if
the timer status is already non-zero or the timer is already stopped the thread continues without waiting. The synchronization operation returns the timer's status and resets it to zero.

**Note:** Only a single user should examine the status of any given timer, since reading the status (directly or indirectly) changes its value. Similarly, only a single thread at a time should synchronize with a given timer. ISRs are not permitted to synchronize with timers, since ISRs are not allowed to block.

### Implementation

**Defining a Timer** A timer is defined using a variable of type `k_timer`. It must then be initialized by calling `k_timer_init()`.

The following code defines and initializes a timer.

```c
struct k_timer my_timer;
extern void my_expiry_function(struct k_timer *timer_id);
k_timer_init(&my_timer, my_expiry_function, NULL);
```

Alternatively, a timer can be defined and initialized at compile time by calling `K_TIMER_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_TIMER_DEFINE(my_timer, my_expiry_function, NULL);
```

**Using a Timer Expiry Function** The following code uses a timer to perform a non-trivial action on a periodic basis. Since the required work cannot be done at interrupt level, the timer's expiry function submits a work item to the system workqueue, whose thread performs the work.

```c
void my_work_handler(struct k_work *work)
{
    /* do the processing that needs to be done periodically */
    ...
}
K_WORK_DEFINE(my_work, my_work_handler);

void my_timer_handler(struct k_timer *dummy)
{
    k_work_submit(&my_work);
}
K_TIMER_DEFINE(my_timer, my_timer_handler, NULL);
...
/* start periodic timer that expires once every second */
k_timer_start(&my_timer, K_SECONDS(1), K_SECONDS(1));
```

**Reading Timer Status** The following code reads a timer's status directly to determine if the timer has expired on not.
Using Timer Status Synchronization

The following code performs timer status synchronization to allow a thread to do useful work while ensuring that a pair of protocol operations are separated by the specified time interval.

```c
K_TIMER_DEFINE(my_status_timer, NULL, NULL);

... /* start one shot timer that expires after 200 ms */
k_timer_start(&my_status_timer, K_MSEC(200), K_NO_WAIT);

/* do work */
...

/* check timer status */
if (k_timer_status_get(&my_status_timer) > 0) {
    /* timer has expired */
} else if (k_timer_remaining_get(&my_status_timer) == 0) {
    /* timer was stopped (by someone else) before expiring */
} else {
    /* timer is still running */
}
```

**Note:** If the thread had no other work to do it could simply sleep between the two protocol operations, without using a timer.

**Suggested Uses**

Use a timer to initiate an asynchronous operation after a specified amount of time.

Use a timer to determine whether or not a specified amount of time has elapsed. In particular, timers should be used when higher precision and/or unit control is required than that afforded by the simpler `k_sleep()` and `k_usleep()` calls.

Use a timer to perform other work while carrying out operations involving time limits.

**Note:** If a thread needs to measure the time required to perform an operation it can read the system timer.
**clock or the hardware clock** directly, rather than using a timer.

**Configuration Options**  Related configuration options:

- None

**API Reference**  
*group timerApis*

**Defines**

```c
K_TIMER_DEFINE(name, expiry_fn, stop_fn)
```

Safely define and initialize a timer.

The timer can be accessed outside the module where it is defined using:

```c
extern struct k_timer <name>;
```

**Parameters**

- **name** – Name of the timer variable.
- **expiry_fn** – Function to invoke each time the timer expires.
- **stop_fn** – Function to invoke if the timer is stopped while running.

**Typedefs**

```c
typedef void (*k_timer_expiry_t)(struct k_timer *timer)
```

Timer expiry function type.

A timer's expiry function is executed by the system clock interrupt handler each time the timer expires. The expiry function is optional, and is only invoked if the timer has been initialized with one.

**Param timer**

Address of timer.

```c
typedef void (*k_timer_stop_t)(struct k_timer *timer)
```

Timer stop function type.

A timer's stop function is executed if the timer is stopped prematurely. The function runs in the context of call that stops the timer. As k_timer_stop() can be invoked from an ISR, the stop function must be callable from interrupt context (isr-ok).

The stop function is optional, and is only invoked if the timer has been initialized with one.

**Param timer**

Address of timer.
Functions

void k_timer_init(struct k_timer *timer, k_timer_expiry_t expiry_fn, k_timer_stop_t stop_fn)
Initialize a timer.
This routine initializes a timer, prior to its first use.

Parameters
• timer – Address of timer.
• expiry_fn – Function to invoke each time the timer expires.
• stop_fn – Function to invoke if the timer is stopped while running.

void k_timer_start(struct k_timer *timer, k_timeout_t duration, k_timeout_t period)
Start a timer.
This routine starts a timer, and resets its status to zero. The timer begins counting down using
the specified duration and period values.
Attempting to start a timer that is already running is permitted. The timer's status is reset to
zero and the timer begins counting down using the new duration and period values.

Parameters
• timer – Address of timer.
• duration – Initial timer duration.
• period – Timer period.

void k_timer_stop(struct k_timer *timer)
Stop a timer.
This routine stops a running timer prematurely. The timer's stop function, if one exists, is
invoked by the caller.
Attempting to stop a timer that is not running is permitted, but has no effect on the timer.

Function properties (list may not be complete)

isr-ok

Note: The stop handler has to be callable from ISRs if k_timer_stop is to be called from ISRs.

Parameters
• timer – Address of timer.

uint32_t k_timer_status_get(struct k_timer *timer)
Read timer status.
This routine reads the timer's status, which indicates the number of times it has expired since
its status was last read.
Calling this routine resets the timer's status to zero.

Parameters
• timer – Address of timer.

Returns
Timer status.

uint32_t k_timer_status_sync(struct k_timer *timer)

Synchronize thread to timer expiration.

This routine blocks the calling thread until the timer's status is non-zero (indicating that it has expired at least once since it was last examined) or the timer is stopped. If the timer status is already non-zero, or the timer is already stopped, the caller continues without waiting.

Calling this routine resets the timer's status to zero.

This routine must not be used by interrupt handlers, since they are not allowed to block.

Parameters
- \textit{timer} – Address of timer.

Returns
- Timer status.

\textit{k_ticks_t} k_timer_expires_ticks(const struct k_timer *timer)

Get next expiration time of a timer, in system ticks.

This routine returns the future system uptime reached at the next time of expiration of the timer, in units of system ticks. If the timer is not running, current system time is returned.

Parameters
- \textit{timer} – The timer object

Returns
- Uptime of expiration, in ticks

\textit{k_ticks_t} k_timer_remaining_ticks(const struct k_timer *timer)

Get time remaining before a timer next expires, in system ticks.

This routine computes the time remaining before a running timer next expires, in units of system ticks. If the timer is not running, it returns zero.

\textit{static inline uint32_t} k_timer_remaining_get(struct k_timer *timer)

Get time remaining before a timer next expires.

This routine computes the (approximate) time remaining before a running timer next expires. If the timer is not running, it returns zero.

Parameters
- \textit{timer} – Address of timer.

Returns
- Remaining time (in milliseconds).

void k_timer_user_data_set(struct k_timer *timer, void *user_data)

Associate user-specific data with a timer.

This routine records the \textit{user_data} with the \textit{timer}, to be retrieved later.

It can be used e.g. in a timer handler shared across multiple subsystems to retrieve data specific to the subsystem this timer is associated with.

Parameters
- \textit{timer} – Address of timer.
- \textit{user_data} – User data to associate with the timer.

void *k_timer_user_data_get(const struct k_timer *timer)

Retrieve the user-specific data from a timer.

Parameters
- \textit{timer} – Address of timer.
Returns
The user data.

3.1.5 Other

These pages cover other kernel services.

Atomic Services

An atomic variable is one that can be read and modified by threads and ISRs in an uninterruptible manner. It 32-bit on 32-bit machines and 64-bit on 64-bit machines.

- Concepts
- Implementation
  - Defining an Atomic Variable
  - Manipulating an Atomic Variable
  - Manipulating an Array of Atomic Variables
  - Memory Ordering
- Suggested Uses
- Configuration Options
- API Reference

Concepts  Any number of atomic variables can be defined (limited only by available RAM).

Using the kernel’s atomic APIs to manipulate an atomic variable guarantees that the desired operation occurs correctly, even if higher priority contexts also manipulate the same variable.

The kernel also supports the atomic manipulation of a single bit in an array of atomic variables.

Implementation

Defining an Atomic Variable  An atomic variable is defined using a variable of type atomic_t.

By default an atomic variable is initialized to zero. However, it can be given a different value using ATOMIC_INIT:

```
atomic_t flags = ATOMIC_INIT(0xFF);
```

Manipulating an Atomic Variable  An atomic variable is manipulated using the APIs listed at the end of this section.

The following code shows how an atomic variable can be used to keep track of the number of times a function has been invoked. Since the count is incremented atomically, there is no risk that it will become corrupted in mid-increment if a thread calling the function is interrupted if by a higher priority context that also calls the routine.
atomic_t call_count;

int call_counting_routine(void)
{
    /* increment invocation counter */
    atomic_inc(&call_count);

    /* do rest of routine's processing */
    ...
}

Manipulating an Array of Atomic Variables  
An array of 32-bit atomic variables can be defined in the conventional manner. However, you can also define an N-bit array of atomic variables using ATOMIC_DEFINE.

A single bit in an array of atomic variables can be manipulated using the APIs listed at the end of this section that end with _bit().

The following code shows how a set of 200 flag bits can be implemented using an array of atomic variables.

#define NUM_FLAG_BITS 200

ATOMIC_DEFINE(flag_bits, NUM_FLAG_BITS);

/* set specified flag bit & return its previous value */
int set_flag_bit(int bit_position)
{
    return (int)atomic_set_bit(flag_bits, bit_position);
}

Memory Ordering  
For consistency and correctness, all Zephyr atomic APIs are expected to include a full memory barrier (in the sense of e.g. “serializing” instructions on x86, “DMB” on ARM, or a “sequentially consistent” operation as defined by the C++ memory model) where needed by hardware to guarantee a reliable picture across contexts. Any architecture-specific implementations are responsible for ensuring this behavior.

Suggested Uses  
Use an atomic variable to implement critical section processing that only requires the manipulation of a single 32-bit value.

Use multiple atomic variables to implement critical section processing on a set of flag bits in a bit array longer than 32 bits.

Note: Using atomic variables is typically far more efficient than using other techniques to implement critical sections such as using a mutex or locking interrupts.

Configuration Options  
Related configuration options:

- CONFIG_ATOMIC_OPERATIONS_BUILTIN
- CONFIG_ATOMIC_OPERATIONS_ARCH
- CONFIG_ATOMIC_OPERATIONS_C
Important: All atomic services APIs can be used by both threads and ISRs.

group atomic_apis

Defines

ATOMIC_INIT(i)

Initialize an atomic variable.

This macro can be used to initialize an atomic variable. For example,

```c
atomic_t my_var = ATOMIC_INIT(75);
```

Parameters

- `i` – Value to assign to atomic variable.

ATOMIC_PTR_INIT(p)

Initialize an atomic pointer variable.

This macro can be used to initialize an atomic pointer variable. For example,

```c
atomic_ptr_t my_ptr = ATOMIC_PTR_INIT(&data);
```

Parameters

- `p` – Pointer value to assign to atomic pointer variable.

ATOMIC_BITMAP_SIZE(num_bits)

This macro computes the number of atomic variables necessary to represent a bitmap with `num_bits`.

Parameters

- `num_bits` – Number of bits.

ATOMIC_DEFINE(name, num_bits)

Define an array of atomic variables.

This macro defines an array of atomic variables containing at least `num_bits` bits.

Note: If used from file scope, the bits of the array are initialized to zero; if used from within a function, the bits are left uninitialized.

Parameters

- `name` – Name of array of atomic variables.
- `num_bits` – Number of bits needed.

Functions
static inline bool atomic_test_bit(const atomic_t *target, int bit)
  Atomically test a bit.

  This routine tests whether bit number bit of target is set or not. The target may be a single
  atomic variable or an array of them.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where
applicable).

**Parameters**
- target – Address of atomic variable or array.
- bit – Bit number (starting from 0).

**Returns**
  true if the bit was set, false if it wasn't.

static inline bool atomic_test_and_clear_bit(atomic_t *target, int bit)
  Atomically test and clear a bit.

  Atomically clear bit number bit of target and return its old value. The target may be a single
  atomic variable or an array of them.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where
applicable).

**Parameters**
- target – Address of atomic variable or array.
- bit – Bit number (starting from 0).

**Returns**
  true if the bit was set, false if it wasn't.

static inline bool atomic_test_and_set_bit(atomic_t *target, int bit)
  Atomically set a bit.

  Atomically set bit number bit of target and return its old value. The target may be a single
  atomic variable or an array of them.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where
applicable).

**Parameters**
- target – Address of atomic variable or array.
- bit – Bit number (starting from 0).

**Returns**
  true if the bit was set, false if it wasn't.

static inline void atomic_clear_bit(atomic_t *target, int bit)
  Atomically clear a bit.

  Atomically clear bit number bit of target. The target may be a single atomic variable or an
  array of them.
Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

**Parameters**
- *target* – Address of atomic variable or array.
- *bit* – Bit number (starting from 0).

```c
static inline void atomic_set_bit(atomic_t *target, int bit)
```
Atomically set a bit.

Atomically set bit number *bit* of *target*. The target may be a single atomic variable or an array of them.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

**Parameters**
- *target* – Address of atomic variable or array.
- *bit* – Bit number (starting from 0).
- *val* – true for 1, false for 0.

```c
static inline bool atomic_cas(atomic_t *target, atomic_val_t old_value, atomic_val_t new_value)
```
Atomic compare-and-set.

This routine performs an atomic compare-and-set on *target*. If the current value of *target* equals *old_value*, *target* is set to *new_value*. If the current value of *target* does not equal *old_value*, *target* is left unchanged.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

**Parameters**
- *target* – Address of atomic variable.
- *old_value* – Original value to compare against.
• new_value – New value to store.

Returns
true if new_value is written, false otherwise.

static inline bool atomic_ptr_cas(atomic_ptr_t *target, atomic_ptr_val_t old_value, atomic_ptr_val_t new_value)

Atomic compare-and-set with pointer values.
This routine performs an atomic compare-and-set on target. If the current value of target equals old_value, target is set to new_value. If the current value of target does not equal old_value, target is left unchanged.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.
• old_value – Original value to compare against.
• new_value – New value to store.

Returns
true if new_value is written, false otherwise.

static inline atomic_val_t atomic_add(atomic_t *target, atomic_val_t value)

Atomic addition.
This routine performs an atomic addition on target.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.
• value – Value to add.

Returns
Previous value of target.

static inline atomic_val_t atomic_sub(atomic_t *target, atomic_val_t value)

Atomic subtraction.
This routine performs an atomic subtraction on target.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.
• value – Value to subtract.

Returns
Previous value of target.
static inline atomic_val_t atomic_inc(atomic_t *target)
Atomic increment.
This routine performs an atomic increment by 1 on target.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.

Returns
Previous value of target.

static inline atomic_val_t atomic_dec(atomic_t *target)
Atomic decrement.
This routine performs an atomic decrement by 1 on target.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.

Returns
Previous value of target.

static inline atomic_val_t atomic_get(const atomic_t *target)
Atomic get.
This routine performs an atomic read on target.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.

Returns
Value of target.

static inline atomic_ptr_val_t atomic_ptr_get(const atomic_ptr_t *target)
Atomic get a pointer value.
This routine performs an atomic read on target.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of pointer variable.
Returns
Value of target.

static inline atomic_val_t atomic_set(atomic_t *target, atomic_val_t value)
Atomic get-and-set.
This routine atomically sets target to value and returns the previous value of target.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.
• value – Value to write to target.

Returns
Previous value of target.

static inline atomic_ptr_val_t atomic_ptr_set(atomic_ptr_t *target, atomic_ptr_val_t value)
Atomic get-and-set for pointer values.
This routine atomically sets target to value and returns the previous value of target.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.
• value – Value to write to target.

Returns
Previous value of target.

static inline atomic_val_t atomic_clear(atomic_t *target)
Atomic clear.
This routine atomically sets target to zero and returns its previous value. (Hence, it is equivalent to atomic_set(target, 0).)

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.

Returns
Previous value of target.

static inline atomic_ptr_val_t atomic_ptr_clear(atomic_ptr_t *target)
Atomic clear of a pointer value.
This routine atomically sets target to zero and returns its previous value. (Hence, it is equivalent to atomic_set(target, 0).)
Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.

Returns
Previous value of target.

static inline atomic_val_t atomic_or(atomic_t *target, atomic_val_t value)
Atomic bitwise inclusive OR.
This routine atomically sets target to the bitwise inclusive OR of target and value.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.
• value – Value to OR.

Returns
Previous value of target.

static inline atomic_val_t atomic_xor(atomic_t *target, atomic_val_t value)
Atomic bitwise exclusive OR (XOR).
This routine atomically sets target to the bitwise exclusive OR (XOR) of target and value.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.
• value – Value to XOR.

Returns
Previous value of target.

static inline atomic_val_t atomic_and(atomic_t *target, atomic_val_t value)
Atomic bitwise AND.
This routine atomically sets target to the bitwise AND of target and value.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).
static inline atomic_val_t atomic_nand(atomic_t *target, atomic_val_t value)
    Atomic bitwise NAND.
    This routine atomically sets target to the bitwise NAND of target and value. (This operation is equivalent to target = ~(target & value).)

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- target – Address of atomic variable.
- value – Value to NAND.

Returns

Previous value of target.

Floating Point Services

The kernel allows threads to use floating point registers on board configurations that support these registers.

Note: Floating point services are currently available only for boards based on ARM Cortex-M SoCs supporting the Floating Point Extension, the Intel x86 architecture, the SPARC architecture and ARCv2 SoCs supporting the Floating Point Extension. The services provided are architecture specific.

The kernel does not support the use of floating point registers by ISRs.

Concepts

- No FP registers mode
- Unshared FP registers mode
- Shared FP registers mode

Implementation

- Performing Floating Point Arithmetic

Suggested Uses

Configuration Options

API Reference

Concepts The kernel can be configured to provide only the floating point services required by an application. Three modes of operation are supported, which are described below. In addition, the kernel's support for the SSE registers can be included or omitted, as desired.
No FP registers mode  This mode is used when the application has no threads that use floating point registers. It is the kernel’s default floating point services mode.

If a thread uses any floating point register, the kernel generates a fatal error condition and aborts the thread.

Unshared FP registers mode  This mode is used when the application has only a single thread that uses floating point registers.

On x86 platforms, the kernel initializes the floating point registers so they can be used by any thread (initialization in skipped on ARM Cortex-M platforms and ARCv2 platforms). The floating point registers are left unchanged whenever a context switch occurs.

Note: The behavior is undefined, if two or more threads attempt to use the floating point registers, as the kernel does not attempt to detect (or prevent) multiple threads from using these registers.

Shared FP registers mode  This mode is used when the application has two or more threads that use floating point registers. Depending upon the underlying CPU architecture, the kernel supports one or more of the following thread sub-classes:

- non-user: A thread that cannot use any floating point registers
- FPU user: A thread that can use the standard floating point registers
- SSE user: A thread that can use both the standard floating point registers and SSE registers

The kernel initializes and enables access to the floating point registers, so they can be used by any thread, then saves and restores these registers during context switches to ensure the computations performed by each FPU user or SSE user are not impacted by the computations performed by the other users.

ARM Cortex-M architecture (with the Floating Point Extension)

Note: The Shared FP registers mode is the default Floating Point Services mode in ARM Cortex-M.

On the ARM Cortex-M architecture with the Floating Point Extension, the kernel treats all threads as FPU users when shared FP registers mode is enabled. This means that any thread is allowed to access the floating point registers. The ARM kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them.

Pretag a thread that intends to use the FP registers by using one of the techniques listed below.

- A statically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `k_thread_create()`.

Pretagging a thread with the `K_FP_REGS` option instructs the MPU-based stack protection mechanism to properly configure the size of the thread’s guard region to always guarantee stack overflow detection, and enable lazy stacking for the given thread upon thread creation.

During thread context switching the ARM kernel saves the callee-saved floating point registers, if the switched-out thread has been using them. Additionally, the caller-saved floating point registers are saved on the thread’s stack. If the switched-in thread has been using the floating point registers, the kernel restores the callee-saved FP registers of the switched-in thread and the caller-saved FP context is restored from the thread’s stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers.

Each thread that intends to use the floating point registers must provide an extra 72 bytes of stack space where the callee-saved FP context can be saved.
Lazy Stacking is currently enabled in Zephyr applications on ARM Cortex-M architecture, minimizing interrupt latency, when the floating point context is active.

When the MPU-based stack protection mechanism is not enabled, lazy stacking is always active in the Zephyr application. When the MPU-based stack protection is enabled, the following rules apply with respect to lazy stacking:

- Lazy stacking is activated by default on threads that are pretagged with `K_FP_REGS`
- Lazy stacking is activated dynamically on threads that are not pretagged with `K_FP_REGS`, as soon as the kernel detects that they are using the floating point registers.

If an ARM thread does not require use of the floating point registers any more, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching.

**ARM64 architecture**

Note: The Shared FP registers mode is the default Floating Point Services mode on ARM64. The compiler is free to optimize code using FP/SIMD registers, and library functions such as memcpy are known to make use of them.

On the ARM64 (Aarch64) architecture the kernel treats each thread as a FPU user on a case-by-case basis. A “lazy save” algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are not saved when switching from an FPU user to a non-user thread, and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don’t have a persistent register context, there are no provision for saving an ISR’s FPU context either, hence the IRQ disabling.

Each thread object becomes 512 bytes larger when Shared FP registers mode is enabled.

**ARCv2 architecture**

On the ARCv2 architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques.

- A statically-created ARC thread can be tagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created ARC thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

If an ARC thread does not require use of the floating point registers any more, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching.

During thread context switching the ARC kernel saves the callee-saved floating point registers, if the switched-out thread has been using them. Additionally, the caller-saved floating point registers are saved on the thread’s stack. If the switched-in thread has been using the floating point registers, the kernel restores the callee-saved FP registers of the switched-in thread and the caller-saved FP context is restored from the thread’s stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers. An extra 16 bytes (single floating point hardware) or 32 bytes (double floating point hardware) of stack space is required to load and store floating point registers.

**RISC-V architecture**

On the RISC-V architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques:

- A statically-created RISC-V thread can be tagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
• A dynamically-created RISC-V thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

• A running RISC-V thread can be tagged by calling `k_float_enable()`. This function can only be called from the thread itself.

If a RISC-V thread no longer requires the use of the floating point registers, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching. This function can only be called from the thread itself.

During thread context switching the RISC-V kernel saves the callee-saved floating point registers, if the switched-out thread is tagged with `K_FP_REGS`. Additionally, the caller-saved floating point registers are saved on the thread's stack. If the switched-in thread has been tagged with `K_FP_REGS`, then the kernel restores the callee-saved FP registers of the switched-in thread and the caller-saved FP context is restored from the thread’s stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers. An extra 84 bytes (single floating point hardware) or 164 bytes (double floating point hardware) of stack space is required to load and store floating point registers.

**SPARC architecture**  On the SPARC architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques:

• A statically-created thread can be tagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.

• A dynamically-created thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

During thread context switch at exit from interrupt handler, the SPARC kernel saves all floating point registers, if the FPU was enabled in the switched-out thread. Floating point registers are saved on the thread’s stack. Floating point registers are restored when a thread context is restored iff they were saved at the context save. Saving and restoring of the floating point registers is synchronous and thus not lazy. The FPU is always disabled when an ISR is called (independent of `CONFIG_FPU_SHARING`).

Floating point disabling with `k_float_disable()` is not implemented.

When `CONFIG_FPU_SHARING` is used, then 136 bytes of stack space is required for each FPU user thread to load and store floating point registers. No extra stack is required if `CONFIG_FPU_SHARING` is not used.

**x86 architecture**  On the x86 architecture the kernel treats each thread as a non-user, FPU user or SSE user on a case-by-case basis. A “lazy save” algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are *not* saved when switching from an FPU user to a non-user thread, and then back to the original FPU user. The following table indicates the amount of additional stack space a thread must provide so the registers can be saved properly.

<table>
<thead>
<tr>
<th>Thread type</th>
<th>FP register use</th>
<th>Extra stack space required</th>
</tr>
</thead>
<tbody>
<tr>
<td>cooperative</td>
<td>any</td>
<td>0 bytes</td>
</tr>
<tr>
<td>preemptive</td>
<td>none</td>
<td>0 bytes</td>
</tr>
<tr>
<td>preemptive</td>
<td>FPU</td>
<td>108 bytes</td>
</tr>
<tr>
<td>preemptive</td>
<td>SSE</td>
<td>464 bytes</td>
</tr>
</tbody>
</table>

The x86 kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them. The thread is tagged as an SSE user if the kernel has been configured to support the SSE registers, or as an FPU user if the SSE registers are not supported. If this would result in a thread that is an FPU user being tagged as an SSE user, or if the application wants to avoid the exception handling overhead involved in auto-tagging threads, it is possible to pretag a thread using one of the techniques listed below.

• A statically-created x86 thread can be pretagged by passing the `K_FP_REGS` or `K_SSE_REGS` option to `K_THREAD_DEFINE`.

• A dynamically-created x86 thread can be pretagged by passing the `K_FP_REGS` or `K_SSE_REGS` option to `k_thread_create()`.
• An already-created x86 thread can pretag itself once it has started by passing the \texttt{K_FP_REGS} or \texttt{K_SSE_REGS} option to \texttt{k_float_enable()}. If an x86 thread uses the floating point registers infrequently it can call \texttt{k_float_disable()} to remove its tagging as an FPU user or SSE user. This eliminates the need for the kernel to take steps to preserve the contents of the floating point registers during context switches when there is no need to do so. When the thread again needs to use the floating point registers it can re-tag itself as an FPU user or SSE user by calling \texttt{k_float_enable()}.

\textbf{Implementation}

\textbf{Performing Floating Point Arithmetic} \hspace{1em} No special coding is required for a thread to use floating point arithmetic if the kernel is properly configured.

The following code shows how a routine can use floating point arithmetic to avoid overflow issues when computing the average of a series of integer values.

```c
int average(int *values, int num_values) {
    double sum;
    int i;

    sum = 0.0;

    for (i = 0; i < num_values; i++) {
        sum += *values;
        values++;
    }

    return (int)((sum / num_values) + 0.5);
}
```

\textbf{Suggested Uses} \hspace{1em} Use the kernel floating point services when an application needs to perform floating point operations.

\textbf{Configuration Options} \hspace{1em} To configure unshared FP registers mode, enable the \texttt{CONFIG_FPU} configuration option and leave the \texttt{CONFIG_FPU_SHARING} configuration option disabled.

To configure shared FP registers mode, enable both the \texttt{CONFIG_FPU} configuration option and the \texttt{CONFIG_FPU_SHARING} configuration option. Also, ensure that any thread that uses the floating point registers has sufficient added stack space for saving floating point register values during context switches, as described above.

For x86, use the \texttt{CONFIG_X86_SSE} configuration option to enable support for SSEx instructions.

\textbf{API Reference}

\textit{group float APIs}

\textbf{Version}

Kernel version handling and APIs related to kernel version being used.
API Reference

```c
uint32_t sys_kernel_version_get(void)
```

Returns the kernel version of the present build.

The kernel version is a four-byte value, whose format is described in the file “kernel_version.h”.

Returns

- `kernel version`
- `SYS_KERNEL_VER_MAJOR(ver)`
- `SYS_KERNEL_VER_MINOR(ver)`
- `SYS_KERNEL_VER_PATCHLEVEL(ver)`

Fatal Errors

Software Errors Triggered in Source Code

Zephyr provides several methods for inducing fatal error conditions through either build-time checks, conditionally compiled assertions, or deliberately invoked panic or oops conditions.

Runtime Assertions

Zephyr provides some macros to perform runtime assertions which may be conditionally compiled. Their definitions may be found in include/zephyr/sys/__assert.h.

Assertions are enabled by setting the `__ASSERT_ON` preprocessor symbol to a non-zero value. There are two ways to do this:

- Use the `CONFIG_ASSERT` and `CONFIG_ASSERT_LEVEL` kconfig options.
- Add `-D__ASSERT_ON=<level>` to the project’s CFLAGS, either on the build command line or in a CMakeLists.txt.

The `__ASSERT_ON` method takes precedence over the kconfig option if both are used.

Specifying an assertion level of 1 causes the compiler to issue warnings that the kernel contains debug-type `__ASSERT()` statements; this reminder is issued since assertion code is not normally present in a final product. Specifying assertion level 2 suppresses these warnings.

Assertions are enabled by default when running Zephyr test cases, as configured by the `CONFIG_TEST` option.

The policy for what to do when encountering a failed assertion is controlled by the implementation of `assert_post_action()`. Zephyr provides a default implementation with weak linkage which invokes a kernel oops if the thread that failed the assertion was running in user mode, and a kernel panic otherwise.

`__ASSERT()`

The `__ASSERT()` macro can be used inside kernel and application code to perform optional runtime checks which will induce a fatal error if the check does not pass. The macro takes a string message which will be printed to provide context to the assertion. In addition, the kernel will print a text representation of the expression code that was evaluated, and the file and line number where the assertion can be found.

For example:

```c
__ASSERT(foo == 0xF0CACC1A, "Invalid value of foo, got 0x%x", foo);
```

If at runtime `foo` had some unexpected value, the error produced may look like the following:

```
ASSERTION FAIL [foo == 0xF0CACC1A] @ ZEPHYR_BASE/tests/kernel/fatal/src/main.c:367
   Invalid value of foo, got 0xdeadbeef
   [0:00:00.000,000] <err> os: r0/a1: 0x00000004 r1/a2: 0x0000016f r2/a3: 0x00000000
```

(continues on next page)
The __ASSERT_EVAL() macro can also be used inside kernel and application code, with special semantics for the evaluation of its arguments. It makes use of the __ASSERT() macro, but has some extra flexibility. It allows the developer to specify different actions depending whether the __ASSERT() macro is enabled or not. This can be particularly useful to prevent the compiler from generating comments (errors, warnings or remarks) about variables that are only used with __ASSERT() being assigned a value, but otherwise unused when the __ASSERT() macro is disabled.

Consider the following example:

```c
int x;
x = foo();
__ASSERT(x != 0, "foo() returned zero!");
```

If __ASSERT() is disabled, then 'x' is assigned a value, but never used. This type of situation can be resolved using the __ASSERT_EVAL() macro.

```c
__ASSERT_EVAL ((void) foo(),
    int x = foo(),
    x != 0,
    "foo() returned zero!");
```

The first parameter tells __ASSERT_EVAL() what to do if __ASSERT() is disabled. The second parameter tells __ASSERT_EVAL() what to do if __ASSERT() is enabled. The third and fourth parameters are the parameters it passes to __ASSERT().

__ASSERT NO MSG() The __ASSERT NO MSG() macro can be used to perform an assertion that reports the failed test and its location, but lacks additional debugging information provided to assist the user in diagnosing the problem; its use is discouraged.

Build Assertions Zephyr provides two macros for performing build-time assertion checks. These are evaluated completely at compile-time, and are always checked.

BUILD_ASSERT() This has the same semantics as C's _Static_assert or C++’s static_assert. If the evaluation fails, a build error will be generated by the compiler. If the compiler supports it, the provided message will be printed to provide further context.

Unlike __ASSERT(), the message must be a static string, without printf()-like format codes or extra arguments.

For example, suppose this check fails:

```c
BUILD_ASSERT(FOO == 2000, "Invalid value of FOO");
```

With GCC, the output resembles:
Kernel Oops  A kernel oops is a software triggered fatal error invoked by koops(). This should be used to indicate an unrecoverable condition in application logic.

The fatal error reason code generated will be K_ERR_KERNEL_OOPS.

Kernel Panic  A kernel panic is a software triggered fatal error invoked by k_panic(). This should be used to indicate that the Zephyr kernel is in an unrecoverable state. Implementations of k_sys_fatal_error_handler() should not return if the kernel encounters a panic condition, as the entire system needs to be reset.

Threads running in user mode are not permitted to invoke k_panic(), and doing so will generate a kernel oops instead. Otherwise, the fatal error reason code generated will be K_ERR_KERNEL_PANIC.

Exceptions

Spurious Interrupts  If the CPU receives a hardware interrupt on an interrupt line that has not had a handler installed with IRQ_CONNECT() or irq_connect_dynamic(), then the kernel will generate a fatal error with the reason code K_ERR_SPURIOUS_IRQ().

Stack Overflows  In the event that a thread pushes more data onto its execution stack than its stack buffer provides, the kernel may be able to detect this situation and generate a fatal error with a reason code of K_ERR_STACK_CHK_FAIL.

If a thread is running in user mode, then stack overflows are always caught, as the thread will simply not have permission to write to adjacent memory addresses outside of the stack buffer. Because this is enforced by the memory protection hardware, there is no risk of data corruption to memory that the thread would not otherwise be able to write to.

If a thread is running in supervisor mode, or if CONFIG_USERSPACE is not enabled, depending on configuration stack overflows may or may not be caught. CONFIG_HW_STACK_PROTECTION is supported on some architectures and will catch stack overflows in supervisor mode, including when handling a system call on behalf of a user thread. Typically this is implemented via dedicated CPU features, or read-only MMU/MPU guard regions placed immediately adjacent to the stack buffer. Stack overflows caught in this way can detect the overflow, but cannot guarantee against data corruption and should be treated as a very serious condition impacting the health of the entire system.

If a platform lacks memory management hardware support, CONFIG_STACK_SENTINEL is a software-only stack overflow detection feature which periodically checks if a sentinel value at the end of the stack buffer has been corrupted. It does not require hardware support, but provides no protection against data corruption. Since the checks are typically done at interrupt exit, the overflow may be detected a nontrivial amount of time after the stack actually overflowed.

Finally, Zephyr supports GCC compiler stack canaries via CONFIG_STACK_CANARIES. If enabled, the compiler will insert a canary value randomly generated at boot into function stack frames, checking that the canary has not been overwritten at function exit. If the check fails, the compiler invokes __stack_chk_fail(), whose Zephyr implementation invokes a fatal stack overflow error. An error in this case does not indicate that the entire stack buffer has overflowed, but instead that the current function stack frame has been corrupted. See the compiler documentation for more details.
Other Exceptions  Any other type of unhandled CPU exception will generate an error code of K_ERR_CPU_EXCEPTION.

Fatal Error Handling  The policy for what to do when encountering a fatal error is determined by the implementation of the \texttt{k.sys.fatal_error_handler()} function. This function has a default implementation with weak linkage that calls \texttt{LOG_PANIC()} to dump all pending logging messages and then unconditionally halts the system with \texttt{k.fatal.halt()}.

Applications are free to implement their own error handling policy by overriding the implementation of \texttt{k.sys.fatal_error_handler()}. If the implementation returns, the faulting thread will be aborted and the system will otherwise continue to function. See the documentation for this function for additional details and constraints.

Functions

\texttt{FUNC_NORETURN void k_fatal_halt(unsigned int reason)}

\texttt{Halt the system on a fatal error.}

\texttt{Invokes architecture-specific code to power off or halt the system in a low power state. Lacking that, lock interrupts and sit in an idle loop.}

\texttt{Parameters}

\texttt{• reason – Fatal exception reason code}
void k_sys_fatal_error_handler(unsigned int reason, const z_arch_esf_t *esf)
    Fatal error policy handler.

This function is not invoked by application code, but is declared as a weak symbol so that
applications may introduce their own policy.

The default implementation of this function halts the system unconditionally. Depending on
architecture support, this may be a simple infinite loop, power off the hardware, or exit an
emulator.

If this function returns, then the currently executing thread will be aborted.

A few notes for custom implementations:

- If the error is determined to be unrecoverable, LOG_PANIC() should be invoked to flush
  any pending logging buffers.
- K_ERR_KERNEL_PANIC indicates a severe unrecoverable error in the kernel itself, and
  should not be considered recoverable. There is an assertion in z_fatal_error() to enforce
  this.
- Even outside of a kernel panic, unless the fault occurred in user mode, the kernel it-
  self may be in an inconsistent state, with API calls to kernel objects possibly exhibiting
  undefined behavior or triggering another exception.

Fatal error policy handler.

Test Objective:

- To verify architecture layer provides a mechanism to issue an interprocessor interrupt
to all other CPUs in the system that calls the scheduler IPI. We simply add a hook in
z_sched_ipi(), in order to check if it has been called once in another CPU except the
caller, when arch_sched_ipi() is called.

Testing techniques:

- Interface testing, function and block box testing, dynamic analysis and testing

Prerequisite Conditions:

- CONFIG_SMP=y , and the HW platform must support SMP.
- CONFIG_TRACE_SCHED_IPI=y was set.

Input Specifications:

- N/A

Test Procedure:

a. In main thread, given a global variable sched_ipi_has_called equaled zero.
b. Call arch_sched_ipi() then sleep for 100ms.
c. In z_sched_ipi() handler, increment the sched_ipi_has_called.
d. In main thread, check the sched_ipi_has_called is not equaled to zero.
e. Repeat step 1 to 4 for 3 times.

Expected Test Result:

- The pointer of current cpu data that we got from function call is correct.

Pass/Fail Criteria:

- Successful if the check of step 4 are all passed.
- Failure if one of the check of step 4 is failed.
Assumptions and Constraints:

- This test using for the platform that support SMP, in our current scenario, only x86_64 and arc supported.

**See also:**

*arch_sched_ipt()*

**Parameters**

- `reason` – The reason for the fatal error
- `esf` – Exception context, with details and partial or full register state when the error occurred. May in some cases be NULL.

**Thread Local Storage (TLS)**

Thread Local Storage (TLS) allows variables to be allocated on a per-thread basis. These variables are stored in the thread stack which means every thread has its own copy of these variables.

Zephyr currently requires toolchain support for TLS.

**Configuration** To enable thread local storage in Zephyr, `CONFIG_THREAD_LOCAL_STORAGE` needs to be enabled. Note that this option may not be available if the architecture or the SoC does not have the hidden option `CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE` enabled, which means the architecture or the SoC does not have the necessary code to support thread local storage and/or the toolchain does not support TLS.

`CONFIG_ERRNO_IN_TLS` can be enabled together with `CONFIG_ERRNO` to let the variable `errno` be a thread local variable. This allows user threads to access the value of `errno` without making a system call.

**Declaring and Using Thread Local Variables** The keyword `__thread` can be used to declare thread local variables.

For example, to declare a thread local variable in header files:

```c
extern __thread int i;
```

And to declare the actual variable in source files:

```c
__thread int i;
```

Keyword `static` can also be used to limit the variable within a source file:

```c
static __thread int j;
```

Using the thread local variable is the same as using other variable, for example:

```c
void testing(void) {
    i = 10;
}
```

### 3.2 Device Driver Model
3.2.1 Introduction

The Zephyr kernel supports a variety of device drivers. Whether a driver is available depends on the board and the driver.

The Zephyr device model provides a consistent device model for configuring the drivers that are part of a system. The device model is responsible for initializing all the drivers configured into the system.

Each type of driver (e.g. UART, SPI, I2C) is supported by a generic type API.

In this model the driver fills in the pointer to the structure containing the function pointers to its API functions during driver initialization. These structures are placed into the RAM section in initialization level order.

3.2.2 Standard Drivers

Device drivers which are present on all supported board configurations are listed below.

- **Interrupt controller**: This device driver is used by the kernel’s interrupt management subsystem.
- **Timer**: This device driver is used by the kernel’s system clock and hardware clock subsystem.
- **Serial communication**: This device driver is used by the kernel’s system console subsystem.
- **Entropy**: This device driver provides a source of entropy numbers for the random number generator subsystem.

**Important**: Use the random API functions for random values. Entropy functions should not be directly used as a random number generator source as some hardware implementations are designed to be an entropy seed source for random number generators and will not provide cryptographically secure random number streams.

3.2.3 Synchronous Calls

Zephyr provides a set of device drivers for multiple boards. Each driver should support an interrupt-based implementation, rather than polling, unless the specific hardware does not provide any interrupt.
High-level calls accessed through device-specific APIs, such as i2c.h or spi.h, are usually intended as synchronous. Thus, these calls should be blocking.

### 3.2.4 Driver APIs

The following APIs for device drivers are provided by device.h. The APIs are intended for use in device drivers only and should not be used in applications.

- **DEVICE_DEFINE()**: Create device object and related data structures including setting it up for boot-time initialization.
- **DEVICE_NAME_GET()**: Converts a device identifier to the global identifier for a device object.
- **DEVICE_GET()**: Obtain a pointer to a device object by name.
- **DEVICE_DECLARE()**: Declare a device object. Use this when you need a forward reference to a device that has not yet been defined.

### 3.2.5 Driver Data Structures

The device initialization macros populate some data structures at build time which are split into read-only and runtime-mutable parts. At a high level we have:

```c
struct device {
    const char *name;
    const void *config;
    const void *api;
    void *const data;
};
```

The `config` member is for read-only configuration data set at build time. For example, base memory mapped IO addresses, IRQ line numbers, or other fixed physical characteristics of the device. This is the `config` pointer passed to `DEVICE_DEFINE()` and related macros.

The `data` struct is kept in RAM, and is used by the driver for per-instance runtime housekeeping. For example, it may contain reference counts, semaphores, scratch buffers, etc.

The `api` struct maps generic subsystem APIs to the device-specific implementations in the driver. It is typically read-only and populated at build time. The next section describes this in more detail.

### 3.2.6 Subsystems and API Structures

Most drivers will be implementing a device-independent subsystem API. Applications can simply program to that generic API, and application code is not specific to any particular driver implementation.

A subsystem API definition typically looks like this:

```c
typedef int (*subsystem_do_this_t)(const struct device *dev, int foo, int bar);
typedef void (*subsystem_do_that_t)(const struct device *dev, void *baz);

struct subsystem_api {
    subsystem_do_this_t do_this;
    subsystem_do_that_t do_that;
};
```

(continues on next page)
static inline int subsystem_do_this(const struct device *dev, int foo, int bar)
{
    struct subsystem_api *api;
    api = (struct subsystem_api *)dev->api;
    return api->do_this(dev, foo, bar);
}

static inline void subsystem_do_that(const struct device *dev, void *baz)
{
    struct subsystem_api *api;
    api = (struct subsystem_api *)dev->api;
    api->do_that(dev, baz);
}

A driver implementing a particular subsystem will define the real implementation of these APIs, and populate an instance of subsystem_api structure:

static int my_driver_do_this(const struct device *dev, int foo, int bar)
{
    ...
}

static void my_driver_do_that(const struct device *dev, void *baz)
{
    ...
}

static struct subsystem_api my_driver_api_funcs = {
    .do_this = my_driver_do_this,
    .do_that = my_driver_do_that
};

The driver would then pass my_driver_api_funcs as the api argument to DEVICE_DEFINE().

Note: Since pointers to the API functions are referenced in the api struct, they will always be included in the binary even if unused; gc-sections linker option will always see at least one reference to them. Providing for link-time size optimizations with driver APIs in most cases requires that the optional feature be controlled by a Kconfig option.

3.2.7 Device-Specific API Extensions

Some devices can be cast as an instance of a driver subsystem such as GPIO, but provide additional functionality that cannot be exposed through the standard API. These devices combine subsystem operations with device-specific APIs, described in a device-specific header.

A device-specific API definition typically looks like this:

#include <zephyr/drivers/subsystem.h>

/* When extensions need not be invoked from user mode threads */
int specific_do_that(const struct device *dev, int foo);

/* When extensions must be invokable from user mode threads */

(continues on next page)
A driver implementing extensions to the subsystem will define the real implementation of both the subsystem API and the specific APIs:

```c
static int generic_do_this(const struct device *dev, void *arg)
{
  ...
}

static struct generic_api api {
  ...
  .do_this = generic_do_this,
  ...
};

/* supervisor-only API is globally visible */
int specific_do_that(const struct device *dev, int foo)
{
  ...
}

/* syscall API passes through a translation */
int z_impl_specific_from_user(const struct device *dev, int bar)
{
  ...
}

#ifdef CONFIG_USERSPACE
  #include <zephyr/syscall_handler.h>

  int z_vrfy_specific_from_user(const struct device *dev, int bar)
  {
    Z_OOPS(Z_SYSCALL_SPECIFIC_DRIVER(dev, K_OBJ_DRIVER_GENERIC, &api));
    return z_impl_specific_do_that(dev, bar)
  }
  #include <syscalls/specific_from_user_mrsh.c>
#endif /* CONFIG_USERSPACE */
```

Applications use the device through both the subsystem and specific APIs.

**Note:** Public API for device-specific extensions should be prefixed with the compatible for the device to which it applies. For example, if adding special functions to support the Maxim DS3231 the identifier fragment `specific` in the examples above would be `maxim_ds3231`.

### 3.2.8 Single Driver, Multiple Instances

Some drivers may be instantiated multiple times in a given system. For example there can be multiple GPIO banks, or multiple UARTs. Each instance of the driver will have a different `config` struct and data
struct.

Configuring interrupts for multiple drivers instances is a special case. If each instance needs to configure a different interrupt line, this can be accomplished through the use of per-instance configuration functions, since the parameters to IRQ_CONNECT() need to be resolvable at build time.

For example, let's say we need to configure two instances of my_driver, each with a different interrupt line. In drivers/subsystem/subsystem_my_driver.h:

```c
typedef void (*my_driver_config_irq_t)(const struct device *dev);

struct my_driver_config {
    DEVICE_MMIO_ROM;
    my_driver_config_irq_t config_func;
};
```

In the implementation of the common init function:

```c
void my_driver_isr(const struct device *dev)
{
    /* Handle interrupt */
    ...
}

int my_driver_init(const struct device *dev)
{
    const struct my_driver_config *config = dev->config;
    DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);
    /* Do other initialization stuff */
    ...
    config->config_func(dev);
    return 0;
}
```

Then when the particular instance is declared:

```c
#if CONFIG_MY DRIVER_0
DEVICE_DECLARE(my_driver_0);

static void my_driver_config_irq_0(void)
{
    IRQ_CONNECT(MY_DRIVER_0_IRQ, MY_DRIVER_0_PRI, my_driver_isr,
                DEVICE_GET(my_driver_0), MY_DRIVER_0_FLAGS);
}

const static struct my_driver_config my_driver_config_0 = {
    DEVICE_MMIO_ROM_INIT(DT_DRV_INST(0)),
    .config_func = my_driver_config_irq_0
}

static struct my_data_0;

DEVICE_DEFINE(my_driver_0, MY_DRIVER_0_NAME, my_driver_init,
              NULL, &my_data_0, &my_driver_config_0,
```
Note the use of `DEVICE_DECLARE()` to avoid a circular dependency on providing the IRQ handler argument and the definition of the device itself.

### 3.2.9 Initialization Levels

Drivers may depend on other drivers being initialized first, or require the use of kernel services. `DEVICE_DEFINE()` and related APIs allow the user to specify at what time during the boot sequence the init function will be executed. Any driver will specify one of four initialization levels:

**EARLY**

Used very early in the boot process, right after entering the C domain (`z_cstart()`). This can be used in architectures and SoCs that extend or implement architecture code and use drivers or system services that have to be initialized before the Kernel calls any architecture specific initialization code.

**PRE_KERNEL_1**

Used for devices that have no dependencies, such as those that rely solely on hardware present in the processor/SOC. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. The interrupt subsystem will be configured however so it’s OK to set up interrupts. Init functions at this level run on the interrupt stack.

**PRE_KERNEL_2**

Used for devices that rely on the initialization of devices initialized as part of the **PRE_KERNEL_1 level**. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. Init functions at this level run on the interrupt stack.

**POST_KERNEL**

Used for devices that require kernel services during configuration. Init functions at this level run in context of the kernel main task.

**APPLICATION**

Used for application components (i.e. non-kernel components) that need automatic configuration. These devices can use all services provided by the kernel during configuration. Init functions at this level run on the kernel main task.

Within each initialization level you may specify a priority level, relative to other devices in the same initialization level. The priority level is specified as an integer value in the range 0 to 99; lower values indicate earlier initialization. The priority level must be a decimal integer literal without leading zeroes or sign (e.g. 32), or an equivalent symbolic name (e.g. `#define MY_INIT_PRIO 32`); symbolic expressions are not permitted (e.g. `CONFIG_KERNEL_INIT_PRIORITY_DEFAULT + 5`).

Drivers and other system utilities can determine whether startup is still in pre-kernel states by using the `k_is_pre_kernel()` function.

### 3.2.10 System Drivers

In some cases you may just need to run a function at boot. For such cases, the `SYS_INIT` can be used. This macro does not take any config or runtime data structures and there isn’t a way to later get a device pointer by name. The same device policies for initialization level and priority apply.
3.2.11 Error handling

In general, it’s best to use `__ASSERT()` macros instead of propagating return values unless the failure is expected to occur during the normal course of operation (such as a storage device full). Bad parameters, programming errors, consistency checks, pathological/unrecoverable failures, etc., should be handled by assertions.

When it is appropriate to return error conditions for the caller to check, 0 should be returned on success and a POSIX `errno.h` code returned on failure. See https://github.com/zephyrproject-rtos/zephyr/wiki/Naming-Conventions#return-codes for details about this.

3.2.12 Memory Mapping

On some systems, the linear address of peripheral memory-mapped I/O (MMIO) regions cannot be known at build time:

- The I/O ranges must be probed at runtime from the bus, such as with PCI express
- A memory management unit (MMU) is active, and the physical address of the MMIO range must be mapped into the page tables at some virtual memory location determined by the kernel.

These systems must maintain storage for the MMIO range within RAM and establish the mapping within the driver’s init function. Other systems do not care about this and can use MMIO physical addresses directly from DTS and do not need any RAM-based storage for it.

For drivers that may need to deal with this situation, a set of APIs under the DEVICE_MMIO scope are defined, along with a mapping function `device_map()`.

Device Model Drivers with one MMIO region

The simplest case is for drivers which need to maintain one MMIO region. These drivers will need to use the `DEVICE_MMIO_ROM` and `DEVICE_MMIO_RAM` macros in the definitions for their `config_info` and `driver_data` structures, with initialization of the `config_info` from DTS using `DEVICE_MMIO_ROM_INIT`.

A call to `DEVICE_MMIO_MAP()` is made within the init function:

```c
#include <device.h>

struct my_driver_config {
    DEVICE_MMIO_ROM; /* Must be first */
    ...
};

struct my_driver_dev_data {
    DEVICE_MMIO_RAM; /* Must be first */
    ...
};

const static struct my_driver_config my_driver_config_0 = {
    DEVICE_MMIO_ROM_INIT(DT_DRV_INST(...)),
    ...
};

int my_driver_init(const struct device *dev)
{
    ...
    DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);
    ...
}

int my_driver_some_function(const struct device *dev)
{
    ...
}
```

(continues on next page)
The particular expansion of these macros depends on configuration. On a device with no MMU or PCI-e, DEVICE_MMIO_MAP and DEVICE_MMIO_RAM expand to nothing.

Device Model Drivers with multiple MMIO regions

Some drivers may have multiple MMIO regions. In addition, some drivers may already be implementing a form of inheritance which requires some other data to be placed first in the config_info and driver_data structures.

This can be managed with the DEVICE_MMIO_NAMED variant macros. These require that DEV_CFG() and DEV_DATA() macros be defined to obtain a properly typed pointer to the driver's config_info or dev_data structs. For example:

```c
struct my_driver_config {
    ...
    DEVICE_MMIO_NAMED_ROM(corge);
    DEVICE_MMIO_NAMED_ROM(grault);
    ...
}

struct my_driver_dev_data {
    ...
    DEVICE_MMIO_NAMED_RAM(corge);
    DEVICE_MMIO_NAMED_RAM(grault);
    ...
}

#define DEV_CFG(_dev) \ 
    ((const struct my_driver_config *)((_dev)->config))

#define DEV_DATA(_dev) \ 
    ((struct my_driver_dev_data *)((_dev)->data))

const static struct my_driver_config my_driver_config_0 = {
    ...
    DEVICE_MMIO_NAMED_ROM_INIT(corge, DT_DRV_INST(...)),
    DEVICE_MMIO_NAMED_ROM_INIT(grault, DT_DRV_INST(...)),
    ...
}

int my_driver_init(const struct device *dev)
{
    ...
    DEVICE_MMIO_NAMED_MAP(dev, corge, K_MEM_CACHE_NONE);
    DEVICE_MMIO_NAMED_MAP(dev, grault, K_MEM_CACHE_NONE);
    ...
}

int my_driver_some_function(const struct device *dev)
```
Device Model Drivers with multiple MMIO regions in the same DT node

Some drivers may have multiple MMIO regions defined into the same DT device node using the `reg-names` property to differentiate them, for example:

```
/dts-v1/;
/
{
    a-driver@40000000 {
        reg = <0x40000000 0x1000>,
              <0x40001000 0x1000>;
        reg-names = "corge", "grault";
    }
};
```

This can be managed as seen in the previous section but this time using the `DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME` macro instead. So the only difference would be in the driver config struct:

```
const static struct my_driver_config my_driver_config_0 = {
    ...
    DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(corge, DT_DRV_INST(...)),
    DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(grault, DT_DRV_INST(...)),
    ...
}
```

Drivers that do not use Zephyr Device Model

Some drivers or driver-like code may not use Zephyr’s device model, and alternative storage must be arranged for the MMIO data. An example of this are timer drivers, or interrupt controller code. This can be managed with the `DEVICE_MMIO_TOLEVEL` set of macros, for example:

```
DEVICE_MMIO_TOLEVEL_STATIC(my_regs, DT_DRV_INST(...));

void some_init_code(...) {
    ...
    DEVICE_MMIO_TOLEVEL_MAP(my_regs, K_MEM_CACHE_NONE);
    ...
}

void some_function(...) {
    ...
    sys_write32(DEVICE_MMIO_TOLEVEL_GET(my_regs), 0xDEADBEEF);
    ...
}
```
Drivers that do not use DTS

Some drivers may not obtain the MMIO physical address from DTS, such as is the case with PCI-E. In this case the `device_map()` function may be used directly:

```c
void some_init_code(...) {
    ...
    struct pcie_bar mbar;
    bool bar_found = pcie_get_mbar(bdf, index, &mbar);
    device_map(DEVICE_MMIO_RAM_PTR(dev), mbar.phys_addr, mbar.size, K_MEM_CACHE_NONE);
    ...
}
```

For these cases, `DEVICE_MMIO_ROM` directives may be omitted.

### 3.2.13 API Reference

**group device_model**

Device Model.

**Defines**

**DEVICE_HANDLE_SEP**

Flag value used in lists of device handles to separate distinct groups.

This is the minimum value for the `device_handle_t` type.

**DEVICE_HANDLE_ENDS**

Flag value used in lists of device handles to indicate the end of the list.

This is the maximum value for the `device_handle_t` type.

**DEVICE_HANDLE_NULL**

Flag value used to identify an unknown device.

**DEVICE_NAME_GET(dev_id)**

Expands to the name of a global device object.

Return the full name of a device object symbol created by `DEVICE_DEFINE()`, using the `dev_id` provided to `DEVICE_DEFINE()`. This is the name of the global variable storing the device structure, not a pointer to the string in the `device::name` field.

It is meant to be used for declaring extern symbols pointing to device objects before using the `DEVICE_GET` macro to get the device object.

This macro is normally only useful within device driver source code. In other situations, you are probably looking for `device_get_binding()`.

**Parameters**

- `dev_id` – Device identifier.

**Returns**

The full name of the device object defined by device definition macros.
DEVICE_DEFINE(dev_id, name, init_fn, pm, data, config, level, prio, api)

Create a device object and set it up for boot time initialization.

This macro defines a `device` that is automatically configured by the kernel during system initialization. This macro should only be used when the device is not being allocated from a devicetree node. If you are allocating a device from a devicetree node, use `DEVICE_DT_DEFINE()` or `DEVICE_DT_INST_DEFINE()` instead.

**Parameters**

- **dev_id** – A unique token which is used in the name of the global device structure as a C identifier.
- **name** – A string name for the device, which will be stored in `device::name`. This name can be used to look up the device with `device_get_binding()`. This must be less than `Z_DEVICE_MAX_NAME_LEN` characters (including terminating NULL) in order to be looked up from user mode.
- **init_fn** – Pointer to the device's initialization function, which will be run by the kernel during system initialization.
- **pm** – Pointer to the device's power management resources, a `pm_device`, which will be stored in `device::pm` field. Use NULL if the device does not use PM.
- **data** – Pointer to the device's private mutable data, which will be stored in `device::data`.
- **config** – Pointer to the device's private constant data, which will be stored in `device::config`.
- **level** – The device's initialization level. See System Initialization for details.
- **prio** – The device's priority within its initialization level. See SYS_INIT() for details.
- **api** – Pointer to the device's API structure. Can be NULL.

DEVICE_DT_NAME(node_id)

Return a string name for a devicetree node.

This macro returns a string literal usable as a device's name from a devicetree node identifier.

**Parameters**

- **node_id** – The devicetree node identifier.

**Returns**

The value of the node's `label` property, if it has one. Otherwise, the node's full name in `node-name@unit-address` form.

DEVICE_DT_DEFINE(node_id, init_fn, pm, data, config, level, prio, api, ...)

Create a device object from a devicetree node identifier and set it up for boot time initialization.

This macro defines a `device` that is automatically configured by the kernel during system initialization. The global device object's name as a C identifier is derived from the node's dependency ordinal. `device::name` is set to `DEVICE_DT_NAME(node_id)`.

The device is declared with extern visibility, so a pointer to a global device object can be obtained with `DEVICE_DT_GET(node_id)` from any source file that includes `<zephyr/device.h>`. Before using the pointer, the referenced object should be checked using `device_is_ready()`.

**Parameters**

- **node_id** – The devicetree node identifier.
- **init_fn** – Pointer to the device's initialization function, which will be run by the kernel during system initialization.
• pm – Pointer to the device's power management resources, a pm_device, which will be stored in device::pm. Use NULL if the device does not use PM.

• data – Pointer to the device's private mutable data, which will be stored in device::data.

• config – Pointer to the device's private constant data, which will be stored in device::config field.

• level – The device's initialization level. See SYS_INIT() for details.

• prio – The device's priority within its initialization level. See SYS_INIT() for details.

• api – Pointer to the device's API structure. Can be NULL.

DEVICE_DT_INST_DEFINE(inst, ...
)

Like DEVICE_DT_DEFINE(), but uses an instance of a DT_DRV_COMPAT compatible instead of a node identifier.

Parameters

• inst – Instance number. The node_id argument to DEVICE_DT_DEFINE() is set to DT_DRV_INST(inst).

• ... – Other parameters as expected by DEVICE_DT_DEFINE().

DEVICE_DT_NAME_GET(node_id)

The name of the global device object for node_id.

Returns the name of the global device structure as a C identifier. The device must be allocated using DEVICE_DT_DEFINE() or DEVICE_DT_INST_DEFINE() for this to work.

This macro is normally only useful within device driver source code. In other situations, you are probably looking for DEVICE_DT_GET().

Parameters

• node_id – Devicetree node identifier

Returns

The name of the device object as a C identifier

DEVICE_DT_GET(node_id)

Get a device reference from a devicetree node identifier.

Returns a pointer to a device object created from a devicetree node, if any device was allocated by a driver.

If no such device was allocated, this will fail at linker time. If you get an error that looks like undefined reference to __device_dts_ord_<N>, that is what happened. Check to make sure your device driver is being compiled, usually by enabling the Kconfig options it requires.

Parameters

• node_id – A devicetree node identifier

Returns

A pointer to the device object created for that node

DEVICE_DT_INST_GET(inst)

Get a device reference for an instance of a DT_DRV_COMPAT compatible.

This is equivalent to DEVICE_DT_GET(DT_DRV_INST(inst)).

Parameters

• inst – DT_DRV_COMPAT instance number
Returns
A pointer to the device object created for that instance

DEVICE_DT_GET_ANY(compat)
Get a device reference from a devicetree compatible.
If an enabled devicetree node has the given compatible and a device object was created from it, this returns a pointer to that device.
If there no such devices, this returns NULL.
If there are multiple, this returns an arbitrary one.
If this returns non-NULL, the device must be checked for readiness before use, e.g. with device_is_ready().

Parameters
• compat – lowercase-and-underscores devicetree compatible

Returns
a pointer to a device, or NULL

DEVICE_DT_GET_ONE(compat)
Get a device reference from a devicetree compatible.
If an enabled devicetree node has the given compatible and a device object was created from it, this returns a pointer to that device.
If there no such devices, this will fail at compile time.
If there are multiple, this returns an arbitrary one.
If this returns non-NULL, the device must be checked for readiness before use, e.g. with device_is_ready().

Parameters
• compat – lowercase-and-underscores devicetree compatible

Returns
a pointer to a device

DEVICE_DT_GET_OR_NULL(node_id)
Utility macro to obtain an optional reference to a device.
If the node identifier refers to a node with status okay, this returns DEVICE_DT_GET(node_id).
Otherwise, it returns NULL.

Parameters
• node_id – devicetree node identifier

Returns
a device reference for the node identifier, which may be NULL.

DEVICE_GET(dev_id)
Obtain a pointer to a device object by name.
Return the address of a device object created by DEVICE_DEFINE(), using the dev_id provided to DEVICE_DEFINE().

Parameters
• dev_id – Device identifier.

Returns
A pointer to the device object created by DEVICE_DEFINE()
DEVICE_DECLARE(dev_id)
Declare a static device object.

This macro can be used at the top-level to declare a device, such that DEVICE_GET() may be used before the full declaration in DEVICE_DEFINE().

This is often useful when configuring interrupts statically in a device's init or per-instance config function, as the init function itself is required by DEVICE_DEFINE() and use of DEVICE_GET() inside it creates a circular dependency.

Parameters
- dev_id – Device identifier.

DEVICE_INIT_DT_GET(node_id)
Get a init_entry reference from a devicetree node.

Parameters
- node_id – A devicetree node identifier

Returns
A pointer to the init_entry object created for that node

DEVICE_INIT_GET(dev_id)
Get a init_entry reference from a device identifier.

Parameters
- dev_id – Device identifier.

Returns
A pointer to the init_entry object created for that device

Typedefs

typedef int16_t device_handle_t
Type used to represent a “handle” for a device.

Every device has an associated handle. You can get a pointer to a device from its handle and vice versa, but the handle uses less space than a pointer. The device.h API mainly uses handles to store lists of multiple devices in a compact way.

The extreme values and zero have special significance. Negative values identify functionality that does not correspond to a Zephyr device, such as the system clock or a SYS_INIT() function.

See also:
device_handle_get()

See also:
device_from_handle()

typedef int (*device_visitor_callback_t)(const struct device *dev, void *context)
Prototype for functions used when iterating over a set of devices.

Such a function may be used in API that identifies a set of devices and provides a visitor API supporting caller-specific interaction with each device in the set.

The visit is said to succeed if the visitor returns a non-negative value.
See also:

device_required_foreach()

See also:

device_supported_foreach()

Param dev

a device in the set being iterated

Param context

state used to support the visitor function

Return

A non-negative number to allow walking to continue, and a negative error code to case the iteration to stop.

Functions

static inline device_handle_t device_handle_get(const struct device *dev)

Get the handle for a given device.

Parameters

• dev – the device for which a handle is desired.

Returns

the handle for the device, or DEVICE_HANDLE_NULL if the device does not have an associated handle.

static inline const struct device *device_from_handle(device_handle_t dev_handle)

Get the device corresponding to a handle.

Parameters

• dev_handle – the device handle

Returns

the device that has that handle, or a null pointer if dev_handle does not identify a device.

static inline const device_handle_t *device_required_handles_get(const struct device *dev, size_t *count)

Get the device handles for devicetree dependencies of this device.

This function returns a pointer to an array of device handles. The length of the array is stored in the count parameter.

The array contains a handle for each device that dev requires directly, as determined from the devicetree. This does not include transitive dependencies; you must recursively determine those.

Parameters

• dev – the device for which dependencies are desired.

• count – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if the device has no devicetree dependencies.

Returns

a pointer to a sequence of count device handles, or a null pointer if dev does not have any dependency data.
static inline const device_handle_t *device_injected_handles_get(const struct device *dev, size_t *count)

Get the device handles for injected dependencies of this device.

This function returns a pointer to an array of device handles. The length of the array is stored in the count parameter.

The array contains a handle for each device that dev manually injected as a dependency, via providing extra arguments to ZDEVICE_DEFINE. This does not include transitive dependencies; you must recursively determine those.

Parameters

• dev – the device for which injected dependencies are desired.

• count – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if the device has no devicetree dependencies.

Returns

a pointer to a sequence of *count device handles, or a null pointer if dev does not have any dependency data.

static inline const device_handle_t *device_supported_handles_get(const struct device *dev, size_t *count)

Get the set of handles that this device supports.

This function returns a pointer to an array of device handles. The length of the array is stored in the count parameter.

The array contains a handle for each device that dev “supports” — that is, devices that require dev directly — as determined from the devicetree. This does not include transitive dependencies; you must recursively determine those.

Parameters

• dev – the device for which supports are desired.

• count – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if nothing in the devicetree depends on dev.

Returns

a pointer to a sequence of *count device handles, or a null pointer if dev does not have any dependency data.

int device_required_foreach(const struct device *dev, device_visitor_callback_t visitor_cb, void *context)

Visit every device that dev directly requires.

Zephyr maintains information about which devices are directly required by another device; for example an I2C-based sensor driver will require an I2C controller for communication. Required devices can derive from statically-defined devicetree relationships or dependencies registered at runtime.

This API supports operating on the set of required devices. Example uses include making sure required devices are ready before the requiring device is used, and releasing them when the requiring device is no longer needed.

There is no guarantee on the order in which required devices are visited.

If the visitor function returns a negative value iteration is halted, and the returned value from the visitor is returned from this function.

Note: This API is not available to unprivileged threads.
Parameters

- **dev** – a device of interest. The devices that this device depends on will be used as the set of devices to visit. This parameter must not be null.
- **visitor_cb** – the function that should be invoked on each device in the dependency set. This parameter must not be null.
- **context** – state that is passed through to the visitor function. This parameter may be null if visitor tolerates a null context.

Returns

The number of devices that were visited if all visits succeed, or the negative value returned from the first visit that did not succeed.

```c
int device_supported_foreach(const struct device *dev, device_visitor_callback_t visitor_cb, void *context)
```

Visit every device that dev directly supports.

Zephyr maintains information about which devices are directly supported by another device; for example an I2C controller will support an I2C-based sensor driver. Supported devices can derive from statically-defined devicetree relationships.

This API supports operating on the set of supported devices. Example uses include iterating over the devices connected to a regulator when it is powered on.

There is no guarantee on the order in which required devices are visited.

If the visitor function returns a negative value iteration is halted, and the returned value from the visitor is returned from this function.

**Note:** This API is not available to unprivileged threads.

Parameters

- **dev** – a device of interest. The devices that this device supports will be used as the set of devices to visit. This parameter must not be null.
- **visitor_cb** – the function that should be invoked on each device in the support set. This parameter must not be null.
- **context** – state that is passed through to the visitor function. This parameter may be null if visitor tolerates a null context.

Returns

The number of devices that were visited if all visits succeed, or the negative value returned from the first visit that did not succeed.

```c
const struct device *device_get_binding(const char *name)
```

Get a device reference from its device::name field.

This function iterates through the devices on the system. If a device with the given name field is found, and that device initialized successfully at boot time, this function returns a pointer to the device.

If no device has the given name, this function returns NULL.

This function also returns NULL when a device is found, but it failed to initialize successfully at boot time. (To troubleshoot this case, set a breakpoint on your device driver's initialization function.)

Parameters

- **name** – device name to search for. A null pointer, or a pointer to an empty string, will cause NULL to be returned.
Returns

pointer to device structure with the given name; NULL if the device is not found
or if the device with that name's initialization function failed.

bool device_is_ready(const struct device *dev)

Verify that a device is ready for use.

Indicates whether the provided device pointer is for a device known to be in a state where it
can be used with its standard API.

This can be used with device pointers captured from DEVICE_DT_GET(), which does not in-
clude the readiness checks of device_get_binding(). At minimum this means that the device
has been successfully initialized.

Parameters

• dev – pointer to the device in question.

Return values

• true – If the device is ready for use.
• false – If the device is not ready for use or if a NULL device pointer is passed
as argument.

struct device_state

#include <device.h> Runtime device dynamic structure (in RAM) per driver instance.

Fields in this are expected to be default-initialized to zero. The kernel driver infrastructure
and driver access functions are responsible for ensuring that any non-zero initialization is
done before they are accessed.

Public Members

uint8_t init_res

Device initialization return code (positive errno value).

Device initialization functions return a negative errno code if they fail. In Zephyr, errno
values do not exceed 255, so we can store the positive result value in a uint8_t type.

bool initialized

Indicates the device initialization function has been invoked.

struct device

#include <device.h> Runtime device structure (in ROM) per driver instance.

Public Members

const char *name

Name of the device instance

const void *config

Address of device instance config information

const void *api

Address of the API structure exposed by the device instance
struct device_state *state
   Address of the common device state

void *data
   Address of the device instance private data

const device_handle_t *handles
   Optional pointer to handles associated with the device.
   This encodes a sequence of sets of device handles that have some relationship to this node. The individual sets are extracted with dedicated API, such as device_required_handles_get().

struct pm_device *pm
   Reference to the device PM resources (only available if CONFIG_PM_DEVICE is enabled).

3.3 User Mode

Zephyr offers the capability to run threads at a reduced privilege level which we call user mode. The current implementation is designed for devices with MPU hardware.

For details on creating threads that run in user mode, please see Lifecycle.

3.3.1 Overview

Threat Model

User mode threads are considered to be untrusted by Zephyr and are therefore isolated from other user mode threads and from the kernel. A flawed or malicious user mode thread cannot leak or modify the private data/resources of another thread or the kernel, and cannot interfere with or control another user mode thread or the kernel.

Example use-cases of Zephyr’s user mode features:

- The kernel can protect against many unintentional programming errors which could otherwise silently or spectacularly corrupt the system.
- The kernel can sandbox complex data parsers such as interpreters, network protocols, and file systems such that malicious third-party code or data cannot compromise the kernel or other threads.
- The kernel can support the notion of multiple logical “applications”, each with their own group of threads and private data structures, which are isolated from each other if one crashes or is otherwise compromised.

Design Goals  For threads running in a non-privileged CPU state (hereafter referred to as ‘user mode’) we aim to protect against the following:

- We prevent access to memory not specifically granted, or incorrect access to memory that has an incompatible policy, such as attempting to write to a read-only area.
  - Access to thread stack buffers will be controlled with a policy which partially depends on the underlying memory protection hardware.
    * A user thread will by default have read/write access to its own stack buffer.
    * A user thread will never by default have access to user thread stacks that are not members of the same memory domain.
* A user thread will never by default have access to thread stacks owned by a supervisor thread, or thread stacks used to handle system call privilege elevations, interrupts, or CPU exceptions.

* A user thread may have read/write access to the stacks of other user threads in the same memory domain, depending on hardware.
  
  · On MPU systems, threads may only access their own stack buffer.
  
  · On MMU systems, threads may access any user thread stack in the same memory domain. Portable code should not assume this.

  − By default, program text and read-only data are accessible to all threads on read-only basis, kernel-wide. This policy may be adjusted.

  − User threads by default are not granted default access to any memory except what is noted above.

  · We prevent use of device drivers or kernel objects not specifically granted, with the permission granularity on a per object or per driver instance basis.

  · We validate kernel or driver API calls with incorrect parameters that would otherwise cause a crash or corruption of data structures private to the kernel. This includes:
    
    − Using the wrong kernel object type.

    − Using parameters outside of proper bounds or with nonsensical values.

    − Passing memory buffers that the calling thread does not have sufficient access to read or write, depending on the semantics of the API.

    − Use of kernel objects that are not in a proper initialization state.

  · We ensure the detection and safe handling of user mode stack overflows.

  · We prevent invoking system calls to functions excluded by the kernel configuration.

  · We prevent disabling of or tampering with kernel-defined and hardware-enforced memory protections.

  · We prevent re-entry from user to supervisor mode except through the kernel-defined system calls and interrupt handlers.

  · We prevent the introduction of new executable code by user mode threads, except to the extent to which this is supported by kernel system calls.

We are specifically not protecting against the following attacks:

  · The kernel itself, and any threads that are executing in supervisor mode, are assumed to be trusted.

  · The toolchain and any supplemental programs used by the build system are assumed to be trusted.

  · The kernel build is assumed to be trusted. There is considerable build-time logic for creating the tables of valid kernel objects, defining system calls, and configuring interrupts. The .elf binary files that are worked with during this process are all assumed to be trusted code.

  · We can’t protect against mistakes made in memory domain configuration done in kernel mode that exposes private kernel data structures to a user thread. RAM for kernel objects should always be configured as supervisor-only.

  · It is possible to make top-level declarations of user mode threads and assign them permissions to kernel objects. In general, all C and header files that are part of the kernel build producing zephyr.elf are assumed to be trusted.

  · We do not protect against denial of service attacks through thread CPU starvation. Zephyr has no thread priority aging and a user thread of a particular priority can starve all threads of lower priority, and also other threads of the same priority if time-slicing is not enabled.

  · There are build-time defined limits on how many threads can be active simultaneously, after which creation of new user threads will fail.
• Stack overflows for threads running in supervisor mode may be caught, but the integrity of the system cannot be guaranteed.

High-level Policy Details

Broadly speaking, we accomplish these thread-level memory protection goals through the following mechanisms:

• Any user thread will only have access to a subset of memory: typically its stack, program text, read-only data, and any partitions configured in the Memory Protection Design it belongs to. Access to any other RAM must be done on the thread’s behalf through system calls, or specifically granted by a supervisor thread using the memory domain APIs. Newly created threads inherit the memory domain configuration of the parent. Threads may communicate with each other by having shared membership of the same memory domains, or via kernel objects such as semaphores and pipes.

• User threads cannot directly access memory belonging to kernel objects. Although pointers to kernel objects are used to reference them, actual manipulation of kernel objects is done through system call interfaces. Device drivers and threads stacks are also considered kernel objects. This ensures that any data inside a kernel object that is private to the kernel cannot be tampered with.

• User threads by default have no permission to access any kernel object or driver other than their own thread object. Such access must be granted by another thread that is either in supervisor mode or has permission on both the receiving thread object and the kernel object being granted access to. The creation of new threads has an option to automatically inherit permissions of all kernel objects granted to the parent, except the parent thread itself.

• For performance and footprint reasons Zephyr normally does little or no parameter error checking for kernel object or device driver APIs. Access from user mode through system calls involves an extra layer of handler functions, which are expected to rigorously validate access permissions and type of the object, check the validity of other parameters through bounds checking or other means, and verify proper read/write access to any memory buffers involved.

• Thread stacks are defined in such a way that exceeding the specified stack space will generate a hardware fault. The way this is done specifically varies per architecture.

Constraints

All kernel objects, thread stacks, and device driver instances must be defined at build time if they are to be used from user mode. Dynamic use-cases for kernel objects will need to go through pre-defined pools of available objects.

There are some constraints if additional application binary data is loaded for execution after the kernel starts:

• Loaded object code will not be able to define any kernel objects that will be recognized by the kernel. This code will instead need to use APIs for requesting kernel objects from pools.

• Similarly, since the loaded object code will not be part of the kernel build process, this code will not be able to install interrupt handlers, instantiate device drivers, or define system calls, regardless of what mode it runs in.

• Loaded object code that does not come from a verified source should always be entered with the CPU already in user mode.

3.3.2 Memory Protection Design

Zephyr’s memory protection design is geared towards microcontrollers with MPU (Memory Protection Unit) hardware. We do support some architectures, such as x86, which have a paged MMU (Memory Management Unit), but in that case the MMU is used like an MPU with an identity page table.
All of the discussion below will be using MPU terminology; systems with MMUs can be considered to have an MPU with an unlimited number of programmable regions.

There are a few different levels on how memory access is configured when Zephyr memory protection features are enabled, which we will describe here:

**Boot Time Memory Configuration**

This is the configuration of the MPU after the kernel has started up. It should contain the following:

- Any configuration of memory regions which need to have special caching or write-back policies for basic hardware and driver function. Note that most MPUs have the concept of a default memory access policy map, which can be enabled as a “background” mapping for any area of memory that doesn’t have an MPU region configuring it. It is strongly recommended to use this to maximize the number of available MPU regions for the end user. On ARMv7-M/ARMv8-M this is called the System Address Map, other CPUs may have similar capabilities.

- A read-only, executable region or regions for program text and ro-data, that is accessible to user mode. This could be further sub-divided into a read-only region for ro-data, and a read-only, executable region for text, but this will require an additional MPU region. This is required so that threads running in user mode can read ro-data and fetch instructions.

- Depending on configuration, user-accessible read-write regions to support extra features like GCOV, HEP, etc.

Assuming there is a background map which allows supervisor mode to access any memory it needs, and regions are defined which grant user mode access to text/ro-data, this is sufficient for the boot time configuration.

**Hardware Stack Overflow**

CONFIG_HW_STACK_PROTECTION is an optional feature which detects stack buffer overflows when the system is running in supervisor mode. This catches issues when the entire stack buffer has overflowed, and not individual stack frames, use compiler-assisted CONFIG_STACK_CANARIES for that.

Like any crash in supervisor mode, no guarantees can be made about the overall health of the system after a supervisor mode stack overflow, and any instances of this should be treated as a serious error. However it’s still very useful to know when these overflows happen, as without robust detection logic the system will either crash in mysterious ways or behave in an undefined manner when the stack buffer overflows.

Some systems implement this feature by creating at runtime a ‘guard’ MPU region which is set to be read-only and is at either the beginning or immediately preceding the supervisor mode stack buffer. If the stack overflows an exception will be generated.

This feature is optional and is not required to catch stack overflows in user mode; disabling this may free 1-2 MPU regions depending on the MPU design.

Other systems may have dedicated CPU support for catching stack overflows and no extra MPU regions will be required.

**Thread Stack**

Any thread running in user mode will need access to its own stack buffer. On context switch into a user mode thread, a dedicated MPU region will be programmed with the bounds of the stack buffer. A thread exceeding its stack buffer will start pushing data onto memory it doesn’t have access to and a memory access violation exception will be generated.
Thread Resource Pools

A small subset of kernel APIs, invoked as system calls, require heap memory allocations. This memory is used only by the kernel and is not accessible directly by user mode. In order to use these system calls, invoking threads must assign themselves to a resource pool, which is a k_heap object. Memory is drawn from a thread's resource pool using `z_thread_malloc()` and freed with `k_free()`.

The APIs which use resource pools are as follows, with any alternatives noted for users who do not want heap allocations within their application:

- `k_stack_alloc_init()` sets up a k_stack with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare k_stacks that are automatically initialized at boot with `K_STACK_DEFINE()`, or to initialize the k_stack in supervisor mode with `k_stack_init()`.

- `k_pipe_alloc_init()` sets up a k_pipe object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare k_pipes that are automatically initialized at boot with `K_PIPE_DEFINE()`, or to initialize the k_pipe in supervisor mode with `k_pipe_init()`.

- `k_msgq_alloc_init()` sets up a k_msgq object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare a k_msgq that is automatically initialized at boot with `K_MSGQ_DEFINE()`, or to initialize the k_msgq in supervisor mode with `k_msgq_init()`.

- `k_poll()` when invoked from user mode, needs to make a kernel-side copy of the provided events array while waiting for an event. This copy is freed when `k_poll()` returns for any reason.

- `k_queue_alloc_prepend()` and `k_queue_alloc_append()` allocate a container structure to place the data in, since the internal bookkeeping information that defines the queue cannot be placed in the memory provided by the user.

- `k_object_alloc()` allows for entire kernel objects to be dynamically allocated at runtime and a usable pointer to them returned to the caller.

The relevant API is `k_thread_heap_assign()` which assigns a k_heap to draw these allocations from for the target thread.

If the system heap is enabled, then the system heap may be used with `k_thread_system_pool_assign()`, but it is preferable for different logical applications running on the system to have their own pools.

Memory Domains

The kernel ensures that any user thread will have access to its own stack buffer, plus program text and read-only data. The memory domain APIs are the way to grant access to additional blocks of memory to a user thread.

Conceptually, a memory domain is a collection of some number of memory partitions. The maximum number of memory partitions in a domain is limited by the number of available MPU regions. This is why it is important to minimize the number of boot-time MPU regions.

Memory domains are not intended to control access to memory from supervisor mode. In some cases this may be unavoidable; for example some architectures do not allow for the definition of regions which are read-only to user mode but read-write to supervisor mode. A great deal of care must be taken when working with such regions to not unintentionally cause the kernel to crash when accessing such a region. Any attempt to use memory domain APIs to control supervisor mode access is at best undefined behavior; supervisor mode access policy is only intended to be controlled by boot-time memory regions.

Memory domain APIs are only available to supervisor mode. The only control user mode has over memory domains is that any user thread's child threads will automatically become members of the parent's domain.
All threads are members of a memory domain, including supervisor threads (even though this has no implications on their memory access). There is a default domain `k_mem_domain_default` which will be assigned to threads if they have not been specifically assigned to a domain, or inherited a memory domain membership from their parent thread. The main thread starts as a member of the default domain.

**Memory Partitions** Each memory partition consists of a memory address, a size, and access attributes. It is intended that memory partitions are used to control access to system memory. Defining memory partitions are subject to the following constraints:

- The partition must represent a memory region that can be programmed by the underlying memory management hardware, and needs to conform to any underlying hardware constraints. For example, many MPU-based systems require that partitions be sized to some power of two, and aligned to their own size. For MMU-based systems, the partition must be aligned to a page and the size some multiple of the page size.

- Partitions within the same memory domain may not overlap each other. There is no notion of precedence among partitions within a memory domain. Partitions within a memory domain are assumed to have a higher precedence than any boot-time memory regions, however whether a memory domain partition can overlap a boot-time memory region is architecture specific.

- The same partition may be specified in multiple memory domains. For example there may be a shared memory area that multiple domains grant access to.

- Care must be taken in determining what memory to expose in a partition. It is not appropriate to provide direct user mode access to any memory containing private kernel data.

- Memory domain partitions are intended to control access to system RAM. Configuration of memory partitions which do not correspond to RAM may not be supported by the architecture; this is true for MMU-based systems.

There are two ways to define memory partitions: either manually or automatically.

**Manual Memory Partitions** The following code declares a global array `buf`, and then declares a read-write partition for it which may be added to a domain:

```c
uint8_t __aligned(32) buf[32];
K_MEM_PARTITION_DEFINE(my_partition, buf, sizeof(buf), K_MEM_PARTITION_P_RW_U_RW);
```

This does not scale particularly well when we are trying to contain multiple objects spread out across several C files into a single partition.

**Automatic Memory Partitions** Automatic memory partitions are created by the build system. All globals which need to be placed inside a partition are tagged with their destination partition. The build system will then coalesce all of these into a single contiguous block of memory, zero any BSS variables at boot, and define a memory partition of appropriate base address and size which contains all the tagged data.

Automatic memory partitions are only configured as read-write regions. They are defined with `K_APPMEM_PARTITION_DEFINE()`. Global variables are then routed to this partition using `K_APP_DMEM()` for initialized data and `K_APP_BMEM()` for BSS.

```c
#include <zephyr/app_memory/app_memdomain.h>

/* Declare a k_mem_partition "my_partition" that is read-write to * user mode. Note that we do not specify a base address or size. */
K_APPMEM_PARTITION_DEFINE(my_partition);
```

(continues on next page)
/* The global variable var1 will be inside the bounds of my_partition * and be initialized with 37 at boot. */

K_APP_DMEM(my_partition) int var1 = 37;

/* The global variable var2 will be inside the bounds of my_partition * and be zeroed at boot size K_APP_BMEM() was used, indicating a BSS * variable. */

K_APP_BMEM(my_partition) int var2;

The build system will ensure that the base address of my_partition will be properly aligned, and the total size of the region conforms to the memory management hardware requirements, adding padding if necessary.

If multiple partitions are being created, a variadic preprocessor macro can be used as provided in app_macro_support.h:

FOR_EACH(K_APPMEM_PARTITION_DEFINE, part0, part1, part2);

**Automatic Partitions for Static Library Globals** The build-time logic for setting up automatic memory partitions is in scripts/build/gen_app_partitions.py. If a static library is linked into Zephyr, it is possible to route all the globals in that library to a specific memory partition with the --library argument.

For example, if the Newlib C library is enabled, the Newlib globals all need to be placed in z_libc_partition. The invocation of the script in the top-level CMakeLists.txt adds the following:

```bash
gen_app_partitions.py ... --library libc.a z_libc_partition...
```

For pre-compiled libraries there is no support for expressing this in the project-level configuration or build files; the toplevel CMakeLists.txt must be edited.

For Zephyr libraries created using zephyr_library or zephyr_library_named the zephyr_library_app_memory function can be used to specify the memory partition where all
globals in the library should be placed.

Pre-defined Memory Partitions  There are a few memory partitions which are pre-defined by the system:

- **z_malloc_partition** - This partition contains the system-wide pool of memory used by libc malloc(). Due to possible starvation issues, it is not recommended to draw heap memory from a global pool, instead it is better to define various sys_heap objects and assign them to specific memory domains.

- **z_libc_partition** - Contains globals required by the C library and runtime. Required when using either the Minimal C library or the Newlib C Library. Required when CONFIG_STACK_CANARIES is enabled.

Library-specific partitions are listed in include/app_memory/partitions.h. For example, to use theMBEDTLS library from user mode, the k_mbedtls_partition must be added to the domain.

Memory Domain Usage

Create a Memory Domain  A memory domain is defined using a variable of type k_mem_domain. It must then be initialized by calling k_mem_domain_init().

The following code defines and initializes an empty memory domain.

```c
struct k_mem_domain app0_domain;

k_mem_domain_init(&app0_domain, 0, NULL);
```

Add Memory Partitions into a Memory Domain  There are two ways to add memory partitions into a memory domain.

This first code sample shows how to add memory partitions while creating a memory domain.

```c
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                         K_MEM_PARTITION_P_RW_U_RW);
K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                         K_MEM_PARTITION_P_RW_U_RO);

struct k_mem_partition *app0_parts[] = {
    app0_part0,
    app0_part1
};

k_mem_domain_init(&app0_domain, ARRAY_SIZE(app0_parts), app0_parts);
```

This second code sample shows how to add memory partitions into an initialized memory domain one by one.

```c
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];
```

(continues on next page)
K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
    K_MEM_PARTITION_P_RW_U_RW);
K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
    K_MEM_PARTITION_P_RW_U_RO);

k_mem_domain_add_partition(&app0_domain, &app0_part0);
k_mem_domain_add_partition(&app0_domain, &app0_part1);

Note: The maximum number of memory partitions is limited by the maximum number of MPU regions
or the maximum number of MMU tables.

Memory Domain Assignment Any thread may join a memory domain, and any memory domain may
have multiple threads assigned to it. Threads are assigned to memory domains with an API call:
k_mem_domain_add_thread(&app0_domain, app_thread_id);

If the thread was already a member of some other domain (including the default domain), it will be
removed from it in favor of the new one.
In addition, if a thread is a member of a memory domain, and it creates a child thread, that thread will
belong to the domain as well.

Remove a Memory Partition from a Memory Domain The following code shows how to remove a
memory partition from a memory domain.
k_mem_domain_remove_partition(&app0_domain, &app0_part1);

The k_mem_domain_remove_partition() API finds the memory partition that matches the given param-
er and removes that partition from the memory domain.

Available Partition Attributes When defining a partition, we need to set access permission attributes
to the partition. Since the access control of memory partitions relies on either an MPU or MMU, the
available partition attributes would be architecture dependent.
The complete list of available partition attributes for a specific architecture is found in the architecture-
specific include file include/arch/<arch name>/arch.h, (for example, include/arch/arm/aarch32/
arch.h.) Some examples of partition attributes are:

/* Denote partition is privileged read/write, unprivileged read/write */
K_MEM_PARTITION_P_RW_U_RW
/* Denote partition is privileged read/write, unprivileged read-only */
K_MEM_PARTITION_P_RW_U_RO

In almost all cases K_MEM_PARTITION_P_RW_U_RW is the right choice.

Configuration Options

Related configuration options:

- CONFIG_MAX_DOMAIN_PARTITIONS
API Reference

The following memory domain APIs are provided by include/zephyr/kernel.h:

**group mem_domain_apis**

**Defines**

```c
K_MEM_PARTITION_DEFINE(name, start, size, attr)
```

Statically declare a memory partition.

**Functions**

```c
int k_mem_domain_init(struct k_mem_domain *domain, uint8_t num_parts, struct k_mem_partition *parts[])
```

Initialize a memory domain.

Initialize a memory domain with given name and memory partitions.

See documentation for `k_mem_domain_add_partition()` for details about partition constraints.

Do not call `k_mem_domain_init()` on the same memory domain more than once, doing so is undefined behavior.

**Parameters**

- `domain` – The memory domain to be initialized.
- `num_parts` – The number of array items of “parts” parameter.
- `parts` – An array of pointers to the memory partitions. Can be NULL if `num_parts` is zero.

**Return values**

- 0 – if successful
- -EINVAL – if invalid parameters supplied
- -ENOMEM – if insufficient memory

```c
int k_mem_domain_add_partition(struct k_mem_domain *domain, struct k_mem_partition *part)
```

Add a memory partition into a memory domain.

Add a memory partition into a memory domain. Partitions must conform to the following constraints:

- Partitions in the same memory domain may not overlap each other.
- Partitions must not be defined which expose private kernel data structures or kernel objects.
- The starting address alignment, and the partition size must conform to the constraints of the underlying memory management hardware, which varies per architecture.
- Memory domain partitions are only intended to control access to memory from user mode threads.
- If CONFIG_EXECUTE_XOR_WRITE is enabled, the partition must not allow both writes and execution.

Violating these constraints may lead to CPU exceptions or undefined behavior.
Parameters

- domain – The memory domain to be added a memory partition.
- part – The memory partition to be added

Return values

- 0 – if successful
- EINVAL – if invalid parameters supplied
- ENOSPC – if no free partition slots available

int k_mem_domain_remove_partition(struct k_mem_domain *domain, struct k_mem_partition *part)

Remove a memory partition from a memory domain.

Parameters

- domain – The memory domain to be removed a memory partition.
- part – The memory partition to be removed

Return values

- 0 – if successful
- EINVAL – if invalid parameters supplied
- ENOENT – if no matching partition found

int k_mem_domain_add_thread(struct k_mem_domain *domain, k_tid_t thread)

Add a thread into a memory domain.

Parameters

- domain – The memory domain that the thread is going to be added into.
- thread – ID of thread going to be added into the memory domain.

Returns

0 if successful, fails otherwise.

Variables

struct k_mem_domain k_mem_domain_default

Default memory domain

All threads are a member of some memory domain, even if running in supervisor mode. Threads belong to this default memory domain if they haven't been added to or inherited membership from some other domain.

This memory domain has the z_libc_partition partition for the C library added to it if exists.

struct k_mem_partition

#include <mem_domain.h> Memory Partition.

A memory partition is a region of memory in the linear address space with a specific access policy.
The alignment of the starting address, and the alignment of the size value may have varying requirements based on the capabilities of the underlying memory management hardware; arbitrary values are unlikely to work.

Public Members

```c
uintptr_t start
    start address of memory partition
size_t size
    size of memory partition
k_mem_partition_attr_t attr
    attribute of memory partition
```

```c
struct k_mem_domain
    #include <mem_domain.h> Memory Domain.
A memory domain is a collection of memory partitions, used to represent a user thread's access policy for the linear address space. A thread may be a member of only one memory domain, but any memory domain may have multiple threads that are members.
Supervisor threads may also be a member of a memory domain; this has no implications on their memory access but can be useful as any child threads inherit the memory domain membership of the parent.
A user thread belonging to a memory domain with no active partitions will have guaranteed access to its own stack buffer, program text, and read-only data.

Public Members

```c
struct k_mem_partition partitions[CONFIG_MAX_DOMAIN_PARTITIONS]
    partitions in the domain
sys_dlist_t mem_domain_q
    Doubly linked list of member threads
uint8_t num_partitions
    number of active partitions in the domain
```

3.3.3 Kernel Objects

A kernel object can be one of three classes of data:

- A core kernel object, such as a semaphore, thread, pipe, etc.
- A thread stack, which is an array of `z_thread_stack_element` and declared with `K_THREAD_STACK_DEFINE()`
- A device driver instance (const struct device) that belongs to one of a defined set of subsystems
The set of known kernel objects and driver subsystems is defined in include/kernel.h as `k_objects`.

Kernel objects are completely opaque to user threads. User threads work with addresses to kernel objects when making API calls, but may never dereference these addresses, doing so will cause a memory protection fault. All kernel objects must be placed in memory that is not accessible by user threads.

Since user threads may not directly manipulate kernel objects, all use of them must go through system calls. In order to perform a system call on a kernel object, checks are performed by system call handler functions that the kernel object address is valid and that the calling thread has sufficient permissions to work with it.

Permission on an object also has the semantics of a reference to an object. This is significant for certain object APIs which do temporary allocations, or objects which themselves have been allocated from a runtime memory pool.

If an object loses all references, two events may happen:

- If the object has an associated cleanup function, the cleanup function may be called to release any runtime-allocated buffers the object was using.
- If the object itself was dynamically allocated, the memory for the object will be freed.

### Object Placement

Kernel objects that are only used by supervisor threads have no restrictions and can be located anywhere in the binary, or even declared on stacks. However, to prevent accidental or intentional corruption by user threads, they must not be located in any memory that user threads have direct access to.

In order for a static kernel object to be usable by a user thread via system call APIs, several conditions must be met on how the kernel object is declared:

- The object must be declared as a top-level global at build time, such that it appears in the ELF symbol table. It is permitted to declare kernel objects with static scope. The post-build script `scripts/build/gen_kobject_list.py` scans the generated ELF file to find kernel objects and places their memory addresses in a special table of kernel object metadata. Kernel objects may be members of arrays or embedded within other data structures.
- Kernel objects must be located in memory reserved for the kernel. They must not be located in any memory partitions that are user-accessible.
- Any memory reserved for a kernel object must be used exclusively for that object. Kernel objects may not be members of a union data type.

Kernel objects that are found but do not meet the above conditions will not be included in the generated table that is used to validate kernel object pointers passed in from user mode.

The debug output of the `scripts/build/gen_kobject_list.py` script may be useful when debugging why some object was unexpectedly not being tracked. This information will be printed if the script is run with the `--verbose` flag, or if the build system is invoked with verbose output.

### Dynamic Objects

Kernel objects may also be allocated at runtime if `CONFIG_DYNAMIC_OBJECTS` is enabled. In this case, the `k_object_alloc()` API may be used to instantiate an object from the calling thread’s resource pool. Such allocations may be freed in two ways:

- Supervisor threads may call `k_object_free()` to force a dynamic object to be released.
- If an object’s references drop to zero (which happens when no threads have permissions on it) the object will be automatically freed. User threads may drop their own permission on an object with `k_object_release()`, and their permissions are automatically cleared when a thread terminates. Supervisor threads may additionally revoke references for another thread using `k_object_access_revoke()`. 

436 Chapter 3. Kernel
Because permissions are also used for reference counting, it is important for supervisor threads to acquire permissions on objects they are using even though the access control aspects of the permission system are not enforced.

**Implementation Details**  The `scripts/build/gen_kobject_list.py` script is a post-build step which finds all the valid kernel object instances in the binary. It accomplishes this by parsing the DWARF debug information present in the generated ELF file for the kernel.

Any instances of structs or arrays corresponding to kernel objects that meet the object placement criteria will have their memory addresses placed in a special perfect hash table of kernel objects generated by the ‘gperf’ tool. When a system call is made and the kernel is presented with a memory address of what may or may not be a valid kernel object, the address can be validated with a constant-time lookup in this table.

Drivers are a special case. All drivers are instances of `device`, but it is important to know what subsystem a driver belongs to so that incorrect operations, such as calling a UART API on a sensor driver object, can be prevented. When a device struct is found, its API pointer is examined to determine what subsystem the driver belongs to.

The table itself maps kernel object memory addresses to instances of `z_object`, which has all the metadata for that object. This includes:

- A bitfield indicating permissions on that object. All threads have a numerical ID assigned to them at build time, used to index the permission bitfield for an object to see if that thread has permission on it. The size of this bitfield is controlled by the `CONFIG_MAX_THREAD_BYTES` option and the build system will generate an error if this value is too low.
- A type field indicating what kind of object this is, which is some instance of `k_objects`.
- A set of flags for that object. This is currently used to track initialization state and whether an object is public or not.
- An extra data field. The semantics of this field vary by object type, see the definition of `z_object_data`.

Dynamic objects allocated at runtime are tracked in a runtime red/black tree which is used in parallel to the gperf table when validating object pointers.

**Supervisor Thread Access Permission**

Supervisor threads can access any kernel object. However, permissions for supervisor threads are still tracked for two reasons:

- If a supervisor thread calls `k_thread_user_mode_enter()`, the thread will then run in user mode with any permissions it had been granted (in many cases, by itself) when it was a supervisor thread.
- If a supervisor thread creates a user thread with the `K_INHERIT_PERMS` option, the child thread will be granted the same permissions as the parent thread, except the parent thread object.

**User Thread Access Permission**

By default, when a user thread is created, it will only have access permissions on its own thread object. Other kernel objects by default are not usable. Access to them needs to be explicitly or implicitly granted. There are several ways to do this.

- If a thread is created with the `K_INHERIT_PERMS`, that thread will inherit all the permissions of the parent thread, except the parent thread object.
- A thread that has permission on an object, or is running in supervisor mode, may grant permission on that object to another thread via the `k_object_access_grant()` API. The convenience pseudo-function `k_thread_access_grant()` may also be used, which accepts an arbitrary number
of pointers to kernel objects and calls `k_object_access_grant()` on each of them. The thread being granted permission, or the object whose access is being granted, do not need to be in an initialized state. If the caller is from user mode, the caller must have permissions on both the kernel object and the target thread object.

- Supervisor threads may declare a particular kernel object to be a public object, usable by all current and future threads with the `k_object_access_all_grant()` API. You must assume that any untrusted or exploited code will then be able to access the object. Use this API with caution!

- If a thread was declared statically with `K_THREAD_DEFINE()`, then the `K_THREAD_ACCESS_GRANT()` may be used to grant that thread access to a set of kernel objects at boot time.

Once a thread has been granted access to an object, such access may be removed with the `k_object_access_revoke()` API. This API is not available to user threads, however user threads may use `k_object_release()` to relinquish their own permissions on an object.

API calls from supervisor mode to set permissions on kernel objects that are not being tracked by the kernel will be no-ops. Doing the same from user mode will result in a fatal error for the calling thread.

Objects allocated with `k_object_alloc()` implicitly grant permission on the allocated object to the calling thread.

**Initialization State**

Most operations on kernel objects will fail if the object is considered to be in an uninitialized state. The appropriate init function for the object must be performed first.

Some objects will be implicitly initialized at boot:

- Kernel objects that were declared with static initialization macros (such as `K_SEM_DEFINE` for semaphores) will be in an initialized state at build time.

- Device driver objects are considered initialized after their init function is run by the kernel early in the boot process.

If a kernel object is initialized with a private static initializer, the object must have `z_object_init()` called on it at some point by a supervisor thread, otherwise the kernel will consider the object uninitialized if accessed by a user thread. This is very uncommon, typically only for kernel objects that are embedded within some larger struct and initialized statically.

```c
struct foo {
    struct k_sem sem;
    ...
};

struct foo my_foo = {
    .sem = Z_SEM_INITIALIZER(my_foo.sem, 0, 1),
    ...
};

... z_object_init(&my_foo.sem);
...
```

**Creating New Kernel Object Types**

When implementing new kernel features or driver subsystems, it may be necessary to define some new kernel object types. There are different steps needed for creating core kernel objects and new driver subsystems.
Creating New Core Kernel Objects

- In scripts/build/gen_kobject_list.py, add the name of the struct to the kobjects list.

Instances of the new struct should now be tracked.

Creating New Driver Subsystem Kernel Objects

All driver instances are device. They are differentiated by what API struct they are set to.

- In scripts/build/gen_kobject_list.py, add the name of the API struct for the new subsystem to the subsystems list.

Driver instances of the new subsystem should now be tracked.

Configuration Options

Related configuration options:

- CONFIG_USERSPACE
- CONFIG_MAX_THREAD_BYTES

API Reference

group usermode_apis

Defines

K_THREAD_ACCESS_GRANT(name_, ...)
  Grant a static thread access to a list of kernel objects.
  For threads declared with K_THREAD_DEFINE(), grant the thread access to a set of kernel objects. These objects do not need to be in an initialized state. The permissions will be granted when the threads are initialized in the early boot sequence.
  All arguments beyond the first must be pointers to kernel objects.

Parameters

- name_ – Name of the thread, as passed to K_THREAD_DEFINE()

K_OBJ_FLAG_INITIALIZED
  Object initialized

K_OBJ_FLAG_PUBLIC
  Object is Public

K_OBJ_FLAG_ALLOC
  Object allocated

K_OBJ_FLAG_DRIVER
  Driver Object
Functions

void k_object_access_grant(const void *object, struct k_thread *thread)
Grant a thread access to a kernel object

The thread will be granted access to the object if the caller is from supervisor mode, or the
caller is from user mode AND has permissions on both the object and the thread whose access
is being granted.

Parameters
• object – Address of kernel object
• thread – Thread to grant access to the object

void k_object_access_revoke(const void *object, struct k_thread *thread)
Revoke a thread’s access to a kernel object

The thread will lose access to the object if the caller is from supervisor mode, or the caller is
from user mode AND has permissions on both the object and the thread whose access is being
revoked.

Parameters
• object – Address of kernel object
• thread – Thread to remove access to the object

void k_object_release(const void *object)
Release an object.

Allows user threads to drop their own permission on an object Their permissions are automat-
ically cleared when a thread terminates.

Parameters
• object – The object to be released

void k_object_access_all_grant(const void *object)
Grant all present and future threads access to an object

If the caller is from supervisor mode, or the caller is from user mode and have sufficient
permissions on the object, then that object will have permissions granted to it for all current
and future threads running in the system, effectively becoming a public kernel object.

Use of this API should be avoided on systems that are running untrusted code as it is possible
for such code to derive the addresses of kernel objects and perform unwanted operations on
them.

It is not possible to revoke permissions on public objects; once public, any thread may use it.

Parameters
• object – Address of kernel object

static inline void k_object_free(void *obj)
Free an object.

Parameters
• obj –

3.3.4 System Calls

User threads run with a reduced set of privileges than supervisor threads: certain CPU instructions may
not be used, and they have access to only a limited part of the memory map. System calls (may) allow
user threads to perform operations not directly available to them.
When defining system calls, it is very important to ensure that access to the API's private data is done exclusively through system call interfaces. Private kernel data should never be made available to user mode threads directly. For example, the \texttt{k\_queue} APIs were intentionally not made available as they store bookkeeping information about the queue directly in the queue buffers which are visible from user mode.

APIs that allow the user to register callback functions that run in supervisor mode should never be exposed as system calls. Reserve these for supervisor-mode access only.

This section describes how to declare new system calls and discusses a few implementation details relevant to them.

**Components**

All system calls have the following components:

- A \texttt{C prototype} prefixed with \texttt{\_\_syscall} for the API. It will be declared in some header under \texttt{include} or in another \texttt{SYSCALL\_INCLUDE\_DIRS} directory. This prototype is never implemented manually, instead it gets created by the \texttt{scripts\_build\_gen\_syscalls.py} script. What gets generated is an inline function which either calls the implementation function directly (if called from supervisor mode) or goes through privilege elevation and validation steps (if called from user mode).

- An \texttt{implementation function}, which is the real implementation of the system call. The implementation function may assume that all parameters passed in have been validated if it was invoked from user mode.

- A \texttt{verification function}, which wraps the implementation function and does validation of all the arguments passed in.

- An \texttt{unmarshalling function}, which is an automatically generated handler that must be included by user source code.

**C Prototype**

The \texttt{C prototype} represents how the API is invoked from either user or supervisor mode. For example, to initialize a semaphore:

\begin{verbatim}
\_\_syscall void k\_sem\_init(struct k\_sem \*sem, unsigned int initial\_count, 
unsigned int limit);
\end{verbatim}

The \texttt{\_\_syscall} attribute is very special. To the C compiler, it simply expands to `static inline`. However to the post-build \texttt{scripts\_build\_parse\_syscalls.py} script, it indicates that this API is a system call. The \texttt{scripts\_build\_parse\_syscalls.py} script does some parsing of the function prototype, to determine the data types of its return value and arguments, and has some limitations:

- Array arguments must be passed in as pointers, not arrays. For example, \texttt{int foo[]} or \texttt{int foo[12]} is not allowed, but should instead be expressed as \texttt{int \*foo}.

- Function pointers horribly confuse the limited parser. The workaround is to typedef them first, and then express in the argument list in terms of that typedef.

- \texttt{\_\_syscall} must be the first thing in the prototype.

The preprocessor is intentionally not used when determining the set of system calls to generate. However, any generated system calls that don't actually have a verification function defined (because the related feature is not enabled in the kernel configuration) will instead point to a special verification for unimplemented system calls. Data type definitions for APIs should not have conditional visibility to the compiler.

Any header file that declares system calls must include a special generated header at the very bottom of the header file. This header follows the naming convention \texttt{syscalls/<name of header file>}. For example, at the bottom of \texttt{include/sensor.h}:
C prototype functions must be declared in one of the directories listed in the CMake variable SYSCALL_INCLUDE_DIRS. This list always contains ${ZEPHYR_BASE}/include, but will also contain APPLICATION_SOURCE_DIR when CONFIG_APPLICATION_DEFINED_SYSCALL is set, or ${ZEPHYR_BASE}/subsys/testsuite/ztest/include when CONFIG_ZTEST is set. Additional paths can be added to the list through the CMake command line or in CMake code that is run before ${ZEPHYR_BASE}/cmake/app/boilerplate.cmake is run.

Invocation Context  Source code that uses system call APIs can be made more efficient if it is known that all the code inside a particular C file runs exclusively in user mode, or exclusively in supervisor mode. The system will look for the definition of macros __ZEPHYR_SUPERVISOR__ or __ZEPHYR_USER__, typically these will be added to the compiler flags in the build system for the related files.

- If CONFIG_USERSPACE is not enabled, all APIs just directly call the implementation function.
- Otherwise, the default case is to make a runtime check to see if the processor is currently running in user mode, and either make the system call or directly call the implementation function as appropriate.
- If __ZEPHYR_SUPERVISOR__ is defined, then it is assumed that all the code runs in supervisor mode and all APIs just directly call the implementation function. If the code was actually running in user mode, there will be a CPU exception as soon as it tries to do something it isn't allowed to do.
- If __ZEPHYR_USER__ is defined, then it is assumed that all the code runs in user mode and system calls are unconditionally made.

Implementation Details  Declaring an API with __syscall causes some code to be generated in C and header files by the scripts/build/gen_syscalls.py script, all of which can be found in the project out directory under include/generated/:

- The system call is added to the enumerated type of system call IDs, which is expressed in include/generated/syscall_list.h. It is the name of the API in uppercase, prefixed with K_SYSCALL_.
- An entry for the system call is created in the dispatch table _k_syscall_table, expressed in include/generated/syscall_dispatch.c
- A weak verification function is declared, which is just an alias of the ‘unimplemented system call’ verifier. This is necessary since the real verification function may or may not be built depending on the kernel configuration. For example, if a user thread makes a sensor subsystem API call, but the sensor subsystem is not enabled, the weak verifier will be invoked instead.
- An unmarshalling function is defined in include/generated/<name>_mrsh.c

The body of the API is created in the generated system header. Using the example of k_sem_init(), this API is declared in include/kernel.h. At the bottom of include/kernel.h is:

```c
#include <syscalls/kernel.h>

Inside this header is the body of k_sem_init():
```

```c
static inline void k_sem_init(struct k_sem * sem, unsigned int initial_count, unsigned int limit) {

#define CONFIG_USERSPACE

    if (z_syscall_trap()) {
        arch_syscall_invoke3(*(uintptr_t *)&sem, *(uintptr_t *)&initial_count,
            *(uintptr_t *)&limit, K_SYSCALL_K_SEM_INIT);
        return;
    }

    (continues on next page)
```
This generates an inline function that takes three arguments with void return value. Depending on context it will either directly call the implementation function or go through a system call elevation. A prototype for the implementation function is also automatically generated.

The final layer is the invocation of the system call itself. All architectures implementing system calls must implement the seven inline functions _arch_syscall_invoke0() through _arch_syscall_invoke6(). These functions marshal arguments into designated CPU registers and perform the necessary privilege elevation. Parameters of API inline function, before being passed as arguments to system call, are C casted to uintptr_t which matches size of register. Exception to above is passing 64-bit parameters on 32-bit systems, in which case 64-bit parameters are split into lower and higher part and passed as two consecutive arguments. There is always a uintptr_t type return value, which may be neglected if not needed.

Fig. 3.3: System Call execution flow

Some system calls may have more than six arguments, but number of arguments passed via registers is limited to six for all architectures. Additional arguments will need to be passed in an array in the source memory space, which needs to be treated as untrusted memory in the verification function. This code (packing, unpacking and validation) is generated automatically as needed in the stub above and in the unmarshalling function.

System calls return uintptr_t type value that is C casted, by wrapper, to a return type of API prototype declaration. This means that 64-bit value may not be directly returned, from a system call to its wrapper, on 32-bit systems. To solve the problem the automatically generated wrapper function defines 64-bit intermediate variable, which is considered untrusted buffer, on its stack and passes pointer to that variable to the system call, as a final argument. Upon return from the system call the value written to that buffer will be returned by the wrapper function. The problem does not exist on 64-bit systems which are able to return 64-bit values directly.

Implementation Function

The implementation function is what actually does the work for the API. Zephyr normally does little to no error checking of arguments, or does this kind of checking with assertions. When writing the implementation function, validation of any parameters is optional and should be done with assertions.

All implementation functions must follow the naming convention, which is the name of the API prefixed with z_impl_. Implementation functions may be declared in the same header as the API as a static inline
function or declared in some C file. There is no prototype needed for implementation functions, these are automatically generated.

Verification Function

The verification function runs on the kernel side when a user thread makes a system call. When the user thread makes a software interrupt to elevate to supervisor mode, the common system call entry point uses the system call ID provided by the user to look up the appropriate unmarshalling function for that system call and jump into it. This in turn calls the verification function.

Verification and unmarshalling functions only run when system call APIs are invoked from user mode. If an API is invoked from supervisor mode, the implementation is simply called and there is no software trap.

The purpose of the verification function is to validate all the arguments passed in. This includes:

- Any kernel object pointers provided. For example, the semaphore APIs must ensure that the semaphore object passed in is a valid semaphore and that the calling thread has permission on it.
- Any memory buffers passed in from user mode. Checks must be made that the calling thread has read or write permissions on the provided buffer.
- Any other arguments that have a limited range of valid values.

Verification functions involve a great deal of boilerplate code which has been made simpler by some macros in include/zephyr/syscall_handler.h. Verification functions should be declared using these macros.

Argument Validation  Several macros exist to validate arguments:

- Z_SYSCALL_OBJ() Checks a memory address to assert that it is a valid kernel object of the expected type, that the calling thread has permissions on it, and that the object is initialized.
- Z_SYSCALL_OBJ_INIT() is the same as Z_SYSCALL_OBJ(), except that the provided object may be uninitialized. This is useful for verifiers of object init functions.
- Z_SYSCALL_OBJ_NEVER_INIT() is the same as Z_SYSCALL_OBJ(), except that the provided object must be uninitialized. This is not used very often, currently only for k_thread_create().
- Z_SYSCALL_MEMORY_READ() validates a memory buffer of a particular size. The calling thread must have read permissions on the entire buffer.
- Z_SYSCALL_MEMORY_WRITE() is the same as Z_SYSCALL_MEMORY_READ() but the calling thread must additionally have write permissions.
- Z_SYSCALL_MEMORY_ARRAY_READ() validates an array whose total size is expressed as separate arguments for the number of elements and the element size. This macro correctly accounts for multiplication overflow when computing the total size. The calling thread must have read permissions on the total size.
- Z_SYSCALL_MEMORY_ARRAY_WRITE() is the same as Z_SYSCALL_MEMORY_ARRAY_READ() but the calling thread must additionally have write permissions.
- Z_SYSCALL_VERIFY_MSG() does a runtime check of some boolean expression which must evaluate to true otherwise the check will fail. A variant Z_SYSCALL_VERIFY exists which does not take a message parameter, instead printing the expression tested if it fails. The latter should only be used for the most obvious of tests.
- Z_SYSCALL_DRIVER_OP() checks at runtime if a driver instance is capable of performing a particular operation. While this macro can be used by itself, it's mostly a building block for macros that are automatically generated for every driver subsystem. For instance, to validate the GPIO driver, one could use the Z_SYSCALL_DRIVER_GPIO() macro.
• Z_SYSCALL_SPECIFIC_DRIVER() is a runtime check to verify that a provided pointer is a valid instance of a specific device driver, that the calling thread has permissions on it, and that the driver has been initialized. It does this by checking the API structure pointer that is stored within the driver instance and ensuring that it matches the provided value, which should be the address of the specific driver's API structure.

If any check fails, the macros will return a nonzero value. The macro Z_OOPS() can be used to induce a kernel oops which will kill the calling thread. This is done instead of returning some error condition to keep the APIs the same when calling from supervisor mode.

Verifier Definition All system calls are dispatched to a verifier function with a prefixed z_vrfy_ name based on the system call. They have exactly the same return type and argument types as the wrapped system call. Their job is to execute the system call (generally by calling the implementation function) after having validated all arguments.

The verifier is itself invoked by an automatically generated unmarshaller function which takes care of unpacking the register arguments from the architecture layer and casting them to the correct type. This is defined in a header file that must be included from user code, generally somewhere after the definition of the verifier in a translation unit (so that it can be inlined).

For example:

```c
static int z_vrfy_k_sem_take(struct k_sem *sem, int32_t timeout)
{
    Z_OOPS(Z_SYSCALL_OBJ(sem, K_OBJ_SEM));
    return z_impl_k_sem_take(sem, timeout);
}
#include <syscalls/k_sem_take_mrsh.c>
```

Verification Memory Access Policies Parameters passed to system calls by reference require special handling, because the value of these parameters can be changed at any time by any user thread that has access to the memory that parameter points to. If the kernel makes any logical decisions based on the contents of this memory, this can open up the kernel to attacks even if checking is done. This is a class of exploits known as TOCTOU (Time Of Check to Time Of Use).

The proper procedure to mitigate these attacks is to make a copies in the verification function, and only perform parameter checks on the copies, which user threads will never have access to. The implementation functions get passed the copy and not the original data sent by the user. The z_user_to_copy() and z_user_from_copy() APIs exist for this purpose.

There is one exception in place, with respect to large data buffers which are only used to provide a memory area that is either only written to, or whose contents are never used for any validation or control flow. Further discussion of this later in this section.

As a first example, consider a parameter which is used as an output parameter for some integral value:

```c
int z_vrfy_some_syscall(int *out_param)
{
    int local_out_param;
    int ret;

    ret = z_impl_some_syscall(&local_out_param);
    Z_OOPS(z_user_to_copy(out_param, &local_out_param, sizeof(*out_param)));
    return ret;
}
```

Here we have allocated local_out_param on the stack, passed its address to the implementation function, and then used z_user_to_copy() to fill in the memory passed in by the caller.

It might be tempting to do something more concise:

```c
int z_vrfy_some_syscall(int *out_param)
{
    ret = z_impl_some_syscall(out_param);
    Z_OOPS(z_user_to_copy(out_param, sizeof(*out_param)));
    return ret;
}
```
int z_vrfy_some_syscall(int *out_param)
{
    Z_OOPS(Z_SYSCALL_MEMORY_WRITE(out_param, sizeof(*out_param)));
    return z_impl_some_syscall(out_param);
}

However, this is unsafe if the implementation ever does any reads to this memory as part of its logic. For example, it could be used to store some counter value, and this could be meddled with by user threads that have access to its memory. It is by far safest for small integral values to do the copying as shown in the first example.

Some parameters may be input/output. For instance, it’s not uncommon to see APIs which pass in a pointer to some size_t which is a maximum allowable size, which is then updated by the implementation to reflect the actual number of bytes processed. This too should use a stack copy:

int z_vrfy_in_out_syscall(size_t *size_ptr)
{
    size_t size;
    int ret;
    Z_OOPS(z_user_from_copy(&size, size_ptr, sizeof(size));
    ret = z_impl_in_out_syscall(&size);
    Z_OOPS(z_user_to_copy(size_ptr, &size, sizeof(size));
    return ret;
}

Many system calls pass in structures or even linked data structures. All should be copied. Typically this is done by allocating copies on the stack:

struct bar {
    ...
};

struct foo {
    ...
    struct bar *bar_left;
    struct bar *bar_right;
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar bar_right_copy;
    struct bar bar_left_copy;
    Z_OOPS(z_user_from_copy(&foo_copy, foo, sizeof(*foo)));
    Z_OOPS(z_user_from_copy(&bar_right_copy, foo_copy.bar_right, sizeof(struct bar)));
    foo_copy.bar_right = &bar_right_copy;
    Z_OOPS(z_user_from_copy(&bar_left_copy, foo_copy.bar_left, sizeof(struct bar)));
    foo_copy.bar_left = &bar_left_copy;
    return z_impl_must_alloc(&foo_copy);
}

In some cases the amount of data isn’t known at compile time or may be too large to allocate on the stack. In this scenario, it may be necessary to draw memory from the caller’s resource pool via
z_thread_malloc(). This should always be considered last resort. Functional safety programming
guidelines heavily discourage usage of heap and the fact that a resource pool is used must be clearly
documented. Any issues with allocation must be reported, to a caller, with returning the -ENOMEM. The
Z_OOPS() should never be used to verify if resource allocation has been successful.

```c
struct bar {
    ...
};

struct foo {
    size_t count;
    struct bar *bar_list; /* array of struct bar of size count */
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar *bar_list_copy;
    size_t bar_list_bytes;

    /* Safely copy foo into foo_copy */
    Z_OOPS(z_user_from_copy(&foo_copy, foo, sizeof(*foo)));

    /* Bounds check the count member, in the copy we made */
    if (foo_copy.count > 32) {
        return -EINVAL;
    }

    /* Allocate RAM for the bar_list, replace the pointer in
    * foo_copy */
    bar_list_bytes = foo_copy.count * sizeof(struct_bar);
    bar_list_copy = z_thread_malloc(bar_list_bytes);
    if (bar_list_copy == NULL) {
        return -ENOMEM;
    }
    Z_OOPS(z_user_from_copy(bar_list_copy, foo_copy.bar_list,
                        bar_list_bytes));
    foo_copy.bar_list = bar_list_copy;

    ret = z_impl_must_alloc(&foo_copy);

    /* All done with the memory, free it and return */
    k_free(foo_copy.bar_list_copy);
    return ret;
}
```

Finally, we must consider large data buffers. These represent areas of user memory which either have
data copied out of, or copied into. It is permitted to pass these pointers to the implementation function
directly. The caller's access to the buffer still must be validated with Z_SYSCALL_MEMORY APIs. The
following constraints need to be met:

- If the buffer is used by the implementation function to write data, such as data captured from some
  MMIO region, the implementation function must only write this data, and never read it.
- If the buffer is used by the implementation function to read data, such as a block of memory to
  write to some hardware destination, this data must be read without any processing. No conditional
  logic can be implemented due to the data buffer's contents. If such logic is required a copy must
  be made.
• The buffer must only be used synchronously with the call. The implementation must not ever save the buffer address and use it asynchronously, such as when an interrupt fires.

```c
int z_vrfy_get_data_from_kernel(void *buf, size_t size)
{
    Z_OOPS(Z_SYSCALL_MEMORY_WRITE(buf, size));
    return z_impl_get_data_from_kernel(buf, size);
}
```

**Verification Return Value Policies** When verifying system calls, it’s important to note which kinds of verification failures should propagate a return value to the caller, and which should simply invoke `Z_OOPS()` which kills the calling thread. The current conventions are as follows:

1. For system calls that are defined but not compiled, invocations of these missing system calls are routed to `handler_no_syscall()` which invokes `Z_OOPS()`.

2. Any invalid access to memory found by the set of `Z_SYSCALL_MEMORY` APIs, `z_user_from_copy()`, `z_user_to_copy()` should trigger a `Z_OOPS`. This happens when the caller doesn’t have appropriate permissions on the memory buffer or some size calculation overflowed.

3. Most system calls take kernel object pointers as an argument, checked either with one of the `Z_SYSCALL_OBJ` functions, `Z_SYSCALL_DRIVER_0000`, or manually using `z_object_validate()`. These can fail for a variety of reasons: missing driver API, bad kernel object pointer, wrong kernel object type, or improper initialization state. These issues should always invoke `Z_OOPS()`.

4. Any error resulting from a failed memory heap allocation, often from invoking `z_thread_malloc()`, should propagate `-ENOMEM` to the caller.

5. General parameter checks should be done in the implementation function, in most cases using `CHECKIF()`.
   - The behavior of `CHECKIF()` depends on the kernel configuration, but if user mode is enabled, `CONFIG_RUNTIME_ERROR_CHECKS` is enforced, which guarantees that these checks will be made and a return value propagated.

6. It is totally forbidden for any kind of kernel mode callback function to be registered from user mode. APIs which simply install callbacks shall not be exposed as system calls. Some driver subsystem APIs may take optional function callback pointers. User mode verification functions for these APIs must enforce that these are NULL and should invoke `Z_OOPS()` if not.

7. Some parameter checks are enforced only from user mode. These should be checked in the verification function and propagate a return value to the caller if possible.

There are some known exceptions to these policies currently in Zephyr:

- `k_thread_join()` and `k_thread_abort()` are no-ops if the thread object isn’t initialized. This is because for threads, the initialization bit pulls double-duty to indicate whether a thread is running, cleared upon exit. See #23030.
- `k_thread_create()` invokes `Z_OOPS()` for parameter checks, due to a great deal of existing code ignoring the return value. This will also be addressed by #23030.
- `k_thread_abort()` invokes `Z_OOPS()` if an essential thread is aborted, as the function has no return value.
- Various system calls related to logging invoke `Z_OOPS()` when bad parameters are passed in as they do not propagate errors.

**Configuration Options**

Related configuration options:

- `CONFIG_USERSPACE`
APIs

Helper macros for creating system call verification functions are provided in `include/zephyr/syscall_handler.h`:

- `Z_SYSCALL_OBJ()`
- `Z_SYSCALL_OBJ_INIT()`
- `Z_SYSCALL_OBJ_NEVER_INIT()`
- `Z_OOPS()`
- `Z_SYSCALL_MEMORY_READ()`
- `Z_SYSCALL_MEMORY_WRITE()`
- `Z_SYSCALL_MEMORY_ARRAY_READ()`
- `Z_SYSCALL_MEMORY_ARRAY_WRITE()`
- `Z_SYSCALL_VERIFY_MSG()`
- `Z_SYSCALL_VERIFY`

Functions for invoking system calls are defined in `include/zephyr/syscall.h`:

- `_arch_syscall_invoke0()`
- `_arch_syscall_invoke1()`
- `_arch_syscall_invoke2()`
- `_arch_syscall_invoke3()`
- `_arch_syscall_invoke4()`
- `_arch_syscall_invoke5()`
- `_arch_syscall_invoke6()`

3.3.5 MPU Stack Objects

Thread Stack Creation

Thread stacks are declared statically with `K_THREAD_STACK_DEFINE()` or embedded within structures using `K_THREAD_STACK_MEMBER()`.

For architectures which utilize memory protection unit (MPU) hardware, stacks are physically contiguous allocations. This contiguous allocation has implications for the placement of stacks in memory, as well as the implementation of other features such as stack protection and userspace. The implications for placement are directly attributed to the alignment requirements for MPU regions. This is discussed in the memory placement section below.

Stack Guards

Stack protection mechanisms require hardware support that can restrict access to memory. Memory protection units can provide this kind of support. The MPU provides a fixed number of regions. Each region contains information about the start, end, size, and access attributes to be enforced on that particular region.

Stack guards are implemented by using a single MPU region and setting the attributes for that region to not allow write access. If invalid accesses occur, a fault ensues. The stack guard is defined at the bottom (the lowest address) of the stack.
Memory Placement

During stack creation, a set of constraints are enforced on the allocation of memory. These constraints include determining the alignment of the stack and the correct sizing of the stack. During linking of the binary, these constraints are used to place the stacks properly.

The main source of the memory constraints is the MPU design for the SoC. The MPU design may require specific constraints on the region definition. These can include alignment of beginning and end addresses, sizes of allocations, or even interactions between overlapping regions.

Some MPUs require that each region be aligned to a power of two. These SoCs will have CONFIG_MPU.Requires.Power.Of.Two.Alignment defined. This means that a 1500 byte stack should be aligned to a 2kB boundary and the stack size should also be adjusted to 2kB to ensure that nothing else is placed in the remainder of the region. SoCs which include the unmodified ARM v7m MPU will have these constraints.

Some ARM MPUs use start and end addresses to define MPU regions and both the start and end addresses require 32 byte alignment. An example of this kind of MPU is found in the NXP FRDM K64F.

MPUs may have a region priority mechanisms that use the highest priority region that covers the memory access to determine the enforcement policy. Others may logically OR regions to determine enforcement policy.

Size and alignment constraints may result in stack allocations being larger than the requested size. Region priority mechanisms may result in some added complexity when implementing stack guards.

3.3.6 MPU Backed Userspace

The MPU backed userspace implementation requires the creation of a secondary set of stacks. These stacks exist in a 1:1 relationship with each thread stack defined in the system. The privileged stacks are created as a part of the build process.

A post-build script scripts/build/gen_kobject_list.py scans the generated ELF file and finds all of the thread stack objects. A set of privileged stacks, a lookup table, and a set of helper functions are created and added to the image.

During the process of dropping a thread to user mode, the privileged stack information is filled in and later used by the swap and system call infrastructure to configure the MPU regions properly for the thread stack and guard (if applicable).

During system calls, the user mode thread’s access to the system call and the passed-in parameters are all validated. The user mode thread is then elevated to privileged mode, the stack is switched to use the privileged stack, and the call is made to the specified kernel API. On return from the kernel API, the thread is set back to user mode and the stack is restored to the user stack.

3.4 Memory Management

The following contains various topics regarding memory management.

3.4.1 Memory Heaps

Zephyr provides a collection of utilities that allow threads to dynamically allocate memory.

Synchronized Heap Allocator

Creating a Heap The simplest way to define a heap is statically, with the K_HEAP_DEFINE macro. This creates a static k_heap variable with a given name that manages a memory region of the specified size.
Heaps can also be created to manage arbitrary regions of application-controlled memory using `k_heap_init()`.

**Allocating Memory** Memory can be allocated from a heap using `k_heap_alloc()`, passing it the address of the heap object and the number of bytes desired. This function similarly to standard C `malloc()`, returning a NULL pointer on an allocation failure.

The heap supports blocking operation, allowing threads to go to sleep until memory is available. The final argument is a `k_timeout_t` timeout value indicating how long the thread may sleep before returning, or else one of the constant timeout values `K_NO_WAIT` or `K_FOREVER`.

**Releasing Memory** Memory allocated with `k_heap_alloc()` must be released using `k_heap_free()`. Similar to standard C `free()`, the pointer provided must be either a NULL value or a pointer previously returned by `k_heap_alloc()` for the same heap. Freeing a NULL value is defined to have no effect.

**Low Level Heap Allocator**

The underlying implementation of the `k_heap` abstraction is provided a data structure named `sys_heap`. This implements exactly the same allocation semantics, but provides no kernel synchronization tools. It is available for applications that want to manage their own blocks of memory in contexts (for example, userspace) where synchronization is unavailable or more complicated. Unlike `k_heap`, all calls to any `sys_heap` functions on a single heap must be serialized by the caller. Simultaneous use from separate threads is disallowed.

**Implementation** Internally, the `sys_heap` memory block is partitioned into “chunks” of 8 bytes. All allocations are made out of a contiguous region of chunks. The first chunk of every allocation or unused block is prefixed by a chunk header that stores the length of the chunk, the length of the next lower (“left”) chunk in physical memory, a bit indicating whether the chunk is in use, and chunk-indexed link pointers to the previous and next chunk in a “free list” to which unused chunks are added.

The heap code takes reasonable care to avoid fragmentation. Free block lists are stored in “buckets” by their size, each bucket storing blocks within one power of two (i.e., a bucket for blocks of 3-4 chunks, another for 5-8, 9-16, etc...) this allows new allocations to be made from the smallest/most-fragmented blocks available. Also, as allocations are freed and added to the heap, they are automatically combined with adjacent free blocks to prevent fragmentation.

All metadata is stored at the beginning of the contiguous block of heap memory, including the variable-length list of bucket list heads (which depend on heap size). The only external memory required is the `sys_heap` structure itself.

The `sys_heap` functions are unsynchronized. Care must be taken by any users to prevent concurrent access. Only one context may be inside one of the API functions at a time.

The heap code takes care to present high performance and reliable latency. All `sys_heap` API functions are guaranteed to complete within constant time. On typical architectures, they will all complete within 1-200 cycles. One complexity is that the search of the minimum bucket size for an allocation (the set of free blocks that “might fit”) has a compile-time upper bound of iterations to prevent unbounded list searches, at the expense of some fragmentation resistance. This `CONFIG_SYS_HEAP_ALLOC_LOOPS` value may be chosen by the user at build time, and defaults to a value of 3.

**Multi-Heap Wrapper Utility**

The `sys_heap` utility requires that all managed memory be in a single contiguous block. It is common for complicated microcontroller applications to have more complicated memory setups that they still want to manage dynamically as a “heap”. For example, the memory might exist as separate discontiguous...
regions, different areas may have different cache, performance or power behavior, peripheral devices may only be able to perform DMA to certain regions, etc...

For those situations, Zephyr provides a `sys_multi_heap` utility. Effectively this is a simple wrapper around a set of one or more `sys_heap` objects. It should be initialized after its child heaps via `sys_multi_heap_init()`, after which each heap can be added to the managed set via `sys_multi_heap_add_heap()`. No destruction utility is provided; just as for `sys_heap`, applications that want to destroy a multi heap should simply ensure all allocated blocks are freed (or at least will never be used again) and repurpose the underlying memory for another usage.

It has a single pair of allocation entry points, `sys_multi_heap_alloc()` and `sys_multi_heap_aligned_alloc()`. These behave identically to the `sys_heap` functions with similar names, except that they also accept an opaque “configuration” parameter. This pointer is uninspected by the multi heap code itself; instead it is passed to a callback function provided at initialization time. This application-provided callback is responsible for doing the underlying allocation from one of the managed heaps, and may use the configuration parameter in any way it likes to make that decision.

When unused, a multi heap may be freed via `sys_multi_heap_free()`. The application does not need to pass a configuration parameter. Memory allocated from any of the managed `sys_heap` objects may be freed with in the same way.

**System Heap**

The system heap is a predefined memory allocator that allows threads to dynamically allocate memory from a common memory region in a `malloc()`-like manner.

Only a single system heap is defined. Unlike other heaps or memory pools, the system heap cannot be directly referenced using its memory address.

The size of the system heap is configurable to arbitrary sizes, subject to space availability.

A thread can dynamically allocate a chunk of heap memory by calling `k_malloc()`. The address of the allocated chunk is guaranteed to be aligned on a multiple of pointer sizes. If a suitable chunk of heap memory cannot be found `NULL` is returned.

When the thread is finished with a chunk of heap memory it can release the chunk back to the system heap by calling `k_free()`.

**Defining the Heap Memory Pool** The size of the heap memory pool is specified using the `CONFIG_HEAP_MEM_POOL_SIZE` configuration option.

By default, the heap memory pool size is zero bytes. This value instructs the kernel not to define the heap memory pool object. The maximum size is limited by the amount of available memory in the system. The project build will fail in the link stage if the size specified can not be supported.

**Allocating Memory** A chunk of heap memory is allocated by calling `k_malloc()`.

The following code allocates a 200 byte chunk of heap memory, then fills it with zeros. A warning is issued if a suitable chunk is not obtained.

```c
char *mem_ptr;

mem_ptr = k_malloc(200);
if (mem_ptr != NULL) {
    memset(mem_ptr, 0, 200);
    ...
} else {
    printf("Memory not allocated");
}
```
Releasing Memory  A chunk of heap memory is released by calling \texttt{k.free()}. The following code allocates a 75 byte chunk of memory, then releases it once it is no longer needed.

\begin{verbatim}
char *mem_ptr;
mem_ptr = k_malloc(75);
... /* use memory block */
k_free(mem_ptr);
\end{verbatim}

Suggested Uses  Use the heap memory pool to dynamically allocate memory in a \texttt{malloc()}-like manner.

Configuration Options  Related configuration options:

- \texttt{CONFIG_HEAP_MEM_POOL_SIZE}

API Reference

\texttt{group heap_apis}

Defines

\texttt{K_HEAP_DEFINE(name, bytes)}

Define a static \texttt{k_heap}. This macro defines and initializes a static memory region and \texttt{k_heap} of the requested size. After kernel start, &name can be used as if \texttt{k_heap_init()} had been called.

Note that this macro enforces a minimum size on the memory region to accommodate metadata requirements. Very small heaps will be padded to fit.

Parameters

- \texttt{name} – Symbol name for the struct \texttt{k_heap} object
- \texttt{bytes} – Size of memory region, in bytes

\texttt{K_HEAP_DEFINE_NOCACHE(name, bytes)}

Define a static \texttt{k_heap} in uncached memory.

This macro defines and initializes a static memory region and \texttt{k_heap} of the requested size in uncached memory. After kernel start, &name can be used as if \texttt{k_heap_init()} had been called.

Note that this macro enforces a minimum size on the memory region to accommodate metadata requirements. Very small heaps will be padded to fit.

Parameters

- \texttt{name} – Symbol name for the struct \texttt{k_heap} object
- \texttt{bytes} – Size of memory region, in bytes

Functions

\texttt{void k_heap_init(struct k_heap *h, void *mem, size_t bytes)}

Initialize a \texttt{k_heap}.

This constructs a synchronized \texttt{k_heap} object over a memory region specified by the user. Note that while any alignment and size can be passed as valid parameters, internal alignment
restrictions inside the inner sys_heap mean that not all bytes may be usable as allocated memory.

Parameters
• h – Heap struct to initialize
• mem – Pointer to memory.
• bytes – Size of memory region, in bytes

`void *k_heap_aligned_alloc(struct k_heap *h, size_t align, size_t bytes, k_timeout_t timeout)`
Allocate aligned memory from a `k_heap`.

Behaves in all ways like `k_heap_alloc()`, except that the returned memory (if available) will have a starting address in memory which is a multiple of the specified power-of-two alignment value in bytes. The resulting memory can be returned to the heap using `k_heap_free()`.

Function properties (list may not be complete)

**isr-ok**

Note: `timeout` must be set to `K_NO_WAIT` if called from ISR.

Note: When `CONFIG_MULTITHREADING=n` any `timeout` is treated as `K_NO_WAIT`.

Parameters
• h – Heap from which to allocate
• align – Alignment in bytes, must be a power of two
• bytes – Number of bytes requested
• timeout – How long to wait, or `K_NO_WAIT`

Returns
Pointer to memory the caller can now use

`void *k_heap_alloc(struct k_heap *h, size_t bytes, k_timeout_t timeout)`
Allocate memory from a `k_heap`.

Allocates and returns a memory buffer from the memory region owned by the heap. If no memory is available immediately, the call will block for the specified timeout (constructed via the standard timeout API, or `K_NO_WAIT` or `K_FOREVER`) waiting for memory to be freed. If the allocation cannot be performed by the expiration of the timeout, NULL will be returned. Allocated memory is aligned on a multiple of pointer sizes.

Function properties (list may not be complete)

**isr-ok**

Note: `timeout` must be set to `K_NO_WAIT` if called from ISR.

Note: When `CONFIG_MULTITHREADING=n` any `timeout` is treated as `K_NO_WAIT`.

Parameters
• **h** – Heap from which to allocate

• **bytes** – Desired size of block to allocate

• **timeout** – How long to wait, or K_NO_WAIT

**Returns**
A pointer to valid heap memory, or NULL.

```c
void k_heap_free(struct k_heap *h, void *mem)
```
Free memory allocated by `k_heap_alloc()`

Returns the specified memory block, which must have been returned from `k_heap_alloc()`, to the heap for use by other callers. Passing a NULL block is legal, and has no effect.

**Parameters**

• **h** – Heap to which to return the memory

• **mem** – A valid memory block, or NULL

```c
void *k_aligned_alloc(size_t align, size_t size)
```
Allocate memory from the heap with a specified alignment.

This routine provides semantics similar to `aligned_alloc();` memory is allocated from the heap with a specified alignment. However, one minor difference is that `k_aligned_alloc()` accepts any non-zero `size`, whereas `aligned_alloc()` only accepts a `size` that is an integral multiple of `align`.

Above, `aligned_alloc()` refers to: C11 standard (ISO/IEC 9899:2011): 7.22.3.1 The `aligned_alloc` function (p: 347-348)

**Parameters**

• **align** – Alignment of memory requested (in bytes).

• **size** – Amount of memory requested (in bytes).

**Returns**
Address of the allocated memory if successful; otherwise NULL.

```c
void *k_malloc(size_t size)
```
Allocate memory from the heap.

This routine provides traditional `malloc()` semantics. Memory is allocated from the heap memory pool. Allocated memory is aligned on a multiple of pointer sizes.

**Parameters**

• **size** – Amount of memory requested (in bytes).

**Returns**
Address of the allocated memory if successful; otherwise NULL.

```c
void k_free(void *ptr)
```
Free memory allocated from heap.

This routine provides traditional `free()` semantics. The memory being returned must have been allocated from the heap memory pool.

If `ptr` is NULL, no operation is performed.

**Parameters**

• **ptr** – Pointer to previously allocated memory.
void *k_calloc(size_t nmemb, size_t size)
Allocate memory from heap, array style.
This routine provides traditional calloc() semantics. Memory is allocated from the heap memory pool and zeroed.

Parameters
• nmemb – Number of elements in the requested array
• size – Size of each array element (in bytes).

Returns
Address of the allocated memory if successful; otherwise NULL.

struct k_heap
#include <kernel.h>

Heap listener
group heap_listener_apis

Defines

HEAP_ID_FROM_POINTER(heap_pointer)
Construct heap identifier from heap pointer.
Construct a heap identifier from a pointer to the heap object, such as sys_heap.

Parameters
• heap_pointer – Pointer to the heap object

HEAP_ID_LIBC
Libc heap identifier.
Identifier of the global libc heap.

HEAP_LISTENER_ALLOC_DEFINE(name, _heap_id, _alloc_cb)
Define heap event listener node for allocation event.
Sample usage:
void on_heap_alloc(uintptr_t heap_id, void *mem, size_t bytes)
{
    LOG_INF("Memory allocated at %p, size %ld", heap_id, mem, bytes);
}

HEAP_LISTENER_ALLOC_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_alloc);

Parameters
• name – Name of the heap event listener object
• _heap_id – Identifier of the heap to be listened
• _alloc_cb – Function to be called for allocation event
HEAP_LISTENER_FREE_DEFINE(name, _heap_id, _free_cb)
Define heap event listener node for free event.
Sample usage:

```c
void on_heap_free(uintptr_t heap_id, void *mem, size_t bytes)
{
    LOG_INF("Memory freed at %p, size %ld", heap_id, mem, bytes);
}
HEAP_LISTENER_FREE_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_free);
```

**Parameters**
- `name` – Name of the heap event listener object
- `_heap_id` – Identifier of the heap to be listened
- `_free_cb` – Function to be called for free event

HEAP_LISTENER_RESIZE_DEFINE(name, _heap_id, _resize_cb)
Define heap event listener node for resize event.
Sample usage:

```c
void on_heap_resized(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)
{
    LOG_INF("Libc heap end moved from %p to %p", old_heap_end, new_heap_end);
}
HEAP_LISTENER_RESIZE_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_resized);
```

**Parameters**
- `name` – Name of the heap event listener object
- `_heap_id` – Identifier of the heap to be listened
- `_resize_cb` – Function to be called when the listened heap is resized

**Typedefs**

typedef void (*heap_listener_resize_cb_t)(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)
Callback used when heap is resized.

**Note:** Minimal C library does not emit this event.

**Param heap_id**
Identifier of heap being resized

**Param old_heap_end**
Pointer to end of heap before resize

**Param new_heap_end**
Pointer to end of heap after resize
typedef void (*heap_listener_alloc_cb_t)(uintptr_t heap_id, void *mem, size_t bytes)
Callback used when there is heap allocation.

**Note:** Heaps managed by libraries outside of code in Zephyr main code repository may not emit this event.

**Note:** The number of bytes allocated may not match exactly to the request to the allocation function. Internal mechanism of the heap may allocate more than requested.

**Param heap_id**
Heap identifier

**Param mem**
Pointer to the allocated memory

**Param bytes**
Size of allocated memory

typedef void (*heap_listener_free_cb_t)(uintptr_t heap_id, void *mem, size_t bytes)
Callback used when memory is freed from heap.

**Note:** Heaps managed by libraries outside of code in Zephyr main code repository may not emit this event.

**Note:** The number of bytes freed may not match exactly to the request to the allocation function. Internal mechanism of the heap dictates how memory is allocated or freed.

**Param heap_id**
Heap identifier

**Param mem**
Pointer to the freed memory

**Param bytes**
Size of freed memory

**Enums**

eenum heap_event_types

**Values:**

enumerator HEAP_EVT_UNKNOWN = 0

enumerator HEAP_RESIZE

enumerator HEAP_ALLOC
enumerator HEAP_FREE

enumerator HEAP_REALLOC

enumerator HEAP_MAX_EVENTS

**Functions**

```c
void heap_listener_register(struct heap_listener *listener)
```

Register heap event listener.

Add the listener to the global list of heap listeners that can be notified by different heap implementations upon certain events related to the heap usage.

**Parameters**

- `listener` – Pointer to the `heap_listener` object

```c
void heap_listener_unregister(struct heap_listener *listener)
```

Unregister heap event listener.

Remove the listener from the global list of heap listeners that can be notified by different heap implementations upon certain events related to the heap usage.

**Parameters**

- `listener` – Pointer to the `heap_listener` object

```c
void heap_listener_notify_alloc(uintptr_t heap_id, void *mem, size_t bytes)
```

Notify listeners of heap allocation event.

Notify registered heap event listeners with matching heap identifier that an allocation has been done on heap.

**Parameters**

- `heap_id` – Heap identifier
- `mem` – Pointer to the allocated memory
- `bytes` – Size of allocated memory

```c
void heap_listener_notify_free(uintptr_t heap_id, void *mem, size_t bytes)
```

Notify listeners of heap free event.

Notify registered heap event listeners with matching heap identifier that memory is freed on heap.

**Parameters**

- `heap_id` – Heap identifier
- `mem` – Pointer to the freed memory
- `bytes` – Size of freed memory

```c
void heap_listener_notify_resize(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)
```

Notify listeners of heap resize event.

Notify registered heap event listeners with matching heap identifier that the heap has been resized.

**Parameters**
heap_id – Heap identifier  
old_heap_end – Address of the heap end before the change  
new_heap_end – Address of the heap end after the change

```c
struct heap_listener
    #include <heap_listener.h>

Public Members

sys_snnode_t node
    Singly linked list node

uintptr_t heap_id
    Identifier of the heap whose events are listened.  
    It can be a heap pointer, if the heap is represented as an object, or 0 in the case of the 
    global libc heap.

dtype heap_event_types event
    The heap event to be notified.

3.4.2 Shared Multi Heap

The shared multi-heap memory pool manager uses the multi-heap allocator to manage a set of reserved 
memory regions with different capabilities / attributes (cacheable, non-cacheable, etc...).

All the different regions can be added at run-time to the shared multi-heap pool providing an opaque 
“attribute” value (an integer or enum value) that can be used by drivers or applications to request 
memory with certain capabilities.

This framework is commonly used as follow:

1. At boot time some platform code initialize the shared multi-heap framework using 
   `shared_multi_heap_pool_init()` and add the memory regions to the pool with 
   `shared_multi_heap_add()`, possibly gathering the needed information for the regions from the 
   DT.

2. Each memory region encoded in a `shared_multi_heap_region` structure. This structure is also 
   carrying an opaque and user-defined integer value that is used to define the region capabilities (for 
   example: cacheability, cpu affinity, etc...)

```c
    // Init the shared multi-heap pool
    shared_multi_heap_pool_init()

    // Fill the struct with the data for cacheable memory
    struct shared_multi_heap_region cacheable_r0 = {
        .addr = addr_r0,
        .size = size_r0,
        .attr = SMH_REG_ATTR_CACHEABLE,
    };

    // Add the region to the pool
    shared_multi_heap_add(&cacheable_r0, NULL);
```

(continues on next page)
// Add another cacheable region
struct shared_multi_heap_region cacheable_r1 = {
    .addr = addr_r1,
    .size = size_r1,
    .attr = SMH_REG_ATTR_CACHEABLE,
};
shared_multi_heap_add(&cacheable_r0, NULL);

// Add a non-cacheable region
struct shared_multi_heap_region non_cacheable_r2 = {
    .addr = addr_r2,
    .size = size_r2,
    .attr = SMH_REG_ATTR_NON_CACHEABLE,
};
shared_multi_heap_add(&non_cacheable_r2, NULL);

3. When a driver or application needs some dynamic memory with a certain capability, it can use
   shared_multi_heap_alloc() (or the aligned version) to request the memory by using the opaque
   parameter to select the correct set of attributes for the needed memory. The framework will take
   care of selecting the correct heap (thus memory region) to carve memory from, based on the
   opaque parameter and the runtime state of the heaps (available memory, heap state, etc...)

// Allocate 4K from cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_CACHEABLE, 0x1000);

// Allocate 4K from non-cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_NON_CACHEABLE, 0x1000);

Adding new attributes

The API does not enforce any attributes, but at least it defines the two most common ones:
   SMH_REG_ATTR_CACHEABLE and SMH_REG_ATTR_NON_CACHEABLE

group shared_multi_heap
    Shared Multi-Heap (SMH) interface.

    The shared multi-heap manager uses the multi-heap allocator to manage a set of memory regions
    with different capabilities / attributes (cacheable, non-cacheable, etc...).

    All the different regions can be added at run-time to the shared multi-heap pool providing an
    opaque "attribute" value (an integer or enum value) that can be used by drivers or applications to
    request memory with certain capabilities.

    This framework is commonly used as follow:

    • At boot time some platform code initialize the shared multi-heap framework using
      shared_multi_heap_pool_init and add the memory regions to the pool with
      shared_multi_heap_add, possibly gathering the needed information for the regions from the
      DT.

    • Each memory region encoded in a shared_multi_heap_region structure. This structure is also
      carrying an opaque and user-defined integer value that is used to define the region capabilities
      (for example: cacheability, cpu affinity, etc...)

3.4. Memory Management
• When a driver or application needs some dynamic memory with a certain capability, it can use
`shared_multi_heap_alloc` (or the aligned version) to request the memory by using the opaque
parameter to select the correct set of attributes for the needed memory. The framework will
take care of selecting the correct heap (thus memory region) to carve memory from, based
on the opaque parameter and the runtime state of the heaps (available memory, heap state,
etc...)}

**Defines**

`MAX_SHARED_MULTI_HEAP_ATTR`

Maximum number of standard attributes.

** Enums**

```c
enum smh_reg_attr

SMH region attributes enumeration type.

Enumeration type for some common memory region attributes.
```

**Values:**

- `SMH_REG_ATTR_CACHEABLE`
- `SMH_REG_ATTR_NON_CACHEABLE`
- `SMH_REG_ATTR_NUM`

`must be the last item`

**Functions**

```c
int shared_multi_heap_pool_init(void)

Init the pool.
```

This must be the first function to be called to initialize the shared multi-heap pool. All the
individual heaps must be added later with `shared_multi_heap_add`.

**Note:** As for the generic multi-heap allocator the expectation is that this function will be
called at soc- or board-level.

**Return values**

- `0` – on success.
- `-EALREADY` – when the pool was already inited.
- `other` – errno codes
void *shared_multi_heap_alloc(unsigned int attr, size_t bytes)
Allocate memory from the memory shared multi-heap pool.
Allocates a block of memory of the specified size in bytes and with a specified capability / attribute. The opaque attribute parameter is used by the backend to select the correct heap to allocate memory from.

Parameters
• attr – capability / attribute requested for the memory block.
• bytes – requested size of the allocation in bytes.

Return values
• ptr – a valid pointer to heap memory.
• err – NULL if no memory is available.

void *shared_multi_heap_aligned_alloc(unsigned int attr, size_t align, size_t bytes)
Allocate aligned memory from the memory shared multi-heap pool.
Allocates a block of memory of the specified size in bytes and with a specified capability / attribute. Takes an additional parameter specifying a power of two alignment in bytes.

Parameters
• attr – capability / attribute requested for the memory block.
• align – power of two alignment for the returned pointer, in bytes.
• bytes – requested size of the allocation in bytes.

Return values
• ptr – a valid pointer to heap memory.
• err – NULL if no memory is available.

void shared_multi_heap_free(void *block)
Free memory from the shared multi-heap pool.
Used to free the passed block of memory that must be the return value of a previously call to shared_multi_heap_alloc or shared_multi_heap_aligned_alloc.

Parameters
• block – block to free, must be a pointer to a block allocated by shared_multi_heap_alloc or shared_multi_heap_aligned_alloc.

int shared_multi_heap_add(struct shared_multi_heap_region *region, void *user_data)
Add an heap region to the shared multi-heap pool.
This adds a shared multi-heap region to the multi-heap pool.

Parameters
• user_data – pointer to any data for the heap.
• region – pointer to the memory region to be added.

Return values
• 0 – on success.
• -EINVAL – when the region attribute is out-of-bound.
• -ENOMEM – when there are no more heaps available.
• other – errno codes
struct shared_multi_heap_region

#include <shared_multi_heap.h> SMH region struct. This struct is carrying information about the memory region to be added in the multi-heap pool.

Public Members

unsigned int attr
Memory heap attribute

uintptr_t addr
Memory heap starting virtual address

size_t size
Memory heap size in bytes

3.4.3 Memory Slabs

A memory slab is a kernel object that allows memory blocks to be dynamically allocated from a designated memory region. All memory blocks in a memory slab have a single fixed size, allowing them to be allocated and released efficiently and avoiding memory fragmentation concerns.

- Concepts
  - Internal Operation
- Implementation
  - Defining a Memory Slab
  - Allocating a Memory Block
  - Releasing a Memory Block
- Suggested Uses
- Configuration Options
- API Reference

Concepts

Any number of memory slabs can be defined (limited only by available RAM). Each memory slab is referenced by its memory address.

A memory slab has the following key properties:

- The block size of each block, measured in bytes. It must be at least 4N bytes long, where N is greater than 0.
- The number of blocks available for allocation. It must be greater than zero.
- A buffer that provides the memory for the memory slab's blocks. It must be at least “block size” times “number of blocks” bytes long.
The memory slab’s buffer must be aligned to an N-byte boundary, where N is a power of 2 larger than 2
(i.e. 4, 8, 16, ...). To ensure that all memory blocks in the buffer are similarly aligned to this boundary,
the block size must also be a multiple of N.

A memory slab must be initialized before it can be used. This marks all of its blocks as unused.

A thread that needs to use a memory block simply allocates it from a memory slab. When the thread
finishes with a memory block, it must release the block back to the memory slab so the block can be
reused.

If all the blocks are currently in use, a thread can optionally wait for one to become available. Any
number of threads may wait on an empty memory slab simultaneously; when a memory block becomes
available, it is given to the highest-priority thread that has waited the longest.

Unlike a heap, more than one memory slab can be defined, if needed. This allows for a memory slab with
smaller blocks and others with larger-sized blocks. Alternatively, a memory pool object may be used.

**Internal Operation**  A memory slab’s buffer is an array of fixed-size blocks, with no wasted space
between the blocks.

The memory slab keeps track of unallocated blocks using a linked list; the first 4 bytes of each unused
block provide the necessary linkage.

**Implementation**

**Defining a Memory Slab**  A memory slab is defined using a variable of type `k_mem_slab`. It must then
be initialized by calling `k_mem_slab_init()`.

The following code defines and initializes a memory slab that has 6 blocks that are 400 bytes long, each
of which is aligned to a 4-byte boundary.

```c
struct k_mem_slab my_slab;
char __aligned(4) my_slab_buffer[6 * 400];
k_mem_slab_init(&my_slab, my_slab_buffer, 400, 6);
```

Alternatively, a memory slab can be defined and initialized at compile time by calling
`K_MEM_SLAB_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both
the memory slab and its buffer.

```c
K_MEM_SLAB_DEFINE(my_slab, 400, 6, 4);
```

Similarly, you can define a memory slab in private scope:

```c
K_MEM_SLAB_DEFINE_STATIC(my_slab, 400, 6, 4);
```

**Allocating a Memory Block**  A memory block is allocated by calling `k_mem_slab_alloc()`.

The following code builds on the example above, and waits up to 100 milliseconds for a memory block
to become available, then fills it with zeroes. A warning is printed if a suitable block is not obtained.

```c
char *block_ptr;
if (k_mem_slab_alloc(&my_slab, &block_ptr, 100) == 0)) {
    memset(block_ptr, 0, 400);
    ...
} else {
```
Releasing a Memory Block

A memory block is released by calling `k_mem_slab_free()`.

The following code builds on the example above, and allocates a memory block, then releases it once it is no longer needed.

```c
char *block_ptr;

k_mem_slab_alloc(&my_slab, &block_ptr, K_FOREVER);
...
/* use memory block pointed at by block_ptr */

k_mem_slab_free(&my_slab, &block_ptr);
```

Suggested Uses

Use a memory slab to allocate and free memory in fixed-size blocks.

Use memory slab blocks when sending large amounts of data from one thread to another, to avoid unnecessary copying of the data.

Configuration Options

Related configuration options:
- `CONFIG_MEM_SLAB_TRACE_MAX_UTILIZATION`

API Reference

`group mem_slab_apis`

**Defines**

```c
K_MEM_SLAB_DEFINE(name, slab_block_size, slab_num_blocks, slab_align)
```

Statically define and initialize a memory slab in a public (non-static) scope.

The memory slab's buffer contains `slab_num_blocks` memory blocks that are `slab_block_size` bytes long. The buffer is aligned to a `slab_align`-byte boundary. To ensure that each memory block is similarly aligned to this boundary, `slab_block_size` must also be a multiple of `slab_align`.

The memory slab can be accessed outside the module where it is defined using:

```c
extern struct k_mem_slab <name>;
```

**Note:** This macro cannot be used together with a static keyword. If such a use-case is desired, use `K_MEM_SLAB_DEFINE_STATIC` instead.

**Parameters**

- `name` – Name of the memory slab.
• slab_block_size – Size of each memory block (in bytes).
• slab_num_blocks – Number memory blocks.
• slab_align – Alignment of the memory slab's buffer (power of 2).

\texttt{K\_MEM\_SLAB\_DEFINE\_STATIC(name, slab_block_size, slab_num_blocks, slab_align)}

Statically define and initialize a memory slab in a private (static) scope.

The memory slab's buffer contains \texttt{slab_num_blocks} memory blocks that are \texttt{slab_block_size} bytes long. The buffer is aligned to a \texttt{slab_align} -byte boundary. To ensure that each memory block is similarly aligned to this boundary, \texttt{slab_block_size} must also be a multiple of \texttt{slab_align}.

**Parameters**

• \texttt{name} – Name of the memory slab.
• \texttt{slab_block_size} – Size of each memory block (in bytes).
• \texttt{slab_num_blocks} – Number memory blocks.
• \texttt{slab_align} – Alignment of the memory slab's buffer (power of 2).

**Functions**

\texttt{int k\_mem\_slab\_init(struct k\_mem\_slab *slab, void *buffer, size\_t block\_size, uint32\_t num\_blocks)}

Initialize a memory slab.

Initializes a memory slab, prior to its first use.

The memory slab's buffer contains \texttt{slab_num_blocks} memory blocks that are \texttt{slab_block_size} bytes long. The buffer must be aligned to an N-byte boundary matching a word boundary, where N is a power of 2 (i.e. 4 on 32-bit systems, 8, 16, ...). To ensure that each memory block is similarly aligned to this boundary, \texttt{slab_block_size} must also be a multiple of N.

**Parameters**

• \texttt{slab} – Address of the memory slab.
• \texttt{buffer} – Pointer to buffer used for the memory blocks.
• \texttt{block\_size} – Size of each memory block (in bytes).
• \texttt{num\_blocks} – Number of memory blocks.

**Return values**

• 0 – on success
• -EINVAL – invalid data supplied

\texttt{int k\_mem\_slab\_alloc(struct k\_mem\_slab *slab, void **mem, k\_timeout\_t timeout)}

Allocate memory from a memory slab.

This routine allocates a memory block from a memory slab.

**Function properties (list may not be complete)**

\texttt{isr-ok}

---

**Note:** \texttt{timeout} must be set to \texttt{K\_NO\_WAIT} if called from ISR.

---

**Note:** When \texttt{CONFIG\_MULTITHREADING=n} any \texttt{timeout} is treated as \texttt{K\_NO\_WAIT}.
Parameters

- **slab** – Address of the memory slab.
- **mem** – Pointer to block address area.
- **timeout** – Non-negative waiting period to wait for operation to complete. Use K_NO_WAIT to return without waiting, or K_FOREVER to wait as long as necessary.

Return values

- **0** – Memory allocated. The block address area pointed at by **mem** is set to the starting address of the memory block.
- **-ENOMEM** – Returned without waiting.
- **-EAGAIN** – Waiting period timed out.
- **-EINVAL** – Invalid data supplied

```c
void k_mem_slab_free(struct k_mem_slab *slab, void **mem)
```
Free memory allocated from a memory slab.

This routine releases a previously allocated memory block back to its associated memory slab.

Parameters

- **slab** – Address of the memory slab.
- **mem** – Pointer to block address area (as set by `k_mem_slab_alloc()`).

```c
static inline uint32_t k_mem_slab_num_used_get(struct k_mem_slab *slab)
```
Get the number of used blocks in a memory slab.

This routine gets the number of memory blocks that are currently allocated in `slab`.

Parameters

- **slab** – Address of the memory slab.

Returns

Number of allocated memory blocks.

```c
static inline uint32_t k_mem_slab_max_used_get(struct k_mem_slab *slab)
```
Get the number of maximum used blocks so far in a memory slab.

This routine gets the maximum number of memory blocks that were allocated in `slab`.

Parameters

- **slab** – Address of the memory slab.

Returns

Maximum number of allocated memory blocks.

```c
static inline uint32_t k_mem_slab_num_free_get(struct k_mem_slab *slab)
```
Get the number of unused blocks in a memory slab.

This routine gets the number of memory blocks that are currently unallocated in `slab`.

Parameters

- **slab** – Address of the memory slab.

Returns

Number of unallocated memory blocks.
int k_mem_slab_runtime_stats_get(struct k_mem_slab *slab, struct sys_memory_stats *stats)
Get the memory stats for a memory slab.

This routine gets the runtime memory usage stats for the slab \textit{slab}.

**Parameters**
- \textit{slab} – Address of the memory slab
- \textit{stats} – Pointer to memory into which to copy memory usage statistics

**Return values**
- 0 – Success
- -EINVAL – Any parameter points to NULL

int k_mem_slab_runtime_stats_reset_max(struct k_mem_slab *slab)
Reset the maximum memory usage for a slab.

This routine resets the maximum memory usage for the slab \textit{slab} to its current usage.

**Parameters**
- \textit{slab} – Address of the memory slab

**Return values**
- 0 – Success
- -EINVAL – Memory slab is NULL

### 3.4.4 Memory Blocks Allocator

The Memory Blocks Allocator allows memory blocks to be dynamically allocated from a designated memory region, where:

- All memory blocks have a single fixed size.
- Multiple blocks can be allocated or freed at the same time.
- A group of blocks allocated together may not be contiguous. This is useful for operations such as scatter-gather DMA transfers.
- Bookkeeping of allocated blocks is done outside of the associated buffer (unlike memory slab). This allows the buffer to reside in memory regions where these can be powered down to conserve energy.

- **Concepts**
  - \textit{Internal Operation}
- **Memory Blocks Allocator**
- **Multi Memory Blocks Allocator Group**
- **Usage**
  - \textit{Defining a Memory Blocks Allocator}
  - \textit{Allocating Memory Blocks}
  - \textit{Releasing a Memory Block}
  - \textit{Using Multi Memory Blocks Allocator Group}
- **API Reference**
Concepts

Any number of Memory Blocks Allocator can be defined (limited only by available RAM). Each allocator is referenced by its memory address.

A memory blocks allocator has the following key properties:

- The block size of each block, measured in bytes. It must be at least $4N$ bytes long, where $N$ is greater than 0.
- The number of blocks available for allocation. It must be greater than zero.
- A buffer that provides the memory for the memory slab's blocks. It must be at least “block size” times “number of blocks” bytes long.
- A blocks bitmap to keep track of which block has been allocated.

The buffer must be aligned to an $N$-byte boundary, where $N$ is a power of 2 larger than 2 (i.e. 4, 8, 16, ...). To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of $N$.

Due to the use of internal bookkeeping structures and their creation, each memory blocks allocator must be declared and defined at compile time.

Internal Operation

Each buffer associated with an allocator is an array of fixed-size blocks, with no wasted space between the blocks.

The memory blocks allocator keeps track of unallocated blocks using a bitmap.

Memory Blocks Allocator

Internally, the memory blocks allocator uses a bitmap to keep track of which blocks have been allocated. Each allocator, utilizing the sys_bitarray interface, gets memory blocks one by one from the backing buffer up to the requested number of blocks. All the metadata about an allocator is stored outside of the backing buffer. This allows the memory region of the backing buffer to be powered down to conserve energy, as the allocator code never touches the content of the buffer.

Multi Memory Blocks Allocator Group

The Multi Memory Blocks Allocator Group utility functions provide a convenient to manage a group of allocators. A custom allocator choosing function is used to choose which allocator to use among this group.

An allocator group should be initialized at runtime via sys_multi_mem_blocks_init(). Each allocator can then be added via sys_multi_mem_blocks_add_allocator().

To allocate memory blocks from group, sys_multi_mem_blocks_alloc() is called with an opaque “configuration” parameter. This parameter is passed directly to the allocator choosing function so that an appropriate allocator can be chosen. After an allocator is chosen, memory blocks are allocated via sys_mem_blocks_alloc().

Allocated memory blocks can be freed via sys_multi_mem_blocks_free(). The caller does not need to pass a configuration parameter. The allocator code matches the passed in memory addresses to find the correct allocator and then memory blocks are freed via sys_mem_blocks_free().

Usage

Defining a Memory Blocks Allocator A memory blocks allocator is defined using a variable of type sys_mem_blocks_t. It needs to be defined and initialized at compile time by calling SYS_MEM_BLOCKS_DEFINE.
The following code defines and initializes a memory blocks allocator which has 4 blocks that are 64 bytes long, each of which is aligned to a 4-byte boundary:

```c
SYS_MEM_BLOCKS_DEFINE(allocator, 64, 4, 4);
```

Similarly, you can define a memory slab in private scope:

```c
SYS_MEM_BLOCKS_DEFINE_STATIC(static_allocator, 64, 4, 4);
```

A pre-defined buffer can also be provided to the allocator where the buffer can be placed separately. Note that the alignment of the buffer needs to be done at its definition.

```c
uint8_t __aligned(4) backing_buffer[64 * 4];
SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(allocator, 64, 4, backing_buffer);
```

### Allocating Memory Blocks

Memory blocks can be allocated by calling `sys_mem_blocks_alloc()`.

```c
int ret;
uintptr_t blocks[2];
ret = sys_mem_blocks_alloc(allocator, 2, blocks);
```

If `ret == 0`, the array `blocks` will contain an array of memory addresses pointing to the allocated blocks.

### Releasing a Memory Block

Memory blocks are released by calling `sys_mem_blocks_free()`.

The following code builds on the example above which allocates 2 memory blocks, then releases them once they are no longer needed.

```c
int ret;
uintptr_t blocks[2];
ret = sys_mem_blocks_alloc(allocator, 2, blocks);
... /* perform some operations on the allocated memory blocks */
ret = sys_mem_blocks_free(allocator, 2, blocks);
```

### Using Multi Memory Blocks Allocator Group

The following code demonstrates how to initialize an allocator group:

```c
sys_mem_blocks_t *choice_fn(struct sys_multi_mem_blocks *group, void *cfg)
{
    ...
}
SYS_MEM_BLOCKS_DEFINE(allocator0, 64, 4, 4);
SYS_MEM_BLOCKS_DEFINE(allocator1, 64, 4, 4);
static sys_multi_mem_blocks_t alloc_group;
sys_multi_mem_blocks_init(&alloc_group, choice_fn);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator0);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator1);
```

To allocate and free memory blocks from the group:

```c
```
```
int ret;
uintptr_t blocks[1];
size_t blk_size;

ret = sys_multi_mem_blocks_alloc(&alloc_group, UINT_TO_POINTER(0),
                                 1, blocks, &blk_size);
ret = sys_multi_mem_blocks_free(&alloc_group, 1, blocks);
```

### API Reference

**group mem_blocks_apis**

**Defines**

SYS_MEM_BLOCKS_DEFINE(name, blk_sz, num_blks, buf_align)

Create a memory block object with a new backing buffer.

**Parameters**

- name – Name of the memory block object.
- blk_sz – Size of each memory block (in bytes).
- num_blks – Total number of memory blocks.
- buf_align – Alignment of the memory block buffer (power of 2).

SYS_MEM_BLOCKS_DEFINE_STATIC(name, blk_sz, num_blks, buf_align)

Create a static memory block object with a new backing buffer.

**Parameters**

- name – Name of the memory block object.
- blk_sz – Size of each memory block (in bytes).
- num_blks – Total number of memory blocks.
- buf_align – Alignment of the memory block buffer (power of 2).

SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(name, blk_sz, num_blks, buf)

Create a memory block object with a providing backing buffer.

**Parameters**

- name – Name of the memory block object.
- blk_sz – Size of each memory block (in bytes).
- num_blks – Total number of memory blocks.
- buf – Backing buffer of type uint8_t.

SYS_MEM_BLOCKS_DEFINE_STATIC_WITH_EXT_BUF(name, blk_sz, num_blks, buf)

Create a static memory block object with a providing backing buffer.

**Parameters**

- name – Name of the memory block object.
- blk_sz – Size of each memory block (in bytes).
- num_blks – Total number of memory blocks.
buf – Backing buffer of type uint8_t.

**Typedefs**

typedef struct sys_mem_blocks sys_mem_blocks_t
    Memory Blocks Allocator.

typedef struct sys_multi_mem_blocks sys_multi_mem_blocks_t
    Multi Memory Blocks Allocator.

typedef sys_mem_blocks_t *(sys_multi_mem_blocks_choice_fn_t)(struct sys_multi_mem_blocks *group, void *cfg)
    Multi memory blocks allocator choice function.

    This is a user-provided functions whose responsibility is selecting a specific memory blocks
    allocator based on the opaque cfg value, which is specified by the user as an argument to
    sys_multi_mem_blocks_alloc(). The callback returns a pointer to the chosen allocator where
    the allocation is performed.

    NULL may be returned, which will cause the allocation to fail and a -EINVAL reported to the
    calling code.

    **Param group**
    Multi memory blocks allocator structure.

    **Param cfg**
    An opaque user-provided value. It may be interpreted in any way by the applica-
    tion.

    **Return**
    A pointer to the chosen allocator, or NULL if none is chosen.

**Functions**

int sys_mem_blocks_alloc(sys_mem_blocks_t *mem_block, size_t count, void **out_blocks)
    Allocate multiple memory blocks.

    Allocate multiple memory blocks, and place their pointers into the output array.

    **Parameters**

    • mem_block – Pointer to memory block object.
    • count – [in] Number of blocks to allocate.
    • out_blocks – [out] Output array to be populated by pointers to the memory
      blocks. It must have at least count elements.

    **Return values**

    • 0 – Successful
    • -EINVAL – Invalid argument supplied.
    • -ENOMEM – Not enough blocks for allocation.

int sys_mem_blocks_alloc_contiguous(sys_mem_blocks_t *mem_block, size_t count, void **out_block)
    Allocate a contiguous set of memory blocks.

    Allocate multiple memory blocks, and place their pointers into the output array.
Parameters
- mem_block – Pointer to memory block object.
- count – [in] Number of blocks to allocate.
- out_block – [out] Output pointer to the start of the allocated block set

Return values
- 0 – Successful
- -EINVAL – Invalid argument supplied.
- -ENOMEM – Not enough contiguous blocks for allocation.

```
int sys_mem_blocks_get(sys_mem_blocks_t *mem_block, void *in_block, size_t count)
```

Force allocation of a specified blocks in a memory block object.

Allocate a specified blocks in a memory block object. Note: use caution when mixing sys_mem_blocks_get and sys_mem_blocks_alloc, allocation may take any of the free memory space

Parameters
- mem_block – Pointer to memory block object.
- in_block – [in] Address of the first required block to allocate
- count – [in] Number of blocks to allocate.

Return values
- 0 – Successful
- -EINVAL – Invalid argument supplied.
- -ENOMEM – Some of blocks are taken and cannot be allocated

```
int sys_mem_blocks_is_region_free(sys_mem_blocks_t *mem_block, void *in_block, size_t count)
```

check if the region is free

Parameters
- mem_block – Pointer to memory block object.
- in_block – [in] Address of the first block to check
- count – [in] Number of blocks to check.

Return values
- 1 – All memory blocks are free
- 0 – At least one of the memory blocks is taken

```
int sys_mem_blocks_free(sys_mem_blocks_t *mem_block, size_t count, void **in_blocks)
```

Free multiple memory blocks.

Free multiple memory blocks according to the array of memory block pointers.

Parameters
- mem_block – Pointer to memory block object.
- count – [in] Number of blocks to free.

Return values
- 0 – Successful
Free contiguous multiple memory blocks.

Free contiguous multiple memory blocks

**Parameters**

- `mem_block` – Pointer to memory block object.
- `block` – [in] Pointer to the first memory block
- `count` – [in] Number of blocks to free.

**Return values**

- 0 – Successful
- EINVAL – Invalid argument supplied.
-EFAULT – Invalid pointer supplied.

**void sys_multi_mem_blocks_init(sys_multi_mem_blocks_t *group, sys_multi_mem_blocks_choice_fn_t choice_fn)**

Initialize multi memory blocks allocator group.

Initialize a sys_multi_mem_block struct with the specified choice function. Note that individual allocator must be added later with sys_multi_mem_blocks_add_allocator.

**Parameters**

- `group` – Multi memory blocks allocator structure.
- `choice_fn` – A sys_multi_mem_blocks_choice_fn_t callback used to select the allocator to be used at allocation time

**void sys_multi_mem_blocks_add_allocator(sys_multi_mem_blocks_t *group, sys_mem_blocks_t *alloc)**

Add an allocator to an allocator group.

This adds a known allocator to an existing multi memory blocks allocator group.

**Parameters**

- `group` – Multi memory blocks allocator structure.
- `alloc` – Allocator to add

**int sys_multi_mem_blocks_alloc(sys_multi_mem_blocks_t *group, void *cfg, size_t count, void **out_blocks, size_t *blk_size)**

Allocate memory from multi memory blocks allocator group.

Just as for `sys_mem_blocks_alloc()`, allocates multiple blocks of memory. Takes an opaque configuration pointer passed to the choice function, which is used by integration code to choose an allocator.

**Parameters**

- `cfg` – [in] Opaque configuration parameter, as for `sys_multi_mem_blocks_choice_fn_t`
- `count` – [in] Number of blocks to allocate
- `out_blocks` – [out] Output array to be populated by pointers to the memory blocks. It must have at least `count` elements.
• blk_size – [out] If not NULL, output the block size of the chosen allocator.

Return values
• 0 – Successful
• -EINVAL – Invalid argument supplied, or no allocator chosen.
• -ENOMEM – Not enough blocks for allocation.

int sys_multi_mem_blocks_free(sys_multi_mem_blocks_t *group, size_t count, void ***in_blocks)

Free memory allocated from multi memory blocks allocator group.
Free previous allocated memory blocks from sys_multi_mem_blocks_alloc().
Note that all blocks in in_blocks must be from the same allocator.

Parameters
• count – [in] Number of blocks to free.
• in_blocks – [in] Input array of pointers to the memory blocks.

Return values
• 0 – Successful
• -EINVAL – Invalid argument supplied, or no allocator chosen.
• -EFAULT – Invalid pointer(s) supplied.

3.4.5 Demand Paging

Demand paging provides a mechanism where data is only brought into physical memory as required by current execution context. The physical memory is conceptually divided in page-sized page frames as regions to hold data.

• When the processor tries to access data and the data page exists in one of the page frames, the execution continues without any interruptions.
• When the processor tries to access the data page that does not exist in any page frames, a page fault occurs. The paging code then brings in the corresponding data page from backing store into physical memory if there is a free page frame. If there is no more free page frames, the eviction algorithm is invoked to select a data page to be paged out, thus freeing up a page frame for new data to be paged in. If this data page has been modified after it is first paged in, the data will be written back into the backing store. If no modifications is done or after written back into backing store, the data page is now considered paged out and the corresponding page frame is now free. The paging code then invokes the backing store to page in the data page corresponding to the location of the requested data. The backing store copies that data page into the free page frame. Now the data page is in physical memory and execution can continue.

There are functions where paging in and out can be invoked manually using k_mem_page_in() and k_mem_page_out(). k_mem_page_in() can be used to page in data pages in anticipation that they are required in the near future. This is used to minimize number of page faults as these data pages are already in physical memory, and thus minimizing latency. k_mem_page_out() can be used to page out data pages where they are not going to be accessed for a considerable amount of time. This frees up page frames so that the next page in can be executed faster as the paging code does not need to invoke the eviction algorithm.
Terminology

Data Page
A data page is a page-sized region of data. It may exist in a page frame, or be paged out to some backing store. Its location can always be looked up in the CPU's page tables (or equivalent) by virtual address. The data type will always be void * or in some cases uint8_t * when doing pointer arithmetic.

Page Frame
A page frame is a page-sized physical memory region in RAM. It is a container where a data page may be placed. It is always referred to by physical address. Zephyr has a convention of using uintptr_t for physical addresses. For every page frame, a struct z_page_frame is instantiated to store metadata. Flags for each page frame:

• Z_PAGE_FRAME_PINNED indicates a page frame is pinned in memory and should never be paged out.
• Z_PAGE_FRAME_RESERVED indicates a physical page reserved by hardware and should not be used at all.
• Z_PAGE_FRAME_MAPPED is set when a physical page is mapped to virtual memory address.
• Z_PAGE_FRAME_BUSY indicates a page frame is currently involved in a page-in/out operation.
• Z_PAGEFRAME_BACKED indicates a page frame has a clean copy in the backing store.

Z_SCRATCH_PAGE
The virtual address of a special page provided to the backing store to: * Copy a data page from Z_SCRATCH_PAGE to the specified location; or, * Copy a data page from the provided location to Z_SCRATCH_PAGE. This is used as an intermediate page for page in/out operations. This scratch needs to be mapped read/write for backing store code to access. However the data page itself may only be mapped as read-only in virtual address space. If this page is provided as-is to backing store, the data page must be re-mapped as read/write which has security implications as the data page is no longer read-only to other parts of the application.

Paging Statistics
Paging statistics can be obtained via various function calls when CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS is enabled:

• Overall statistics via k_mem_paging_stats_get()

• Per-thread statistics via k_mem_paging_thread_stats_get() if CONFIG_DEMAND_PAGING_THREAD_STATS is enabled

• Execution time histogram can be obtained when CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM is enabled, and CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS is defined. Note that the timing is highly dependent on the architecture, SoC or board. It is highly recommended that k_mem_paging_eviction_histogram_bounds[] and k_mem_paging_backing_store_histogram_bounds[] be defined for a particular application.
  – Execution time histogram of eviction algorithm via k_mem_paging_histogram_eviction_get()
  – Execution time histogram of backing store doing page-in via k_mem_paging_histogram_backing_store_page_in_get()
  – Execution time histogram of backing store doing page-out via k_mem_paging_histogram_backing_store_page_out_get()

Eviction Algorithm
The eviction algorithm is used to determine which data page and its corresponding page frame can be paged out to free up a page frame for the next page in operation. There are two functions which are
called from the kernel paging code:

- `k_mem_paging_eviction_init()` is called to initialize the eviction algorithm. This is called at `POST_KERNEL`.
- `k_mem_paging_eviction_select()` is called to select a data page to evict. A function argument `dirty` is written to signal the caller whether the selected data page has been modified since it is first paged in. If the `dirty` bit is returned as set, the paging code signals to the backing store to write the data page back into storage (thus updating its content). The function returns a pointer to the page frame corresponding to the selected data page.

Currently, a NRU (Not-Recently-Used) eviction algorithm has been implemented as a sample. This is a very simple algorithm which ranks each data page on whether they have been accessed and modified. The selection is based on this ranking.

To implement a new eviction algorithm, the two functions mentioned above must be implemented.

**Backing Store**

Backing store is responsible for paging in/out data page between their corresponding page frames and storage. These are the functions which must be implemented:

- `k_mem_paging_backing_store_init()` is called to initialized the backing store at `POST_KERNEL`.
- `k_mem_paging_backing_store_location_get()` is called to reserve a backing store location so a data page can be paged out. This location token is passed to `k_mem_paging_backing_store_page_out()` to perform actual page out operation.
- `k_mem_paging_backing_store_location_free()` is called to free a backing store location (the location token) which can then be used for subsequent page out operation.
- `k_mem_paging_backing_store_page_in()` copies a data page from the backing store location associated with the provided location token to the page pointed by `Z_SCRATCH_PAGE`.
- `k_mem_paging_backing_store_page_out()` copies a data page from `Z_SCRATCH_PAGE` to the backing store location associated with the provided location token.
- `k_mem_paging_backing_store_page_finalize()` is invoked after `k_mem_paging_backing_store_page_in()` so that the page frame struct may be updated for internal accounting. This can be a no-op.

To implement a new backing store, the functions mentioned above must be implemented. `k_mem_paging_backing_store_page_finalize()` can be an empty function if so desired.

**API Reference**

`group mem-demand-paging`

**Functions**

```c
int k_mem_page_out(void *addr, size_t size)
```

Evict a page-aligned virtual memory region to the backing store

Useful if it is known that a memory region will not be used for some time. All the data pages within the specified region will be evicted to the backing store if they weren’t already, with their associated page frames marked as available for mappings or page-ins.

None of the associated page frames mapped to the provided region should be pinned.

Note that there are no guarantees how long these pages will be evicted, they could take page faults immediately.
If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by ISRs as the backing store may be in-use.

**Parameters**
- `addr` – Base page-aligned virtual address
- `size` – Page-aligned data region size

**Return values**
- `0` – Success
- `-ENOMEM` – Insufficient space in backing store to satisfy request. The region may be partially paged out.

```c
void k_mem_page_in(void *addr, size_t size)
```

Load a virtual data region into memory

After the function completes, all the page frames associated with this function will be paged in. However, they are not guaranteed to stay there. This is useful if the region is known to be used soon.

If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by ISRs as the backing store may be in-use.

**Parameters**
- `addr` – Base page-aligned virtual address
- `size` – Page-aligned data region size

```c
void k_mem_pin(void *addr, size_t size)
```

Pin an aligned virtual data region, paging in as necessary

After the function completes, all the page frames associated with this region will be resident in memory and pinned such that they stay that way. This is a stronger version of `z_mem_page_in()`.

If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by ISRs as the backing store may be in-use.

**Parameters**
- `addr` – Base page-aligned virtual address
- `size` – Page-aligned data region size

```c
void k_mem_unpin(void *addr, size_t size)
```

Un-pin an aligned virtual data region

After the function completes, all the page frames associated with this region will be no longer marked as pinned. This does not evict the region, follow this with `z_mem_page_out()` if you need that.

**Parameters**
- `addr` – Base page-aligned virtual address
- `size` – Page-aligned data region size

```c
void k_mem_paging_stats_get(struct k_mem_paging_stats_t *stats)
```

Get the paging statistics since system startup

This populates the paging statistics struct being passed in as argument.

**Parameters**
- `stats` – [inout] Paging statistics struct to be filled.
void k_mem_paging_thread_stats_get(struct k_thread *thread, struct k_mem_paging_stats_t *stats)

Get the paging statistics since system startup for a thread
This populates the paging statistics struct being passed in as argument for a particular thread.

Parameters

- thread – [in] Thread
- stats – [inout] Paging statistics struct to be filled.

void k_mem_paging_histogram_eviction_get(struct k_mem_paging_histogram_t *hist)

Get the eviction timing histogram
This populates the timing histogram struct being passed in as argument.

Parameters

- hist – [inout] Timing histogram struct to be filled.

void k_mem_paging_histogramBacking_store_page_in_get(struct k_mem_paging_histogram_t *hist)

Get the backing store page-in timing histogram
This populates the timing histogram struct being passed in as argument.

Parameters

- hist – [inout] Timing histogram struct to be filled.

void k_mem_paging_histogramBacking_store_page_out_get(struct k_mem_paging_histogram_t *hist)

Get the backing store page-out timing histogram
This populates the timing histogram struct being passed in as argument.

Parameters

- hist – [inout] Timing histogram struct to be filled.

eviction

eviction

eviction

Eviction Algorithm APIs

group mem-demand-paging-eviction

Eviction algorithm APIs

Functions

struct z_page_frame *k_mem_paging_eviction_select(bool *dirty)

Select a page frame for eviction
The kernel will invoke this to choose a page frame to evict if there are no free page frames.
This function will never be called before the initial k_mem_paging_eviction_init().
This function is invoked with interrupts locked.

Parameters

- dirty – [out] Whether the page to evict is dirty

Returns

The page frame to evict
void k_mem_paging_eviction_init(void)
Initialization function
Called at POST_KERNEL to perform any necessary initialization tasks for the eviction algorythm. \textit{k\_mem\_paging\_eviction\_select()} is guaranteed to never be called until this has returned, and this will only be called once.

**Backing Store APIs**

\textit{group mem-demand-paging-backing-store}

Backing store APIs

**Functions**

int k_mem_paging_backing_store_location_get(struct z_page_frame *pf, uintptr_t *location,
bool page_fault)

Reserve or fetch a storage location for a data page loaded into a page frame

The returned location token must be unique to the mapped virtual address. This location will be used in the backing store to page out data page contents for later retrieval. The location value must be page-aligned.

This function may be called multiple times on the same data page. If its page frame has its Z\_PAGE\_FRAME\_BACKED bit set, it is expected to return the previous backing store location for the data page containing a cached clean copy. This clean copy may be updated on page-out, or used to discard clean pages without needing to write out their contents.

If the backing store is full, some other backing store location which caches a loaded data page may be selected, in which case its associated page frame will have the Z\_PAGE\_FRAME\_BACKED bit cleared (as it is no longer cached).

pf->addr will indicate the virtual address the page is currently mapped to. Large, sparse backing stores which can contain the entire address space may simply generate location tokens purely as a function of pf->addr with no other management necessary.

This function distinguishes whether it was called on behalf of a page fault. A free backing store location must always be reserved in order for page faults to succeed. If the page\_fault parameter is not set, this function should return -ENOMEM even if one location is available.

This function is invoked with interrupts locked.

**Parameters**

- \textit{pf} – Virtual address to obtain a storage location
- \textit{location} – [\textbf{out}] storage location token
- \textit{page\_fault} – Whether this request was for a page fault

**Returns**

0 Success

-ENOMEM Backing store is full

void k_mem_paging_backing_store_location_free(uintptr_t location)
Free a backing store location

Any stored data may be discarded, and the location token associated with this address may be re-used for some other data page.

This function is invoked with interrupts locked.

**Parameters**
void k_mem_paging_backing_store_page_out(uintptr_t location)
Copy a data page from Z_SCRATCH_PAGE to the specified location
Immediately before this is called, Z_SCRATCH_PAGE will be mapped read-write to the intended source page frame for the calling context.
Calls to this and k_mem_paging_backing_store_page_in() will always be serialized, but interrupts may be enabled.

Parameters

• location – Location token to free

void k_mem_paging_backing_store_page_in(uintptr_t location)
Copy a data page from the provided location to Z_SCRATCH_PAGE.
Immediately before this is called, Z_SCRATCH_PAGE will be mapped read-write to the intended destination page frame for the calling context.
Calls to this and k_mem_paging_backing_store_page_out() will always be serialized, but interrupts may be enabled.

Parameters

• location – Location token for the data page

void k_mem_paging_backing_store_page_finalize(struct z_page_frame *pf, uintptr_t location)
Update internal accounting after a page-in
This is invoked after k_mem_paging_backing_store_page_in() and interrupts have been re-locked, making it safe to access the z_page_frame data. The location value will be the same passed to k_mem_paging_backing_store_page_in().
The primary use-case for this is to update custom fields for the backing store in the page frame, to reflect where the data should be evicted to if it is paged out again. This may be a no-op in some implementations.
If the backing store caches paged-in data pages, this is the appropriate time to set the Z_PAGE_FRAME_BACKED bit. The kernel only skips paging out clean data pages if they are noted as clean in the page tables and the Z_PAGE_FRAME_BACKED bit is set in their associated page frame.

Parameters

• pf – Page frame that was loaded in
• location – Location of where the loaded data page was retrieved

void k_mem_paging_backing_store_init(void)
Backing store initialization function.
The implementation may expect to receive page in/out calls as soon as this returns, but not before that. Called at POST_KERNEL.
This function is expected to do two things:

• Initialize any internal data structures and accounting for the backing store.

• If the backing store already contains all or some loaded kernel data pages at boot time, Z_PAGE_FRAME_BACKED should be appropriately set for their associated page frames, and any internal accounting set up appropriately.
3.5 Data Structures

Zephyr provides a library of common general purpose data structures used within the kernel, but useful by application code in general. These include list and balanced tree structures for storing ordered data, and a ring buffer for managing “byte stream” data in a clean way.

Note that in general, the collections are implemented as “intrusive” data structures. The “node” data is the only struct used by the library code, and it does not store a pointer or other metadata to indicate what user data is “owned” by that node. Instead, the expectation is that the node will be itself embedded within a user-defined struct. Macros are provided to retrieve a user struct address from the embedded node pointer in a clean way. The purpose behind this design is to allow the collections to be used in contexts where dynamic allocation is disallowed (i.e. there is no need to allocate node objects because the memory is provided by the user).

Note also that these libraries are uniformly unsynchronized; access to them is not threadsafe by default. These are data structures, not synchronization primitives. The expectation is that any locking needed will be provided by the user.

3.5.1 Single-linked List

Zephyr provides a `sys_slist_t` type for storing simple singly-linked list data (i.e. data where each list element stores a pointer to the next element, but not the previous one). This supports constant-time access to the first (head) and last (tail) elements of the list, insertion before the head and after the tail of the list and constant time removal of the head. Removal of subsequent nodes requires access to the “previous” pointer and thus can only be performed in linear time by searching the list.

The `sys_slist_t` struct may be instantiated by the user in any accessible memory. It should be initialized with either `sys_slist_init()` or by static assignment from `SYS_SLIST_STATIC_INIT` before use. Its interior fields are opaque and should not be accessed by user code.

The end nodes of a list may be retrieved with `sys_slist_peek_head()` and `sys_slist_peek_tail()`, which will return NULL if the list is empty, otherwise a pointer to a `sys_snode_t` struct.

The `sys_snode_t` struct represents the data to be inserted. In general, it is expected to be allocated/controlled by the user, usually embedded within a struct which is to be added to the list. The container struct pointer may be retrieved from a list node using `SYS_SLIST_CONTAINER`, passing it the struct name of the containing struct and the field name of the node. Internally, the `sys_snode_t` struct contains only a next pointer, which may be accessed with `sys_slist_peek_next()`.

Lists may be modified by adding a single node at the head or tail with `sys_slist_prepend()` and `sys_slist_append()`. They may also have a node added to an interior point with `sys_slist_insert()`, which inserts a new node after an existing one. Similarly `sys_slist_remove()` will remove a node given a pointer to its predecessor. These operations are all constant time.

Convenience routines exist for more complicated modifications to a list. `sys_slist_merge_slist()` will append an entire list to an existing one. `sys_slist_append_list()` will append a bounded subset of an existing list in constant time. And `sys_slist_find_and_remove()` will search a list (in linear time) for a given node and remove it if present.

Finally the slist implementation provides a set of “for each” macros that allows for iterating over a list in a natural way without needing to manually traverse the next pointers. `SYS_SLIST_FOR_EACH_NODE` will enumerate every node in a list given a local variable to store the node pointer. `SYS_SLIST_FOR_EACH_NODE_SAFE` behaves similarly, but has a more complicated implementation that requires an extra scratch variable for storage and allows the user to delete the iterated node during the iteration. Each of those macros also exists in a “container” variant (`SYS_SLIST_FOR_EACH_CONTAINER` and `SYS_SLIST_FOR_EACH_CONTAINER_SAFE`) which assigns a local variable of a type that matches the user's container struct and not the node struct, performing the required offsets internally. And `SYS_SLIST_ITERATE_FROM_NODE` exists to allow for enumerating a node and all its successors only, without inspecting the earlier part of the list.
Single-linked List Internals

The slist code is designed to be minimal and conventional. Internally, a `sys_slist_t` struct is nothing more than a pair of “head” and “tail” pointer fields. And a `sys_sn ode_t` stores only a single “next” pointer.

![Image of a single-linked list](image1.png)

Fig. 3.4: An slist containing three elements.

![Image of an empty list](image2.png)

Fig. 3.5: An empty slist

The specific implementation of the list code, however, is done with an internal “Z_GENLIST” template API which allows for extracting those fields from arbitrary structures and emits an arbitrarily named set of functions. This allows for implementing more complicated single-linked list variants using the same basic primitives. The genlist implementor is responsible for a custom implementation of the primitive operations only: an “init” step for each struct, and a “get” and “set” primitives for each of head, tail and next pointers on their relevant structs. These inline functions are passed as parameters to the genlist macro expansion.

Only one such variant, sflist, exists in Zephyr at the moment.

Flagged List

The `sys_sflist_t` is implemented using the described genlist template API. With the exception of symbol naming (“sflist” instead of “slist”) and the additional API described next, it operates in all ways identically to the slist API.

It adds the ability to associate exactly two bits of user defined “flags” with each list node. These can be accessed and modified with `sys_sfn ode_flags_get()` and `sys_sfn ode_flags_set()`. Internally, the flags are stored unioned with the bottom bits of the next pointer and incur no SRAM storage overhead when compared with the simpler slist code.

Single-linked List API Reference

`group single-linked-list_apis`

`Defines`
SYS_SLIST_FOR_EACH_NODE(__sl, __sn)
Provide the primitive to iterate on a list Note: the loop is unsafe and thus __sn should not be removed.
User MUST add the loop statement curly braces enclosing its own code:

SYS_SLIST_FOR_EACH_NODE(1, n) {
    <user code>
}

This and other SYS_SLIST_*( ) macros are not thread safe.

Parameters

• __sl – A pointer on a sys_slist_t to iterate on
• __sn – A sys_snode_t pointer to peek each node of the list

SYS_SLIST_ITERATE_FROM_NODE(__sl, __sn)
Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __sn should not be removed.
User MUST add the loop statement curly braces enclosing its own code:

SYS_SLIST_ITERATE_FROM_NODE(1, n) {
    <user code>
}

Like SYS_SLIST_FOR_EACH_NODE(), but __dn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.
This and other SYS_SLIST_*( ) macros are not thread safe.

Parameters

• __sl – A pointer on a sys_slist_t to iterate on
• __sn – A sys_snode_t pointer to peek each node of the list it contains the starting node, or NULL to start from the head

SYS_SLIST_FOR_EACH_NODE_SAFE(__sl, __sn, __sns)
Provide the primitive to safely iterate on a list Note: __sn can be removed, it will not break the loop.
User MUST add the loop statement curly braces enclosing its own code:

SYS_SLIST_FOR_EACH_NODE_SAFE(1, n, s) {
    <user code>
}

This and other SYS_SLIST_*( ) macros are not thread safe.

Parameters

• __sl – A pointer on a sys_slist_t to iterate on
• __sn – A sys_snode_t pointer to peek each node of the list
• __sns – A sys_snode_t pointer for the loop to run safely
SYS_SLIST_FOR_EACH_CONTAINER(__sl, __cn, __n)

Provide the primitive to iterate on a list under a container. Note: the loop is unsafe and thus __cn should not be detached.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_SLIST_FOR_EACH_CONTAINER(l, c, n) {
  <user code>
}
```

**Parameters**

- __sl – A pointer on a sys_slist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __n – The field name of sys_node_t within the container struct

SYS_SLIST_FOR_EACH_CONTAINER_SAFE(__sl, __cn, __cns, __n)

Provide the primitive to safely iterate on a list under a container. Note: __cn can be detached, it will not break the loop.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_SLIST_FOR_EACH_NODE_SAFE(l, c, cn, n) {
  <user code>
}
```

**Parameters**

- __sl – A pointer on a sys_slist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __cns – A pointer for the loop to run safely
- __n – The field name of sys_node_t within the container struct

SYS_SLIST_STATIC_INIT(ptr_to_list)

**Functions**

**static inline void sys_slist_init(sys_slist_t *list)**

Initialize a list.

**Parameters**

- list – A pointer on the list to initialize

**static inline sys_snode_t *sys_slist_peek_head(sys_slist_t *list)**

Peek the first node from the list.

**Parameters**

- list – A pointer on the list to peek the first node from

**Returns**

A pointer on the first node of the list (or NULL if none)

**static inline sys_snode_t *sys_slist_peek_tail(sys_slist_t *list)**

Peek the last node from the list.

**Parameters**
• list – A point on the list to peek the last node from

Returns
A pointer on the last node of the list (or NULL if none)

static inline bool sys_slist_is_empty(sys_slist_t *list)
Test if the given list is empty.

Parameters
• list – A pointer on the list to test

Returns
a boolean, true if it's empty, false otherwise

static inline sys_snnode_t *sys_slist_peek_next_no_check(sys_snnode_t *node)
Peek the next node from current node, node is not NULL.
Faster then sys_slist_peek_next() if node is known not to be NULL.

Parameters
• node – A pointer on the node where to peek the next node

Returns
a pointer on the next node (or NULL if none)

static inline void sys_slist_prepend(sys_slist_t *list, sys_snnode_t *node)
Prepend a node to the given list.
This and other sys_slist_*() functions are not thread safe.

Parameters
• list – A pointer on the list to affect
• node – A pointer on the node to prepend

static inline void sys_slist_append(sys_slist_t *list, sys_snnode_t *node)
Append a node to the given list.
This and other sys_slist_*() functions are not thread safe.

Parameters
• list – A pointer on the list to affect
• node – A pointer on the node to append

static inline void sys_slist_append_list(sys_slist_t *list, void *head, void *tail)
Append a list to the given list.
Append a singly-linked, NULL-terminated list consisting of nodes containing the pointer to the
next node as the first element of a node, to list. This and other sys_slist_*() functions are not
thread safe.

FIXME: Why are the element parameters void *?

Parameters
• list – A pointer on the list to affect
- head – A pointer to the first element of the list to append
- tail – A pointer to the last element of the list to append

static inline void sys_slist_merge_slist(sys_slist_t *list, sys_slist_t *list_to_append)
merge two slists, appending the second one to the first

When the operation is completed, the appending list is empty. This and other sys_slist_*() functions are not thread safe.

Parameters
- list – A pointer on the list to affect
- list_to_append – A pointer to the list to append.

static inline void sys_slist_insert(sys_slist_t *list, sys_snodet *prev, sys_snodet *node)
Insert a node to the given list.

This and other sys_slist_*() functions are not thread safe.

Parameters
- list – A pointer on the list to affect
- prev – A pointer on the previous node
- node – A pointer on the node to insert

static inline sys_snodet *sys_slist_get_not_empty(sys_slist_t *list)
Fetch and remove the first node of the given list.
List must be known to be non-empty. This and other sys_slist_*() functions are not thread safe.

Parameters
- list – A pointer on the list to affect

Returns
A pointer to the first node of the list

static inline sys_snodet *sys_slist_get(sys_slist_t *list)
Fetch and remove the first node of the given list.
This and other sys_slist_*() functions are not thread safe.

Parameters
- list – A pointer on the list to affect

Returns
A pointer to the first node of the list (or NULL if empty)

static inline void sys_slist_remove(sys_slist_t *list, sys_snodet *prev_node, sys_snodet *node)
Remove a node.
This and other sys_slist_*() functions are not thread safe.

Parameters
- list – A pointer on the list to affect
- prev_node – A pointer on the previous node (can be NULL, which means the node is the list’s head)
- node – A pointer on the node to remove
static inline bool sys_slist_find_and_remove(sys_slist_t *list, sys_sn node)
    Find and remove a node from a list.
    This and other sys_slist_() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• node – A pointer on the node to remove from the list

Returns
    true if node was removed

Flagged List API Reference

group flagged-single-linked-list_apis

Defines

SYS_SFLIST_FOR_EACH_NODE(__sl, __sn)
    Provide the primitive to iterate on a list Note: the loop is unsafe and thus __sn should not be removed.
    User MUST add the loop statement curly braces enclosing its own code:

    SYS_SFLIST_FOR_EACH_NODE(l, n) {
        <user code>
    }

This and other SYS_SFLIST_*() macros are not thread safe.

Parameters

• __sl – A pointer on a sys_sflist_t to iterate on
• __sn – A sys_sfnode_t pointer to peek each node of the list

SYS_SFLIST_ITERATE_FROM_NODE(__sl, __sn)
    Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __sn should not be removed.
    User MUST add the loop statement curly braces enclosing its own code:

    SYS_SFLIST_ITERATE_FROM_NODE(l, n) {
        <user code>
    }

Like SYS_SFLIST_FOR_EACH_NODE(), but __dn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.

This and other SYS_SFLIST_*() macros are not thread safe.

Parameters

• __sl – A pointer on a sys_sflist_t to iterate on
• __sn – A sys_sfnode_t pointer to peek each node of the list it contains the starting node, or NULL to start from the head
SYS_SFLIST_FOR_EACH_NODE_SAFE(__sl, __sn, __sns)

Provide the primitive to safely iterate on a list. Note: __sn can be removed, it will not break the loop.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_SFLIST_FOR_EACH_NODE_SAFE(1, n, s) {
    <user code>
}
```

This and other SYS_SFLIST_*() macros are not thread safe.

**Parameters**

- __sl – A pointer on a sys_sflist_t to iterate on
- __sn – A sys_sfnode_t pointer to peek each node of the list
- __sns – A sys_sfnode_t pointer for the loop to run safely

---

SYS_SFLIST_CONTAINER(__ln, __cn, __n)
SYS_SFLIST_PEEK_HEAD_CONTAINER(__sl, __cn, __n)
SYS_SFLIST_PEEK_TAIL_CONTAINER(__sl, __cn, __n)
SYS_SFLIST_PEEK_NEXT_CONTAINER(__cn, __n)
SYS_SFLIST_FOR_EACH_CONTAINER(__sl, __cn, __n)

Provide the primitive to iterate on a list under a container. Note: the loop is unsafe and thus __cn should not be detached.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_SFLIST_FOR_EACH_CONTAINER(1, c, n) {
    <user code>
}
```

**Parameters**

- __sl – A pointer on a sys_sflist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __n – The field name of sys_sfnode_t within the container struct

---

SYS_SFLIST_FOR_EACH_CONTAINER_SAFE(__sl, __cn, __cns, __n)

Provide the primitive to safely iterate on a list under a container. Note: __cn can be detached, it will not break the loop.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_SFLIST_FOR_EACH_NODE_SAFE(l, c, cn, n) {
    <user code>
}
```

**Parameters**

- __sl – A pointer on a sys_sflist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __cns – A pointer for the loop to run safely
- __n – The field name of sys_sfnode_t within the container struct
SYS_SFLIST_STATIC_INIT(ptr_to_list)

SYS_SFLIST_FLAGS_MASK

Functions

static inline void sys_sflist_init(sys_sflist_t *list)
Initialize a list.

Parameters

- list – A pointer on the list to initialize

static inline uint8_t sys_sfnode_flags_get(sys_sfnode_t *node)
Fetch flags value for a particular sfnode.

Parameters

- node – A pointer to the node to fetch flags from

Returns

The value of flags, which will be between 0 and 3

static inline sys_sfnode_t *sys_sflist_peek_head(sys_sflist_t *list)
Peek the first node from the list.

Parameters

- list – A point on the list to peek the first node from

Returns

A pointer on the first node of the list (or NULL if none)

static inline sys_sfnode_t *sys_sflist_peek_tail(sys_sflist_t *list)
Peek the last node from the list.

Parameters

- list – A point on the list to peek the last node from

Returns

A pointer on the last node of the list (or NULL if none)

static inline void sys_sfnode_init(sys_sfnode_t *node, uint8_t flags)
Initialize an sflist node.

Set an initial flags value for this slist node, which can be a value between 0 and 3. These flags will persist even if the node is moved around within a list, removed, or transplanted to a different slist.

This is ever so slightly faster than sys_sfnode_flags_set() and should only be used on a node that hasn’t been added to any list.

Parameters

- node – A pointer to the node to set the flags on
- flags – A value between 0 and 3 to set the flags value

static inline void sys_sfnode_flags_set(sys_sfnode_t *node, uint8_t flags)
Set flags value for an sfnode.

Set a flags value for this slist node, which can be a value between 0 and 3. These flags will persist even if the node is moved around within a list, removed, or transplanted to a different slist.

Parameters
• node – A pointer to the node to set the flags on
• flags – A value between 0 and 3 to set the flags value

static inline bool sys_sflist_is_empty(sys_sflist_t *list)
Test if the given list is empty.

Parameters
• list – A pointer on the list to test

Returns
a boolean, true if it’s empty, false otherwise

static inline sys_sfnode_t *sys_sflist_peek_next_no_check(sys_sfnode_t *node)
Peek the next node from current node, node is not NULL.
Faster then sys_sflist_peek_next() if node is known not to be NULL.

Parameters
• node – A pointer on the node where to peek the next node

Returns
a pointer on the next node (or NULL if none)

static inline void sys_sflist_prepend(sys_sflist_t *list, sys_sfnode_t *node)
Prepend a node to the given list.
This and other sys_sflist_*() functions are not thread safe.

Parameters
• list – A pointer on the list to affect
• node – A pointer on the node to prepend

static inline void sys_sflist_append(sys_sflist_t *list, sys_sfnode_t *node)
Append a node to the given list.
This and other sys_sflist_*() functions are not thread safe.

Parameters
• list – A pointer on the list to affect
• node – A pointer on the node to append

static inline void sys_sflist_append_list(sys_sflist_t *list, void *head, void *tail)
Append a list to the given list.
Append a singly-linked, NULL-terminated list consisting of nodes containing the pointer to the
next node as the first element of a node, to list. This and other sys_sflist_*() functions are not
thread safe.

FIXME: Why are the element parameters void *?

Parameters
• list – A pointer on the list to affect
• head – A pointer to the first element of the list to append
tail – A pointer to the last element of the list to append

static inline void sys_sflist_merge_sflist(sys_sflist_t *list, sys_sflist_t *list_to_append)
merge two sflists, appending the second one to the first

When the operation is completed, the appending list is empty. This and other sys_sflist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• list_to_append – A pointer to the list to append.

static inline void sys_sflist_insert(sys_sflist_t *list, sys_sfnode_t *prev, sys_sfnode_t *node)
Insert a node to the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• prev – A pointer on the previous node
• node – A pointer on the node to insert

static inline sys_sfnode_t *sys_sflist_get_not_empty(sys_sflist_t *list)
Fetch and remove the first node of the given list.

List must be known to be non-empty. This and other sys_sflist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect

Returns

A pointer to the first node of the list

static inline sys_sfnode_t *sys_sflist_get(sys_sflist_t *list)
Fetch and remove the first node of the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect

Returns

A pointer to the first node of the list (or NULL if empty)

static inline void sys_sflist_remove(sys_sflist_t *list, sys_sfnode_t *prev_node, sys_sfnode_t *node)
Remove a node.

This and other sys_sflist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• prev_node – A pointer on the previous node (can be NULL, which means the node is the list’s head)
• node – A pointer on the node to remove

static inline bool sys_sflist_find_and_remove(sys_sflist_t *list, sys_sfnode_t *node)
Find and remove a node from a list.

This and other sys_sflist_*() functions are not thread safe.
Parameters

- `list` – A pointer on the list to affect
- `node` – A pointer on the node to remove from the list

Returns

true if node was removed

### 3.5.2 Double-linked List

Similar to the single-linked list in many respects, Zephyr includes a double-linked implementation. This provides the same algorithmic behavior for all the existing slist operations, but also allows for constant-time removal and insertion (at all points: before or after the head, tail or any internal node). To do this, the list stores two pointers per node, and thus has somewhat higher runtime code and memory space needs.

A `sys_dlist_t` struct may be instantiated by the user in any accessible memory. It must be initialized with `sys_dlist_init()` or `SYS_DLIST_STATIC_INIT` before use. The `sys_dnode_t` struct is expected to be provided by the user for any nodes added to the list (typically embedded within the struct to be tracked, as described above). It must be initialized in zeroed/bss memory or with `sys_dnode_init()` before use.

Primitive operations may retrieve the head/tail of a list and the next/prev pointers of a node with `sys_dlist_peek_head()`, `sys_dlist_peek_tail()`, `sys_dlist_peek_next()` and `sys_dlist_peek_prev()`. These can all return NULL where appropriate (i.e. for empty lists, or nodes at the endpoints of the list).

A dlist can be modified in constant time by removing a node with `sys_dlist_remove()`, by adding a node to the head or tail of a list with `sys_dlist_prepend()` and `sys_dlist_append()`, or by inserting a node before an existing node with `sys_dlist_insert()`.

As for slist, each node in a dlist can be processed in a natural code block style using `SYS_DLIST_FOR_EACH_NODE`. This macro also exists in a “FROM_NODE” form which allows for iterating from a known starting point, a “SAFE” variant that allows for removing the node being inspected within the code block, a “CONTAINER” style that provides the pointer to a containing struct instead of the raw node, and a “CONTAINER_SAFE” variant that provides both properties.

Convenience utilities provided by dlist include `sys_dlist_insert_at()`, which inserts a node that linearly searches through a list to find the right insertion point, which is provided by the user as a C callback function pointer, and `sys_dnode_is_linked()`, which will affirmatively return whether or not a node is currently linked into a dlist or not (via an implementation that has zero overhead vs. the normal list processing).

**Double-linked List Internals**

Internally, the dlist implementation is minimal: the `sys_dlist_t` struct contains “head” and “tail” pointer fields, the `sys_dnode_t` contains “prev” and “next” pointers, and no other data is stored. But in practice the two structs are internally identical, and the list struct is inserted as a node into the list itself. This allows for a very clean symmetry of operations:

- An empty list has backpointers to itself in the list struct, which can be trivially detected.
- The head and tail of the list can be detected by comparing the prev/next pointers of a node vs. the list struct address.
- An insertion or deletion never needs to check for the special case of inserting at the head or tail. There are never any NULL pointers within the list to be avoided. Exactly the same operations are run, without tests or branches, for all list modification primitives.

Effectively, a dlist of N nodes can be thought of as a “ring” of “N+1” nodes, where one node represents the list tracking struct.
Fig. 3.6: A dlist containing three elements. Note that the list struct appears as a fourth “element” in the list.

Fig. 3.7: An dlist containing just one element.

Fig. 3.8: An empty dlist.
Doubly-linked List API Reference

group doubly-linked-list_apis

Defines

SYS_DLIST_FOR_EACH_NODE(__dl, __dn)

Provide the primitive to iterate on a list Note: the loop is unsafe and thus __dn should not be removed.

User MUST add the loop statement curly braces enclosing its own code:

SYS_DLIST_FOR_EACH_NODE(l, n) {
    <user code>
}

This and other SYS_DLIST_*() macros are not thread safe.

Parameters

- __dl – A pointer on a sys_dlist_t to iterate on
- __dn – A sys_dnode_t pointer to peek each node of the list

SYS_DLIST_ITERATE_FROM_NODE(__dl, __dn)

Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __dn should not be removed.

User MUST add the loop statement curly braces enclosing its own code:

SYS_DLIST_ITERATE_FROM_NODE(l, n) {
    <user code>
}

Like SYS_DLIST_FOR_EACH_NODE(), but __dn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.

This and other SYS_DLIST_*() macros are not thread safe.

Parameters

- __dl – A pointer on a sys_dlist_t to iterate on
- __dn – A sys_dnode_t pointer to peek each node of the list; it contains the starting node, or NULL to start from the head

SYS_DLIST_FOR_EACH_NODE_SAFE(__dl, __dn, __dns)

Provide the primitive to safely iterate on a list Note: __dn can be removed, it will not break the loop.

User MUST add the loop statement curly braces enclosing its own code:

SYS_DLIST_FOR_EACH_NODE_SAFE(l, n, s) {
    <user code>
}

This and other SYS_DLIST_*() macros are not thread safe.

Parameters

- __dl – A pointer on a sys_dlist_t to iterate on
- __dn – A sys_dnode_t pointer to peek each node of the list
• __dns – A sys_dnode_t pointer for the loop to run safely

```c
SYS_DLST_CONTAINER(__dn, __cn, __n)
SYS_DLST_PEEK_HEAD_CONTAINER(__dl, __cn, __n)
SYS_DLST_PEEK_NEXT_CONTAINER(__dl, __cn, __n)
SYS_DLST_FOR_EACH_CONTAINER(__dl, __cn, __n)
```

Provide the primitive to iterate on a list under a container. Note: the loop is unsafe and thus __cn should not be detached.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_DLST_FOR_EACH_CONTAINER(1, c, n) {
    <user code>
}
```

**Parameters**

- __dl – A pointer on a sys_dlist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __n – The field name of sys_dnode_t within the container struct

```c
SYS_DLST_FOR_EACH_CONTAINER_SAFE(__dl, __cn, __cns, __n)
```

Provide the primitive to safely iterate on a list under a container. Note: __cn can be detached, it will not break the loop.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_DLST_FOR_EACH_CONTAINER_SAFE(1, c, cn, n) {
    <user code>
}
```

**Parameters**

- __dl – A pointer on a sys_dlist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __cns – A pointer for the loop to run safely
- __n – The field name of sys_dnode_t within the container struct

```c
SYS_DLST_STATIC_INIT(ptr_to_list)
```

**Typedefs**

typedef struct _dnode sys_dlist_t

typedef struct _dnode sys_dnode_t

**Functions**
static inline void sys_dlist_init(sys_dlist_t *list)
initialize list to its empty state

Parameters
• list – the doubly-linked list

static inline void sys_dnode_init(sys_dnode_t *node)
initialize node to its state when not in a list

Parameters
• node – the node

static inline bool sys_dnode_is_linked(const sys_dnode_t *node)
check if a node is a member of any list

Parameters
• node – the node

Returns
true if node is linked into a list, false if it is not

static inline bool sys_dlist_is_head(sys_dlist_t *list, sys_dnode_t *node)
check if a node is the list's head

Parameters
• list – the doubly-linked list to operate on
• node – the node to check

Returns
true if node is the head, false otherwise

static inline bool sys_dlist_is_tail(sys_dlist_t *list, sys_dnode_t *node)
check if a node is the list's tail

Parameters
• list – the doubly-linked list to operate on
• node – the node to check

Returns
true if node is the tail, false otherwise

static inline bool sys_dlist_is_empty(sys_dlist_t *list)
check if the list is empty

Parameters
• list – the doubly-linked list to operate on

Returns
true if empty, false otherwise

static inline bool sys_dlist_has_multiple_nodes(sys_dlist_t *list)
check if more than one node present

This and other sys_dlist_() functions are not thread safe.

Parameters
• list – the doubly-linked list to operate on

Returns
ture if multiple nodes, false otherwise
static inline sys_dnode_t *sys_dlist_peek_head(sys_dlist_t *list)
    get a reference to the head item in the list

Parameters
• list – the doubly-linked list to operate on

Returns
a pointer to the head element, NULL if list is empty

static inline sys_dnode_t *sys_dlist_peek_head_not_empty(sys_dlist_t *list)
    get a reference to the head item in the list

The list must be known to be non-empty.

Parameters
• list – the doubly-linked list to operate on

Returns
a pointer to the head element

static inline sys_dnode_t *sys_dlist_peek_next_no_check(sys_dlist_t *list, sys_dnode_t *node)
    get a reference to the next item in the list, node is not NULL.

Faster than sys_dlist_peek_next() if node is known not to be NULL.

Parameters
• list – the doubly-linked list to operate on
• node – the node from which to get the next element in the list

Returns
a pointer to the next element from a node, NULL if node is the tail

static inline sys_dnode_t *sys_dlist_peek_next(sys_dlist_t *list, sys_dnode_t *node)
    get a reference to the next item in the list

Parameters
• list – the doubly-linked list to operate on
• node – the node from which to get the next element in the list

Returns
a pointer to the next element from a node, NULL if node is the tail or NULL (when node comes from reading the head of an empty list).

static inline sys_dnode_t *sys_dlist_peek_prev_no_check(sys_dlist_t *list, sys_dnode_t *node)
    get a reference to the previous item in the list, node is not NULL.

Faster than sys_dlist_peek_prev() if node is known not to be NULL.

Parameters
• list – the doubly-linked list to operate on
• node – the node from which to get the previous element in the list

Returns
a pointer to the previous element from a node, NULL if node is the tail

static inline sys_dnode_t *sys_dlist_peek_prev(sys_dlist_t *list, sys_dnode_t *node)
    get a reference to the previous item in the list

Parameters
• list – the doubly-linked list to operate on
• node – the node from which to get the previous element in the list
Returns
a pointer to the previous element from a node, NULL if node is the tail or NULL
(when node comes from reading the head of an empty list).

static inline sys_dnode_t *sys_dlist_peek_tail(sys_dlist_t *list)
get a reference to the tail item in the list

Parameters
• list – the doubly-linked list to operate on

Returns
a pointer to the tail element, NULL if list is empty

static inline void sys_dlist_append(sys_dlist_t *list, sys_dnode_t *node)
add node to tail of list

This and other sys_dlist_*() functions are not thread safe.

Parameters
• list – the doubly-linked list to operate on
• node – the element to append

static inline void sys_dlist_prepend(sys_dlist_t *list, sys_dnode_t *node)
add node to head of list

This and other sys_dlist_*() functions are not thread safe.

Parameters
• list – the doubly-linked list to operate on
• node – the element to append

static inline void sys_dlist_insert(sys_dnode_t *successor, sys_dnode_t *node)
Insert a node into a list.

Insert a node before a specified node in a dlist.

Parameters
• successor – the position before which “node” will be inserted
• node – the element to insert

static inline void sys_dlist_insert_at(sys_dlist_t *list, sys_dnode_t *node, int (*cond)(sys_dnode_t *node, void *data), void *data)
insert node at position

Insert a node in a location depending on a external condition. The cond() function checks if
the node is to be inserted before the current node against which it is checked. This and other
sys_dlist_*() functions are not thread safe.

Parameters
• list – the doubly-linked list to operate on
• node – the element to insert
• cond – a function that determines if the current node is the correct insert point
• data – parameter to cond()

static inline void sys_dlist_remove(sys_dnode_t *node)
remove a specific node from a list

The list is implicit from the node. The node must be part of a list. This and other sys_dlist_*() functions are not thread safe.
Parameters

- node – the node to remove

static inline sys_dnode_t *sys_dlist_get(sys_dlist_t *list)

get the first node in a list

This and other sys_dlist_*() functions are not thread safe.

Parameters

- list – the doubly-linked list to operate on

Returns

the first node in the list, NULL if list is empty

3.5.3 Multi Producer Single Consumer Packet Buffer

A Multi Producer Single Consumer Packet Buffer (MPSC_PBUF) is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that consumes the data. However, it is possible that another context may interfere to flush the data and never come back (panic case). Packet is produced in two steps: first requested amount of data is allocated, producer fills the data and commits it. Consuming a packet is also performed in two steps: consumer claims the packet, gets pointer to it and length and later on packet is freed. This approach reduces memory copying.

A MPSC Packet Buffer has the following key properties:

- Allocate, commit scheme used for packet producing.
- Claim, free scheme used for packet consuming.
- Allocator ensures that contiguous memory of requested length is allocated.
- Following policies can be applied when requested space cannot be allocated:
  - **Overwrite**: oldest entries are dropped until requested amount of memory can be allocated. For each dropped packet user callback is called.
  - **No overwrite**: When requested amount of space cannot be allocated, allocation fails.
- Dedicated, optimized API for storing short packets.
- Allocation with timeout.

Internals

Each packet in the buffer contains MPSC_PBUF specific header which is used for internal management. Header consists of 2 bit flags. In order to optimize memory usage, header can be added on top of the user header using MPSC_PBUF_HDR and remaining bits in the first word can be application specific. Header consists of following flags:

- valid - bit set to one when packet contains valid user packet
- busy - bit set when packet is being consumed (claimed but not free)

Header state:

<table>
<thead>
<tr>
<th>valid</th>
<th>busy</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>space is free</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>valid packet</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>claimed valid packet</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>internal skip packet</td>
</tr>
</tbody>
</table>

3.5. Data Structures
Packet buffer space contains free space, valid user packets and internal skip packets. Internal skip packets indicates padding, e.g. at the of the buffer.

**Allocation**  Using pairs for read and write indexes, available space is determined. If space can be allocated, temporary write index is moved and pointer to a space within buffer is returned. Packet header is reset. If allocation required wrapping of the write index, a skip packet is added to the end of buffer. If space cannot be allocated and overwrite is disabled then NULL pointer is returned or context blocks if allocation was with timeout.

**Allocation with overwrite**  If overwrite is enabled, oldest packets are dropped until requested amount of space can be allocated. When packets are dropped busy flag is checked in the header to ensure that currently consumed packet is not overwritten. In that case, skip packet is added before busy packet and packets following the busy packet are dropped. When busy packet is being freed, such situation is detected and packet is converted to skip packet to avoid double processing.

**Usage**

**Packet header definition**  Packet header details can be found in include/zephyr/sys/mpsc_packet.h. API functions can be found in include/zephyr/sys/mpsc_pbuf.h. Headers are split to avoid include spam when declaring the packet.

User header structure must start with internal header:

```c
#include <zephyr/sys/mpsc_packet.h>

struct foo_header {
    MPSC_PBUF_HDR;
    uint32_t length: 32 - MPSC_PBUF_HDR_BITS;
};
```

**Packet buffer configuration**  Configuration structure contains buffer details, configuration flags and callbacks. Following callbacks are used by the packet buffer:

- Drop notification - callback called whenever a packet is dropped due to overwrite.
- Get packet length - callback to determine packet length

**Packet producing**  Standard, two step method:

```c
foo_packet *packet = mpsc_pbuf_alloc(buffer, len, K_NO_WAIT);
fill_data(packet);
mpsc_pbuf_commit(buffer, packet);
```

Performance optimized storing of small packets:

- 32 bit word packet
- 32 bit word with pointer packet

Note that since packets are written by value, they should already contain valid bit set in the header.

```c
mpsc_pbuf_put_word(buffer, data);
mpsc_pbuf_put_word_ext(buffer, data, ptr);
```
Packet consuming  Two step method:

```c
foo_packet *packet = mpsc_pbuf_claim(buffer);
process(packet);
mpsc_pbuf_free(buffer, packet);
```

### 3.5.4 Single Producer Single Consumer Packet Buffer

A Single Producer Single Consumer Packet Buffer (SPSC_PBUF) is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that produces packets and a single context that consumes the data.

Implementation is focused on performance and memory footprint.

Packets are added to the buffer using `spsc_pbuf_write()` which copies a data into the buffer. If the buffer is full error is returned.

Packets are copied out of the buffer using `spsc_pbuf_read()`.

### 3.5.5 Balanced Red/Black Tree

For circumstances where sorted containers may become large at runtime, a list becomes problematic due to algorithmic costs of searching it. For these situations, Zephyr provides a balanced tree implementation which has runtimes on search and removal operations bounded at $O(\log_2(N))$ for a tree of size $N$. This is implemented using a conventional red/black tree as described by multiple academic sources.

The `rbtree` tracking struct for a rbtree may be initialized anywhere in user accessible memory. It should contain only zero bits before first use. No specific initialization API is needed or required.

Unlike a list, where position is explicit, the ordering of nodes within an rbtree must be provided as a predicate function by the user. A function of type `rb_lessthan_t()` should be assigned to the `lessthan_fn` field of the `rbtree` struct before any tree operations are attempted. This function should, as its name suggests, return a boolean True value if the first node argument is “less than” the second in the ordering desired by the tree. Note that “equal” is not allowed, nodes within a tree must have a single fixed order for the algorithm to work correctly.

As with the slist and dlist containers, nodes within an rbtree are represented as a `rbnode` structure which exists in user-managed memory, typically embedded within the the data structure being tracked in the tree. Unlike the list code, the data within an rbnode is entirely opaque. It is not possible for the user to extract the binary tree topology and “manually” traverse the tree as it is for a list.

Nodes can be inserted into a tree with `rb_insert()` and removed with `rb_remove()`. Access to the “first” and “last” nodes within a tree (in the sense of the order defined by the comparison function) is provided by `rb_get_min()` and `rb_get_max()`. There is also a predicate, `rb_contains()`, which returns a boolean True if the provided node pointer exists as an element within the tree. As described above, all of these routines are guaranteed to have at most log time complexity in the size of the tree.

There are two mechanisms provided for enumerating all elements in an rbtree. The first, `rb_walk()`, is a simple callback implementation where the caller specifies a C function pointer and an untyped argument to be passed to it, and the tree code calls that function for each node in order. This has the advantage of a very simple implementation, at the cost of a somewhat more cumbersome API for the user (not unlike ISO C’s `bsearch()` routine). It is a recursive implementation, however, and is thus not always available in environments that forbid the use of unbounded stack techniques like recursion.

There is also a `RB_FOR_EACH` iterator provided, which, like the similar APIs for the lists, works to iterate over a list in a more natural way, using a nested code block instead of a callback. It is also nonrecursive, though it requires log-sized space on the stack by default (however, this can be configured to use a...
fixed/maximally size buffer instead where needed to avoid the dynamic allocation). As with the lists, this is also available in a `RB_FOR_EACH_CONTAINER` variant which enumerates using a pointer to a container field and not the raw node pointer.

**Tree Internals**

As described, the Zephyr rbtree implementation is a conventional red/black tree as described pervasively in academic sources. Low level details about the algorithm are out of scope for this document, as they match existing conventions. This discussion will be limited to details notable or specific to the Zephyr implementation.

The core invariant guaranteed by the tree is that the path from the root of the tree to any leaf is no more than twice as long as the path to any other leaf. This is achieved by associating one bit of “color” with each node, either red or black, and enforcing a rule that no red child can be a child of another red child (i.e. that the number of black nodes on any path to the root must be the same, and that no more than that number of “extra” red nodes may be present). This rule is enforced by a set of rotation rules used to “fix” trees following modification.

![Tree Internals Diagram](image)

**Fig. 3.9:** A maximally unbalanced rbtree with a black height of two. No more nodes can be added underneath the rightmost node without rebalancing.

These rotations are conceptually implemented on top of a primitive that “swaps” the position of one node with another in the list. Typical implementations effect this by simply swapping the nodes internal “data” pointers, but because the Zephyr `rbn`ode is intrusive, that cannot work. Zephyr must include somewhat more elaborate code to handle the edge cases (for example, one swapped node can be the root, or the two may already be parent/child).

The `rbn`ode struct for a Zephyr rbtree contains only two pointers, representing the “left”, and “right” children of a node within the binary tree. Traversal of a tree for rebalancing following modification,
however, routinely requires the ability to iterate “upwards” from a node as well. It is very common for red/black trees in the industry to store a third “parent” pointer for this purpose. Zephyr avoids this requirement by building a “stack” of node pointers locally as it traverses downward through the tree and updating it appropriately as modifications are made. So a Zephyr rbtree can be implemented with no more runtime storage overhead than a dlist.

These properties, of a balanced tree data structure that works with only two pointers of data per node and that works without any need for a memory allocation API, are quite rare in the industry and are somewhat unique to Zephyr.

Red/Black Tree API Reference

\texttt{group rbtree\_apis}

\textbf{Defines}

\texttt{RB\_FOR\_EACH}(tree, node)

Walk a tree in-order without recursing.

While \texttt{rb\_walk()} is very simple, recursing on the C stack can be clumsy for some purposes and on some architectures wastes significant memory in stack frames. This macro implements a non-recursive “foreach” loop that can iterate directly on the tree, at a moderate cost in code size.

Note that the resulting loop is not safe against modifications to the tree. Changes to the tree structure during the loop will produce incorrect results, as nodes may be skipped or duplicated. Unlike linked lists, no \texttt{SAFE} variant exists.

Note also that the macro expands its arguments multiple times, so they should not be expressions with side effects.

\textbf{Parameters}

- tree – A pointer to a struct rbtree to walk
- node – The symbol name of a local struct rbnode* variable to use as the iterator

\texttt{RB\_FOR\_EACH\_CONTAINER}(tree, node, field)

Loop over rbtree with implicit container field logic.

As for \texttt{RB\_FOR\_EACH()}, but “node” can have an arbitrary type containing a struct rbnode.

\textbf{Parameters}

- tree – A pointer to a struct rbtree to walk
- node – The symbol name of a local iterator
- field – The field name of a struct rbnode inside node

\textbf{Typedefs}

typedef bool (*\texttt{rb\_lessthan\_t})(struct rbnode *a, struct rbnode *b)

Red/black tree comparison predicate.

Compares the two nodes and returns true if node A is strictly less than B according to the tree’s sorting criteria, false otherwise.

Note that during insert, the new node being inserted will always be “A”, where “B” is the existing node within the tree against which it is being compared. This trait can be used
(with care!) to implement “most/least recently added” semantics between nodes which would otherwise compare as equal.

typedef void (*rb_visit_t)(struct rbnode *node, void *cookie)

Functions

void rb_insert(struct rbtree *tree, struct rbnode *node)
    Insert node into tree.
void rb_remove(struct rbtree *tree, struct rbnode *node)
    Remove node from tree.
static inline struct rbnode *rb_get_min(struct rbtree *tree)
    Returns the lowest-sorted member of the tree.
static inline struct rbnode *rb_get_max(struct rbtree *tree)
    Returns the highest-sorted member of the tree.
bool rb_contains(struct rbtree *tree, struct rbnode *node)
    Returns true if the given node is part of the tree.
    Note that this does not internally dereference the node pointer (though the tree's lessthan callback might!), it just tests it for equality with items in the tree. So it's feasible to use this to implement a "set" construct by simply testing the pointer value itself.
static inline void rb_walk(struct rbtree *tree, rb_visit_t visit_fn, void *cookie)
    Walk/enumerate a rbtree.
    Very simple recursive enumeration. Low code size, but requiring a separate function can be clumsy for the user and there is no way to break out of the loop early. See RB_FOR_EACH for an iterative implementation.

struct rbtree
    #include <rb.h>

3.5.6 Ring Buffers

A ring buffer is a circular buffer, whose contents are stored in first-in-first-out order.

For circumstances where an application needs to implement asynchronous “streaming” copying of data, Zephyr provides a struct ring_buf abstraction to manage copies of such data in and out of a shared buffer of memory.

Two content data modes are supported:

- **Byte mode**: raw bytes can be enqueued and dequeued.
- **Data item mode**: Multiple 32-bit word data items with metadata can be enqueued and dequeued from the ring buffer in chunks of up to 1020 bytes. Each data item also has two associated metadata values: a type identifier and a 16-bit integer value, both of which are application-specific.

While the underlying data structure is the same, it is not legal to mix these two modes on a single ring buffer instance. A ring buffer initialized with a byte count must be used only with the “bytes” API, one initialized with a word count must use the “items” calls.

- **Concepts**
  - **Byte mode**
Any number of ring buffers can be defined (limited only by available RAM). Each ring buffer is referenced by its memory address.

A ring buffer has the following key properties:

- A **data buffer** of bytes or 32-bit words. The data buffer contains the raw bytes or 32-bit words that have been added to the ring buffer but not yet removed.

- A **data buffer size**, measured in bytes or 32-byte words. This governs the maximum amount of data (including possible metadata values) the ring buffer can hold.

A ring buffer must be initialized before it can be used. This sets its data buffer to empty.

A struct `ring_buf` may be placed anywhere in user-accessible memory, and must be initialized with `ring_buf_init()` or `ring_buf_element_init()` before use. This must be provided a region of user-controlled memory for use as the buffer itself. Note carefully that the units of the size of the buffer passed change (either bytes or words) depending on how the ring buffer will be used later. Macros for combining these steps in a single static declaration exist for convenience. `RING_BUF_DECLARE` will declare and statically initialize a ring buffer with a specified byte count, where `RING_BUF_ITEM_DECLARE` will declare and statically initialize a buffer with a given count of 32 bit words. `RING_BUF_ITEM_SIZEOF` will compute the size in 32-bit words corresponding to a type or an expression. Note: rounds up if the size is not a multiple of 32 bits.

“Bytes” data may be copied into the ring buffer using `ring_buf_put()`, passing a data pointer and byte count. These bytes will be copied into the buffer in order, as many as will fit in the allocated buffer. The total number of bytes copied (which may be fewer than provided) will be returned. Likewise `ring_buf_get()` will copy bytes out of the ring buffer in the order that they were written, into a user-provided buffer, returning the number of bytes that were transferred.

To avoid multiply-copied-data situations, a “claim” API exists for byte mode. `ring_buf_put_claim()` takes a byte size value from the user and returns a pointer to memory internal to the ring buffer that can be used to receive those bytes, along with a size of the contiguous internal region (which may be smaller than requested). The user can then copy data into that region at a later time without assembling all the bytes in a single region first. When complete, `ring_buf_put_finish()` can be used to signal the buffer that the transfer is complete, passing the number of bytes actually transferred. At this point a new transfer can be initiated. Similarly, `ring_buf_get_claim()` returns a pointer to internal ring buffer data from which the user can read without making a verbatim copy, and `ring_buf_get_finish()` signals the buffer with how many bytes have been consumed and allows for a new transfer to begin.

“Items” mode works similarly to bytes mode, except that all transfers are in units of 32 bit words and all memory is assumed to be aligned on 32 bit boundaries. The write and read operations are `ring_buf_item_put()` and `ring_buf_item_get()`, and work otherwise identically to the bytes mode APIs. There no “claim” API provided for items mode. One important difference is that unlike...
**ring_buf_put()**, **ring_buf_item_put()** will not do a partial transfer; it will return an error in the case where the provided data does not fit in its entirety.

The user can manage the capacity of a ring buffer without modifying it using either **ring_buf_space_get()** or **ring_buf_item_space_get()** which returns the number of free bytes or free 32-bit item words respectively, or by testing the **ring_buf_is_empty()** predicate.

Finally, a **ring_buf_reset()** call exists to immediately empty a ring buffer, discarding the tracking of any bytes or items already written to the buffer. It does not modify the memory contents of the buffer itself, however.

**Byte mode** A byte mode ring buffer instance is declared using **RING_BUF_DECLARE()** and accessed using: **ring_buf_put_claim()**, **ring_buf_put_finish()**, **ring_buf_get_claim()**, **ring_buf_get_finish()**, **ring_buf_put()** and **ring_buf_get()**.

Data can be copied into the ring buffer (see **ring_buf_put()**) or ring buffer memory can be used directly by the user. In the latter case, the operation is split into three stages:

1. allocating the buffer (**ring_buf_put_claim()**) when user requests the destination location where data can be written.
2. writing the data by the user (e.g. buffer written by DMA).
3. indicating the amount of data written to the provided buffer (**ring_buf_put_finish()**). The amount can be less than or equal to the allocated amount.

Data can be retrieved from a ring buffer through copying (see **ring_buf_get()**) or accessed directly by address. In the latter case, the operation is split into three stages:

1. retrieving source location with valid data written to a ring buffer (see **ring_buf_get_claim()**).
2. processing data
3. freeing processed data (see **ring_buf_get_finish()**). The amount freed can be less than or equal to the retrieved amount.

**Data item mode** A data item mode ring buffer instance is declared using **RING_BUF_ITEM_DECLARE()** and accessed using **ring_buf_item_put()** and **ring_buf_item_get()**.

A ring buffer data item is an array of 32-bit words from 0 to 1020 bytes in length. When a data item is **enqueued** (**ring_buf_item_put()**), its contents are copied to the data buffer, along with its associated metadata values (which occupy one additional 32-bit word). If the ring buffer has insufficient space to hold the new data item the enqueue operation fails.

A data item is **dequeued** (**ring_buf_item_get()**) from a ring buffer by removing the oldest enqueued item. The contents of the dequeued data item, as well as its two metadata values, are copied to areas supplied by the retriever. If the ring buffer is empty, or if the data array supplied by the retriever is not large enough to hold the data item's data, the dequeue operation fails.

**Concurrency** The ring buffer APIs do not provide any concurrency control. Depending on usage (particularly with respect to number of concurrent readers/writers) applications may need to protect the ring buffer with mutexes and/or use semaphores to notify consumers that there is data to read.

For the trivial case of one producer and one consumer, concurrency control shouldn’t be needed.

**Internal Operation** Data streamed through a ring buffer is always written to the next byte within the buffer, wrapping around to the first element after reaching the end, thus the “ring” structure. Internally, the struct **ring_buf** contains its own buffer pointer and its size, and also a set of “head” and “tail” indices representing where the next read and write operations may occur.

This boundary is invisible to the user using the normal put/get APIs, but becomes a barrier to the “claim” API, because obviously no contiguous region can be returned that crosses the end of the buffer. This
can be surprising to application code, and produce performance artifacts when transfers need to happen close to the end of the buffer, as the number of calls to claim/finish needs to double for such transfers.

**Implementation**

**Defining a Ring Buffer**  A ring buffer is defined using a variable of type `ring_buf`. It must then be initialized by calling `ring_buf_init()` or `ring_buf_item_init()`.

The following code defines and initializes an empty **data item mode** ring buffer (which is part of a larger data structure). The ring buffer's data buffer is capable of holding 64 words of data and metadata information.

```c
#define MY_RING_BUF_WORDS 64

struct my_struct {  
    struct ring_buf rb;  
    uint32_t buffer[MY_RING_BUF_WORDS];  
    ...  
};

struct my_struct ms;

void init_my_struct {  
    ring_buf_item_init(&ms.rb, MY_RING_BUF_WORDS, ms.buffer);  
    ...  
}
```

Alternatively, a ring buffer can be defined and initialized at compile time using one of two macros at file scope. Each macro defines both the ring buffer itself and its data buffer.

The following code defines a **data item mode** ring buffer:

```c
#define MY_RING_BUF_WORDS 93
RING_BUF_ITEM_DECLARE(my_ring_buf, MY_RING_BUF_WORDS);
```

The following code defines a ring buffer intended to be used for raw bytes:

```c
#define MY_RING_BUF_BYTES 93
RING_BUF_DECLARE(my_ring_buf, MY_RING_BUF_BYTES);
```

**Enqueuing Data**  Bytes are copied to a **byte mode** ring buffer by calling `ring_buf_put()`.

```c
uint8_t my_data[MY_RING_BUF_BYTES];
uint32_t ret;

ret = ring_buf_put(&ring_buf, my_data, MY_RING_BUF_BYTES);
if (ret != MY_RING_BUF_BYTES) {  
    /* not enough room, partial copy. */  
    ...  
}
```

Data can be added to a **byte mode** ring buffer by directly accessing the ring buffer’s memory. For example:

```c
uint32_t size;
uint32_t rx_size;
uint8_t *data;
int err;
```

(continues on next page)
/* Allocate buffer within a ring buffer memory. */
size = ring_buf_put_claim(&ring_buf, &data, MY_RING_BUF_BYTES);

/* Work directly on a ring buffer memory. */
rx_size = uart_rx(data, size);

/* Indicate amount of valid data. rx_size can be equal or less than size. */
err = ring_buf_put_finish(&ring_buf, rx_size);
if (err != 0) {
    /* This shouldn't happen unless rx_size > size */
    ...
}

A data item is added to a ring buffer by calling `ring_buf_item_put()`.

```c
uint32_t data[MY_DATA_WORDS];
int ret;
ret = ring_buf_item_put(&ring_buf, TYPE_FOO, 0, data, MY_DATA_WORDS);
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}
```

If the data item requires only the type or application-specific integer value (i.e. it has no data array), a size of 0 and data pointer of `NULL` can be specified.

```c
int ret;
ret = ring_buf_item_put(&ring_buf, TYPE_BAR, 17, NULL, 0);
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}
```

### Retrieving Data

Data bytes are copied out from a `byte mode` ring buffer by calling `ring_buf_get()`.

For example:

```c
uint8_t my_data[MY_DATA_BYTES];
size_t ret;
ret = ring_buf_get(&ring_buf, my_data, sizeof(my_data));
if (ret != sizeof(my_data)) {
    /* Fewer bytes copied. */
} else {
    /* Requested amount of bytes retrieved. */
    ...
}
```

Data can be retrieved from a `byte mode` ring buffer by direct operations on the ring buffer's memory.

For example:

```c
uint32_t size;
uint32_t proc_size;
uint8_t *data;
```
int err;

/* Get buffer within a ring buffer memory. */
size = ring_buf_get_claim(&ring_buf, &data, MY_RING_BUF_BYTES);

/* Work directly on a ring buffer memory. */
proc_size = process(data, size);

/* Indicate amount of data that can be freed. proc_size can be equal or less than size. */
err = ring_buf_get_finish(&ring_buf, proc_size);
if (err != 0) {
    /* proc_size exceeds amount of valid data in a ring buffer. */
    ...
}

A data item is removed from a ring buffer by calling ring_buf_item_get().

    uint32_t my_data[MY_DATA_WORDS];
    uint16_t my_type;
    uint8_t my_value;
    uint8_t my_size;
    int ret;

    my_size = MY_DATA_WORDS;
    ret = ring_buf_item_get(&ring_buf, &my_type, &my_value, my_data, &my_size);
    if (ret == -EMSGSIZE) {
        printk("Buffer is too small, need %d uint32_t\n", my_size);
    } else if (ret == -EAGAIN) {
        printk("Ring buffer is empty\n");
    } else {
        printk("Got item of type %u value %u of size %u dwords\n", 
            my_type, my_value, my_size);
            ...
    }

Configuration Options

Related configuration options:

- CONFIG_RING_BUFFER: Enable ring buffer.

API Reference

The following ring buffer APIs are provided by include/zephyr/sys/ring_buffer.h:

group ring_buffer_apis

Defines

RING_BUF_DECLARE(name, size8)
    Define and initialize a ring buffer for byte data.
This macro establishes a ring buffer of an arbitrary size. The basic storage unit is a byte. The ring buffer can be accessed outside the module where it is defined using:

```
extern struct ring_buf <name>;
```

**Parameters**
- `name` – Name of the ring buffer.
- `size8` – Size of ring buffer (in bytes).

```
RING_BUF_ITEM_DECLARE(name, size32)
```

Define and initialize an “item based” ring buffer.

This macro establishes an “item based” ring buffer. Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

The ring buffer can be accessed outside the module where it is defined using:

```
extern struct ring_buf <name>;
```

**Parameters**
- `name` – Name of the ring buffer.
- `size32` – Size of ring buffer (in 32-bit words).

```
RING_BUF_ITEM_DECLARE_SIZE(name, size32)
```

Define and initialize an “item based” ring buffer.

This exists for backward compatibility reasons. `RING_BUF_ITEM_DECLARE` should be used instead.

**Parameters**
- `name` – Name of the ring buffer.
- `size32` – Size of ring buffer (in 32-bit words).

```
RING_BUF_ITEM_DECLARE_POW2(name, pow)
```

Define and initialize a power-of-2 sized “item based” ring buffer.

This macro establishes an “item based” ring buffer by specifying its size using a power of 2. This exists mainly for backward compatibility reasons. `RING_BUF_ITEM_DECLARE` should be used instead.

**Parameters**
- `name` – Name of the ring buffer.
- `pow` – Ring buffer size exponent.

```
RING_BUF_ITEM_SIZEOF(expr)
```

Compute the ring buffer size in 32-bit needed to store an element.

The argument can be a type or an expression. Note: rounds up if the size is not a multiple of 32 bits.

**Parameters**
- `expr` – Expression or type to compute the size of
Functions

static inline void ring_buf_init(struct ring_buf *buf, uint32_t size, uint8_t *data)
Initialize a ring buffer for byte data.
This routine initializes a ring buffer, prior to its first use. It is only used for ring buffers not
defined using RING_BUF_DECLARE.

Parameters
- buf – Address of ring buffer.
- size – Ring buffer size (in bytes).
- data – Ring buffer data area (uint8_t data[size]).

static inline void ring_buf_item_init(struct ring_buf *buf, uint32_t size, uint32_t *data)
Initialize an “item based” ring buffer.
This routine initializes a ring buffer, prior to its first use. It is only used for ring buffers not
defined using RING_BUF_ITEM_DECLARE.
Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with
a 16-bit type identifier and an 8-bit integer value.
Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with
a 16-bit type identifier and an 8-bit integer value.

Parameters
- buf – Address of ring buffer.
- size – Ring buffer size (in 32-bit words)
- data – Ring buffer data area (uint32_t data[size]).

static inline bool ring_buf_is_empty(struct ring_buf *buf)
Determine if a ring buffer is empty.

Parameters
- buf – Address of ring buffer.

Returns
true if the ring buffer is empty, or false if not.

static inline void ring_buf_reset(struct ring_buf *buf)
Reset ring buffer state.

Parameters
- buf – Address of ring buffer.

static inline uint32_t ring_buf_space_get(struct ring_buf *buf)
Determine free space in a ring buffer.

Parameters
- buf – Address of ring buffer.

Returns
Ring buffer free space (in bytes).

static inline uint32_t ring_buf_item_space_get(struct ring_buf *buf)
Determine free space in an “item based” ring buffer.

Parameters
- buf – Address of ring buffer.
Returns
Ring buffer free space (in 32-bit words).

static inline uint32_t ring_buf_capacity_get(struct ring_buf *buf)
Return ring buffer capacity.

Parameters
• buf – Address of ring buffer.

Returns
Ring buffer capacity (in bytes).

static inline uint32_t ring_buf_size_get(struct ring_buf *buf)
Determine used space in a ring buffer.

Parameters
• buf – Address of ring buffer.

Returns
Ring buffer space used (in bytes).

uint32_t ring_buf_put_claim(struct ring_buf *buf, uint8_t **data, uint32_t size)
Allocate buffer for writing data to a ring buffer.
With this routine, memory copying can be reduced since internal ring buffer can be used
directly by the user. Once data is written to allocated area number of bytes written must be
confirmed (see ring_buf_put_finish).

Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent
write operations, either by preventing all writers from being preemted or by using a
mutex to govern writes to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item access (calls prefixed
with ring_buf_item_).

Parameters
• data – [out] Pointer to the address. It is set to a location within ring buffer.

Returns
Size of allocated buffer which can be smaller than requested if there is not enough
free space or buffer wraps.

int ring_buf_put_finish(struct ring_buf *buf, uint32_t size)
Indicate number of bytes written to allocated buffers.
The number of bytes must be equal to or lower than the sum corresponding to all preceding
ring_buf_put_claim invocations (or even 0). Surplus bytes will be returned to the available
free buffer space.

Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent
write operations, either by preventing all writers from being preemted or by using a
mutex to govern writes to the ring buffer.
Warning: Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters
• buf – Address of ring buffer.
• size – Number of valid bytes in the allocated buffers.

Return values
• 0 – Successful operation.
• -EINVAL – Provided size exceeds free space in the ring buffer.

```c
uint32_t ring_buf_put(struct ring_buf *buf, const uint8_t *data, uint32_t size)
```

Write (copy) data to a ring buffer.

This routine writes data to a ring buffer buf.

Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters
• buf – Address of ring buffer.
• data – Address of data.
• size – Data size (in bytes).

Return values
Number – of bytes written.

```c
uint32_t ring_buf_get_claim(struct ring_buf *buf, uint8_t **data, uint32_t size)
```

Get address of a valid data in a ring buffer.

With this routine, memory copying can be reduced since internal ring buffer can be used directly by the user. Once data is processed it must be freed using ring_buf_get_finish.

Warning: Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters
• data – [out] Pointer to the address. It is set to a location within ring buffer.

3.5. Data Structures

Returns
Number of valid bytes in the provided buffer which can be smaller than requested if there is not enough free space or buffer wraps.

int ring_buf_get_finish(struct ring_buf *buf, uint32_t size)
Indicate number of bytes read from claimed buffer.
The number of bytes must be equal or lower than the sum corresponding to all preceding ring_buf_get_claim invocations (or even 0). Surplus bytes will remain available in the buffer.

Warning: Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item mode (calls prefixed with ring_buf_item_).

Parameters
• buf – Address of ring buffer.
• size – Number of bytes that can be freed.

Return values
• 0 – Successful operation.
• -EINVAL – Provided size exceeds valid bytes in the ring buffer.

uint32_t ring_buf_get(struct ring_buf *buf, uint8_t *data, uint32_t size)
Read data from a ring buffer.
This routine reads data from a ring buffer buf.

Warning: Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item mode (calls prefixed with ring_buf_item_).

Parameters
• buf – Address of ring buffer.
• data – Address of the output buffer. Can be NULL to discard data.
• size – Data size (in bytes).

Return values
Number – of bytes written to the output buffer.
uint32_t ring_buf_peek(struct ring_buf *buf, uint8_t *data, uint32_t size)
Peek at data from a ring buffer. This routine reads data from a ring buffer buf without removal.

**Warning:** Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preemptioned or by using a mutex to govern reads to the ring buffer.

**Warning:** Ring buffer instance should not mix byte access and item mode (calls prefixed with ring_buf_item_).

**Warning:** Multiple calls to peek will result in the same data being ‘peeked’ multiple times. To remove data, use either ring_buf_get or ring_buf_get_claim followed by ring_buf_get_finish with a non-zero size.

**Parameters**
- buf – Address of ring buffer.
- data – Address of the output buffer. Cannot be NULL.
- size – Data size (in bytes).

**Return values**
- Number – of bytes written to the output buffer.

int ring_buf_item_put(struct ring_buf *buf, uint16_t type, uint8_t value, uint32_t *data, uint8_t size32)
Write a data item to a ring buffer.

This routine writes a data item to ring buffer buf. The data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

**Warning:** Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preemptioned or by using a mutex to govern writes to the ring buffer.

**Parameters**
- buf – Address of ring buffer.
- type – Data item’s type identifier (application specific).
- value – Data item’s integer value (application specific).
- data – Address of data item.
- size32 – Data item size (number of 32-bit words).

**Return values**
- 0 – Data item was written.
- -EMSGSIZE – Ring buffer has insufficient free space.
int ring_buf_item_get(struct ring_buf *buf, uint16_t *type, uint8_t *value, uint32_t *data, uint8_t *size32)

Read a data item from a ring buffer.

This routine reads a data item from ring buffer buf. The data item is an array of 32-bit words (up to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

**Warning:** Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

**Parameters**

- `buf` – Address of ring buffer.
- `type` – Area to store the data item’s type identifier.
- `value` – Area to store the data item’s integer value.
- `data` – Area to store the data item. Can be NULL to discard data.
- `size32` – Size of the data item storage area (number of 32-bit chunks).

**Return values**

- `0` – Data item was fetched; `size32` now contains the number of 32-bit words read into data area `data`.
- `-EAGAIN` – Ring buffer is empty.
- `-EMSGSIZE` – Data area `data` is too small; `size32` now contains the number of 32-bit words needed.

### 3.6 Executing Time Functions

The timing functions can be used to obtain execution time of a section of code to aid in analysis and optimization.

Please note that the timing functions may use a different timer than the default kernel timer, where the timer being used is specified by architecture, SoC or board configuration.

#### 3.6.1 Configuration

To allow using the timing functions, `CONFIG_TIMING_FUNCTIONS` needs to be enabled.

#### 3.6.2 Usage

To gather timing information:

1. Call `timing_init()` to initialize the timer.
2. Call `timing_start()` to signal the start of gathering of timing information. This usually starts the timer.
3. Call `timing_counter_get()` to mark the start of code execution.
4. Call `timing_counter_get()` to mark the end of code execution.
5. Call `timing_cycles_get()` to get the number of timer cycles between start and end of code execution.
6. Call `timing_cycles_to_ns()` with total number of cycles to convert number of cycles to nanoseconds.

7. Repeat from step 3 to gather timing information for other blocks of code.

8. Call `timing_stop()` to signal the end of gathering of timing information. This usually stops the timer.

**Example**

This shows an example on how to use the timing functions:

```c
#include <zephyr/timing/timing.h>

void gather_timing(void)
{
    timing_t start_time, end_time;
    uint64_t total_cycles;
    uint64_t total_ns;

    timing_init();
    timing_start();

    start_time = timing_counter_get();
    code_execution_to_beMeasured();
    end_time = timing_counter_get();

    total_cycles = timing_cycles_get(&start_time, &end_time);
    total_ns = timing_cycles_to_ns(total_cycles);

    timing_stop();
}
```

### 3.6.3 API documentation

#### group timing_api

Timing Measurement APIs.

#### Functions

- **void timing_init(void)**
  
  Initialize the timing subsystem.

  Perform the necessary steps to initialize the timing subsystem.

- **void timing_start(void)**
  
  Signal the start of the timing information gathering.

  Signal to the timing subsystem that timing information will be gathered from this point forward.
void timing_stop(void)
    Signal the end of the timing information gathering.
    Signal to the timing subsystem that timing information is no longer being gathered from this point forward.

static inline timing_t timing_counter_get(void)
    Return timing counter.

    Returns
    Timing counter.

static inline uint64_t timing_cycles_get(volatile timing_t *const start, volatile timing_t *const end)
    Get number of cycles between start and end.
    For some architectures or SoCs, the raw numbers from counter need to be scaled to obtain actual number of cycles.

    Parameters
    • start – Pointer to counter at start of a measured execution.
    • end – Pointer to counter at stop of a measured execution.

    Returns
    Number of cycles between start and end.

static inline uint64_t timing_freq_get(void)
    Get frequency of counter used (in Hz).

    Returns
    Frequency of counter used for timing in Hz.

static inline uint64_t timing_cycles_to_ns(uint64_t cycles)
    Convert number of cycles into nanoseconds.

    Parameters
    • cycles – Number of cycles

    Returns
    Converted time value

static inline uint64_t timing_cycles_to_ns_avg(uint64_t cycles, uint32_t count)
    Convert number of cycles into nanoseconds with averaging.

    Parameters
    • cycles – Number of cycles
    • count – Times of accumulated cycles to average over

    Returns
    Converted time value

static inline uint32_t timing_freq_get_mhz(void)
    Get frequency of counter used (in MHz).

    Returns
    Frequency of counter used for timing in MHz.

3.7 Time Utilities
3.7.1 Overview

Uptime in Zephyr is based on the a tick counter. With the default CONFIG_TICKLESS_KERNEL this counter advances at a nominally constant rate from zero at the instant the system started. The POSIX equivalent to this counter is something like CLOCK_MONOTONIC or, in Linux, CLOCK_MONOTONIC_RAW. k_uptime_get() provides a millisecond representation of this time.

Applications often need to correlate the Zephyr internal time with external time scales used in daily life, such as local time or Coordinated Universal Time. These systems interpret time in different ways and may have discontinuities due to leap seconds and local time offsets like daylight saving time.

Because of these discontinuities, as well as significant inaccuracies in the clocks underlying the cycle counter, the offset between time estimated from the Zephyr clock and the actual time in a “real” civil time scale is not constant and can vary widely over the runtime of a Zephyr application.

The time utilities API supports:

- converting between time representations
- synchronizing and aligning time scales

For terminology and concepts that support these functions see Concepts Underlying Time Support in Zephyr.

3.7.2 Time Utility APIs

Representation Transformation

Time scale instants can be represented in multiple ways including:

- Seconds since an epoch. POSIX representations of time in this form include time_t and struct timespec, which are generally interpreted as a representation of “UNIX Time”.
- Calendar time as a year, month, day, hour, minutes, and seconds relative to an epoch. POSIX representations of time in this form include struct tm.

Keep in mind that these are simply time representations that must be interpreted relative to a time scale which may be local time, UTC, or some other continuous or discontinuous scale.

Some necessary transformations are available in standard C library routines. For example, time_t measuring seconds since the POSIX EPOCH is converted to struct tm representing calendar time with gmtime(). Sub-second timestamps like struct timespec can also use this to produce the calendar time representation and deal with sub-second offsets separately.

The inverse transformation is not standardized: APIs like mktime() expect information about time zones. Zephyr provides this transformation with timeutil_timegm() and timeutil_timegm64().

Functions

int64_t timeutil_timegm64(const struct tm *tm)

Convert broken-down time to a POSIX epoch offset in seconds.

See also:

Parameters

- tm – pointer to broken down time.
Returns
the corresponding time in the POSIX epoch time scale.

\[ \text{timeutil\_timegm}(\text{const struct} \ \text{tm} *\text{tm}) \]
Convert broken-down time to a POSIX epoch offset in seconds.

See also:

Parameters
• \text{tm} – pointer to broken down time.

Returns
the corresponding time in the POSIX epoch time scale. If the time cannot be
represented then (time\_t)-1 is returned and \text{errno} is set to \text{ERANGE}.

Time Scale Synchronization

There are several factors that affect synchronizing time scales:

• The rate of discrete instant representation change. For example Zephyr uptime is tracked in ticks
which advance at events that nominally occur at \text{CONFIG\_SYS\_CLOCK\_TICKS\_PER\_SEC} Hertz, while
an external time source may provide data in whole or fractional seconds (e.g. microseconds).

• The absolute offset required to align the two scales at a single instant.

• The relative error between observable instants in each scale, required to align multiple instants
consistently. For example a reference clock that’s conditioned by a 1-pulse-per-second GPS signal
will be much more accurate than a Zephyr system clock driven by a RC oscillator with a +/- 250
ppm error.

Synchronization or alignment between time scales is done with a multi-step process:

• An instant in a time scale is represented by an (unsigned) 64-bit integer, assumed to advance at a
fixed nominal rate.

• \text{timeutil\_sync\_config} records the nominal rates of a reference time scale/source (e.g. TAI) and
a local time source (e.g. \text{k\_uptime\_ticks()}).

• \text{timeutil\_sync\_instant} records the representation of a single instant in both the reference and
local time scales.

• \text{timeutil\_sync\_state} provides storage for an initial instant, a recently received second observa-
tion, and a skew that can adjust for relative errors in the actual rate of each time scale.

• \text{timeutil\_sync\_ref\_from\_local()} and \text{timeutil\_sync\_local\_from\_ref()} convert instants in
one time scale to another taking into account skew that can be estimated from the two instances
stored in the state structure by \text{timeutil\_sync\_estimate\_skew()}. 

Functions

\text{int timeutil\_sync\_state\_update(struct timeutil\_sync\_state \ *tsp, const struct \timeutil\_sync\_instant \ *inst)}
Record a new instant in the time synchronization state.
Note that this updates only the latest persisted instant. The skew is not adjusted automatically.
Parameters

- `tsp` – pointer to a `timeutil_sync_state` object.
- `inst` – the new instant to be recorded. This becomes the base instant if there is no base instant, otherwise the value must be strictly after the base instant in both the reference and local time scales.

Return values

- `0` – if installation succeeded in providing a new base
- `1` – if installation provided a new latest instant
- `-EINVAL` – if the new instant is not compatible with the base instant

```c
int timeutil_sync_state_set_skew(struct timeutil_sync_state *tsp, float skew, const struct timeutil_sync_instant *base)
```
Update the state with a new skew and possibly base value.

Set the skew from a value retrieved from persistent storage, or calculated based on recent skew estimations including from `timeutil_sync_estimate_skew()`.

Optionally update the base timestamp. If the base is replaced the latest instant will be cleared until `timeutil_sync_state_update()` is invoked.

Parameters

- `tsp` – pointer to a time synchronization state.
- `skew` – the skew to be used. The value must be positive and shouldn’t be too far away from 1.
- `base` – optional new base to be set. If provided this becomes the base timestamp that will be used along with skew to convert between reference and local timescale instants. Setting the base clears the captured latest value.

Returns

0 if skew was updated

Returns

- `EINVAL` if skew was not valid

```c
float timeutil_sync_estimate_skew(const struct timeutil_sync_state *tsp)
```
Estimate the skew based on current state.

Using the base and latest syncpoints from the state determine the skew of the local clock relative to the reference clock. See `timeutil_sync_state::skew`.

Parameters

- `tsp` – pointer to a time synchronization state. The base and latest syncpoints must be present and the latest syncpoint must be after the base point in the local time scale.

Returns

the estimated skew, or zero if skew could not be estimated.

```c
int timeutil_sync_ref_from_local(const struct timeutil_sync_state *tsp, uint64_t local, uint64_t *refp)
```
Interpolate a reference timescale instant from a local instant.

Parameters

- `tsp` – pointer to a time synchronization state. This must have a base and a skew installed.
- `local` – an instant measured in the local timescale. This may be before or after the base instant.
refp – where the corresponding instant in the reference timescale should be stored. A negative interpolated reference time produces an error. If interpolation fails the referenced object is not modified.

Return values

• 0 – if interpolated using a skew of 1
• 1 – if interpolated using a skew not equal to 1
• -EINVAL – the times synchronization state is not adequately initialized
• -ERANGE – the interpolated reference time would be negative

int timeutil_sync_local_from_ref(const struct timeutil_sync_state *tsp, uint64_t ref, int64_t *localp)

Interpolate a local timescale instant from a reference instant.

Parameters

• tsp – pointer to a time synchronization state. This must have a base and a skew installed.
• ref – an instant measured in the reference timescale. This may be before or after the base instant.
• localp – where the corresponding instant in the local timescale should be stored. An interpolated value before local time 0 is provided without error. If interpolation fails the referenced object is not modified.

Return values

• 0 – if successful with a skew of 1
• 1 – if successful with a skew not equal to 1
• -EINVAL – the time synchronization state is not adequately initialized
• -ERANGE – refp is null

int32_t timeutil_sync_skew_to_ppb(float skew)

Convert from a skew to an error in parts-per-billion.

A skew of 1.0 has zero error. A skew less than 1 has a positive error (clock is faster than it should be). A skew greater than one has a negative error (clock is slower than it should be).

Note that due to the limited precision of float compared with double the smallest error that can be represented is about 120 ppb. A “precise” time source may have error on the order of 2000 ppb.

A skew greater than 3.14748 may underflow the 32-bit representation; this represents a clock running at less than 1/3 its nominal rate.

Returns

skew error represented as parts-per-billion, or INT32_MIN if the skew cannot be represented in the return type.

struct timeutil_sync_config

#include <timeutil.h> Immutable state for synchronizing two clocks.

Values required to convert durations between two time scales.
**Note:** The accuracy of the translation and calculated skew between sources depends on the resolution of these frequencies. A reference frequency with microsecond or nanosecond resolution would produce the most accurate tracking when the local reference is the Zephyr tick counter. A reference source like an RTC chip with 1 Hz resolution requires a much larger interval between sampled instants to detect relative clock drift.

### Public Members

**uint32_t ref_Hz**

The nominal instance counter rate in Hz.

This value is assumed to be precise, but may drift depending on the reference clock source.

The value must be positive.

**uint32_t local_Hz**

The nominal local counter rate in Hz.

This value is assumed to be inaccurate but reasonably stable. For a local clock driven by a crystal oscillator an error of 25 ppm is common; for an RC oscillator larger errors should be expected. The timeutil_sync infrastructure can calculate the skew between the local and reference clocks and apply it when converting between time scales.

The value must be positive.

#### struct timeutil_sync_instant

```c
#include <timeutil.h>
```

Representation of an instant in two time scales.

Capturing the same instant in two time scales provides a registration point that can be used to convert between those time scales.

### Public Members

**uint64_t ref**

An instant in the reference time scale.

This must never be zero in an initialized `timeutil_sync_instant` object.

**uint64_t local**

The corresponding instance in the local time scale.

This may be zero in a valid `timeutil_sync_instant` object.

#### struct timeutil_sync_state

```c
#include <timeutil.h>
```

State required to convert instants between time scales.

This state in conjunction with functions that manipulate it capture the offset information necessary to convert between two timescales along with information that corrects for skew due to inaccuracies in clock rates.

State objects should be zero-initialized before use.
Public Members

const struct timeutil_sync_config *cfg
    Pointer to reference and local rate information.

struct timeutil_sync_instant base
    The base instant in both time scales.

struct timeutil_sync_instant latest
    The most recent instant in both time scales.
    This is captured here to provide data for skew calculation.

float skew
    The scale factor used to correct for clock skew.
    The nominal rate for the local counter is assumed to be inaccurate but stable, i.e. it will
generally be some parts-per-million faster or slower than specified.
    A duration in observed local clock ticks must be multiplied by this value to produce a
duration in ticks of a clock operating at the nominal local rate.
    A zero value indicates that the skew has not been initialized. If the value is zero when
base is initialized the skew will be set to 1. Otherwise the skew is assigned through
timeutil_sync_state_set_skew().

3.7.3 Concepts Underlying Time Support in Zephyr

Terms from ISO/TC 154/WG 5 N0038 (ISO/WD 8601-1) and elsewhere:

• A time axis is a representation of time as an ordered sequence of instants.
  • A time scale is a way of representing an instant relative to an origin that serves as the epoch.
  • A time scale is monotonic (increasing) if the representation of successive time instants never decreases in value.
  • A time scale is continuous if the representation has no abrupt changes in value, e.g. jumping forward or back when going between successive instants.
  • Civil time generally refers to time scales that legally defined by civil authorities, like local governments, often to align local midnight to solar time.

Relevant Time Scales

International Atomic Time (TAI) is a time scale based on averaging clocks that count in SI seconds. TAI is a monotonic and continuous time scale.

Universal Time (UT) is a time scale based on Earth's rotation. UT is a discontinuous time scale as it requires occasional adjustments (leap seconds) to maintain alignment to changes in Earth's rotation. Thus the difference between TAI and UT varies over time. There are several variants of UT, with UTC being the most common.

UT times are independent of location. UT is the basis for Standard Time (or “local time”) which is the time at a particular location. Standard time has a fixed offset from UT at any given instant, primarily influenced by longitude, but the offset may be adjusted (“daylight saving time”) to align standard time to the local solar time. In a sense local time is “more discontinuous” than UT.
**POSIX Time** is a time scale that counts seconds since the “POSIX epoch” at 1970-01-01T00:00:00Z (i.e. the start of 1970 UTC). **UNIX Time** is an extension of POSIX time using negative values to represent times before the POSIX epoch. Both of these scales assume that every day has exactly 86400 seconds. In normal use instants in these scales correspond to times in the UTC scale, so they inherit the discontinuity.

The continuous analogue is **UNIX Leap Time** which is UNIX time plus all leap-second corrections added after the POSIX epoch (when TAI-UTC was 8 s).

**Example of Time Scale Differences** A positive leap second was introduced at the end of 2016, increasing the difference between TAI and UTC from 36 seconds to 37 seconds. There was no leap second introduced at the end of 1999, when the difference between TAI and UTC was only 32 seconds. The following table shows relevant civil and epoch times in several scales:

<table>
<thead>
<tr>
<th>UTC Date</th>
<th>UNIX time</th>
<th>TAI Date</th>
<th>TAI-UTC</th>
<th>UNIX Leap Time</th>
</tr>
</thead>

</tbody>
</table>

**Functional Requirements** The Zephyr tick counter has no concept of leap seconds or standard time offsets and is a continuous time scale. However it can be relatively inaccurate, with drifts as much as three minutes per hour (assuming an RC timer with 5% tolerance).

There are two stages required to support conversion between Zephyr time and common human time scales:

- Translation between the continuous but inaccurate Zephyr time scale and an accurate external stable time scale;
- Translation between the stable time scale and the (possibly discontinuous) civil time scale.

The API around `timeutil_sync_state_update()` supports the first step of converting between continuous time scales.

The second step requires external information including schedules of leap seconds and local time offset changes. This may be best provided by an external library, and is not currently part of the time utility APIs.

**Selecting an External Source and Time Scale** If an application requires civil time accuracy within several seconds then UTC could be used as the stable time source. However, if the external source adjusts to a leap second there will be a discontinuity: the elapsed time between two observations taken at 1 Hz is not equal to the numeric difference between their timestamps.

For precise activities a continuous scale that is independent of local and solar adjustments simplifies things considerably. Suitable continuous scales include:

- GPS time: epoch of 1980-01-06T00:00:00Z, continuous following TAI with an offset of TAI-GPS=19 s.
- Bluetooth mesh time: epoch of 2000-01-01T00:00:00Z, continuous following TAI with an offset of -32.
- UNIX Leap Time: epoch of 1970-01-01T00:00:00Z, continuous following TAI with an offset of -8.

Because C and Zephyr library functions support conversion between integral and calendar time representations using the UNIX epoch, UNIX Leap Time is an ideal choice for the external time scale.
The mechanism used to populate synchronization points is not relevant: it may involve reading from a local high-precision RTC peripheral, exchanging packets over a network using a protocol like NTP or PTP, or processing NMEA messages received a GPS with or without a 1pps signal.

### 3.8 Utilities

This page contains reference documentation for `<sys/util.h>`, which provides miscellaneous utility functions and macros.

```
group sys-util

Defines

POINTER_TO_UINT(x)
    Cast x, a pointer, to an unsigned integer.

UINT_TO_POINTER(x)
    Cast x, an unsigned integer, to a void*.

POINTER_TO_INT(x)
    Cast x, a pointer, to a signed integer.

INT_TO_POINTER(x)
    Cast x, a signed integer, to a void*.

BITS_PER_LONG
    Number of bits in a long int.

GENMASK(h, l)
    Create a contiguous bitmask starting at bit position l and ending at position h.

LSB_GET(value)
    Extract the Least Significant Bit from value.

FIELD_GET(mask, value)
    Extract a bitfield element from value corresponding to the field mask.

FIELD_PREP(mask, value)
    Prepare a bitfield element using value with mask representing its field position and width.
    The result should be combined with other fields using a logical OR.

ZERO_OR_COMPILE_ERROR(cond)
    0 if cond is true-ish; causes a compile error otherwise.

IS_ARRAY(array)
    Zero if array has an array type, a compile error otherwise.
    This macro is available only from C, not C++.

ARRAY_SIZE(array)
    Number of elements in the given array.
    In C++, due to language limitations, this will accept as array any type that implements operator[]. The results may not be particularly meaningful in this case.
    In C, passing a pointer as array causes a compile error.
```
IS_ARRAY_ELEMENT(array, ptr)

Whether ptr is an element of array.

This macro can be seen as a slightly stricter version of PART_OF_ARRAY in that it also ensures that ptr is aligned to an array-element boundary of array.

In C, passing a pointer as array causes a compile error.

Parameters

- array – the array in question
- ptr – the pointer to check

Returns

1 if ptr is part of array, 0 otherwise

ARRAY_INDEX(array, ptr)

Index of ptr within array.

With CONFIG_ASSERT=y, this macro will trigger a runtime assertion when ptr does not fall into the range of array or when ptr is not aligned to an array-element boundary of array.

In C, passing a pointer as array causes a compile error.

Parameters

- array – the array in question
- ptr – pointer to an element of array

Returns

the array index of ptr within array, on success

PART_OF_ARRAY(array, ptr)

Check if a pointer ptr lies within array.

In C but not C++, this causes a compile error if array is not an array (e.g. if ptr and array are mixed up).

Parameters

- array – an array
- ptr – a pointer

Returns

1 if ptr is part of array, 0 otherwise

ARRAY_INDEX_FLOOR(array, ptr)

Array-index of ptr within array, rounded down.

This macro behaves much like ARRAY_INDEX with the notable difference that it accepts any ptr in the range of array rather than exclusively a ptr aligned to an array-element boundary of array.

With CONFIG_ASSERT=y, this macro will trigger a runtime assertion when ptr does not fall into the range of array.

In C, passing a pointer as array causes a compile error.

Parameters

- array – the array in question
- ptr – pointer to an element of array

Returns

the array index of ptr within array, on success
CONTAINER_OF(ptr, type, field)
Get a pointer to a structure containing the element.

Example:

```c
struct foo {
    int bar;
};

struct foo my_foo;
int *ptr = &my_foo.bar;
struct foo *container = CONTAINER_OF(ptr, struct foo, bar);
```

Above, `container` points at `my_foo`.

**Parameters**
- `ptr` – pointer to a structure element
- `type` – name of the type that `ptr` is an element of
- `field` – the name of the field within the struct `ptr` points to

**Returns**
a pointer to the structure that contains `ptr`

ROUND_UP(x, align)
Value of `x` rounded up to the next multiple of `align`, which must be a power of 2.

ROUND_DOWN(x, align)
Value of `x` rounded down to the previous multiple of `align`, which must be a power of 2.

WB_UP(x)
Value of `x` rounded up to the next word boundary.

WB_DN(x)
Value of `x` rounded down to the previous word boundary.

ceiling_fraction(numerator, divider)
Ceiling function applied to `numerator / divider` as a fraction.

MAX(a, b)
Obtain the maximum of two values.

**Note:** Arguments are evaluated twice. Use Z_MAX for a GCC-only, single evaluation version

MIN(a, b)
Obtain the minimum of two values.

**Note:** Arguments are evaluated twice. Use Z_MIN for a GCC-only, single evaluation version
Parameters
• a – First value.
• b – Second value.

Returns
Minimum value of a and b.

CLAMP(val, low, high)
Clamp a value to a given range.

Note: Arguments are evaluated multiple times. Use Z_CLAMP for a GCC-only, single evaluation version.

Parameters
• val – Value to be clamped.
• low – Lowest allowed value (inclusive).
• high – Highest allowed value (inclusive).

Returns
Clamped value.

IN_RANGE(val, min, max)
Checks if a value is within range.

Note: val is evaluated twice.

Parameters
• val – Value to be checked.
• min – Lower bound (inclusive).
• max – Upper bound (inclusive).

Return values
• true – If value is within range
• false – If the value is not within range

KB(x)
Number of bytes in x kibibytes.

MB(x)
Number of bytes in x mebibytes.

GB(x)
Number of bytes in x gibibytes.

KHZ(x)
Number of Hz in x kHz.

MHZ(x)
Number of Hz in x MHz.
\textbf{WAIT\_FOR}(\textit{expr}, \textit{timeout}, \textit{delay\_stmt})

Wait for an expression to return true with a timeout.

Spin on an expression with a timeout and optional delay between iterations

Commonly needed when waiting on hardware to complete an asynchronous request to read/write/initialize/reset, but useful for any expression.

\textbf{Parameters}

- \textit{expr} – Truth expression upon which to poll, e.g.: XYZREG & XYZREG\_EN
- \textit{timeout} – Timeout to wait for in microseconds, e.g.: 1000 (1ms)
- \textit{delay\_stmt} – Delay statement to perform each poll iteration e.g.: NULL, \textit{k\_yield()}, \textit{k\_msleep(1)} or \textit{k\_busy\_wait(1)}

\textbf{Return values}

- \textit{expr} – As a boolean return, if false then it has timed out.

\textbf{BIT}(\textit{n})

Unsigned integer with bit position \textit{n} set (signed in assembly language).

\textbf{BIT64}(\_\textit{n})

64-bit unsigned integer with bit position \_\textit{n} set.

\textbf{WRITE\_BIT}(\textit{var}, \textit{bit}, \textit{set})

Set or clear a bit depending on a boolean value.

The argument \textit{var} is a variable whose value is written to as a side effect.

\textbf{Parameters}

- \textit{var} – Variable to be altered
- \textit{bit} – Bit number
- \textit{set} – if 0, clears \textit{bit} in \textit{var}; any other value sets \textit{bit}

\textbf{BIT\_MASK}(\textit{n})

Bit mask with bits 0 through \textit{n}-1 (inclusive) set, or 0 if \textit{n} is 0.

\textbf{BIT64\_MASK}(\textit{n})

64-bit bit mask with bits 0 through \textit{n}-1 (inclusive) set, or 0 if \textit{n} is 0.

\textbf{IS\_ENABLED}(\textit{config\_macro})

Check for macro definition in compiler-visible expressions.

This trick was pioneered in Linux as the \texttt{config\_enabled()} macro. It has the effect of taking a macro value that may be defined to “1” or may not be defined at all and turning it into a literal expression that can be handled by the C compiler instead of just the preprocessor. It is often used with a \texttt{CONFIG\_FOO} macro which may be defined to 1 via Kconfig, or left undefined.

That is, it works similarly to \texttt{if defined(CONFIG\_FOO)} except that its expansion is a C expression. Thus, much \texttt{ifdef} usage can be replaced with equivalents like:

\begin{verbatim}
if (IS\_ENABLED(CONFIG\_FOO)) {
    do\_something\_with\_foo
}
\end{verbatim}

This is cleaner since the compiler can generate errors and warnings for \texttt{do\_something\_with\_foo} even when \texttt{CONFIG\_FOO} is undefined.

\textbf{Parameters}

- \textit{config\_macro} – Macro to check
**Returns**

1 if `config_macro` is defined to 1, 0 otherwise (including if `config_macro` is not defined)

\[ \text{COND_CODE}_1(\text{flag, if\_1\_code, else\_code}) \]

Insert code depending on whether \text{flag} expands to 1 or not.

This relies on similar tricks as `IS_ENABLED()`, but as the result of \text{flag} expansion, results in either \text{if\_1\_code} or \text{else\_code} is expanded.

To prevent the preprocessor from treating commas as argument separators, the \text{if\_1\_code} and \text{else\_code} expressions must be inside brackets/parentheses: (). These are stripped away during macro expansion.

Example:

\[ \text{COND_CODE}_1(\text{CONFIG\_FLAG, (uint32\_t x;), (there\_is\_no\_flag();)}) \]

If \text{CONFIG\_FLAG} is defined to 1, this expands to:

\[ \text{uint32\_t x;} \]

It expands to \text{there\_is\_no\_flag();} otherwise.

This could be used as an alternative to:

```c
#if defined(CONFIG_FLAG) && (CONFIG_FLAG == 1)
#define MAYBE_DECLARE(x) uint32_t x
#else
#define MAYBE_DECLARE(x) there_is_no_flag()
#endif
MAYBE_DECLARE(x);
```

However, the advantage of `COND_CODE_1()` is that code is resolved in place where it is used, while the #if method defines `MAYBE_DECLARE` on two lines and requires it to be invoked again on a separate line. This makes `COND_CODE_1()` more concise and also sometimes more useful when used within another macro's expansion.

**Note:** \text{flag} can be the result of preprocessor expansion, e.g. an expression involving \text{NUM\_VA\_ARGS\_LESS\_1(...)}. However, \text{if\_1\_code} is only expanded if \text{flag} expands to the integer literal 1. Integer expressions that evaluate to 1, e.g. after doing some arithmetic, will not work.

**Parameters**

- \text{flag} – evaluated flag
- \text{if\_1\_code} – result if \text{flag} expands to 1; must be in parentheses
- \text{else\_code} – result otherwise; must be in parentheses

\[ \text{COND_CODE}_0(\text{flag, if\_0\_code, else\_code}) \]

Like `COND_CODE_1()` except tests if \text{flag} is 0.

This is like `COND_CODE_1()`, except that it tests whether \text{flag} expands to the integer literal 0. It expands to \text{if\_0\_code} if so, and \text{else\_code} otherwise; both of these must be enclosed in parentheses.
See also:

`COND_CODE_1()`

Parameters

- `_flag` – evaluated flag
- `_if_0_code` – result if `_flag` expands to 0; must be in parentheses
- `_else_code` – result otherwise; must be in parentheses

`IF_ENABLED(_flag, _code)`

Insert code if `_flag` is defined and equals 1.

Like `COND_CODE_1()`, this expands to `_code` if `_flag` is defined to 1; it expands to nothing otherwise.

Example:

```c
IF_ENABLED(CONFIG_FLAG, (uint32_t foo;))
```

If `CONFIG_FLAG` is defined to 1, this expands to:

```c
uint32_t foo;
```

and to nothing otherwise.

It can be considered as a more compact alternative to:

```c
#if defined(CONFIG_FLAG) && (CONFIG_FLAG == 1)
uint32_t foo;
#endif
```

Parameters

- `_flag` – evaluated flag
- `_code` – result if `_flag` expands to 1; must be in parentheses

`IS_EMPTY(…)`

Check if a macro has a replacement expression.

If a is a macro defined to a nonempty value, this will return true, otherwise it will return false. It only works with defined macros, so an additional `#ifdef` test may be needed in some cases.

This macro may be used with `COND_CODE_1()` and `COND_CODE_0()` while processing `__VA_ARGS__` to avoid processing empty arguments.

Example:

```c
#define EMPTY
#define NON_EMPTY 1
#undef UNDEFINED
IS_EMPTY(EMPTY)
IS_EMPTY(NON_EMPTY)
IS_EMPTY(UNDEFINED)
#if defined(EMPTY) && IS_EMPTY(EMPTY) == true
some_conditional_code
#endif
```

In above examples, the invocations of `IS_EMPTY(…)` return true, false, and true; `some_conditional_code` is included.

Parameters
- macro to check for emptiness (may be __VA_ARGS__)

IS_EQ(a, b)
Like a == b, but does evaluation and short-circuiting at C preprocessor time.
This however only works for integer literal from 0 to 255.

LIST_DROP_EMPTY(...)
Remove empty arguments from list.
During macro expansion, __VA_ARGS__ and other preprocessor generated lists may contain empty elements, e.g.:

```c
#define LIST ,a,b,,d,
```

Using EMPTY to show each empty element, LIST contains:

```c
EMPTY, a, b, EMPTY, d
```

When processing such lists, e.g. using FOR_EACH(), all empty elements will be processed, and may require filtering out. To make that process easier, it is enough to invoke LIST_DROP_EMPTY which will remove all empty elements.

Example:

```c
LIST_DROP_EMPTY(LIST)
```

expands to:

```c
a, b, d
```

Parameters
- ... – list to be processed

EMPTY
Macro with an empty expansion.
This trivial definition is provided for readability when a macro should expand to an empty result, which e.g. is sometimes needed to silence checkpatch.

Example:

```c
#define LIST_ITEM(n) , item##n
```

The above would cause checkpatch to complain, but:

```c
#define LIST_ITEM(n) EMPTY, item##n
```

would not.

IDENTITY(V)
Macro that expands to its argument.
This is useful in macros like FOR_EACH() when there is no transformation required on the list elements.

Parameters
- V – any value
GET_ARG_N(N, ...)
Get nth argument from argument list.

Parameters
- N – Argument index to fetch. Counter from 1.
- ... – Variable list of arguments from which one argument is returned.

Returns
Nth argument.

GET_ARGS_LESS_N(N, ...)
Strips n first arguments from the argument list.

Parameters
- N – Number of arguments to discard.
- ... – Variable list of arguments.

Returns
argument list without N first arguments.

UTIL_OR(a, b)
Like a || b, but does evaluation and short-circuiting at C preprocessor time.

This is not the same as the binary || operator; in particular, a should expand to an integer literal 0 or 1. However, b can be any value.

This can be useful when b is an expression that would cause a build error when a is 1.

UTIL_AND(a, b)
Like a && b, but does evaluation and short-circuiting at C preprocessor time.

This is not the same as the binary && operator, however; in particular, a should expand to an integer literal 0 or 1. However, b can be any value.

This can be useful when b is an expression that would cause a build error when a is 0.

LISTIFY(LEN, F, sep, ...)
Generates a sequence of code with configurable separator.

Example:
```c
#define FOO(i, _) MY_PWM ## i
{ LISTIFY(PWM_COUNT, FOO, (,)) }
```

The above two lines expand to:
```
{ MY_PWM0 , MY_PWM1 }
```

Note: Calling LISTIFY with undefined arguments has undefined behavior.

Parameters
- LEN – The length of the sequence. Must be an integer literal less than 255.
- F – A macro function that accepts at least two arguments: F(i, ...). F is called repeatedly in the expansion. Its first argument i is the index in the sequence, and the variable list of arguments passed to LISTIFY are passed through to F.
- sep – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
FOR_EACH(F, sep, ...
Call a macro $F$ on each provided argument with a given separator between each call.

Example:

```
#define F(x) int a##x
FOR_EACH(F, (;), 4, 5, 6);
```

This expands to:

```
int a4;
int a5;
int a6;
```

Parameters

- $F$ – Macro to invoke
- $sep$ – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- $...$ – Variable argument list. The macro $F$ is invoked as $F(element)$ for each element in the list.

FOR_EACH_NONEMPTY_TERM(F, term, ...)

Like FOR_EACH(), but with a terminator instead of a separator, and drops empty elements from the argument list.

The $sep$ argument to FOR_EACH(F, (sep), a, b) is a separator which is placed between calls to $F$, like this:

```
FOR_EACH(F, (sep), a, b) // F(a) sep F(b)
```

By contrast, the $term$ argument to FOR_EACH_NONEMPTY_TERM(F, (term), a, b) is added after each time $F$ appears in the expansion:

```
FOR_EACH_NONEMPTY_TERM(F, (term), a, b) // F(a) term F(b) term
```

Further, any empty elements are dropped:

```
FOR_EACH_NONEMPTY_TERM(F, (term), a, EMPTY, b) // F(a) term F(b) term
```

This is more convenient in some cases, because FOR_EACH_NONEMPTY_TERM() expands to nothing when given an empty argument list, and it’s often cumbersome to write a macro $F$ that does the right thing even when given an empty argument.

One example is when __VA_ARGS__ may or may not be empty, and the results are embedded in a larger initializer:

```
#define SQUARE(x) ((x)*(x))

int my_array[] = {
    FOR_EACH_NONEMPTY_TERM(SQUARE, (,), FOO(...))
    FOR_EACH_NONEMPTY_TERM(SQUARE, (,), BAR(...))
    FOR_EACH_NONEMPTY_TERM(SQUARE, (,), BAZ(...))
};
```

This is more convenient than:
a. figuring out whether the FOO, BAR, and BAZ expansions are empty and adding a comma manually (or not) between FOR_EACH() calls

b. rewriting SQUARE so it reacts appropriately when “x” is empty (which would be necessary if e.g. FOO expands to nothing)

**Parameters**

- **F** – Macro to invoke on each nonempty element of the variable arguments
- **term** – Terminator (e.g. comma or semicolon) placed after each invocation of F. Must be in parentheses; this is required to enable providing a comma as separator.
- **...** – Variable argument list. The macro F is invoked as F(element) for each nonempty element in the list.

**FOR_EACH_IDX(F, sep, ...)**

Call macro F on each provided argument, with the argument’s index as an additional parameter.

This is like **FOR_EACH()**, except F should be a macro which takes two arguments: F(index, variable_arg).

Example:

```c
#define F(idx, x) int a##idx = x
FOR_EACH_IDX(F, (;), 4, 5, 6);
```

This expands to:

```c
int a0 = 4;
int a1 = 5;
int a2 = 6;
```

**Parameters**

- **F** – Macro to invoke
- **sep** – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- **...** – Variable argument list. The macro F is invoked as F(index, element) for each element in the list.

**FOR_EACH_FIXED_ARG(F, sep, fixed_arg, ...)**

Call macro F on each provided argument, with an additional fixed argument as a parameter.

This is like **FOR_EACH()**, except F should be a macro which takes two arguments: F(variable_arg, fixed_arg).

Example:

```c
static void func(int val, void *dev);
FOR_EACH_FIXED_ARG(func, (;), dev, 4, 5, 6);
```

This expands to:

```c
func(4, dev);
func(5, dev);
func(6, dev);
```

**Parameters**
• F – Macro to invoke
• sep – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
• fixed_arg – Fixed argument passed to F as the second macro parameter.
• ... – Variable argument list. The macro F is invoked as F(element, fixed_arg) for each element in the list.

FOR_EACH_IDX_FIXED_ARG(F, sep, fixed_arg, ...)
Calls macro F for each variable argument with an index and fixed argument.
This is like the combination of FOR_EACH_IDX() with FOR_EACH_FIXED_ARG().
Example:

```c
#define F(idx, x, fixed_arg) int fixed_arg##idx = x
FOR_EACH_IDX_FIXED_ARG(F, (;), a, 4, 5, 6);
```
This expands to:
```
int a0 = 4;
int a1 = 5;
int a2 = 6;
```

Parameters
• F – Macro to invoke
• sep – Separator (e.g. comma or semicolon). Must be in parentheses; This is required to enable providing a comma as separator.
• fixed_arg – Fixed argument passed to F as the third macro parameter.
• ... – Variable list of arguments. The macro F is invoked as F(index, element, fixed_arg) for each element in the list.

REVERSE_ARGS(...)
Reverse arguments order.

Parameters
• ... – Variable argument list.

NUM_VA_ARGS_LESS_1(...)
Number of arguments in the variable arguments list minus one.

Parameters
• ... – List of arguments

Returns
Number of variadic arguments in the argument list, minus one

MACRO_MAP_CAT(...)
Mapping macro that pastes results together.
This is similar to FOR_EACH() in that it invokes a macro repeatedly on each element of __VA_ARGS__. However, unlike FOR_EACH(), MACRO_MAP_CAT() pastes the results together into a single token.
For example, with this macro FOO:

```c
#define FOO(x) item_##x##_
```
MACRO_MAP_CAT(FOO, a, b, c), expands to the token:

```
item_a_item_b_item_c_
```

**Parameters**
- ... – Macro to expand on each argument, followed by its arguments. (The macro should take exactly one argument.)

**Returns**
The results of expanding the macro on each argument, all pasted together

MACRO_MAP_CAT_N(N, ...)
Mapping macro that pastes a fixed number of results together.
Similar to MACRO_MAP_CAT(), but expects a fixed number of arguments. If more arguments are given than are expected, the rest are ignored.

**Parameters**
- N – Number of arguments to map
- ... – Macro to expand on each argument, followed by its arguments. (The macro should take exactly one argument.)

**Returns**
The results of expanding the macro on each argument, all pasted together

**Functions**

static inline bool is_power_of_two(unsigned int x)
Is x a power of two?

**Parameters**
- x – value to check

**Returns**
true if x is a power of two, false otherwise

static inline int64_t arithmetic_shift_right(int64_t value, uint8_t shift)
Arithmetic shift right.

**Parameters**
- value – value to shift
- shift – number of bits to shift

**Returns**
value shifted right by shift; opened bit positions are filled with the sign bit

static inline void bytecpy(void *dst, const void *src, size_t size)
Copy size bytes of src into dest. This is guaranteed to be done byte by byte.

**Parameters**
- dst – Pointer to the destination memory.
- src – Pointer to the source of the data.
- size – The number of bytes to copy.
static inline void byteswap(void *a, void *b, size_t size)
    byte by byte swap.

    Swap size bytes between memory regions a and b. This is guaranteed to be done byte by byte.

Parameters
    • a – Pointer to the first memory region.
    • b – Pointer to the second memory region.
    • size – The number of bytes to swap.

int char2hex(char c, uint8_t *x)
    Convert a single character into a hexadecimal nibble.

Parameters
    • c – The character to convert
    • x – The address of storage for the converted number.

Returns
    Zero on success or (negative) error code otherwise.

int hex2char(uint8_t x, char *c)
    Convert a single hexadecimal nibble into a character.

Parameters
    • c – The number to convert
    • x – The address of storage for the converted character.

Returns
    Zero on success or (negative) error code otherwise.

size_t bin2hex(const uint8_t *buf, size_t buflen, char *hex, size_t hexlen)
    Convert a binary array into string representation.

Parameters
    • buf – The binary array to convert
    • buflen – The length of the binary array to convert
    • hex – Address of where to store the string representation.
    • hexlen – Size of the storage area for string representation.

Returns
    The length of the converted string, or 0 if an error occurred.

size_t hex2bin(const char *hex, size_t hexlen, uint8_t *buf, size_t buflen)
    Convert a hexadecimal string into a binary array.

Parameters
    • hex – The hexadecimal string to convert
    • hexlen – The length of the hexadecimal string to convert.
    • buf – Address of where to store the binary data
    • buflen – Size of the storage area for binary data

Returns
    The length of the binary array, or 0 if an error occurred.
static inline uint8_t bcd2bin(uint8_t bcd)
    Convert a binary coded decimal (BCD 8421) value to binary.

Parameters
    • bcd – BCD 8421 value to convert.

Returns
    Binary representation of input value.

static inline uint8_t bin2bcd(uint8_t bin)
    Convert a binary value to binary coded decimal (BCD 8421).

Parameters
    • bin – Binary value to convert.

Returns
    BCD 8421 representation of input value.

uint8_t u8_to_dec(char *buf, uint8_t buflen, uint8_t value)
    Convert a uint8_t value into its ASCII decimal string representation. The string is terminated
    if there is enough space in buf.

Parameters
    • buf – Address of where to store the string representation.
    • buflen – Size of the storage area for string representation.
    • value – The value to convert to decimal string

Returns
    The length of the converted string (excluding terminator if any), or 0 if an error
    occurred.

cchar *utf8_trunc(char *utf8_str)
    Properly truncate a NULL-terminated UTF-8 string.

Take a NULL-terminated UTF-8 string and ensure that if the string has been truncated (by
setting the NULL terminator) earlier by other means, that the string ends with a properly
formatted UTF-8 character (1-4 bytes).

Parameters
    • utf8_str – NULL-terminated string

Returns
    Pointer to the utf8_str

cchar *utf8_lcpy(char *dst, const char *src, size_t n)
    Copies a UTF-8 encoded string from src to dst.

The resulting dst will always be NULL terminated if n is larger than 0, and the dst string will
always be properly UTF-8 truncated.

Parameters
    • dst – The destination of the UTF-8 string.
    • src – The source string
    • n – The size of the dst buffer. Maximum number of characters copied is n - 1.
        If 0 nothing will be done, and the dst will not be NULL terminated.

Returns
    Pointer to the dst
3.9 Iterable Sections

This page contains the reference documentation for the iterable sections APIs, which can be used for defining iterable areas of equally-sized data structures, that can be iterated on using \texttt{STRUCT\_SECTION\_FOREACH}.

3.9.1 Usage

Iterable section elements are typically used by defining the data structure and associated initializer in a common header file, so that they can be instantiated anywhere in the code base.

\begin{verbatim}
struct my_data {
    int a, b;
};

#define DEFINE_DATA(name, _a, _b) \
    STRUCT\_SECTION\_ITERABLE(my_data, name) = { \
        .a = _a, \n        .b = _b, \n    }

...DEFINE_DATA(d1, 1, 2);
DEFINE_DATA(d2, 3, 4);
DEFINE_DATA(d3, 5, 6);
\end{verbatim}

Then the linker has to be setup to place the place the structure in a contiguous segment using one of the linker macros such as \texttt{ITERABLE\_SECTION\_RAM} or \texttt{ITERABLE\_SECTION\_ROM}. Custom linker snippets are normally declared using one of the \texttt{zephyr\_linker\_sources()} CMake functions, using the appropriate section identifier, \texttt{DATA\_SECTIONS} for RAM structures and \texttt{SECTIONS} for ROM ones.

\begin{verbatim}
# CMakeLists.txt
zephyr\_linker\_sources(DATA\_SECTIONS iterables.ld)

# iterables.ld
ITERABLE\_SECTION\_RAM(my_data, 4)
\end{verbatim}

The data can then be accessed using \texttt{STRUCT\_SECTION\_FOREACH}.

\begin{verbatim}
STRUCT\_SECTION\_FOREACH(my_data, data) {
    printk("%p: a: %d, b: %d\n", data, data->a, data->b);
}
\end{verbatim}

\textbf{Note}: The linker is going to place the entries sorted by name, so the example above would visit d1, d2 and d3 in that order, regardless of how they were defined in the code.

3.9.2 API Reference

\begin{verbatim}
group iterable\_section\_apis
    Iterable Sections APIs.
\end{verbatim}
Defines

ITERABLE_SECTION_ROM(struct_type, subalign)
Define a read-only iterable section output.
Define an output section which will set up an iterable area of equally-sized data structures. For use with STRUCT_SECTION_ITERABLE(). Input sections will be sorted by name, per ld's SORT_BY_NAME.
This macro should be used for read-only data.
Note that this keeps the symbols in the image even though they are not being directly referenced. Use this when symbols are indirectly referenced by iterating through the section.

ITERABLE_SECTION_ROM_GC_ALLOWED(struct_type, subalign)
Define a garbage collectable read-only iterable section output.
Define an output section which will set up an iterable area of equally-sized data structures. For use with STRUCT_SECTION_ITERABLE(). Input sections will be sorted by name, per ld's SORT_BY_NAME.
This macro should be used for read-only data.
Note that the symbols within the section can be garbage collected.

ITERABLE_SECTION_RAM(struct_type, subalign)
Define a read-write iterable section output.
Define an output section which will set up an iterable area of equally-sized data structures. For use with STRUCT_SECTION_ITERABLE(). Input sections will be sorted by name, per ld's SORT_BY_NAME.
This macro should be used for read-write data that is modified at runtime.
Note that this keeps the symbols in the image even though they are not being directly referenced. Use this when symbols are indirectly referenced by iterating through the section.

ITERABLE_SECTION_RAM_GC_ALLOWED(struct_type, subalign)
Define a garbage collectable read-write iterable section output.
Define an output section which will set up an iterable area of equally-sized data structures. For use with STRUCT_SECTION_ITERABLE(). Input sections will be sorted by name, per ld's SORT_BY_NAME.
This macro should be used for read-write data that is modified at runtime.
Note that the symbols within the section can be garbage collected.

STRUCT_SECTION_ITERABLE(struct_type, name)
Defines a new element for an iterable section.
Convenience helper combining __in_section() and Z_DECL_ALIGN(). The section name is the struct type prepended with an underscore. The subsection is “static” and the subsubsection is the variable name.
In the linker script, create output sections for these using ITERABLE_SECTION_ROM() or ITERABLE_SECTION_RAM().

Note: In order to store the element in ROM, a const specifier has to be added to the declaration: const STRUCT_SECTION_ITERABLE(...);

STRUCT_SECTION_ITERABLE_ALTERNATE(out_type, struct_type, name)
Defines a new element of alternate data type for an iterable section.
Special variant of \texttt{STRUCT\_SECTION\_ITERABLE()}, for placing alternate data types within the iterable section of a specific data type. The data type sizes and semantics must be equivalent!

\texttt{STRUCT\_SECTION\_FOREACH}(\texttt{struct\_type}, \texttt{iterator})

Iterate over a specified iterable section.

\begin{itemize}
\item \texttt{iterator} for structure instances gathered by \texttt{STRUCT\_SECTION\_ITERABLE()}. The linker must provide a \_\_\texttt{struct\_type}\_\_list\_start symbol and a \_\_\texttt{struct\_type}\_\_list\_end symbol to mark the start and the end of the list of struct objects to iterate over. This is normally done using \texttt{ITERABLE\_SECTION\_ROM()} or \texttt{ITERABLE\_SECTION\_RAM()} in the linker script.
\end{itemize}

\texttt{STRUCT\_SECTION\_GET}(\texttt{struct\_type}, \texttt{i}, \texttt{dst})

Get element from section.

\begin{itemize}
\item \texttt{struct\_type} – \texttt{[in]} Struct type.
\item \texttt{i} – \texttt{[in]} Index.
\item \texttt{dst} – \texttt{[out]} Pointer to location where pointer to element is written.
\end{itemize}

\texttt{STRUCT\_SECTION\_COUNT}(\texttt{struct\_type}, \texttt{dst})

Count elements in a section.

\begin{itemize}
\item \texttt{struct\_type} – \texttt{[in]} Struct type
\item \texttt{dst} – \texttt{[out]} Pointer to location where result is written.
\end{itemize}

\section{3.10 Code And Data Relocation}

\subsection{3.10.1 Overview}

This feature will allow relocating \texttt{.text}, \texttt{.rodata}, \texttt{.data}, and \texttt{.bss} sections from required files and place them in the required memory region. The memory region and file are given to the \texttt{scripts/build/gen_relocate_app.py} script in the form of a string. This script is always invoked from inside cmake.

This script provides a robust way to re-order the memory contents without actually having to modify the code. In simple terms this script will do the job of \texttt{\_\_attribute\_\_((section("name")))} for a bunch of files together.

\subsection{3.10.2 Details}

The memory region and file are given to the \texttt{scripts/build/gen_relocate_app.py} script in the form of a string.

An example of such a string is: \texttt{SRAM2:/home/xyz/zephyr/samples/hello_world/src/main.c, SRAM1:/home/xyz/zephyr/samples/hello_world/src/main2.c}

This script is invoked with the following parameters: \texttt{python3 gen_relocate_app.py -i input_string -o generated_linker -c generated_code}

Kconfig \texttt{CONFIG\_CODE\_DATA\_RELOCATION} option, when enabled in \texttt{prj.conf}, will invoke the script and do the required relocation.
This script also trigger the generation of `linker_relocate.ld` and `code_relocation.c` files. The `linker_relocate.ld` file creates appropriate sections and links the required functions or variables from all the selected files.

**Note:** The text section is split into 2 parts in the main linker script. The first section will have some info regarding vector tables and other debug related info. The second section will have the complete text section. This is needed to force the required functions and data variables to the correct locations. This is due to the behavior of the linker. The linker will only link once and hence this text section had to be split to make room for the generated linker script.

The `code_relocation.c` file has code that is needed for initializing data sections, and a copy of the text sections (if XIP). Also this contains code needed for bss zeroing and for data copy operations from ROM to required memory type.

The procedure to invoke this feature is:

- Enable `CONFIG_CODE_DATA_RELOCATION` in the `prj.conf` file
- Inside the `CMakeLists.txt` file in the project, mention all the files that need relocation.
  
  ```
  zephyr_code_relocate(src/*.c SRAM2)
  
  Where the first argument is the file/files and the second argument is the memory where it must be placed.
  ```

**Note:** The file argument supports limited regular expressions. function `zephyr_code_relocate()` can be called as many times as required. This step has to be performed before the inclusion of `boilerplate.cmake`.

### Additional Configurations

This section shows additional configuration options that can be set in `CMakeLists.txt`

- if the memory is SRAM1, SRAM2, CCD, or AON, then place the full object in the sections for example:
  
  ```
  zephyr_code_relocate(src/file1.c SRAM2)
  zephyr_code_relocate(src/file2.c.c SRAM)
  ```

- if the memory type is appended with _DATA, _TEXT, _RODATA or _BSS, only the selected memory is placed in the required memory region. for example:
  
  ```
  zephyr_code_relocate(src/file1.c SRAM2_DATA)
  zephyr_code_relocate(src/file2.c.c SRAM2_TEXT)
  ```

- Multiple regions can also be appended together such as: SRAM2_DATA_BSS. This will place data and bss inside SRAM2.

### NOCOPY flag

When a NOCOPY option is passed to the `zephyr_code_relocate()` function, the relocation code is not generated in `code_relocation.c`. This flag can be used when we want to move the content of a specific file (or set of files) to a XIP area.

This example will place the .text section of the `xip_external_flash.c` file to the EXTFLASH memory region where it will be executed from (XIP). The .data will be relocated as usual into SRAM.
Sample

A sample showcasing this feature is provided at $ZEPHYR_BASE/samples/application_development/code_relocation/

This is an example of using the code relocation feature.

This example will place .text, .data, .bss from 3 files to various parts in the SRAM using a custom linker file derived from include/arch/arm/aarch32/cortex_m/scripts/linker.ld

A sample showcasing the NOCOPY flag is provided at $ZEPHYR_BASE/samples/application_development/code_relocation_nocopy/
4.1 Cryptography

The crypto section contains information regarding the cryptographic primitives supported by the Zephyr kernel. Use the information to understand the principles behind the operation of the different algorithms and how they were implemented.

The following crypto libraries have been included:

4.1.1 TinyCrypt Cryptographic Library

Overview

The TinyCrypt Library provides an implementation for targeting constrained devices with a minimal set of standard cryptography primitives, as listed below. To better serve applications targeting constrained devices, TinyCrypt implementations differ from the standard specifications (see the Important Remarks section for some important differences). Certain cryptographic primitives depend on other primitives, as mentioned in the list below.

Aside from the Important Remarks section below, valuable information on the usage, security and technicalities of each cryptographic primitive are found in the corresponding header file.

- SHA-256:
  - Type of primitive: Hash function.
  - Requires: –

- HMAC-SHA256:
  - Type of primitive: Message authentication code.
  - Requires: SHA-256

- HMAC-PRNG:
  - Type of primitive: Pseudo-random number generator.
  - Standard Specification: NIST SP 800-90A.
  - Requires: SHA-256 and HMAC-SHA256.

- AES-128:
  - Type of primitive: Block cipher.
- Requires: –

- AES-CBC mode:
  - Type of primitive: Encryption mode of operation.
  - Standard Specification: NIST SP 800-38A.
  - Requires: AES-128.

- AES-CTR mode:
  - Type of primitive: Encryption mode of operation.
  - Standard Specification: NIST SP 800-38A.
  - Requires: AES-128.

- AES-CMAC mode:
  - Type of primitive: Message authentication code.
  - Standard Specification: NIST SP 800-38B.
  - Requires: AES-128.

- AES-CCM mode:
  - Type of primitive: Authenticated encryption.
  - Standard Specification: NIST SP 800-38C.
  - Requires: AES-128.

- ECC-DH:
  - Type of primitive: Key exchange.
  - Requires: ECC auxiliary functions (ecc.h/c).

- ECC-DSA:
  - Type of primitive: Digital signature.
  - Requires: ECC auxiliary functions (ecc.h/c).

**Design Goals**

- Minimize the code size of each cryptographic primitive. This means minimize the size of a board-independent implementation, as presented in TinyCrypt. Note that various applications may require further features, optimizations with respect to other metrics and countermeasures for particular threats. These peculiarities would increase the code size and thus are not considered here.

- Minimize the dependencies among the cryptographic primitives. This means that it is unnecessary to build and allocate object code for more primitives than the ones strictly required by the intended application. In other words, one can select and compile only the primitives required by the application.

**Important Remarks**

The cryptographic implementations in TinyCrypt library have some limitations. Some of these limitations are inherent to the cryptographic primitives themselves, while others are specific to TinyCrypt. Some of these limitations are discussed in-depth below.
General Remarks

• TinyCrypt does not intend to be fully side-channel resistant. Due to the variety of side-channel attacks, many of them making certain boards vulnerable. In this sense, instead of penalizing all library users with side-channel countermeasures such as increasing the overall code size, TinyCrypt only implements certain generic timing-attack countermeasures.

Specific Remarks

• SHA-256:
  – The number of bits_hashed in the state is not checked for overflow. Note however that this will only be a problem if you intend to hash more than $2^{64}$ bits, which is an extremely large window.

• HMAC:
  – The HMAC verification process is assumed to be performed by the application. This compares the computed tag with some given tag. Note that conventional memory-comparison methods (such as memcmp function) might be vulnerable to timing attacks; thus be sure to use a constant-time memory comparison function (such as compare_constant_time function provided in lib/utils.c).

• HMAC-PRNG:
  – Before using HMAC-PRNG, you must find an entropy source to produce a seed. PRNGs only stretch the seed into a seemingly random output of arbitrary length. The security of the output is exactly equal to the unpredictability of the seed.
  – NIST SP 800-90A requires three items as seed material in the initialization step: entropy seed, personalization and a nonce (which is not implemented). TinyCrypt requires the personalization byte array and automatically creates the entropy seed using a mandatory call to the re-seed function.

• AES-128:
  – The current implementation does not support other key-lengths (such as 256 bits). Note that if you need AES-256, it doesn't sound as though your application is running in a constrained environment. AES-256 requires keys twice the size as for AES-128, and the key schedule is 40% larger.

• CTR mode:
  – The AES-CTR mode limits the size of a data message they encrypt to $2^{32}$ blocks. If you need to encrypt larger data sets, your application would need to replace the key after $2^{32}$ block encryptions.

• CBC mode:
  – TinyCrypt CBC decryption assumes that the iv and the ciphertext are contiguous (as produced by TinyCrypt CBC encryption). This allows for a very efficient decryption algorithm that would not otherwise be possible.

• CMAC mode:
  – AES128-CMAC mode of operation offers 64 bits of security against collision attacks. Note however that an external attacker cannot generate the tags him/herself without knowing the MAC key. In this sense, to attack the collision property of AES128-CMAC, an external attacker would need the cooperation of the legal user to produce an exponentially high number of tags (e.g. $2^{64}$) to finally be able to look for collisions and benefit from them. As an extra precaution, the current implementation allows to at most $2^{48}$ calls to tc_cmac_update function before re-calling tc_cmac_setup (allowing a new key to be set), as suggested in Appendix B of SP 800-38B.

• CCM mode:
There are a few tradeoffs for the selection of the parameters of CCM mode. In special, there is a tradeoff between the maximum number of invocations of CCM under a given key and the maximum payload length for those invocations. Both things are related to the parameter ‘q’ of CCM mode. The maximum number of invocations of CCM under a given key is determined by the nonce size, which is: 15-q bytes. The maximum payload length for those invocations is defined as 2^8q bytes.

To achieve minimal code size, TinyCrypt CCM implementation fixes q = 2, which is a quite reasonable choice for constrained applications. The implications of this choice are:

The nonce size is: 13 bytes.
The maximum payload length is: 2^16 bytes = 65 KB.

The mac size parameter is an important parameter to estimate the security against collision attacks (that aim at finding different messages that produce the same authentication tag). TinyCrypt CCM implementation accepts any even integer between 4 and 16, as suggested in SP 800-38C.

TinyCrypt CCM implementation accepts associated data of any length between 0 and (2^16 - 2^8) = 65280 bytes.

TinyCrypt CCM implementation accepts:
* Both non-empty payload and associated data (it encrypts and authenticates the payload and only authenticates the associated data);
* Non-empty payload and empty associated data (it encrypts and authenticates the payload);
* Non-empty associated data and empty payload (it degenerates to an authentication-only mode on the associated data).

RFC-3610, which also specifies CCM, presents a few relevant security suggestions, such as: it is recommended for most applications to use a mac size greater than 8. Besides, it is emphasized that the usage of the same nonce for two different messages which are encrypted with the same key obviously destroys the security properties of CCM mode.

- ECC-DH and ECC-DSA:

TinyCrypt ECC implementation is based on nano-ecc (see https://github.com/iSECPartners/nano-ecc) which in turn is based on micro-ecc (see https://github.com/kmackay/micro-ecc). In the original nano and micro-ecc documentation, there is an important remark about the way integers are represented:

“Integer representation: To reduce code size, all large integers are represented using little-endian words - so the least significant word is first. You can use the ‘ecc_bytes2native()’ and ‘ecc_native2bytes()’ functions to convert between the native integer representation and the standardized octet representation.”

Examples of Applications

It is possible to do useful cryptography with only the given small set of primitives. With this list of primitives it becomes feasible to support a range of cryptography usages:

- Measurement of code, data structures, and other digital artifacts (SHA256);
- Generate commitments (SHA256);
- Construct keys (HMAC-SHA256);
- Extract entropy from strings containing some randomness (HMAC-SHA256);
- Construct random mappings (HMAC-SHA256);
- Construct nonces and challenges (HMAC-PRNG);
- Authenticate using a shared secret (HMAC-SHA256);
- Create an authenticated, replay-protected session (HMAC-SHA256 + HMAC-PRNG);
- Authenticated encryption (AES-128 + AES-CCM);
- Key-exchange (EC-DH);
- Digital signature (EC-DSA);

Test Vectors

The library provides a test program for each cryptographic primitive (see ‘test’ folder). Besides illustrating how to use the primitives, these tests evaluate the correctness of the implementations by checking the results against well-known publicly validated test vectors.

For the case of the HMAC-PRNG, due to the necessity of performing an extensive battery test to produce meaningful conclusions, we suggest the user to evaluate the unpredictability of the implementation by using the NIST Statistical Test Suite (see References).

For the case of the EC-DH and EC-DSA implementations, most of the test vectors were obtained from the site of the NIST Cryptographic Algorithm Validation Program (CAVP), see References.

4.1.2 Random Number Generation

The random API subsystem provides random number generation APIs in both cryptographically and non-cryptographically secure instances. Which random API to use is based on the cryptographic requirements of the random number. The non-cryptographic APIs will return random values much faster if non-cryptographic values are needed.

The cryptographically secure random functions shall be compliant to the FIPS 140-2 [?] recommended algorithms. Hardware based random-number generators (RNG) can be used on platforms with appropriate hardware support. Platforms without hardware RNG support shall use the CTR-DRBG algorithm. The algorithm can be provided by TinyCrypt or mbedTLS depending on your application performance and resource requirements.

Note: The CTR-DRBG generator needs an entropy source to establish and maintain the cryptographic security of the PRNG.
Kconfig Options

These options can be found in the following path `subsys/random/Kconfig`.

- **CONFIG_TEST RANDOM GENERATOR**
  For testing, this option permits random number APIs to return values that are not truly random.

The random number generator choice group allows selection of the RNG source function for the system via the `RNG_GENERATOR_CHOICE` choice group. An override of the default value can be specified in the SOC or board `.defconfig` file by using:

```choice RNG_GENERATOR_CHOICE
    default XOSHIRO_RANDOM_GENERATOR
endchoice```

The random number generators available include:

- **CONFIG_TIMER_RANDOM_GENERATOR**
  enables number generator based on system timer clock. This number generator is not random and used for testing only.

- **CONFIG_ENTROPY_DEVICE_RANDOM_GENERATOR**
  enables a random number generator that uses the enabled hardware entropy gathering driver to generate random numbers.

- **CONFIG_XOSHIRO_RANDOM_GENERATOR**
  enables the Xoshiro128++ pseudo-random number generator, that uses the entropy driver as a seed source.

The CSPRNG_GENERATOR_CHOICE choice group provides selection of the cryptographically secure random number generator source function. An override of the default value can be specified in the SOC or board `.defconfig` file by using:

```choice CSPRNG_GENERATOR_CHOICE
    default CTR_DRBG_CSPRNG_GENERATOR
endchoice```

The cryptographically secure random number generators available include:

- **CONFIG_HARDWARE DEVICE_CS_GENERATOR**
  enables a cryptographically secure random number generator using the hardware random generator driver

- **CONFIG_CTR_DRBG_CSPRNG_GENERATOR**
  enables the CTR-DRBG pseudo-random number generator. The CTR-DRBG is a FIPS140-2 recommended cryptographically secure random number generator.

Personalization data can be provided in addition to the entropy source to make the initialization of the CTR-DRBG as unique as possible.

```CONFIG_CS_CTR_DRBG_PERSONALIZATION
    CTR-DRBG Initialization Personalization string```

API Reference

`group random_api`

Random Function APIs.
uint32_t sys_rand32_get(void)
   Return a 32-bit random value that should pass general randomness tests.

   **Note:** The random value returned is not a cryptographically secure random number value.

   **Returns**
   32-bit random value.

void sys_rand_get(void *dst, size_t len)
   Fill the destination buffer with random data values that should pass general randomness tests.

   **Note:** The random values returned are not considered cryptographically secure random number values.

   **Parameters**
   • dst – [out] destination buffer to fill with random data.
   • len – size of the destination buffer.

int sys_csrand_get(void *dst, size_t len)
   Fill the destination buffer with cryptographically secure random data values.

   **Note:** If the random values requested do not need to be cryptographically secure then use `sys_rand_get()` instead.

   **Parameters**
   • dst – [out] destination buffer to fill.
   • len – size of the destination buffer.

   **Returns**
   0 if success, -EIO if entropy reseed error

### 4.1.3 Crypto APIs

**Overview**

**API Reference**

**Generic API for crypto drivers**

`group crypto`

Crypto APIs.

**Defines**

- `CAP_OPAQUE_KEY_HNDL`
- `CAP_RAW_KEY`

4.1. Cryptography
CAP_KEY_LOADING_API

CAP_INPLACE_OPS
  Whether the output is placed in separate buffer or not

CAP_SEPARATE_IO_BUFS

CAP_SYNC_OPS
  These denotes if the output (completion of a cipher_xxx_op) is conveyed by the op function returning, or it is conveyed by an async notification

CAP_ASYNC_OPS

CAP_AUTONONCE
  Whether the hardware/driver supports autononce feature

CAP_NO_IV_PREFIX
  Don’t prefix IV to cipher blocks

Functions

static inline int crypto_query_hwcaps(const struct device *dev)
  Query the crypto hardware capabilities.

  This API is used by the app to query the capabilities supported by the crypto device. Based on this the app can specify a subset of the supported options to be honored for a session during cipher_begin_session().

  Parameters
  • dev – Pointer to the device structure for the driver instance.

  Returns
  bitmask of supported options.

struct crypto_driver_api
  #include <crypto.h> Crypto driver API definition.

Ciphers API

group crypto_cipher
  Crypto Cipher APIs.

Typedefs

typedef int (*block_op_t)(struct cipher_ctx *ctx, struct cipher_pkt *pkt)

typedef int (*cbc_op_t)(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *iv)

typedef int (*ctr_op_t)(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *ctr)
typedef int (*ccm_op_t)(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)

typedef int (*gcm_op_t)(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)

typedef void (*cipher_completion_cb)(struct cipher_pkt *completed, int status)

Enums

enum cipher_algo
    Cipher Algorithm

    Values:

    enumerator CRYPTO_CIPHER_ALGO_AES = 1

enum cipher_op
    Cipher Operation

    Values:

    enumerator CRYPTO_CIPHER_OP_DECRYPT = 0

    enumerator CRYPTO_CIPHER_OP_ENCRYPT = 1

enum cipher_mode
    Possible cipher mode options.
    More to be added as required.

    Values:

    enumerator CRYPTO_CIPHER_MODE_ECB = 1

    enumerator CRYPTO_CIPHER_MODE_CBC = 2

    enumerator CRYPTO_CIPHER_MODE_CTR = 3

    enumerator CRYPTO_CIPHER_MODE_CCM = 4

    enumerator CRYPTO_CIPHER_MODE_GCM = 5

Functions

static inline int cipher_begin_session(const struct device *dev, struct cipher_ctx *ctx, enum cipher_algo algo, enum cipher_mode mode, enum cipher_op optype)

    Setup a crypto session.

    Initializes one time parameters, like the session key, algorithm and cipher mode which may remain constant for all operations in the session. The state may be cached in hardware and/or driver data state variables.
Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **ctx** – Pointer to the context structure. Various one-time parameters like key, keylength, etc. are supplied via this structure. The structure documentation specifies which fields are to be populated by the app before making this call.
- **algo** – The crypto algorithm to be used in this session. e.g AES
- **mode** – The cipher mode to be used in this session. e.g CBC, CTR
- **optype** – Whether we should encrypt or decrypt in this session

Returns

0 on success, negative errno code on fail.

```c
static inline int cipher_free_session(const struct device *dev, struct cipher_ctx *ctx)
```

Cleanup a crypto session.

Clears the hardware and/or driver state of a previous session.

Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **ctx** – Pointer to the crypto context structure of the session to be freed.

Returns

0 on success, negative errno code on fail.

```c
static inline int cipher_callback_set(const struct device *dev, cipher_completion_cb cb)
```

Registers an async crypto op completion callback with the driver.

The application can register an async crypto op completion callback handler to be invoked by the driver, on completion of a prior request submitted via cipher_do_op(). Based on crypto device hardware semantics, this is likely to be invoked from an ISR context.

Parameters

- **dev** – Pointer to the device structure for the driver instance.
- **cb** – Pointer to application callback to be called by the driver.

Returns

0 on success, -ENOTSUP if the driver does not support async op, negative errno code on other error.

```c
static inline int cipher_block_op(struct cipher_ctx *ctx, struct cipher_pkt *pkt)
```

Perform single-block crypto operation (ECB cipher mode). This should not be overloaded to operate on multiple blocks for security reasons.

Parameters

- **ctx** – Pointer to the crypto context of this op.
- **pkt** – Structure holding the input/output buffer pointers.

Returns

0 on success, negative errno code on fail.

```c
static inline int cipher_cbc_op(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *iv)
```

Perform Cipher Block Chaining (CBC) crypto operation.

Parameters

- **ctx** – Pointer to the crypto context of this op.
- **pkt** – Structure holding the input/output buffer pointers.
• \textit{iv} – Initialization Vector (IV) for the operation. Same IV value should not be reused across multiple operations (within a session context) for security.

**Returns**
0 on success, negative errno code on fail.

static inline int cipher_ctr_op(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *iv)
Perform Counter (CTR) mode crypto operation.

**Parameters**
• \textit{ctx} – Pointer to the crypto context of this op.
• \textit{pkt} – Structure holding the input/output buffer pointers.
• \textit{iv} – Initialization Vector (IV) for the operation. We use a split counter formed by appending IV and ctr. Consequently ivlen = keylen - ctrlen. ‘ctrlen’ is specified during session setup through the ‘ctx.mode_params.ctr_params.ctr_len’ parameter. IV should not be reused across multiple operations (within a session context) for security. The non-IV part of the split counter is transparent to the caller and is fully managed by the crypto provider.

**Returns**
0 on success, negative errno code on fail.

static inline int cipher_ccm_op(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)
Perform Counter with CBC-MAC (CCM) mode crypto operation.

**Parameters**
• \textit{ctx} – Pointer to the crypto context of this op.
• \textit{pkt} – Structure holding the input/output, Associated Data (AD) and auth tag buffer pointers.
• \textit{nonce} – Nonce for the operation. Same nonce value should not be reused across multiple operations (within a session context) for security.

**Returns**
0 on success, negative errno code on fail.

static inline int cipher_gcm_op(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)
Perform Galois/Counter Mode (GCM) crypto operation.

**Parameters**
• \textit{ctx} – Pointer to the crypto context of this op.
• \textit{pkt} – Structure holding the input/output, Associated Data (AD) and auth tag buffer pointers.
• \textit{nonce} – Nonce for the operation. Same nonce value should not be reused across multiple operations (within a session context) for security.

**Returns**
0 on success, negative errno code on fail.

```c
struct cipher_ops
#include <cipher.h>

struct ccm_params
#include <cipher.h>
```
struct 

    #include <cipher.h>

struct 

    #include <cipher.h>

struct 

    #include <cipher.h> Structure encoding session parameters.
    Refer to comments for individual fields to know the contract in terms of who fills what and when w.r.t begin_session() call.

Public Members

struct cipher_ops ops

    Place for driver to return function pointers to be invoked per cipher operation. To be populated by crypto driver on return from begin_session() based on the algo/mode chosen by the app.

union cipher_ctx.[anonymous] key

    To be populated by the app before calling begin_session()

const struct device *device

    The device driver instance this crypto context relates to. Will be populated by the begin_session() API.

void *drv_sessn_state

    If the driver supports multiple simultaneously crypto sessions, this will identify the specific driver state this crypto session relates to. Since dynamic memory allocation is not possible, it is suggested that at build time drivers allocate space for the max simultaneous sessions they intend to support. To be populated by the driver on return from begin_session().

void *app_sessn_state

    Place for the user app to put info relevant stuff for resuming when completion callback happens for async ops. Totally managed by the app.

union cipher_ctx.[anonymous] mode_params

    Cypher mode parameters, which remain constant for all ops in a session. To be populated by the app before calling begin_session().

uint16_t keylen

    Cryptographic keylength in bytes. To be populated by the app before calling begin_session()

uint16_t tflags

    How certain fields are to be interpreted for this session. (A bitmask of CAP_* below.) To be populated by the app before calling begin_session(). An app can obtain the capability flags supported by a hw/driver by calling crypto_query_hwcaps().

struct cipher_pkt

#include <cipher.h> Structure encoding IO parameters of one cryptographic operation like encrypt/decrypt.

The fields which has not been explicitly called out has to be filled up by the app before making the cipher_xxx_op() call.

Public Members

uint8_t *in_buf
Start address of input buffer

int in_len
Bytes to be operated upon

uint8_t *out_buf
Start of the output buffer, to be allocated by the application. Can be NULL for in-place ops. To be populated with contents by the driver on return from op / async callback.

int out_buf_max
Size of the out_buf area allocated by the application. Drivers should not write past the size of output buffer.

int out_len
To be populated by driver on return from cipher_xxx_op() and holds the size of the actual result.

struct cipher_ctx *ctx
Context this packet relates to. This can be useful to get the session details, especially for async ops. Will be populated by the cipher_xxx_op() API based on the ctx parameter.

struct cipher_aead_pkt

#include <cipher.h> Structure encoding IO parameters in AEAD (Authenticated Encryption with Associated Data) scenario like in CCM.

App has to furnish valid contents prior to making cipher_ccm_op() call.

Public Members

uint8_t *ad
Start address for Associated Data. This has to be supplied by app.

uint32_t ad_len
Size of Associated Data. This has to be supplied by the app.

uint8_t *tag
Start address for the auth hash. For an encryption op this will be populated by the driver when it returns from cipher_ccm_op call. For a decryption op this has to be supplied by the app.
4.2 Debugging

4.2.1 Thread analyzer

The thread analyzer module enables all the Zephyr options required to track the thread information, e.g. thread stack size usage and other runtime thread runtime statistics.

The analysis is performed on demand when the application calls `thread_analyzer_run()` or `thread_analyzer_print()`.

For example, to build the synchronization sample with Thread Analyser enabled, do the following:

```bash
west build -b qemu_x86 samples/synchronization/ -- -DCONFIG_QEMU_ICOUNT=n -
-DCONFIG_THREAD_ANALYZER=y \
-DCONFIG_THREAD_ANALYZER_USE_PRINTK=y -DCONFIG_THREAD_ANALYZER_AUTO=y \
-DCONFIG_THREAD_ANALYZER_AUTO_INTERVAL=5
```

When you run the generated application in Qemu, you will get the additional information from Thread Analyzer:

```
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
thread_b: STACK: unused 740 usage 284 / 1024 (27 %); CPU: 0 %
thread_analyzer: STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %
thread_a: STACK: unused 648 usage 376 / 1024 (36 %); CPU: 98 %
idle: STACK: unused 204 usage 116 / 320 (36 %); CPU: 0 %
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
thread_b: Hello World from cpu 0 on qemu_x86!
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
thread_b: STACK: unused 648 usage 376 / 1024 (36 %); CPU: 7 %
thread_analyzer: STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %

```
Configuration

Configure this module using the following options.

- **THREAD_ANALYZER**: enable the module.
- **THREAD_ANALYZER_USE_PRINTK**: use printk for thread statistics.
- **THREAD_ANALYZER_USE_LOG**: use the logger for thread statistics.
- **THREAD_ANALYZER_AUTO**: run the thread analyzer automatically. You do not need to add any code to the application when using this option.
- **THREAD_ANALYZER_AUTO_INTERVAL**: the time for which the module sleeps between consecutive printing of thread analysis in automatic mode.
- **THREAD_ANALYZER_AUTO_STACK_SIZE**: the stack for thread analyzer automatic thread.
- **THREAD_NAME**: enable this option in the kernel to print the name of the thread instead of its ID.
- **THREAD_RUNTIME_STATS**: enable this option to print thread runtime data such as utilization (This options is automatically selected by THREAD_ANALYZER).

API documentation

*group* **thread_analyzer**

Module for analyzing threads.
This module implements functions and the configuration that simplifies thread analysis.

*Typedefs*

typedef void (*thread_analyzer_cb)(struct thread_analyzer_info *info)

Thread analyzer stack size callback function.
Callback function with thread analysis information.

**Param info**

Thread analysis information.

*Functions*

void **thread_analyzer_run**(thread_analyzer_cb cb)

Run the thread analyzer and provide information to the callback.
This function analyzes the current state for all threads and calls a given callback on every thread found.

**Parameters**

- **cb** – The callback function handler

void **thread_analyzer_print**(void)

Run the thread analyzer and print stack size statistics.
This function runs the thread analyzer and prints the output in standard form.

struct thread_analyzer_info

```
#include <thread_analyzer.h>
```
Public Members

const char *name
    The name of the thread or stringified address of the thread handle if name is not set.

size_t stack_size
    The total size of the stack

size_t stack_used
    Stack size in used

4.2.2 Core Dump

The core dump module enables dumping the CPU registers and memory content for offline debugging. This module is called when a fatal error is encountered and prints or stores data according to which backends are enabled.

Configuration

Configure this module using the following options.

- DEBUG_COREDUMP: enable the module.

Here are the options to enable output backends for core dump:

- DEBUG_COREDUMP_BACKEND_LOGGING: use log module for core dump output.
- DEBUG_COREDUMP_BACKEND_NULL: fallback core dump backend if other backends cannot be enabled. All output is sent to null.

Here are the choices regarding memory dump:

- DEBUG_COREDUMP_MEMORY_DUMP_MIN: only dumps the stack of the exception thread, its thread struct, and some other bare minimal data to support walking the stack in the debugger. Use this only if absolute minimum of data dump is desired.

Additional memory can be included in a dump (even with the “DEBUG_COREDUMP_MEMORY_DUMP_MIN” config selected) through one or more core dump devices

Usage

When the core dump module is enabled, during a fatal error, CPU registers and memory content are printed or stored according to which backends are enabled. This core dump data can be fed into a custom-made GDB server as a remote target for GDB (and other GDB compatible debuggers). CPU registers, memory content and stack can be examined in the debugger.

This usually involves the following steps:

1. Get the core dump log from the device depending on enabled backends. For example, if the log module backend is used, get the log output from the log module backend.
2. Convert the core dump log into a binary format that can be parsed by the GDB server. For example, scripts/coredump/coredump_serial_log_parser.py can be used to convert the serial console log into a binary file.
3. Start the custom GDB server using the script scripts/coredump/coredump_gdbserver.py with the core dump binary log file, and the Zephyr ELF file as parameters.
4. Start the debugger corresponding to the target architecture.
**Note:** Developers for Intel ADSP CAVS 15-25 platforms using `ZEPHYR_TOOLCHAIN_VARIANT=zephyr` should use the debugger in the xtensa-intel_apl_adsp toolchain of the SDK.

**Example**  This example uses the log module backend tied to serial console. This was done on qemu_x86 where a null pointer was dereferenced.

This is the core dump log from the serial console, and is stored in coredump.log:

```
Booting from ROM...*** Booting Zephyr OS build zephyr-v2.3.0-1840-g7bba9144a63 ***
Hello World! qemu_x86
E: Page fault at address 0x0 (error code 0x2)
E: Linear address not present in page tables
E: PDE: 0x0000000000115827Writable, User, Execute Enabled
E: PTE: Non-present
E: EAX: 0x00000000, EBX: 0x00000000, ECX: 0x00119d74, EDX: 0x0000003f8
E: ESI: 0x00000000, EDI: 0x00119d10, ESP: 0x00119d00
E: EFLAGS: 0x00000206 CS: 0x0008 CR3: 0x00119000
E: call trace:

E: >>> ZEPHYR FATAL ERROR 0: CPU exception on CPU 0
E: Current thread: 0x00119080 (unknown)
E: #CD:BEGIN#
```

(continues on next page)
1. Run the core dump serial log converter:

   ./scripts/coredump/coredump_serial_log_parser.py coredump.log coredump.bin

2. Start the custom GDB server:

   ./scripts/coredump/coredump_gdbserver.py build/zephyr/zephyr.elf coredump.bin

3. Start GDB:

   <path to SDK>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb build/zephyr/zephyr.elf

4. Inside GDB, connect to the GDB server via port 1234:

   (gdb) target remote localhost:1234

5. Examine the CPU registers:

   (gdb) info registers

   Output from GDB:

   
   | eax   | 0x0   | 0   |
   | ecx   | 0x119d74 | 1154420 |
   | edx   | 0x3f8 | 1016 |
   | ebx   | 0x0   | 0   |
   | esp   | 0x119d00 | 0x119d00 <z_main_stack+844> |
   | ebp   | 0x119d10 | 0x119d10 <z_main_stack+860> |
   | esi   | 0x0   | 0   |
   | edi   | 0x101aa7 | 1055399 |
   | eip   | 0x100459 | 0x100459 <func_3+16> |
   | eflags | 0x206 | [ PF IF ] |
   | cs    | 0x8   | 8   |
   | ss    | <unavailable> |
   | ds    | <unavailable> |
   | es    | <unavailable> |
   | fs    | <unavailable> |
   | gs    | <unavailable> |

6. Examine the backtrace:

   (gdb) bt
Output from GDB:

```c
#0 0x00100459 in func_3 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/src/main.c:14
#1 0x00100477 in func_2 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/src/main.c:21
#2 0x00100492 in func_1 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/src/main.c:28
#3 0x001004c8 in main () at zephyr/rtos/zephyr/samples/hello_world/src/main.c:42
```

File Format

The core dump binary file consists of one file header, one architecture-specific block, and multiple memory blocks. All numbers in the headers below are little endian.

**File Header**  The file header consists of the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header version</td>
<td>uint16_t</td>
<td>Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.</td>
</tr>
<tr>
<td>Target code</td>
<td>uint16_t</td>
<td>Indicate which target (e.g. architecture or SoC) so the parser can instantiate the correct register block parser.</td>
</tr>
<tr>
<td>Pointer size</td>
<td>'uint8_t'</td>
<td>Size of uintptr_t in power of 2. (e.g. 5 for 32-bit, 6 for 64-bit). This is needed to accommodate 32-bit and 64-bit target in parsing the memory block addresses.</td>
</tr>
<tr>
<td>Flags</td>
<td>uint8_t</td>
<td></td>
</tr>
<tr>
<td>Fatal error reason</td>
<td>unsigned int</td>
<td>Reason for the fatal error, as the same in enum k_fatal_error_reason defined in include/zephyr/fatal.h</td>
</tr>
</tbody>
</table>

**Architecture-specific Block**  The architecture-specific block contains the byte stream of data specific to the target architecture (e.g. CPU registers)

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>char</td>
<td>'A' to indicate this is a architecture-specific block.</td>
</tr>
<tr>
<td>Header version</td>
<td>uint16_t</td>
<td>Identify the version of this block. To be interpreted by the target architecture specific block parser.</td>
</tr>
<tr>
<td>Number of bytes</td>
<td>uint16_t</td>
<td>Number of bytes following the header which contains the byte stream for target data. The format of the byte stream is specific to the target and is only being parsed by the target parser.</td>
</tr>
<tr>
<td>Register stream</td>
<td>byte uint8_t</td>
<td>Contains target architecture specific data.</td>
</tr>
</tbody>
</table>

**Memory Block**  The memory block contains the start and end addresses and the data within the memory region.

4.2. Debugging
Table 4.3: Memory Block

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>char</td>
<td>M to indicate this is a memory block.</td>
</tr>
<tr>
<td>Header version</td>
<td>uint16_t</td>
<td>Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.</td>
</tr>
<tr>
<td>Start address</td>
<td>uintptr_t</td>
<td>The start address of the memory region.</td>
</tr>
<tr>
<td>End address</td>
<td>uintptr_t</td>
<td>The end address of the memory region.</td>
</tr>
<tr>
<td>Memory stream byte</td>
<td>uint8_t[]</td>
<td>Contains the memory content between the start and end addresses.</td>
</tr>
</tbody>
</table>

Adding New Target

The architecture-specific block is target specific and requires new dumping routine and parser for new targets. To add a new target, the following needs to be done:

1. Add a new target code to the enum coredump_tgt_code in include/zephyr/debug/coredump.h.
2. Implement arch_coredump_tgt_code_get() simply to return the newly introduced target code.
3. Implement arch_coredump_info_dump() to construct a target architecture block and call coredump_buffer_output() to output the block to core dump backend.
4. Add a parser to the core dump GDB stub scripts under scripts/coredump/gdbstubs/
   1. Extends the gdbstubs.gdbstub.GdbStub class.
   2. During __init__, store the GDB signal corresponding to the exception reason in self.gdb_signal.
   3. Parse the architecture-specific block from self.logfile.get_arch_data(). This needs to match the format as implemented in step 3 (inside arch_coredump_info_dump()).
   4. Implement the abstract method handle_register_group_read_packet where it returns the register group as GDB expected. Refer to GDB's code and documentation on what it is expecting for the new target.
   5. Optionally implement handle_register_single_read_packet for registers not covered in the g packet.
5. Extend get_gdbstub() in scripts/coredump/gdbstubs/__init__.py to return the newly implemented GDB stub.

API documentation

`group coredump_apis`

Coredump APIs.

`Functions`

void coredump(unsigned int reason, const z_arch_esf_t *esf, struct k_thread *thread)

Perform coredump.

Normally, this is called inside z_fatal_error() to generate coredump when a fatal error is encountered. This can also be called on demand whenever a coredump is desired.

`Parameters`
void coredump_memory_dump(uintptr_t start_addr, uintptr_t end_addr)
Dump memory region.

Parameters
• start_addr – Start address of memory region to be dumped
• end_addr – End address of memory region to be dumped

void coredump_buffer_output(uint8_t *buf, size_t buflen)
Output the buffer via coredump.
This outputs the buffer of byte array to the coredump backend. For example, this can be called to output the coredump section containing registers, or a section for memory dump.

Parameters
• buf – Buffer to be send to coredump output
• buflen – Buffer length

int coredump_query(enum coredump_query_id query_id, void *arg)
Perform query on coredump subsystem.
Query the coredump subsystem for information, for example, if there is an error.

Parameters
• query_id – [in] Query ID
• arg – [inout] Pointer to argument for exchanging information

Returns
Depends on the query

int coredump_cmd(enum coredump_cmd_id query_id, void *arg)
Perform command on coredump subsystem.
Perform certain on coredump subsystem, for example, output the stored coredump via logging.

Parameters
• cmd_id – [in] Command ID
• arg – [inout] Pointer to argument for exchanging information

Returns
Depends on the command

Functions

void arch_coredump_info_dump(const z_arch_esf_t *esf)
Architecture-specific handling during coredump.
This dumps architecture-specific information during coredump.

Parameters
• esf – Exception Stack Frame (arch-specific)
uint16_t arch_coredump_tgt_code_get(void)

Get the target code specified by the architecture.

4.2.3 GDB stub

- **Overview**
- **Features**
  - **Enabling GDB Stub**
    - Using Serial Backend
  - **Debugging**
    - Using Serial Backend
  - **Example**

**Overview**

The gdbstub feature provides an implementation of the GDB Remote Serial Protocol (RSP) that allows you to remotely debug Zephyr using GDB.

The protocol supports different connection types: serial, UDP/IP and TCP/IP. Zephyr currently supports only serial device communication.

The GDB program acts as the client while Zephyr acts as the server. When this feature is enabled, Zephyr stops its execution after `gdb_init()` starts gdbstub service and waits for a GDB connection. Once a connection is established it is possible to synchronously interact with Zephyr. Note that currently it is not possible to asynchronously send commands to the target.

**Features**

The following features are supported:

- Add and remove breakpoints
- Continue and step the target
- Print backtrace
- Read or write general registers
- Read or write the memory

**Enabling GDB Stub**

GDB stub can be enabled with the `CONFIG_GDBSTUB` option.

**Using Serial Backend** The serial backend for GDB stub can be enabled with the `CONFIG_GDBSTUB_SERIAL_BACKEND` option.

Since serial backend utilizes UART devices to send and receive GDB commands,

- If there are spare UART devices on the board, set `zephyr,gdbstub-uart` property of the chosen node to the spare UART device so that `printk()` and log messages are not being printed to the same UART device used for GDB.
For boards with only one UART device, printk() and logging must be disabled if they are also using the same UART device for output. GDB related messages may interleave with log messages which may have unintended consequences. Usually this can be done by disabling CONFIG_PRINTK and CONFIG_LOG.

Debugging

Using Serial Backend

1. Build with GDB stub and serial backend enabled.
2. Flash built image onto board and reset the board.
   • Execution should now be paused at gdb_init().
3. Execute GDB on development machine and connect to the GDB stub.

   ```
   target remote <serial device>
   ```

   For example,

   ```
   target remote /dev/ttyUSB1
   ```

4. GDB commands can be used to start debugging.

Example

This is an example using samples/subsys/debug/gdbstub to demonstrate how GDB stub works.

1. Open two terminal windows.
2. On the first terminal, build and run the sample:

   ```
   # From the root of the zephyr repository
   west build -b qemu_x86 samples/subsys/debug/gdbstub
   west build -t run
   ```

3. On the second terminal, start GDB:

   ```
   <SDK install directory>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb
   ```

   1. Tell GDB where to look for the built ELF file:

   ```
   (gdb) file <build directory>/zephyr/zephyr.elf
   ```

   Response from GDB:

   ```
   Reading symbols from <build directory>/zephyr/zephyr.elf...
   ```

   2. Tell GDB to connect to the server:

   ```
   (gdb) target remote localhost:5678
   ```

   Note that QEMU is setup to redirect the serial used for GDB stub in the Zephyr image to a networking port. Hence the connection to localhost, port 5678.

   Response from GDB:

   ```
   Remote debugging using :5678
   arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:232
   232   }
   ```
GDB also shows where the code execution is stopped. In this case, it is at `arch/x86/core/ia32/gdbstub.c`, line 232.

3. Use command `bt` or `backtrace` to show the backtrace of stack frames.

```plaintext
(gdb) bt
#0 arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:232
#1 0x00105068 in gdb_init (arg=0x0) at <ZEPHYR_BASE>/subsys/debug/gdbstub.
    -- c:833
#2 0x001009d6f in z_sys_init_run_level (level=0x1) at <ZEPHYR_BASE>/kernel/
    -- device.c:72
#3 0x0010a40b in z_cstart () at <ZEPHYR_BASE>/kernel/init.c:423
#4 0x00105383 in z_x86_prep_c (arg=0x9500) at <ZEPHYR_BASE>/arch/x86/core/
    -- prep_c.c:58
#5 0x0010000a9 in __csSet () at <ZEPHYR_BASE>/arch/x86/core/ia32/crt0.S:273
```

4. Use command `list` to show the source code and surroundings where code execution is stopped.

```plaintext
(gdb) list
227     }
228
229     void arch_gdb_init(void)
230     {
231         __asm__ volatile("int3");
232     }
233
234     /* Hook current IDT. */
235     _EXCEPTION_CONNECT_NOCODE(z_gdb_debug_isr, IV_DEBUG, 3);
236     _EXCEPTION_CONNECT_NOCODE(z_gdb_break_isr, IV_BREAKPOINT, 3);
```

5. Use command `s` or `step` to step through program until it reaches a different source line. Now that it finished executing `arch_gdb_init()` and is continuing in `gdb_init()`.

```plaintext
(gdb) s
gdb_init (arg=0x0) at /home/dleung5/zephyr/rtos/zephyr/subsys/debug/gdbstub.
    -- c:834
834     return 0;
```

```plaintext
(gdb) list
829     LOG_ERR("Could not initialize gdbstub backend.");
830     return -1;
831     }
832
833     arch_gdb_init();
834     return 0;
835     }
836
837     #ifdef CONFIG_XTENSA
838     /*
```

6. Use command `br` or `break` to setup a breakpoint. This example sets up a breakpoint at `main()`, and let code execution continue without any intervention using command `c` (or `continue`).

```plaintext
(gdb) break main
Breakpoint 1 at 0x1005a9: file <ZEPHYR_BASE>/samples/subsys/debug/gdbstub/
    -- src/main.c, line 32.
(gdb) continue
Continuing.
```
Once code execution reaches `main()`, execution will be stopped and GDB prompt returns.

Breakpoint 1, main () at <ZEPHYR_BASE>/samples/subsys/debug/gdbstub/src/main.c:32

```
32 ret = test();
```

Now GDB is waiting at the beginning of `main()`:

```
(gdb) list
27
28 void main(void)
29 {
30 int ret;
31 32 ret = test();
33 printk("%d\n", ret);
34 }
35
36 K_THREAD_DEFINE(thread, STACKSIZE, thread_entry, NULL, NULL, NULL,
```

7. To examine the value of `ret`, the command `p` or `print` can be used.

```
(gdb) p ret
$1 = 0x11318c
```

Since `ret` has not been assigned a value yet, what it contains is simply a random value.

8. If step (s or step) is used here, it will continue execution until `printk()` is reached, thus skipping the interior of `test()`. To examine code execution inside `test()`, a breakpoint can be set for `test()`, or simply using `si` (or stepi) to execute one machine instruction, where it has the side effect of going into the function.

```
(gdb) si
```

```
test () at <ZEPHYR_BASE>/samples/subsys/debug/gdbstub/src/main.c:13
13 {
(gdb) list
8 #include <zephyr/sys/printk.h>
9
10 #define STACKSIZE 512
11
12 static int test(void)
13 {
14    int a;
15    int b;
16    17 a = 10;
```

9. Here, step can be used to go through all code inside `test()` until it returns. Or the command `finish` can be used to continue execution without intervention until the function returns.

```
(gdb) finish
Run till exit from #0 test () at <ZEPHYR_BASE>/samples/subsys/debug/gdbstub/src/main.c:13
0x001005ae in main () at <ZEPHYR_BASE>/samples/subsys/debug/gdbstub/src/main.c:32
32 ret = test();
Value returned is $2 = 0x1e
```

And now, execution is back to `main()`.
10. Examine `ret` again which should have the return value from `test()`. Sometimes, the assignment is not done until another step is issued, as in this case. This is due to the assignment code is done after returning from function. The assignment code is generated by the toolchain as machine instructions which are not visible when viewing the corresponding C source file.

```
(gdb) p ret
$3 = 0x11318c
(gdb) s
33 printk("%d\n", ret);
(gdb) p ret
$4 = 0x1e
```

11. If `continue` is issued here, code execution will continue indefinitely as there are no breakpoints to further stop execution. Breaking execution in GDB via Ctrl-C does not currently work as the GDB stub does not support this functionality (yet).

### 4.3 Device Management

#### 4.3.1 MCUmgr

**Overview**

The management subsystem allows remote management of Zephyr-enabled devices. The following management operations are available:

- Image management
- File System management
- Log management (currently disabled)
- OS management
- Shell management

over the following transports:

- BLE (Bluetooth Low Energy)
- Serial (UART)
- UDP over IP

The management subsystem is based on the Simple Management Protocol (SMP) provided by MCUmgr, an open source project that provides a management subsystem that is portable across multiple real-time operating systems.

The management subsystem is split in two different locations in the Zephyr tree:

- `zephyrproject-rtos/mcumgr` repo contains a clean import of the MCUmgr project
- `subsys/mgmt/` contains the Zephyr-specific bindings to MCUmgr

Additionally there is a sample that provides management functionality over BLE and serial.

**Command-line Tool**

MCUmgr provides a command-line tool, `mcumgr`, for managing remote devices. The tool is written in the Go programming language.

To install the tool:

```
go version < 1.18
```
go get github.com/apache/mynewt-mcumgr-cli/mcumgr

go version >= 1.18

go install github.com/apache/mynewt-mcumgr-cli/mcumgr@latest

Configuring the transport

There are two command-line options that are responsible for setting and configuring the transport layer to use when communicating with managed device:

- **--conntype** is used to choose the transport used, and
- **--connstring** is used to pass a comma separated list of options in the key=value format, where each valid key depends on the particular conntype.

Valid transports for **--conntype** are serial, ble and udp. Each transport expects a different set of key/value options:

**serial**

**--connstring** accepts the following key values:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dev</td>
<td>the device name for the OS mcumgr is running on (eg, /dev/ttyUSB0, /dev/tty.</td>
</tr>
<tr>
<td></td>
<td>usbserial, COM1, etc).</td>
</tr>
<tr>
<td>baud</td>
<td>the communication speed; must match the baudrate of the server.</td>
</tr>
<tr>
<td>mtu</td>
<td>aka Maximum Transmission Unit, the maximum protocol packet size.</td>
</tr>
</tbody>
</table>

**ble**

**--connstring** accepts the following key values:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctlr_name</td>
<td>an OS specific string for the controller name.</td>
</tr>
<tr>
<td>own_addr_type</td>
<td>can be one of public, random, rpa_pub, rpa_rnd, where random is the default.</td>
</tr>
<tr>
<td>peer_name</td>
<td>the name the peer BLE device advertises, this should match the configuration specified with CONFIG_BT_DEVICE_NAME.</td>
</tr>
<tr>
<td>peer_id</td>
<td>the peer BLE device address or UUID. Only required when peer_name was not given. The format depends on the OS where mcumgr is run, it is a 6 bytes hexadecimal string separated by colons on Linux, or a 128-bit UUID on macOS.</td>
</tr>
<tr>
<td>conn_timeout</td>
<td>a float number representing the connection timeout in seconds.</td>
</tr>
</tbody>
</table>

**udp**

**--connstring** takes the form [addr]:port where:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>addr</td>
<td>can be a DNS name (if it can be resolved to the device IP), IPv4 addr (app must be built with CONFIG_MCUMGR_SMP_UDP_IPV4), or IPv6 addr (app must be built with CONFIG_MCUMGR_SMP_UDP_IPV6)</td>
</tr>
<tr>
<td>port</td>
<td>any valid UDP port.</td>
</tr>
</tbody>
</table>

Saving the connection config

The transport configuration can be managed with the conn sub-command and later used with **--conn** (or -c) parameter to skip typing both **--conntype** and **--connstring**. For example a new config for a serial device that would require typing mcumgr **--conntype** serial **--connstring** dev=/dev/ttyACM0, baud=115200, mtu=512 can be saved with:
mcumgr conn add acm0 type="serial" connstring="dev=/dev/ttyACM0,baud=115200,mtu=512"

Accessing this port can now be done with:

```
mcumgr -c acm0
```

**General options**

Some options work for every `mcumgr` command and might be helpful to debug and fix issues with the communication, among them the following deserve special mention:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-l</code> &lt;log-level&gt;</td>
<td>Configures the log level, which can be one of critical, error, warn, info or debug, from less to most verbose. When there are communication issues, <code>-lDEBUG</code> might be useful to dump the packets for later inspection.</td>
</tr>
<tr>
<td><code>-t</code> &lt;timeout&gt;</td>
<td>Changes the timeout waiting for a response from the default of 10s to a given value. Some commands might take a long time of processing, eg, the erase before an image upload, and might need incrementing the timeout to a larger value.</td>
</tr>
<tr>
<td><code>-r</code> &lt;tries&gt;</td>
<td>Changes the number of retries on timeout from the default of 1 to a given value.</td>
</tr>
</tbody>
</table>

**List of Commands**

Not all commands defined by `mcumgr` (and SMP protocol) are currently supported on Zephyr. The ones that are supported are described in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>echo</td>
<td>Send data to a device and display the echoed back data. This command is part of the OS group, which must be enabled by setting <code>CONFIG_MCUMGR_CMD_OS_MGMT</code>. The echo command itself can be enabled by setting <code>CONFIG_OS_MGMT_ECHO</code>.</td>
</tr>
<tr>
<td>fs</td>
<td>Access files on a device. More info in Filesystem Management.</td>
</tr>
<tr>
<td>image</td>
<td>Manage images on a device. More info in Image Management.</td>
</tr>
<tr>
<td>reset</td>
<td>Perform a soft reset of a device. This command is part of the OS group, which must be enabled by setting <code>CONFIG_MCUMGR_CMD_OS_MGMT</code>. The reset command itself is always enabled and the time taken for a reset to happen can be set with <code>CONFIG_OS_MGMT_RESET_MS</code> (in ms).</td>
</tr>
<tr>
<td>shell</td>
<td>Execute a command in the remote shell. This option is disabled by default and can be enabled with <code>CONFIG_MCUMGR_CMD_SHELL_MGMT = y</code>. To know more about the shell in Zephyr check Shell.</td>
</tr>
<tr>
<td>taskstat</td>
<td>Read task statistics from a device. This command is part of the OS group, which must be enabled by setting <code>CONFIG_MCUMGR_CMD_OS_MGMT</code>. The taskstat command itself can be enabled by setting <code>CONFIG_OS_MGMT_TASKSTAT</code>. <code>CONFIG_THREAD_MONITOR</code> also needs to be enabled otherwise a <code>-8 (MGMT_ERR_ENOTSUP)</code> will be returned.</td>
</tr>
</tbody>
</table>

**Tip:** Running `mcumgr` with no parameters, or `-h` will display the list of commands.

**Tip:** `taskstat` has a few options that might require tweaking. The `CONFIG_THREAD_NAME` must be set to display the task names, otherwise the priority is displayed. Since the taskstat packets are large, they might need increasing the `CONFIG_MCUMGR_BUF_SIZE` option.
**Warning:** To display the correct stack size in the taskstat command, the `CONFIG_THREAD_STACK_INFO` option must be set. To display the correct stack usage in the taskstat command, both `CONFIG_THREAD_STACK_INFO` and `CONFIG_INIT_STACKS` options must be set.

### J-Link Virtual MSD Interaction Note

On boards where a J-Link OB is present which has both CDC and MSC (virtual Mass Storage Device, also known as drag-and-drop) support, the MSD functionality can prevent mcumgr commands over the CDC UART port from working due to how USB endpoints are configured in the J-Link firmware (for example on the Nordic nrf52840dk) because of limiting the maximum packet size (most likely to occur when using image management commands for updating firmware). This issue can be resolved by disabling MSD functionality on the J-Link device, follow the instructions on nordic_segger_msd to disable MSD support.

### Image Management

The image management provided by `mcumgr` is based on the image format defined by MCUboot. For more details on the internals see [MCUboot design and Signing Binaries](https://zephyrproject.org/docs/device-management/mcumgr.html).

To list available images in a device:

```
mcumgr <connection-options> image list
```

This should result in an output similar to this:

```
$ mcumgr -c acm0 image list
Images:
    image=0 slot=0
    version: 1.0.0
    bootable: true
    flags: active confirmed
    hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fc4d5a9ed00cc7
Split status: N/A (0)
```

Where `image` is the number of the image pair in a multi-image system, and `slot` is the number of the slot where the image is stored, 0 for primary and 1 for secondary. This image being active and confirmed means it will run again on next reset. Also relevant is the hash, which is used by other commands to refer to this specific image when performing operations.

An image can be manually erased using:

```
mcumgr <connection-options> image erase
```

The behavior of `erase` is defined by the server (`mcumgr` in the device). The current implementation is limited to erasing the image in the secondary partition.

To upload a new image:

```
mcumgr <connection-options> image upload [-n] [-e] [-u] [-w] <signed-bin>
```

- `-n`: This option allows uploading a new image to a specific set of images in a multi-image system, and is currently only supported by MCUboot when the `CONFIG_MCUBOOT_SERIAL` option is enabled.
- `-e`: This option avoids performing a full erase of the partition before starting a new upload.
Tip: The `-e` option should always be passed in because the upload command already checks if an erase is required, respecting the CONFIG_IMG_ERASE_PROGRESSIVELY setting.

Tip: If the upload command times out while waiting for a response from the device, `-t` might be used to increase the wait time to something larger than the default of 10s. See general_options.

Warning: mcumgr does not understand .hex files, when uploading a new image always use the .bin file.

- `-u`: This option allows upgrading only to newer image version.
- `-w`: This option allows setting the maximum size for the window of outstanding chunks in transit. It is set to 5 by default.

Tip: If the option is set to a value lower than the default one, for example `-w 1`, less chunks are transmitted on the window, resulting in lower risk of errors. Conversely, setting a value higher than 5 increases risk of errors and may impact performance.

After an image upload is finished, a new image list would now have an output like this:

```
$ mcumgr -c acm0 image upload -e build/zephyr/zephyr.signed.bin
  35.69 KiB / 92.92 KiB [==========>---------------] 38.41% 2.97 KiB/s 00m19
```

Now listing the images again:

```
$ mcumgr -c acm0 image list
Images:
  image=0 slot=0
    version: 1.0.0
    bootable: true
    flags: active confirmed
    hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
  image=0 slot=1
    version: 1.1.0
    bootable: true
    flags:
      hash: e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
Split status: N/A (0)
```

To test a new upgrade image the test command is used:

```
mcumgr <connection-options> image test <hash>
```

This command should mark a test upgrade, which means that after the next reboot the bootloader will execute the upgrade and jump into the new image. If no other image operations are executed on the newly running image, it will revert back to the image that was previously running on the device on the subsequent reset. When a test is requested, flags will be updated with pending to inform that a new image will be run after a reset:

```
$ mcumgr -c acm0 image test
  → e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
Images:
  image=0 slot=0
    version: 1.0.0
```

(continues on next page)
bootable: true
flags: active confirmed
hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
image=0 slot=1
version: 1.1.0
bootable: true
flags: pending
hash: e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
Split status: N/A (0)

After a reset the output with change to:

```
$ mcumgr -c acm0 image list
Images:
  image=0 slot=0
  version: 1.1.0
  bootable: true
  flags: active
  hash: e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
  image=0 slot=1
  version: 1.0.0
  bootable: true
  flags: confirmed
  hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
Split status: N/A (0)
```

**Tip:** It’s important to mention that an upgrade only ever happens if the image is valid. The first thing MCUboot does when an upgrade is requested is to validate the image, using the SHA-256 and/or the signature (depending on the configuration). So before uploading an image, one way to be sure it is valid is to run `imgtool verify -k <your-signature-key> <your-image>`, where `-k <your-signature-key>` can be skipped if no signature validation was enabled.

The `confirmed` flag in the secondary slot tells that after the next reset a revert upgrade will be performed to switch back to the original layout.

The command used to confirm that an image is OK and no revert should happen (no hash required) is:

```
mcumgr <connection-options> image confirm [hash]
```

The `confirm` command can also be run passing in a hash so that instead of doing a test/revert procedure, the image in the secondary partition is directly upgraded to.

**Tip:** The whole test/revert cycle does not need to be done using only the `mcumgr` command-line tool. A better alternative is to perform a test and allow the new running image to self-confirm after any checks by calling `boot_write_img_confirmed()`.

**Tip:** Building with `CONFIG_IMG_MGMT_VERBOSE_ERR` enables better error messages when failures happen (but increases the application size).

### Statistics Management

Statistics are used for troubleshooting, maintenance, and usage monitoring; it consists basically of user-defined counters which are tightly connected to `mcumgr` and can be used to track any information for

---

**4.3. Device Management**
easy retrieval. The available sub-commands are:

```
mcumgr <connection-options> stat list
mcumgr <connection-options> stat <section-name>
```

Statistics are organized in sections (also called groups), and each section can be individually queried. Defining new statistics sections is done by using macros available under `<stats/stats.h>`. Each section consists of multiple variables (or counters), all with the same size (16, 32 or 64 bits).

To create a new section `my_stats`:

```
STATS_SECT_START(my_stats)
   STATS_SECT_ENTRY(my_stat_counter1)
   STATS_SECT_ENTRY(my_stat_counter2)
   STATS_SECT_ENTRY(my_stat_counter3)
STATS_SECT_END;

STATS_SECT_DECL(my_stats) my_stats;
```

Each entry can be declared with `STATS_SECT_ENTRY` (or the equivalent `STATS_SECT_ENTRY32`, `STATS_SECT_ENTRY16` or `STATS_SECT_ENTRY64`). All statistics in a section must be declared with the same size.

The statistics counters can either have names or not, depending on the setting of the `CONFIG_STATS_NAMES` option. Using names requires an extra declaration step:

```
STATS_NAME_START(my_stats)
   STATS_NAME(my_stats, my_stat_counter1)
   STATS_NAME(my_stats, my_stat_counter2)
   STATS_NAME(my_stats, my_stat_counter3)
STATS_NAME_END(my_stats);
```

**Tip:** Disabling `CONFIG_STATS_NAMES` will free resources. When this option is disabled the `STATS_NAME*` macros output nothing, so adding them in the code does not increase the binary size.

**Tip:** `CONFIG_STAT_MGMT_MAX_NAME_LEN` sets the maximum length of a section name that can be accepted as parameter for showing the section data, and might require tweaking for long section names.

The final steps to use a statistics section is to initialize and register it:

```
rc = STATS_INIT_AND_REG(my_stats, STATS_SIZE_32, "my_stats");
assert (rc == 0);
```

In the running code a statistics counter can be incremented by 1 using `STATS_INC`, by N using `STATS_INCN` or reset with `STATS_CLEAR`.

Let's suppose we want to increment those counters by 1, 2 and 3 every second. To get a list of stats:

```
$ mcumgr --conn acm0 stat list
stat groups:
   my_stats
```

To get the current value of the counters in `my_stats`:

```
$ mcumgr --conn acm0 stat my_stats
stat group: my_stats
   13 my_stat_counter1
```

(continues on next page)
$ mcumgr --conn acm0 stat my_stats
stat group: my_stats
 16 my_stat_counter1
 32 my_stat_counter2
 48 my_stat_counter3

When CONFIG_STATS_NAMES is disabled the output will look like this:

$ mcumgr --conn acm0 stat my_stats
stat group: my_stats
     8 s0
    16 s1
    24 s2

### Filesystem Management

The filesystem module is disabled by default due to security concerns: because of a lack of access control every file in the FS will be accessible, including secrets, etc. To enable it CONFIG_MCUMGR_CMD_FS_MGMT must be set (y). Once enabled the following sub-commands can be used:

- `mcumgr <connection-options> fs download <remote-file> <local-file>`
- `mcumgr <connection-options> fs upload <local-file> <remote-file>`

Using the `fs` command, requires CONFIG_FILE_SYSTEM to be enabled, and that some particular filesystem is enabled and properly mounted by the running application, eg for littlefs this would mean enabling CONFIG_FILESYSTEM_LITTLEFS, defining a storage partition *Flash map* and mounting the filesystem in the startup (`fs_mount()`).

Uploading a new file to a littlefs storage, mounted under `/lfs`, can be done with:

```
$ mcumgr -c acm0 fs upload foo.txt /lfs/foo.txt
25
Done
```

Where 25 is the size of the file.

For downloading a file, let's first use the `fs` command (CONFIG_FILESYSTEM_SHELL must be enabled) in a remote shell to create a new file:

```
uart:$ fs write /lfs/bar.txt 41 42 43 44 31 32 33 34 0a
uart:$ fs read /lfs/bar.txt
File size: 9
00000000 41 42 43 44 31 32 33 34 0A ABCD1234.
```

Now it can be downloaded using:

```
$ mcumgr -c acm0 fs download /lfs/bar.txt bar.txt
0
9
Done
$ cat bar.txt
ABCD1234
```

Where 0 is the return code, and 9 is the size of the file.

### 4.3. Device Management
**Warning:** The commands might exhaust the system workqueue, if its size is not large enough, so increasing `CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE` might be required for correct behavior.

The size of the stack allocated buffer used to store the blocks, while transferring a file can be adjusted with `CONFIG_FS_MGMT_DL_CHUNK_SIZE`; this allows saving RAM resources.

**Tip:** `CONFIG_FS_MGMT_PATH_SIZE` sets the maximum PATH accepted for a file name. It might require tweaking for longer file names.

## Bootloader Integration

The **Device Firmware Upgrade** subsystem integrates the management subsystem with the bootloader, providing the ability to send and upgrade a Zephyr image to a device.

Currently only the MCUboot bootloader is supported. See **MCUboot** for more information.

## Discord channel

Developers welcome!

- Discord mcumgr channel: https://discord.com/invite/Ck7jw53nU2

### 4.3.2 MCUmgr Callbacks

#### Overview

MCUmgr has a customisable callback/notification system that allows application (and module) code to receive callbacks for MCUmgr events that they are interested in and react to them or return a status code to the calling function that provides control over if the action should be allowed or not. An example of this is with the fs_mgmt group, whereby file access can be gated, the callback allows the application to inspect the request path and allow or deny access to said file, or it can rewrite the provided path to a different path for transparent file redirection support.

#### Implementation

**Enabling** The base callback/notification system can be enabled using `CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS` which will compile the registration and notification system into the code. This will not provide any callbacks by default as the callbacks that are supported by a build must also be selected by enabling the Kconfig's for the required callbacks (see Events for further details). A callback function with the `mgmt_cb` type definition can then be declared and registered by calling `mgmt_callback_register()` for the desired event inside of a `struct mgmt_callback` structure. Handlers are called in the order that they were registered.

With the system enabled, a basic handler can be set up and defined in application code as per:

```c
#include <zephyr/kernel.h>
#include <mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

struct mgmt_callback my_callback;

int32_t my_function(uint32_t event, int32_t rc, bool *abort_more, void *data,
                     struct k_task *self) {
  return 0;  // Example return
}
```

(continues on next page)
size_t data_size) {
    if (event == MGMT_EVT_OP_CMD_DONE) {
        /* This is the event we registered for */
    }

    /* Return OK status code to continue with acceptance to underlying handler */
    return MGMT_ERR_EOK;
}

void main()
{
    my_callback.callback = my_function;
    my_callback.event_id = MGMT_EVT_OP_CMD_DONE;
    mgmt_callback_register(&my_callback);
}

This code registers a handler for the MGMT_EVT_OP_CMD_DONE event, which will be called after a MCUmgr command has been processed and output generated, note that this requires that CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS be enabled to receive this callback.

Multiple callbacks can be setup to use a single function as a common callback, and many different functions can be used for each event by registering each group once, or all notifications for a whole group can be enabled by using one of the MGMT_EVT_OP_*_ALL events, alternatively a handler can setup for every notification by using MGMT_EVT_OP_ALL. When setting up handlers, events can be combined that are in the same group only, for example 5 img_mgmt callbacks can be setup with a single registration call, but to also setup a callback for an os_mgmt callback, this must be done as a separate registration. Group IDs are numerical increments, event IDs are bitmask values, hence the restriction.

Events Events can be selected by enabling their corresponding Kconfig option:

- CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS
  MCUmgr command status (MGMT_EVT_OP_CMD_RECV, MGMT_EVT_OP_CMD_STATUS, MGMT_EVT_OP_CMD_DONE)

- CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK
  fs_mgmt file access (MGMT_EVT_OP_FS_MGMT_FILE_ACCESS)

- CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK
  img_mgmt upload check (MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK)

- CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS
  img_mgmt upload status (MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED, MGMT_EVT_OP_IMG_MGMT_DFU_STARTED, MGMT_EVT_OP_IMG_MGMT_DFU_PENDING, MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED)

- CONFIG_MCUMGR_GRP_OS_OS_RESET_HOOK
  os_mgmt reset check (MGMT_EVT_OP_OS_MGMT_RESET)

Actions Some callbacks expect a return status to either allow or disallow an operation, an example is the fs_mgmt access hook which allows for access to files to be allowed or denied. With these handlers, the first non-OK error code returned by a handler will be returned to the MCUmgr client.

An example of selectively denying file access:

```
#include <zephyr/kernel.h>
#include <mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>
```
# include <string.h>

struct mgmt_callback my_callback;

int32_t my_function(uint32_t event, int32_t rc, bool *abort_more, void *data, size_t data_size)
{
    /* Only run this handler if a previous handler has not failed */
    if (event == MGMT_EVT_OP_FS_MGMT_FILE_ACCESS && rc == MGMT_ERR_EOK) {
        struct fs_mgmt_file_access *fs_data = (struct fs_mgmt_file_access *)data;

        /* Check if this is an upload and deny access if it is, otherwise check the path and deny if it matches a name */
        if (fs_data->upload == true) {
            /* Return an access denied error code to the client and abort calling further handlers */
            *abort_more = true;
            return MGMT_ERR_EACCESSDENIED;
        } else if (strcmp(fs_data->filename, "/lfs1/false_deny.txt") == 0) {
            /* Return a no entry error code to the client, call additional handlers (which will have failed set to true) */
            return MGMT_ERR_ENOENT;
        }
    }

    /* Return OK status code to continue with acceptance to underlying handler */
    return MGMT_ERR_EOK;
}

void main()
{
    my_callback.callback = my_function;
    my_callback.event_id = MGMT_EVT_OP_FS_MGMT_FILE_ACCESS;
    mgmt_callback_register(&my_callback);
}

This code registers a handler for the MGMT_EVT_OP_FS_MGMT_FILE_ACCESS event, which will be called after a fs_mgmt file read/write command has been received to check if access to the file should be allowed or not. Note that this requires that CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK be enabled to receive this callback.

MCUmgr Command Callback Usage/Adding New Event Types To add a callback to a MCUmgr command, mgmt_callback_notify() can be called with the event ID and, optionally, a data struct to pass to the callback (which can be modified by handlers). If no data needs to be passed back, NULL can be used instead, and size of the data set to 0.

An example MCUmgr command handler:
# define MGMT_EVT_GRP_USER_ONE MGMT_EVT_GRP_USER_CUSTOM_START

enum user_one_group_events {
  /** Callback on first post, data is test_struct. */
  MGMT_EVT_OP_USER_ONE_FIRST = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 0),

  /** Callback on second post, data is test_struct. */
  MGMT_EVT_OP_USER_ONE_SECOND = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 1),

  /** Used to enable all user_one events. */
  MGMT_EVT_OP_USER_ONE_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_USER_ONE),
};

struct test_struct {
  uint8_t some_value;
};

static int test_command(struct mgmt_ctxt *ctxt) {
  int rc;
  zcbor_state_t *zse = ctxt->cnbe->zs;
  bool ok;
  struct test_struct test_data = {
    .some_value = 8,
  };

  rc = mgmt_callback_notify(MGMT_EVT_OP_USER_ONE_FIRST, &test_data, sizeof(test_data));

  if (rc != MGMT_ERR_EOK) {
    /* A handler returned a failure code */
    return rc;
  }

  /* All handlers returned success codes */

  ok = zcbor_tstr_put_lit(zse, "output_value") &
  zcbor_int32_put(zse, 1234);

  if (!ok) {
    return MGMT_ERR_EMSGSIZE;
  }

  return MGMT_ERR_EOK;
}

If no response is required for the callback, the function call be called and casted to void.

Migration

If there is existing code using the previous callback system(s) in Zephyr 3.2 or earlier, then it will need to be migrated to the new system. To migrate code, the following callback registration functions will need to be migrated to register for callbacks using `mgmt_callback_register()` (note that `CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS` will need to be set to enable the new notification system in addition to any migrations):

4.3. Device Management
• mgmt_evt
  Using `MGMT_EVT_OP_CMD_RECV` if `MGMT_EVT_OP_CMD_RECV` was used, `MGMT_EVT_OP_CMD_STATUS` if `MGMT_EVT_OP_CMD_STATUS` was used or `MGMT_EVT_OP_CMD_DONE` if `MGMT_EVT_OP_CMD_DONE` was used, where the provided data is `mgmt_evt_op_cmd_arg`. `CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS` needs to be set.

• fs_mgmt_register_evt_cb
  Using `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` where the provided data is `fs_mgmt_file_access`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS` needs to be set.

• img_mgmt_register_callbacks
  Using `MGMT_EVT_OP_IMG_MGMT_DFU_STARTED` if `dfu_started_cb` was used, `MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED` if `dfu_stopped_cb` was used, `MGMT_EVT_OP_IMG_MGMT_DFU_PENDING` if `dfu_pending_cb` was used or `MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED` if `dfu_confirmed_cb` was used. These callbacks do not have any return status. `CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS` needs to be set.

• img_mgmt_set_upload_cb
  Using `MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK` where the provided data is `img_mgmt_upload_check`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK` needs to be set.

• os_mgmt_register_reset_evt_cb
  Using `MGMT_EVT_OP_OS_MGMT_RESET`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS` needs to be set

API Reference

`group mcumgr_callback_api`
MCUmgr callback API.

`Defines`

`MGMT_EVT_GET_GROUP(event)`
Get group from event.

`MGMT_EVT_GET_ID(event)`
Get event ID from event.

`Typedefs`

typedef int32_t (*mgmt_cb)(uint32_t event, int32_t rc, bool *abort_more, void *data, size_t data_size)
Function to be called on MGMT notification/event.
This callback function is used to notify an application or system about a mcumgr mgmt event.
**Param event**
mcumgr_op_t.

**Param rc**
mcumgr_err_t of the previous handler calls, if it is an error then it will be the first error that was returned by a handler (i.e. this handler is being called for a notification only, the return code will be ignored).

**Param abort_more**
Set to true to abort further processing by additional handlers.

**Param data**
Optional event argument.

**Param data_size**
Size of optional event argument (0 if no data is provided).

**Return**
mcumgr_err_t of the status to return to the calling code (only checked when failed is false).

**Enums**

**enum mgmt_cb_groups**
MGMT event callback group IDs. Note that this is not a 1:1 mapping with mcumgr_group_t values.

*Values:*

- enumerator MGMT_EVT_GRP_ALL = 0
- enumerator MGMT_EVT_GRP_SMP
- enumerator MGMT_EVT_GRP_OS
- enumerator MGMT_EVT_GRP_IMG
- enumerator MGMT_EVT_GRP_FS
- enumerator MGMT_EVT_GRP_USER_CUSTOM_START = MGMT_GROUP_ID_PERUSER

**enum smp_all_events**
MGMT event opcodes for all command processing.

*Values:*

- enumerator MGMT_EVT_OP_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_ALL)
  Used to enable all events.

**enum smp_group_events**
MGMT event opcodes for base SMP command processing.

*Values:*

4.3. Device Management
enumerator MGMT_EVT_OP_CMD_RECV = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_SMP, 0)
    Callback when a command is received, data is mgmt_evt_op_cmd_arg().

enumerator MGMT_EVT_OP_CMD_STATUS = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_SMP, 1)
    Callback when a status is updated, data is mgmt_evt_op_cmd_arg().

enumerator MGMT_EVT_OP_CMD_DONE = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_SMP, 2)
    Callback when a command has been processed, data is mgmt_evt_op_cmd_arg().

enumerator MGMT_EVT_OP_CMD_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_SMP)
    Used to enable all smp_group events.

enum fs_mgmt_group_events
    MGMT event opcodes for filesystem management group.
    Values:

enumerator MGMT_EVT_OP_FS_MGMT_FILE_ACCESS =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_FS, 0)
    Callback when a file has been accessed, data is fs_mgmt_file_access().

enumerator MGMT_EVT_OP_FS_MGMT_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_FS)
    Used to enable all fs_mgmt_group events.

enum img_mgmt_group_events
    MGMT event opcodes for image management group.
    Values:

enumerator MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 0)
    Callback when a client sends a file upload chunk, data is img_mgmt_upload_check().

enumerator MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 1)
    Callback when a DFU operation is stopped.

enumerator MGMT_EVT_OP_IMG_MGMT_DFU_STARTED =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 2)
    Callback when a DFU operation is started.

enumerator MGMT_EVT_OP_IMG_MGMT_DFU_PENDING =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 3)
    Callback when a DFU operation has finished being transferred.

enumerator MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 4)
    Callback when an image has been confirmed.

enumerator MGMT_EVT_OP_IMG_MGMT_ALL =
    MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_IMG)
    Used to enable all img_mgmt_group events.
enum os_mgmt_group_events
    MGMT event opcodes for operating system management group.

Values:

enumerator MGMT_EVT_OP_OS_MGMT_RESET = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_OS, 0)
    Callback when a reset command has been received.

enumerator MGMT_EVT_OP_OS_MGMT_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_OS)
    Used to enable all os_mgmt_group events.

Functions

int32_t mgmt_callback_notify(uint32_t event, void *data, size_t data_size)
    This function is called to notify registered callbacks about mcumgr notifications/events.

Parameters

• event – mcumgr_op_t.
• data – Optional event argument.
• data_size – Size of optional event argument (0 if none).

Returns

mcumgr_err_t either MGMT_ERR_EOK if all handlers returned it, or the error code of the first handler that returned an error.

void mgmt_callback_register(struct mgmt_callback *callback)
    Register event callback function.

Parameters

• callback – Callback struct.

void mgmt_callback_unregister(struct mgmt_callback *callback)
    Unregister event callback function.

Parameters

• callback – Callback struct.

struct mgmt_callback
    #include <callbacks.h> MGMT callback struct

Public Members

sys_snode_t node
    Entry list node.

mgmt_cb callback
    Callback that will be called.

uint32_t event_id
    MGMT_EVT_[…] Event ID for handler to be called on.
struct mgmt_evt_op_cmd_arg

Arguments for `MGMT_EVT_OP_CMD_RECV`, `MGMT_EVT_OP_CMD_STATUS` and `MGMT_EVT_OP_CMD_DONE`

Public Members

- `uint16_t group`
  - `mcumgr_group_t`

- `uint8_t id`
  - Message ID within group

- `int err`
  - `mcumgr_err_t`, used in `MGMT_EVT_OP_CMD_DONE`

- `int status`
  - `img_mgmt_id_upload_t`, used in `MGMT_EVT_OP_CMD_STATUS`

MCUmgr fs_mgmt callback API.

struct fs_mgmt_file_access

Structure provided in the `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` notification callback: This callback function is used to notify the application about a pending file read/write request and to authorise or deny it. Access will be allowed so long as all notification handlers return `MGMT_ERR_EOK`, if one returns an error then access will be denied.

Public Members

- `bool upload`
  - True if the request is for uploading data to the file, otherwise false

- `char *filename`
  - Path and filename of file be accesses, note that this can be changed by handlers to redirect file access if needed (as long as it does not exceed the maximum path string size).

MCUmgr img_mgmt callback API.

struct img_mgmt_upload_check

Structure provided in the `MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK` notification callback: This callback function is used to notify the application about a pending firmware upload packet from a client and authorise or deny it. Upload will be allowed so long as all notification handlers return `MGMT_ERR_EOK`, if one returns an error then the upload will be denied.

Public Members

- `struct img_mgmt_upload_action *action`
  - Action to take
4.3.3 Fixing and backporting fixes to Zephyr v2.7 MCUmgr

The processes described in this document apply to both the zephyr repository itself and the MCUmgr module defined in west.yml.

Note: Currently, the backporting process, described in this document, is required only when providing changes to Zephyr version 2.7 LTS.

There are two different processes: one for issues that have also been fixed in the current version of Zephyr (backports), and one for issues that are being fixed only in a previous version.

The upstream MCUmgr repository is located in this page. The Zephyr fork used in version 2.7 and earlier is located here. Versions of Zephyr past 2.7 use the MCUmgr library that is part of the Zephyr code base.

Possible origins of a code change

In Zephyr version 2.7 and earlier, you must first apply the fix to the upstream repository of MCUmgr and then bring it to Zephyr with snapshot updates.

As such, there are four possible ways to apply a change to the 2.7 branch:

• The fix, done directly to the Zephyr held code of the MCUmgr library, is backported to the v2.7-branch.

• The fix, ported to the Zephyr held code from the upstream repository, is backported to the v2.7-branch.

• The fix, done upstream and no longer relevant to the current version, is directly backported to the v2.7-branch.

• The fix, not present upstream and not relevant for the current version of Zephyr, is directly applied to the v2.7-branch.

The first three cases are cases of backports, the last one is a case of a new fix and has no corresponding fix in the current version.

Applying fixes to previous versions of MCUmgr

This section indicates how to apply fixes to previous versions of MCUmgr.

Creating a bug report Every proposed fix requires a bug report submitted for the specified version of Zephyr affected by the bug.

In case the reported bug in a previous version has already been fixed in the current version, the description of the bug must be copied with the following:

• Additional references to the bug in the current version

• The PR for the current version

• The SHAs of the commits, if the PR has already been merged

You must also apply the backport v2.7-branch label to the bug report.
Creating the pull request for the fix  You can either create a backport pull request or a new-fix pull request.

Creating backport pull requests  Backporting a fix means that some or all of the fix commits, as they exist in the current version, are ported to a previous version.

**Note:** Backporting requires the fix for the current version to be already merged.

To create a backport pull request, do the following:

1. Port the fix commits from the current version to the previous version. Even if some of the commits require changes, keep the commit messages of all the ported commits as close to the ones in the original commits as possible, adding the following line:

   "Backporting commit `<sha>`"

   ``<sha>`` indicates the SHA of the commit after it has been already merged in the current version.

1. Create the pull request selecting `v2.7-branch` as the merge target.

1. Update `west.yml` within Zephyr, creating a pull-request to update the MCUmgr library referenced in Zephyr 2.7.

Creating new-fix pull requests  When the fix needed does not have a corresponding fix in the current version, the bug report must follow the ordinary process.

1. Create the pull request selecting `v2.7-branch` as the merge target.

1. Update `west.yml` within Zephyr, creating a pull-request to update the MCUmgr library referenced in Zephyr 2.7.

Configuration management

This chapter describes the maintainers’ side of accepting and merging fixes and backports.

**Prerequisites**  As a maintainer, these are the steps required before proceeding with the merge process:

1. Check if the author has followed the correct steps that are required to apply the fix, as described in *Applying fixes to previous versions of MCUmgr*.

   1. Ensure that the author of the fix has also provided the `west.yml` update for Zephyr 2.7.

The specific merging process depends on where the fix comes from and whether it is a backport or a new fix.

Merging a backported fix  There are two possible sources of backports:

- The Zephyr code base
- A direct fix from upstream

Both cases are similar and differ only in the branch name.

To merge a backported fix after the pull request for the fix has gone through the review process, as a maintainer, do the following:

1. Create a branch named as follow:
Merging a new fix  Merging a new fix, that is not a backport of either any upstream or Zephyr fix, does not require any special treatment. Apply the fix directly at the top of v2.7-branch.

Merge west.yml  As an MCUmgr maintainer, you may not be able to merge the west.yml update, to introduce the fix to Zephyr. However, you are responsible for such a merge to happen as soon as possible after the MCUmgr fixes have been applied to the v2.7-branch of the MCUmgr.

4.3.4 SMP Protocol Specification

This is description of Simple Management Protocol, SMP, that is used by mcumgr to pass requests to devices and receive responses from them.

SMP is an application layer protocol. The underlying transport layer is not in scope of this documentation.

Frame: The envelope

Each frame consists of header and following it data. The Data Length field in the header may be used for reassembly purposes if underlying transport layer supports fragmentation. Frame is encoded in “Big Endian” (Network endianness), where field is more than one byte lone, and takes the following form:

```
| 3    2    1    0 | 7    6    5    4    3    2    1    0 |
| Res       OP   Flags   Data Length |
| Group ID   | Sequence Num | Command ID |
| Data . . . |
```

The original specification states that SMP should support receiving both the “Little-endian” and “Big-endian” frames but in reality the mcumgr library is hardcoded to always treat “Network” side as “Big-endian”.

The Data is optional and is not present when Data Length is zero. The encoding of data depends on the target of group/ID.

Where meaning of fields is:
Field | Description
--- | ---
Res | This is reserved, not-used field and should be always set to 0.
Op | Operation code
Flags | Reserved for flags; there are no flags defined yet, the field should be set to 0
Data Length | Length of the Data field
Group ID | Management Group ID’s
Sequence Num | This is a frame sequence number. The number is increased by one with each request frame. The Sequence Num of a response should match the one in the request.
Command ID | This is a command, within Group.
Data | This is data payload of the Data Length size. It is optional as Data Length may be set to zero, which means that no data follows the header.

**Note:** Contents of a Data depends on a value of an Op, a Group ID, and a Command ID.

**Note:** The Res field may be repurposed by Zephyr for protocol version in the future.

**Operation code** The operation code determines whether an information is written to a device or requested from it and whether a packet contains request to a SMP server or response from it.

Following operation codes are defined.

<table>
<thead>
<tr>
<th>Decimal ID</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>read request</td>
</tr>
<tr>
<td>1</td>
<td>read response</td>
</tr>
<tr>
<td>2</td>
<td>write request</td>
</tr>
<tr>
<td>3</td>
<td>write response</td>
</tr>
</tbody>
</table>

**Management Group ID’s** The SMP protocol supports predefined common groups and allows user defined groups. Below table presents list of common groups:

<table>
<thead>
<tr>
<th>Decimal ID</th>
<th>Group description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Default/OS Management Group</td>
</tr>
<tr>
<td>1</td>
<td>Application/software image management group</td>
</tr>
<tr>
<td>2</td>
<td>Statistics management</td>
</tr>
<tr>
<td>3</td>
<td>Application/system configuration (currently not used by Zephyr)</td>
</tr>
<tr>
<td>4</td>
<td>Application/system log management (currently not used by Zephyr)</td>
</tr>
<tr>
<td>5</td>
<td>Run-time tests (unused by Zephyr)</td>
</tr>
<tr>
<td>6</td>
<td>Split image management (unused by Zephyr)</td>
</tr>
<tr>
<td>7</td>
<td>Test crashing application (unused by Zephyr)</td>
</tr>
<tr>
<td>8</td>
<td>File management</td>
</tr>
<tr>
<td>9</td>
<td>Shell management</td>
</tr>
<tr>
<td>63</td>
<td>Zephyr specific basic commands group</td>
</tr>
<tr>
<td>64</td>
<td>This is the base group for defining an application specific management groups.</td>
</tr>
</tbody>
</table>

The payload for above groups, except for 64 which is not defined, is always CBOR encoded. The group 64, and above, are free to be defined by application developers and are not defined within this documentation.
Minimal response

Regardless of a command issued, as long as there is SMP client on the other side of a request, a response should be issued containing header followed by CBOR map container. Lack of response is only allowed when there is no SMP service or device is non-responsive.

Minimal response SMP data

Minimal response is CBOR directory:

```
{
    (str)"rc" : (int)
}
```

where:

"rc"  | Status/error codes in responses
--- | ---
0 | No error, OK.
1 | Unknown error.
2 | Not enough memory; this error is reported when there is not enough memory to complete response.
3 | Invalid value; a request contains an invalid value.
4 | Timeout; the operation for some reason could not be completed in assumed time.
5 | No entry; the error means that request frame has been missing some information that is required to perform action. It may also mean that requested information is not available.
6 | Bad state; the error means that application or device is in a state that would not allow it to perform or complete a requested action.
7 | Response too long; this error is issued when buffer assigned for gathering response is not big enough.
8 | Not supported; usually issued when requested Group ID or Command ID is not supported by application.
9 | Corrupted payload received.
10 | Device is busy with processing previous SMP request and may not process incoming one. Client should re-try later.
256 | This is base error number of user defined error codes.

Zephyr uses MGMT_ERR_ prefixed definitions gathered in this header file `sys/mgmt/mcumgr/lib/mgmt/include/mgmt/mgmt.h`

Specifications of management groups supported by Zephyr

Default/OS Management Group

OS management group defines following commands:

<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Echo</td>
</tr>
<tr>
<td>1</td>
<td>Console/Terminal echo control; unimplemented by Zephyr</td>
</tr>
<tr>
<td>2</td>
<td>Statistics</td>
</tr>
<tr>
<td>3</td>
<td>Memory pool statistics</td>
</tr>
<tr>
<td>4</td>
<td>Date-time string; unimplemented by Zephyr</td>
</tr>
<tr>
<td>5</td>
<td>System reset</td>
</tr>
<tr>
<td>6</td>
<td>MCUMGR parameters</td>
</tr>
</tbody>
</table>

4.3. Device Management
**Echo command**  
Echo command responses by sending back string that it has received.

**Echo request**  
Echo request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or 2</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```plaintext
{
  (str)"d" : (str)
}
```

where:

- "d" string to be replied by echo service

**Echo response**  
Echo response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>When request OP was 0</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>0</td>
<td>When request OP was 2</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```plaintext
{
  (str)"r" : (str)
}
```

In case of error the CBOR data takes form:

```plaintext
{
  (str)"rc" : (int)
}
```

where:

- "r" Replying echo string
- "rc" Status/error codes in responses

**Task statistics command**  
The command responds with some system statistics.

**Task statistics request**  
Task statistics request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>2</td>
</tr>
</tbody>
</table>

The command sends empty CBOR map as data.
Task statistics response  Task statistics response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>2</td>
</tr>
</tbody>
</table>

CBOR data of response:

```json
{
    (str)"tasks" : {
        (str)<task_name> : {
            (str)"prio" : (uint)
            (str)"tid" : (uint)
            (str)"state" : (uint)
            (str)"stkuse" : (uint)
            (str)"stksiz" : (uint)
            (str)"cswcnt" : (uint)
            (str)"runtime" : (uint)
            (str)"last_checkin" : (uint)
            (str)"next_checkin" : (uint)
        }
    ...
    (str)"rc" : (int)
}
```

where:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;task_name&gt;</td>
<td>string identifying task</td>
</tr>
<tr>
<td>&quot;prio&quot;</td>
<td>task priority</td>
</tr>
<tr>
<td>&quot;tid&quot;</td>
<td>numeric task ID</td>
</tr>
<tr>
<td>&quot;state&quot;</td>
<td>numeric task state</td>
</tr>
<tr>
<td>&quot;stkuse&quot;</td>
<td>task's/thread's stack usage</td>
</tr>
<tr>
<td>&quot;stksiz&quot;</td>
<td>task's/thread's stack size</td>
</tr>
<tr>
<td>&quot;cswcnt&quot;</td>
<td>task's/thread's context switches</td>
</tr>
<tr>
<td>&quot;runtime&quot;</td>
<td>task's/thread's runtime in &quot;ticks&quot;</td>
</tr>
<tr>
<td>&quot;last_checkin&quot;</td>
<td>set to 0 by Zephyr</td>
</tr>
<tr>
<td>&quot;next_checkin&quot;</td>
<td>set to 0 by Zephyr</td>
</tr>
<tr>
<td>&quot;rc&quot;</td>
<td>Status/error codes in responses</td>
</tr>
</tbody>
</table>

**Note:** The unit for “stkuse” and “stksiz” is system dependent and in case of Zephyr this is number of 4 byte word.

Memory pool statistics  The command is used to obtain information on memory pools active in running system.

Memory pool statistic request  Memory pool statistics request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>3</td>
</tr>
</tbody>
</table>

The command sends empty CBOR map as data.
Memory pool statistics response

Memory pool statistics response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>3</td>
</tr>
</tbody>
</table>

CBOR data of response:

```
{
  (str)<pool_name> {
    (str)"blksiz" : (int)
    (str)"nblks" : (int)
    (str)"nfree" : (int)
    (str)"min' : (int)
  }
  ...
  (str)"rc" : (int)
}
```

where:

<table>
<thead>
<tr>
<th>pool_name</th>
<th>string representing the pool name, used as a key for dictionary with pool statistics data</th>
</tr>
</thead>
<tbody>
<tr>
<td>blksiz</td>
<td>size of the memory block in the pool</td>
</tr>
<tr>
<td>nblks</td>
<td>number of blocks in the pool</td>
</tr>
<tr>
<td>nfree</td>
<td>number of free blocks</td>
</tr>
<tr>
<td>min</td>
<td>lowest number of free blocks the pool reached during run-time</td>
</tr>
<tr>
<td>rc</td>
<td>Status/error codes in responses</td>
</tr>
</tbody>
</table>

Date-time command

The command allows to obtain string representing current time-date on a device or set a new time to a device. The time format used, by both set and get operations, is:

```
“yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZZ”
```

Date-time get

The command allows to obtain date-time from a device.

Date-time get request

Date-time request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

The command sends empty CBOR map as data.

Data-time get response

Date-time get response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

CBOR data of response:

```
{
  (str)"datetime" : (str)
  (opt,str)"rc" : (int)
}
```
where:

| “datetime” | String in format yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZZ |
| "rc"       | Status/error codes in responses; may not appear if 0 |

**Date-time set**  The command allows to set date-time to a device.

**Date-time set request**  Date-time set request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

CBOR data of response:

```json
{
  "datetime" : (str)
}
```

where:

| “datetime” | String in format yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZ |

**Data-time set response**  Date-time set response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

CBOR data of response:

```json
{
  "rc" : (int)
}
```

where:

| “rc” | Status/error codes in responses |

**System reset**  Performs reset of system. The device should issue response before resetting so that the SMP client could receive information that the command has been accepted. By default, this command is accepted in all conditions, however if the CONFIG_MCMGR_GRP_OS_OS_RESET_HOOK is enabled and an application registers a callback, the callback will be called when this command is issued and can be used to perform any necessary tidy operations prior to the module rebooting, or to reject the reset request outright altogether with an error response. For details on this functionality, see ref: `mcumgr_callbacks`.

**System reset request**  System reset request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0</td>
<td>5</td>
</tr>
</tbody>
</table>

Normally the command sends empty CBOR map as data, but if previous reset attempt has been responded with “rc” code equal 10 (busy), then following map may be send to force the reset:
System reset response  System reset response header fields

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>0</td>
<td>5</td>
</tr>
</tbody>
</table>

CBOR data of response:

```json
{
    (opt,str)"rc" : (int)
}
```

where:

```
"rc"  Status/error codes in responses; may not appear if 0
```

MCUMGR Parameters  Used to obtain parameters of mcumgr library.

MCUMGR Parameters Request  MCUMGR parameters request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>

The command sends empty CBOR map as data.

MCUMGR Parameters Response  MCUMGR parameters response header fields

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>

CBOR data of response:

```json
{
    (str)"buf_size" : (uint)
    (str)"buf_count" : (uint)
    (opt,str)"rc" : (int)
}
```

where:

```
"buf_size"  Single SMP buffer size, this includes SMP header and CBOR payload
"buf_count"  Number of SMP buffers supported
"rc"  Status/error codes in responses; may not appear if 0
```
Application/software image management group defines following commands:

<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>State of images</td>
</tr>
<tr>
<td>1</td>
<td>Image upload</td>
</tr>
<tr>
<td>2</td>
<td>File (reserved but not supported by Zephyr)</td>
</tr>
<tr>
<td>3</td>
<td>Corelist (reserved but not supported by Zephyr)</td>
</tr>
<tr>
<td>4</td>
<td>Coreload (reserved but not supported by Zephyr)</td>
</tr>
<tr>
<td>5</td>
<td>Image erase</td>
</tr>
</tbody>
</table>

Notion of “slots” and “images” in Zephyr The “slot” and “image” definition comes from mcuboot where “image” would consist of two “slots”, further named “primary” and “secondary”; the application is supposed to run from the “primary slot” and update is supposed to be uploaded to the “secondary slot”; the mcuboot is responsible in swapping slots on boot. This means that pair of slots is dedicated to single upgradable application. In case of Zephyr this gets a little bit confusing because DTS will use “slot0_partition” and “slot1_partition”, as label of fixed-partition dedicated to single application, but will name them as “image-0” and “image-1” respectively.

Currently Zephyr supports at most two images, in which case mapping is as follows:

<table>
<thead>
<tr>
<th>Image</th>
<th>Slot labels</th>
<th>Slot Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>“slot0_partition”</td>
<td>“image-0” “image-1”</td>
</tr>
<tr>
<td>2</td>
<td>“slot2_partition”</td>
<td>“image-2” “image-3”</td>
</tr>
</tbody>
</table>

State of images The command is used to set state of images and obtain list of images with their current state.

Get state of images request Get state of images request header fields:

```
<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
```

The command sends sends empty CBOR map as data.

Get state of images response Get state of images response header fields:

```
<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
```

Note: Below definition of the response contains “image” field that has been marked as optional(opt): the field may not appear in response when target application does not support more than one image. The field is mandatory when application supports more than one application image to allow identifying which image information is listed.

A response will only contain information for valid images, if an image can not be identified as valid it is simply skipped.

CBOR data of successful response:
In case of error the CBOR data takes form:

```
{
  (str,"rc" : (int)
  (str,opt)"rsn" : (str)
}
```

where:

- **"image"** - semi-optional image number; the field is not required when only one image is supported by running application
- **"slot"** - slot number within "image"; each image has two slots: primary (running one) = 0 and secondary (for DFU dual-bank purposes) = 1
- **"version"** - string representing image version, as set with imgtool
- **"hash"** - hash of an upload; this is used to identify an upload session, for example to allow mcumgr library to continue broken session

**Note:** By default mcumgr-cli uses here a few characters of sha256 of the first uploaded chunk.

- **"bootable"** - true if image has bootable flag set; this field does not have to be present if false
- **"pending"** - true if image is set for next swap this field does not have to be present if false
- **"confirmed"** - true if image has been confirmed this field does not have to be present if false
- **"active"** - true if image is currently active application this field does not have to be present if false
- **"permanent"** - true if image is to stay in primary slot after next boot this field does not have to be present if false
- **"splitStatus"** - states whether loader of split image is compatible with application part; this is unused by Zephyr
- **"rc"** - Status/error codes in responses
- **"rsn"** - optional string that clarifies reason for an error; specifically useful for error code 1, unknown error
Note: For more information on how does image/slots function, please refer to the MCUBoot documentation https://www.mcuboot.com/documentation/design/#image-slots

Set state of image request  Set state of image request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```
{
  {
    (str,opt)"hash" : (str)
    (str)"confirm" : (bool)
  }
}
```

If “confirm” is false an image with the “hash” will be set for test, which means that it will not be marked as permanent and upon hard reset the previous application will be restored to the primary slot. In case when “confirm” is true, the “hash” is optional as the currently running application will be assumed as target for confirmation.

Set state of image response  The response takes the same format as Get state of images response

Image upload  The image upload command allows to update application image.

Image upload request  The image upload request is sent for each chunk of image that is uploaded, until complete image gets uploaded to a device.

Set state of image request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of request:

```
{
  {
    (str,opt)"image" : (uint)
    (str,opt)"len" : (uint)
    (str)"off" : (uint)
    (str,opt)"sha" : (str)
    (str,opt)"data" : (byte str)
    (str,opt)"upgrade" : (bool)
  }
}
```

where:
**Image** optional image number; it does not have to appear in request at all, in which case it is assumed to be 0; only request with "off" 0 can contain image number

**"len"** optional length of an image, it only appears in the first packet of request, where “off” is 0

**"off"** offset of image chunk the request carries

**"sha"** string identifying update session; it should only be present if “off” is zero; although name suggests it might be SHA, it can actually be any string

**"data"** optional image data

**"upgrade"** optional flag that states that only upgrade should be allowed, so if version of uploaded software is lower than already on device, the image update should be rejected (unused by Zephyr at this time)

---

**Note:** There is no field representing size of chunk that is carried as “data” because that information is embedded within “data” field itself.

The mcumgr library uses “sha” field to tag ongoing update session, to be able to continue it in case when it gets broken. If library gets request with “off” equal zero it checks stored “sha” within its state and if it matches it will respond to update client application with offset that it should continue with.

---

### Image upload response

Set state of image request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of response:

```
{  
   (str,opt)"off" : (uint)
   (str)"rc" : (int)
   (str,opt)"rsn" : (str)
}
```

where:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>“off”</td>
<td>offset of last successfully written byte of update</td>
</tr>
<tr>
<td>“rc”</td>
<td>Status/error codes in responses</td>
</tr>
<tr>
<td>“rsn”</td>
<td>Optional string that clarifies reason for an error; specifically useful for error code 1, unknown error</td>
</tr>
</tbody>
</table>

The “off” field is only included in responses to successfully processed requests; if “rc” is negative the “off” may not appear.

---

### Image erase

The command is used for erasing image slot on a target device.

**Note:** This is synchronous command which means that a sender of request will not receive response until the command completes.

---

### Image erase request

Image erase request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>5</td>
</tr>
</tbody>
</table>
CBOR data of request:

```json
{
  (str,opt)"slot" : (uint)
}
```

where:

| “slot” | optional slot number, it does not have to appear in the request at all, in which case it is assumed to be 1. |

**Image erase response**  Image erase response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1</td>
<td>5</td>
</tr>
</tbody>
</table>

CBOR data of response:

```json
{
  (str)"rc" : (int)
  (str,opt)"rsn" : (str)
}
```

where:

<table>
<thead>
<tr>
<th>“rc”</th>
<th>Status/error codes in responses</th>
</tr>
</thead>
<tbody>
<tr>
<td>“rsn”</td>
<td>Optional string that clarifies reason for an error; specifically useful for error code 1, unknown error</td>
</tr>
</tbody>
</table>

**Note:** Response from Zephyr running device may have “rc” value of 6, bad state (*Status/error codes in responses*), which means that the secondary image has been marked for next boot already and may not be erased.

**Statistics management**  Statistics management allows to obtain data gathered by Statistics subsystem of Zephyr, enabled by `CONFIG_STATS`.

Statistics management group defines commands:

<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Group data</td>
</tr>
<tr>
<td>1</td>
<td>List groups</td>
</tr>
</tbody>
</table>

**Statistics: group data**  The command is used to obtain data for group specified by a name. The name is one of group names as registered, with `STATS_INIT_AND_REG` macro or `stats_init_and_reg(...)` function call, within module that gathers the statistics.

**Statistics: group data request**  Statistics group data request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>
CBOR Payload of request:

```json
{
    (str)"name" : (str)
}
```

where:

| "name" | is group name |

Statistics: group data response

Statistics group data response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR Payload of response:

```json
{
    (str)"name" : (str)
    (str)"fields" : {
        (str)<entry_name> : (uint)
        ...
    }
    (str)"rc" : (int)
}
```

where:

| "name" | this is name of group the response contains data for |
| "fields" | this is map of entries within groups that consists of pairs where entry name is mapped to value it represents in statistics |
| <entry_name> | single entry to value mapping; value is hardcoded to unsigned integer type, in a CBOR meaning |
| "rc" | Status/error codes in responses |

Statistics: list of groups

The command is used to obtain list of groups of statistics that are gathered on a device. This is a list of names as given to groups with STATS_INIT_AND_REG macro or stats_init_and_reg(...) function calls, within module that gathers the statistics; this means that this command may be considered optional as it is known during compilation what groups will be included into build and listing them is not needed prior to issuing a query.

Statistics: list of groups request

Statistics group list request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

The command sends empty CBOR map as data.

Statistics: list of groups response

Statistics group list request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>
CBOR Payload of response:

```json
{
  (str)"stat_list" : [ 
    (str)<stat_group_name>, ...
  ]
  (str)"rc" : (int)
}
```

where:

- **“stat_list”** array of strings representing group names; this array may be empty if there are no groups
- **“rc”** Status/error codes in responses

### File management

The file management group provides commands that allow to upload and download files to/from a device.

File management group defines following commands:

<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>File download/upload</td>
</tr>
<tr>
<td>1</td>
<td>File status</td>
</tr>
<tr>
<td>2</td>
<td>File hash/checksum</td>
</tr>
<tr>
<td>3</td>
<td>Supported file hash/checksum types</td>
</tr>
</tbody>
</table>

**File download** Command allows to download contents of an existing file from specified path of a target device. The command is stateless and mcumgr does not hold file in open state after response to the command is issued, instead a client application is supposed to keep track of data it has already downloaded, and issue subsequent requests, with modified offset, to gather entire file. Request does not carry size of requested chunk, the size is specified by application itself. Mcumgr server side re-opens a file for each subsequent request, and current specification does not provide means to identify subsequent requests as belonging to specified download session. This means that the file is not locked in any way or exclusively owned by mcumgr, for the time of download session, and may change between requests or even be removed.

**Note:** By default, all file upload requests are unconditionally allowed. However, if the Kconfig option `FS_MGMT_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for `fs_mgmt_on_evt_cb` by calling `fs_mgmt_register_evt_cb()` with the handler supplied. This can be used to allow or decline access to reading from or writing to a particular file, or for rewriting the path supplied by the client.

**File download request** File download request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
  (str)"off" : (uint)
  (str)"name" : (str)
}
```
where:

<table>
<thead>
<tr>
<th>“off”</th>
<th>offset to start download at</th>
</tr>
</thead>
<tbody>
<tr>
<td>“name”</td>
<td>absolute path to a file</td>
</tr>
</tbody>
</table>

**File download response**  
File download response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```
{
  (str)"off" : (uint)
  (str)"data" : (byte str)
  (str)"rc" : (int)
  (str,opt)"len" : (uint)
}
```

In case of error the CBOR data takes form:

```
{
  (str)"rc" : (int)
}
```

where:

| “off” | offset the response is for |
| “data” | chunk of data read from file; it is CBOR encoded stream of bytes with embedded size; “data” appears only in responses where “rc” is 0 |
| “len” | length of file, this field is only mandatory when “off” is 0 |
| “rc” | Status/error codes in responses |

In case when “rc” is not 0, success, the other fields will not appear.

**File upload**  
Allows to upload a file to a specified location. Command will automatically overwrite existing file or create a new one if it does not exist at specified path. The protocol supports stateless upload where each requests carries different chunk of a file and it is client side responsibility to track progress of upload.

Mcumgr server side re-opens a file for each subsequent request, and current specification does not provide means to identify subsequent requests as belonging to specified upload session. This means that the file is not locked in any way or exclusively owned by mcumgr, for the time of upload session, and may change between requests or even be removed.

**Note:**  
Weirdly, the current Zephyr implementation is half-stateless as is able to hold single upload context, holding information on ongoing upload, that consists of bool flag indicating in-progress upload, last successfully uploaded offset and total length only.

**Note:**  
By default, all file upload requests are unconditionally allowed. However, if the Kconfig option `FS_MGMT_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for `fs_mgmt_on_evt_cb` by calling `fs_mgmt_register_evt_cb()` with the handler supplied. This can be
used to allow or decline access to reading from or writing to a particular file, or for rewriting the path supplied by the client.

**File upload request**  
File upload request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>8</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
    (str,"off") : (uint),
    (str,"data") : (str),
    (str,"name") : (str),
    (str,opt)"len" : (uint)
}
```

where:

- "off"  offset to start/continue upload at
- "data"  chunk of data to write to the file; it is CBOR encoded with length embedded
- "name"  absolute path to a file
- "len"  length of file, this field is only mandatory when "off" is 0

**File upload response**  
File upload response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>8</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
    (str,opt)"off" : (uint),
    (str)"rc" : (int)
}
```

where:

- "off"  offset of last successfully written data; appears only when "rc" is 0
- "rc"  Status/error codes in responses

**File status**  
Command allows to retrieve status of an existing file from specified path of a target device.

**File status request**  
File status request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of request:
where:

- **"name"**: absolute path to a file

### File status response

#### File status response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
    (str)"len" : (uint)
}
```

In case of error the CBOR data takes form:

```json
{
    (str)"rc" : (int)
}
```

where:

- **"len"**: length of file (in bytes)
- **"rc"**: Status/error codes in responses (only present if an error occurred)

In case when “rc” is not 0, success, the other fields will not appear.

### File hash/checksum

Command allows to generate a hash/checksum of an existing file at a specified path on a target device. Note that kernel heap memory is required for buffers to be allocated for this to function, and large stack memory buffers are required for generation of the output hash/checksum.

#### File hash/checksum request

#### File hash/checksum request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>2</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
    (str)"name" : (str)
    (str,opt)"type" : (str)
    (str,opt)"off" : (uint)
    (str,opt)"len" : (uint)
}
```

where:
### Hash/checksum types

<table>
<thead>
<tr>
<th>String name</th>
<th>Hash/checksum</th>
<th>Byte string</th>
<th>Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>crc32</td>
<td>IEEE CRC32 checksum</td>
<td>No</td>
<td>4</td>
</tr>
<tr>
<td>sha256</td>
<td>SHA256 (Secure Hash Algorithm)</td>
<td>Yes</td>
<td>32</td>
</tr>
</tbody>
</table>

Note that the default type will be crc32 if it is enabled, or sha256 if crc32 is not enabled.

### File hash/checksum response

File hash/checksum response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8</td>
<td>2</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
    (str)"type" : (str),
    (str,opt)"off" : (uint),
    (str)"len" : (uint),
    (str)"output" : (uint or bstr)
}
```

In case of error the CBOR data takes form:

```json
{
    (str)"rc" : (int)
}
```

where:

<table>
<thead>
<tr>
<th>“rc”</th>
<th>Status/error codes in responses (only present if an error occurred)</th>
</tr>
</thead>
<tbody>
<tr>
<td>“type”</td>
<td>type of hash/checksum that was performed Hash/checksum types</td>
</tr>
<tr>
<td>“off”</td>
<td>offset that hash/checksum calculation started at (only present if off is not 0)</td>
</tr>
<tr>
<td>“len”</td>
<td>length of input data used for hash/checksum generation (in bytes)</td>
</tr>
<tr>
<td>“output”</td>
<td>output hash/checksum</td>
</tr>
</tbody>
</table>

In case when “rc” is not 0, success, the other fields will not appear.

### Supported file hash/checksum types

Command allows listing which hash and checksum types are available on a device. Requires Kconfig CONFIG_MCUMGR_GRP_FS_CHECKSUM_HASH_SUPPORTED_CMD to be enabled.

### Supported file hash/checksum types request

Supported file hash/checksum types request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>3</td>
</tr>
</tbody>
</table>
The command sends empty CBOR map as data.

**Supported file hash/checksum types response**  
Supported file hash/checksum types response header:

```
+-------+-------+-------+
<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8</td>
<td>3</td>
</tr>
</tbody>
</table>
```

CBOR data of successful response:

```json
format (0 = int, 1 = byte array)
{
    (str)"types" : {
        (str)<hash_checksum_name> : {
            (str)"format" : (uint)
            (str)"size" : (uint)
        }
    }
    ...
}
```

In case of error the CBOR data takes form:

```json
{
    (str)"rc" : (int)
}
```

where:

<table>
<thead>
<tr>
<th>&lt;hash_checksum_name&gt;</th>
<th>name of the hash/checksum type</th>
<th>Hash/checksum types</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;format&quot;</td>
<td>format that the hash/checksum returns where 0 is for numerical and 1 is for byte array.</td>
<td></td>
</tr>
<tr>
<td>&quot;size&quot;</td>
<td>size (in bytes) of output hash/checksum response.</td>
<td></td>
</tr>
</tbody>
</table>

In case when “rc” is not 0, success, the other fields will not appear.

**Shell management**  
Shell management allows to pass commands to shell subsystem with use of SMP protocol.

Shell management group defines following commands:

```
+-------+------------------+
<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Shell command line execute</td>
</tr>
</tbody>
</table>
```

**Shell command line execute**  
The command allows to execute command line in a similar way to typing it into a shell, but both a request and a response are transported with use of SMP.

**Shell command line execute request**  
Execute command request header:

```
+-------+-------+-------+
<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>9</td>
<td>0</td>
</tr>
</tbody>
</table>
```

CBOR data of request:
where:

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;argv&quot;</td>
<td>is array consisting of strings representing command and its arguments</td>
</tr>
<tr>
<td>&lt;cmd&gt;</td>
<td>command to be executed</td>
</tr>
<tr>
<td>&lt;arg&gt;</td>
<td>optional arguments to command</td>
</tr>
</tbody>
</table>

**Shell command line execute response**

Command line execute response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>9</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
  (str)"o" : (str),
  (str)"ret" : (int)
}
```

In case of error the CBOR data takes form:

```json
{
  (str)"rc" : (int)
}
```

where:

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;rc&quot;</td>
<td>Status/error codes in responses (only present if an error occurred)</td>
</tr>
<tr>
<td>&quot;o&quot;</td>
<td>command output</td>
</tr>
<tr>
<td>&quot;ret&quot;</td>
<td>return code from shell command execution</td>
</tr>
</tbody>
</table>

In case when “rc” is not 0, success, the other fields will not appear.

**Note:** In older versions of Zephyr, “rc” was used for both the mcumgr status code and shell command execution return code, this legacy behaviour can be restored by enabling `CONFIG_MCUMGR_CMD_SHELL_MGMT_LEGACY_RC_RETURN_CODE`

### 4.3.5 SMP Transport Specification

The documents specifies information needed for implementing server and client side SMP transports.

**BLE (Bluetooth Low Energy)**

MCUmgm Clients need to use following BLE Characteristics, when implementing SMP client:

- **Service UUID:** `8D53DC1D-1DB7-4CD3-868B-8A527460AA84`
- **Characteristic UUID**: `DA2E7828-FBCE-4E01-AE9E-261174997C48`

  All SMP communication utilizes a single GATT characteristic. An SMP request is sent via a GATT Write Without Response command. An SMP response is sent in the form of a GATT Notification.

  If an SMP request or response is too large to fit in a single GATT command, the sender fragments it across several packets. No additional framing is introduced when a request or response is fragmented; the payload is simply split among several packets. Since GATT guarantees ordered delivery of packets, the SMP header in the first fragment contains sufficient information for reassembly.

**UART/serial and console**

SMP protocol specification by MCUmgr subsystem of Zephyr uses basic framing of data to allow multiplexing of UART channel. Multiplexing requires prefixing each frame with two byte marker and terminating it with newline. Currently MCUmgr imposes a 127 byte limit on frame size, although there are no real protocol constraints that require that limit. The limit includes the prefix and the newline character, so the allowed payload size is actually 124 bytes.

Although no such transport exists in Zephyr, it is possible to implement MCUmgr client/server over UART transport that does not have framing at all, or uses hardware serial port control, or other means of framing.

**Frame fragmenting**  SMP protocol over serial is fragmented into MTU size frames; each frame consists of two byte start marker, body and terminating newline character.

There are four types of types of frames: initial, partial, partial-final and initial-final; each frame type differs by start marker and/or body contents.

**Frame formats**  Initial frame requires to be followed by optional sequence of partial frames and finally by partial-final frame. Body is always Base64 encoded, so the body size, here described as MTU - 3, is able to actually carry N = (MTU - 3) / 4 * 3 bytes of raw data.

Body of initial frame is preceded by two byte total packet length, encoded in Big Endian, and equals size of a raw body plus two bytes, size of CRC16; this means that actual body size allowed into an initial frame is N - 2.

If a body size is smaller than N - 4, than it is possible to carry entire body with preceding length and following it CRC in a single frame, here called initial-final; for the description of initial-final frame look below.

Initial frame format:

<table>
<thead>
<tr>
<th>Content</th>
<th>Size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x06 0x09</td>
<td>2 bytes</td>
<td>Frame start marker</td>
</tr>
<tr>
<td>&lt;base64-i&gt;</td>
<td>no more than MTU - 3 bytes</td>
<td>Base64 encoded body</td>
</tr>
<tr>
<td>0x0a</td>
<td>1 byte</td>
<td>Frame termination</td>
</tr>
</tbody>
</table>

<base64-i> is Base64 encoded body of format:

<table>
<thead>
<tr>
<th>Content</th>
<th>Size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>total length</td>
<td>2 bytes</td>
<td>Big endian 16-bit value representing total length of body + 2 bytes for CRC16; note that size of total length field is not added to total length value.</td>
</tr>
<tr>
<td>body</td>
<td>no more than MTU - 5</td>
<td>Raw body data fragment</td>
</tr>
</tbody>
</table>

Initial-final frame format is similar to initial frame format, but differs by <base64-i> definition.
**4.3.6 Device Firmware Upgrade**

**Overview**

The Device Firmware Upgrade subsystem provides the necessary frameworks to upgrade the image of a Zephyr-based application at run time. It currently consists of two different modules:

- `subsys/dfu/boot/`: Interface code to bootloaders
- `subsys/dfu/img_util/`: Image management code

The DFU subsystem deals with image management, but not with the transport or management protocols themselves required to send the image to the target device. For information on these protocols and frameworks please refer to the *Device Management* section.

**Bootloaders**

**MCUboot**  
Zephyr is directly compatible with the open source, cross-RTOS MCUboot boot loader. It interfaces with MCUboot and is aware of the image format required by it, so that Device Firmware Upgrade is available when MCUboot is the boot loader used with Zephyr. The source code itself is hosted in the [MCUboot GitHub Project](https://github.com/mcu-boot/mcuboot) page.

In order to use MCUboot with Zephyr you need to take the following into account:
1. You will need to define the flash partitions required by MCUboot; see Flash map for details.

2. You will have to specify your flash partition as the chosen code partition

```c
/ {
    chosen {
        zephyr,code-partition = &slot0_partition;
    };
};
```

3. Your application’s .conf file needs to enable the CONFIG_BOOTLOADER_MCUBOOT Kconfig option in order for Zephyr to be built in an MCUboot-compatible manner

4. You need to build and flash MCUboot itself on your device

5. You might need to take precautions to avoid mass erasing the flash and also to flash the Zephyr application image at the correct offset (right after the bootloader)

More detailed information regarding the use of MCUboot with Zephyr can be found in the MCUBoot with Zephyr documentation page on the MCUboot website.

### 4.3.7 Over-the-Air Update

**Overview**

Over-the-Air (OTA) Update is a method for delivering firmware updates to remote devices using a network connection. Although the name implies a wireless connection, updates received over a wired connection (such as Ethernet) are still commonly referred to as OTA updates. This approach requires server infrastructure to host the firmware binary and implement a method of signaling when an update is available. Security is a concern with OTA updates; firmware binaries should be cryptographically signed and verified before upgrading.

The Device Firmware Upgrade section discusses upgrading Zephyr firmware using MCUboot. The same method can be used as part of OTA. The binary is first downloaded into an unoccupied code partition, usually named slot1_partition, then upgraded using the MCUboot process.

**Examples of OTA**

**Golioth**  
Golioth is an IoT management platform that includes OTA updates. Devices are configured to observe your available firmware revisions on the Golioth Cloud. When a new version is available, the device downloads and flashes the binary. In this implementation, the connection between cloud and device is secured using TLS/DTLS, and the signed firmware binary is confirmed by MCUboot before the upgrade occurs.

1. A working sample can be found on the Golioth Zephyr-SDK repository
2. The Golioth OTA documentation includes complete information about the versioning process

**Eclipse hawkBit™**  
Eclipse hawkBit™ is an update server framework that uses polling on a REST api to detect firmware updates. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is a hawkbit-api-sample included in the Zephyr mgmt-samples section.

**UpdateHub**  
UpdateHub is a platform for remotely updating embedded devices. Updates can be manually triggered or monitored via polling. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is an updatehub_fota_sample included in the Zephyr mgmt-samples section.
SMP Server  A Simple Management Protocol (SMP) server can be used to update firmware via Bluetooth Low Energy (BLE) or UDP. **MCUmgr** is used to send a signed firmware binary to the remote device where it is verified by MCUboot before the upgrade occurs.

There is an **smp_svr_sample** included in the Zephyr mgmt-samples section.

Lightweight M2M (LWM2M)  The **Lightweight M2M (LWM2M)** protocol includes support for firmware update via `CONFIG_LWM2M_FIRMWARE_UPDATE_OBJ_SUPPORT`. Devices securely connect to an LwM2M server using DTLS. An **lwm2m-client-sample** sample is available but it does not demonstrate the firmware update feature.

4.3.8  SMP Groups

4.4  File Systems

Zephyr RTOS Virtual Filesystem Switch (VFS) allows applications to mount multiple file systems at different mount points (e.g., `/fatfs` and `/lfs`). The mount point data structure contains all the necessary information required to instantiate, mount, and operate on a file system. The File system Switch decouples the applications from directly accessing an individual file system's specific API or internal functions by introducing file system registration mechanisms.

In Zephyr, any file system implementation or library can be plugged into or pulled out through a file system registration API. Each file system implementation must have a globally unique integer identifier; use `FS_TYPE_EXTERNAL_BASE` to avoid clashes with in-tree identifiers.

```c
int fs_register(int type, const struct fs_file_system_t *fs);
int fs_unregister(int type, const struct fs_file_system_t *fs);
```

Zephyr RTOS supports multiple instances of a file system by making use of the mount point as the disk volume name, which is used by the file system library while formatting or mounting a disk.

A file system is declared as:

```c
static struct fs_mount_t mp = {
    .type = FS_FATFS,
    .mnt_point = FATFS_MNTP,
    .fs_data = &fat_fs,
};
```

where

- `FS_FATFS` is the file system type like FATFS or LittleFS.
- `FATFS_MNTP` is the mount point where the file system will be mounted.
- `fat_fs` is the file system data which will be used by `fs_mount()` API.

4.4.1  Samples

Samples for the VFS are mainly supplied in `samples/subsys/fs`, although various examples of the VFS usage are provided as important functionalities in samples for different subsystems. Here is the list of samples worth looking at:

- **samples/subsys/fs/fat_fs** is an example of FAT file system usage with SDHC media;
- **samples/subsys/shell/fs** is an example of Shell fs subsystem, using internal flash partition formatted to LittleFS;
• samples/subsys/usb/mass/ example of USB Mass Storage device that uses FAT FS driver with RAM or SPI connected FLASH, or LittleFS in flash, depending on the sample configuration.

4.4.2 API Reference

group file_system_api
File System APIs.

fs_open open and creation mode flags

FS_0_READ
Open for read flag

FS_0_WRITE
Open for write flag

FS_0_RDWR
Open for read-write flag combination

FS_0_MODE_MASK
Bitmask for read and write flags

FS_0_CREATE
Create file if it does not exist

FS_0_APPEND
Open/create file for append

FS_0_FLAGS_MASK
Bitmask for open/create flags

FS_0_MASK
Bitmask for open flags

fs_seek whence parameter values

FS_SEEK_SET
Seek from the beginning of file

FS_SEEK_CUR
Seek from a current position

FS_SEEK_END
Seek from the end of file
Defines

FS_MOUNT_FLAG_NO_FORMAT
   Flag prevents formatting device if requested file system not found

FS_MOUNT_FLAG_READ_ONLY
   Flag makes mounted file system read-only

FS_MOUNT_FLAG_AUTOMOUNT
   Flag used in pre-defined mount structures that are to be mounted on startup.
   This flag has no impact in user-defined mount structures.

FS_MOUNT_FLAG_USE_DISK_ACCESS
   Flag requests file system driver to use Disk Access API. When the flag is set to the
   fs_mount_t.flags prior to fs_mount call, a file system needs to use the Disk Access API, other-
   wise mount callback for the driver should return -ENOSUP; when the flag is not set the file
   system driver should use Flash API by default, unless it only supports Disc Access API. When
   file system will use Disk Access API and the flag is not set, the mount callback for the file
   system should set the flag on success.

FSTAB_ENTRY_DT_MOUNT_FLAGS(node_id)

FS_FSTAB_ENTRY(node_id)
   The name under which a zephyr,fstab entry mount structure is defined.

FS_FSTAB_DECLARE_ENTRY(node_id)
   Generate a declaration for the externally defined fstab entry.
   This will evaluate to the name of a struct fs_mount_t object.

Enums

enum fs_dir_entry_type
   Values:

   enumerator FS_DIR_ENTRY_FILE = 0
       Identifier for file entry

   enumerator FS_DIR_ENTRY_DIR
       Identifier for directory entry

enum [anonymous]
   Enumeration to uniquely identify file system types.

Zephyr supports in-tree file systems and external ones. Each requires a unique identifier used
   to register the file system implementation and to associate a mount point with the file system
type. This anonymous enum defines global identifiers for the in-tree file systems.

External file systems should be registered using unique identifiers starting at
   FS_TYPE_EXTERNAL_BASE. It is the responsibility of applications that use external file
   systems to ensure that these identifiers are unique if multiple file system implementations are
   used by the application.
   Values:

4.4. File Systems
enumerator FS_FATFS = 0
    Identifier for in-tree FatFS file system.

enumerator FS_LITTLEFS
    Identifier for in-tree LittleFS file system.

enumerator FS_TYPE_EXTERNAL_BASE
    Base identifier for external file systems.

Functions

static inline void fs_file_t_init(struct fs_file_t *zfp)
    Initialize fs_file_t object.
    Initializes the fs_file_t object; the function needs to be invoked on object before first use with fs_open.

    Parameters
        • zfp – Pointer to file object

static inline void fs_dir_t_init(struct fs_dir_t *zdp)
    Initialize fs_dir_t object.
    Initializes the fs_dir_t object; the function needs to be invoked on object before first use with fs_opendir.

    Parameters
        • zdp – Pointer to file object

int fs_open(struct fs_file_t *zfp, const char *file_name, fs_mode_t flags)
    Open or create file.
    Opens or possibly creates a file and associates a stream with it.
    flags can be 0 or a binary combination of one or more of the following identifiers:
        • FS_O_READ open for read
        • FS_O_WRITE open for write
        • FS_O_RDWR open for read/write (FS_O_READ | FS_O_WRITE)
        • FS_O_CREATE create file if it does not exist
        • FS_O_APPEND move to end of file before each write
    If flags are set to 0 the function will attempt to open an existing file with no read/write access; this may be used to e.g. check if the file exists.

    Parameters
        • zfp – Pointer to a file object
        • file_name – The name of a file to open
        • flags – The mode flags

    Return values
        • 0 – on success;
        • -EBUSY – when zfp is already used;
        • -EINVAL – when a bad file name is given;
- EROFS – when opening read-only file for write, or attempting to create a file on a system that has been mounted with the FS_MOUNT_FLAG_READ ONLY flag;
- ENOENT – when the file path is not possible (bad mount point);
- ENOTSUP – when not implemented by underlying file system driver;
- <0 – an other negative errno code, depending on a file system back-end.

```c
int fs_close(struct fs_file_t *zfp)
```

Close file.

Flushes the associated stream and closes the file.

**Parameters**
- zfp – Pointer to the file object

**Return values**
- 0 – on success;
- ENOTSUP – when not implemented by underlying file system driver;
- <0 – a negative errno code on error.

```c
int fs_unlink(const char *path)
```

Unlink file.

Deletes the specified file or directory

**Parameters**
- path – Path to the file or directory to delete

**Return values**
- 0 – on success;
- EINVAL – when a bad file name is given;
- EROFS – if file is read-only, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
- ENOTSUP – when not implemented by underlying file system driver;
- <0 – an other negative errno code on error.

```c
int fs_rename(const char *from, const char *to)
```

Rename file or directory.

Performs a rename and / or move of the specified source path to the specified destination. The source path can refer to either a file or a directory. All intermediate directories in the destination path must already exist. If the source path refers to a file, the destination path must contain a full filename path, rather than just the new parent directory. If an object already exists at the specified destination path, this function causes it to be unlinked prior to the rename (i.e., the destination gets clobbered).

**Note:** Current implementation does not allow moving files between mount points.

**Parameters**
- from – The source path
- to – The destination path

**Return values**
• 0 – on success;
• -EINVAL – when a bad file name is given, or when rename would cause move between mount points;
• -EROFS – if file is read-only, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – an other negative errno code on error.

ssize_t fs_read(struct fs_file_t *zfp, void *ptr, size_t size)
Read file.

Reads up to size bytes of data to ptr pointed buffer, returns number of bytes read. A returned value may be lower than size if there were fewer bytes available than requested.

Parameters
• zfp – Pointer to the file object
• ptr – Pointer to the data buffer
• size – Number of bytes to be read

Return values
• >=0 – a number of bytes read, on success;
• -EBADF – when invoked on zfp that represents unopened/closed file;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – a negative errno code on error.

ssize_t fs_write(struct fs_file_t *zfp, const void *ptr, size_t size)
Write file.

Attempts to write size number of bytes to the specified file. If a negative value is returned from the function, the file pointer has not been advanced. If the function returns a non-negative number that is lower than size, the global errno variable should be checked for an error code, as the device may have no free space for data.

Parameters
• zfp – Pointer to the file object
• ptr – Pointer to the data buffer
• size – Number of bytes to be written

Return values
• >=0 – a number of bytes written, on success;
• -EBADF – when invoked on zfp that represents unopened/closed file;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – an other negative errno code on error.

int fs_seek(struct fs_file_t *zfp, off_t offset, int whence)
Seek file.

Moves the file position to a new location in the file. The offset is added to file position based on the whence parameter.

Parameters
• zfp – Pointer to the file object
• offset – Relative location to move the file pointer to
• whence – Relative location from where offset is to be calculated.
  – FS_SEEK_SET for the beginning of the file;
  – FS_SEEK_CUR for the current position;
  – FS_SEEK_END for the end of the file.

Return values
• 0 – on success;
• -EBADF – when invoked on zfp that represents unopened/closed file;
• -ENOTSUP – if not supported by underlying file system driver;
• <0 – an other negative errno code on error.

off_t fs_tell(struct fs_file_t *zfp)
Get current file position.
Retrieves and returns the current position in the file stream.

The current revision does not validate the file object.

Parameters
• zfp – Pointer to the file object

Return values
• >= 0 a current position in file;
• -EBADF – when invoked on zfp that represents unopened/closed file;
• -ENOTSUP – if not supported by underlying file system driver;
• <0 – an other negative errno code on error.

int fs_truncate(struct fs_file_t *zfp, off_t length)
Truncate or extend an open file to a given size.
Truncates the file to the new length if it is shorter than the current size of the file. Expands the
file if the new length is greater than the current size of the file. The expanded region would
be filled with zeroes.

Note: In the case of expansion, if the volume got full during the expansion process, the
function will expand to the maximum possible length and return success. Caller should check
if the expanded size matches the requested length.

Parameters
• zfp – Pointer to the file object
• length – New size of the file in bytes

Return values
• 0 – on success;
• -EBADF – when invoked on zfp that represents unopened/closed file;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – an other negative errno code on error.
int \texttt{fs\_sync} (struct \texttt{fs\_file\_t} *zfp)

Flush cached write data buffers of an open file.

The function flushes the cache of an open file; it can be invoked to ensure data gets written to the storage media immediately, e.g. to avoid data loss in case if power is removed unexpectedly.

**Note:** Closing a file will cause caches to be flushed correctly so the function need not be called when the file is being closed.

**Parameters**
- zfp – Pointer to the file object

**Return values**
- 0 – on success;
- -EBADF – when invoked on zfp that represents unopened/closed file;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – a negative errno code on error.

int \texttt{fs\_mkdir} (const char *path)

Directory create.

Creates a new directory using specified path.

**Parameters**
- path – Path to the directory to create

**Return values**
- 0 – on success;
- -EROFS – if file is read-only, or when file system has been mounted with the \texttt{FS\_MOUNT\_FLAG\_READ\_ONLY} flag;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – an other negative errno code on error

int \texttt{fs\_opendir} (struct \texttt{fs\_dir\_t} *zdp, const char *path)

Directory open.

Opens an existing directory specified by the path.

**Parameters**
- zdp – Pointer to the directory object
- path – Path to the directory to open

**Return values**
- 0 – on success;
- -EINVAL – when a bad directory path is given;
- -EBUSY – when zdp is already used;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – a negative errno code on error.
int fs_readdir(struct fs_dir_t *zdp, struct fs_dirent *entry)
    Directory read entry.

    Reads directory entries of an open directory. In end-of-dir condition, the function will return
    0 and set the entry->name[0] to 0.

    **Note:** Most existing underlying file systems do not generate POSIX special directory entries
    “.” or “..”. For consistency the abstraction layer will remove these from lower layer results so
    higher layers see consistent results.

**Parameters**
- zdp – Pointer to the directory object
- entry – Pointer to zfs_dirent structure to read the entry into

**Return values**
- 0 – on success or end-of-dir;
- -ENOENT – when no such directory found;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – a negative errno code on error.

int fs_closedir(struct fs_dir_t *zdp)
    Directory close.

    Closes an open directory.

**Parameters**
- zdp – Pointer to the directory object

**Return values**
- 0 – on success;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – a negative errno code on error.

int fs_mount(struct fs_mount_t *mp)
    Mount filesystem.

    Perform steps needed for mounting a file system like calling the file system specific mount
    function and adding the mount point to mounted file system list.

    **Note:** Current implementation of ELM FAT driver allows only following mount points:
    “/RAM:”, “/NAND:”, “/CF:”, “/SD:”, “/SD2:”, “/USB:”, “/USB2:”, “/USB3:” or mount points that
    consist of single digit, e.g: “/0:”, “/1:” and so forth.

**Parameters**
- mp – Pointer to the fs_mount_t structure. Referenced object is not changed if the
    mount operation failed. A reference is captured in the fs infrastructure if the
    mount operation succeeds, and the application must not mutate the structure
    contents until fsUnmount is successfully invoked on the same pointer.

**Return values**
- 0 – on success;
- -ENOENT – when file system type has not been registered;
• -ENOTSUP – when not supported by underlying file system driver; when FS_MOUNT_FLAG_USE_DISK_ACCESS is set but driver does not support it.
• -EROFS – if system requires formatting but FS_MOUNT_FLAG_READ_ONLY has been set;
• <0 – an other negative errno code on error.

int fs_unmount(struct fs_mount_t *mp)
Unmount filesystem.
Perform steps needed to unmount a file system like calling the file system specific unmount function and removing the mount point from mounted file system list.

Parameters
• mp – Pointer to the fs_mount_t structure

Return values
• 0 – on success;
• -EINVAL – if no system has been mounted at given mount point;
• -ENOTSUP – when not supported by underlying file system driver;
• <0 – an other negative errno code on error.

int fs_readmount(int *index, const char **name)
Get path of mount point at index.
This function iterates through the list of mount points and returns the directory name of the mount point at the given index. On success index is incremented and name is set to the mount directory name. If a mount point with the given index does not exist, name will be set to NULL.

Parameters
• index – Pointer to mount point index
• name – Pointer to pointer to path name

Return values
• 0 – on success;
• -ENOENT – if there is no mount point with given index.

int fs_stat(const char *path, struct fs_dirent *entry)
File or directory status.
Checks the status of a file or directory specified by the path.

Note: The file on a storage device may not be updated until it is closed.

Parameters
• path – Path to the file or directory
• entry – Pointer to the zfs_dirent structure to fill if the file or directory exists.

Return values
• 0 – on success;
• -EINVAL – when a bad directory or file name is given;
• -ENOENT – when no such directory or file is found;
• -ENOTSUP – when not supported by underlying file system driver;
• <0 – negative errno code on error.

int fs_statvfs(const char *path, struct fs_statvfs *stat)
Retrieves statistics of the file system volume.
Returns the total and available space in the file system volume.

Parameters
• path – Path to the mounted directory
• stat – Pointer to the zfs_statvfs structure to receive the fs statistics.

Return values
• 0 – on success;
• -EINVAL – when a bad path to a directory, or a file, is given;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – an other negative errno code on error.

int fs_register(int type, const struct fs_file_system_t *fs)
Register a file system.
Register file system with virtual file system. Number of allowed file system types to be registered is controlled with the CONFIG_FILE_SYSTEM_MAX_TYPES Kconfig option.

Parameters
• type – Type of file system (ex: FS_FATFS)
• fs – Pointer to File system

Return values
• 0 – on success;
• -EALREADY – when a file system of a given type has already been registered;
• -ENOSCP – when there is no space left, in file system registry, to add this file system type.

int fs_unregister(int type, const struct fs_file_system_t *fs)
Unregister a file system.
Unregister file system from virtual file system.

Parameters
• type – Type of file system (ex: FS_FATFS)
• fs – Pointer to File system

Return values
• 0 – on success;
• -EINVAL – when file system of a given type has not been registered.

struct fs_mount_t
#include <fs.h> File system mount info structure.

Param node
Entry for the fs_mount_list list

Param type
File system type
Param mnt_point
   Mount point directory name (ex: “/fatfs”)

Param fs_data
   Pointer to file system specific data

Param storage_dev
   Pointer to backend storage device

Param mountp_len
   Length of Mount point string

Param fs
   Pointer to File system interface of the mount point

Param flags
   Mount flags

#include <fs.h>
Structure to receive file or directory information.
Used in functions that reads the directory entries to get file or directory information.

Param dir_entry_type
   Whether file or directory
   • FS_DIR_ENTRY_FILE
   • FS_DIR_ENTRY_DIR

Param name
   Name of directory or file

Param size
   Size of file. 0 if directory

#include <fs.h>
Structure to receive volume statistics.
Used to retrieve information about total and available space in the volume.

Param f_bsize
   Optimal transfer block size

Param f_frsize
   Allocation unit size

Param f_blocks
   Size of FS in f_frsize units

Param f_bfree
   Number of free blocks

#include <fs_interface.h>
File object representing an open file.
The object needs to be initialized with function fs_file_t_init().

Param Pointer
   to FATFS file object structure

Param mp
   Pointer to mount point structure
struct fs_dir_t

#include <fs_interface.h> Directory object representing an open directory.
The object needs to be initialized with function fs_dir_t_init().

Param dirp
Pointer to directory object structure

Param mp
Pointer to mount point structure

struct fs_file_system_t

#include <fs_sys.h> File System interface structure.

Param open
Opens or creates a file, depending on flags given

Param read
Reads nbytes number of bytes

Param write
Writes nbytes number of bytes

Param lseek
Moves the file position to a new location in the file

Param tell
Retrieves the current position in the file

Param truncate
Truncates/expands the file to the new length

Param sync
Flushes the cache of an open file

Param close
Flushes the associated stream and closes the file

Param opendir
Opens an existing directory specified by the path

Param readdir
Reads directory entries of an open directory

Param closedir
Closes an open directory

Param mount
Mounts a file system

Param umount
Unmounts a file system

Param unlink
Deletes the specified file or directory

Param rename
Renames a file or directory

Param mkdir
Creates a new directory using specified path

Param stat
Checks the status of a file or directory specified by the path

Param statvfs
Returns the total and available space on the file system volume
4.5 Formatted Output

Applications as well as Zephyr itself requires infrastructure to format values for user consumption. The standard C99 library `printf()` functionality fulfills this need for streaming output devices or memory buffers, but in an embedded system devices may not accept streamed data and memory may not be available to store the formatted output.

Internal Zephyr API traditionally provided this both for `printf()` and for Zephyr's internal minimal libc, but with separate internal interfaces. Logging, tracing, shell, and other applications made use of either these APIs or standard libc routines based on build options.

The `cbprintf()` public APIs convert C99 format strings and arguments, providing output produced one character at a time through a callback mechanism, replacing the original internal functions and providing support for almost all C99 format specifications. Existing use of `s*printf()` C libraries in Zephyr can be converted to `snprintfcb()` to avoid pulling in libc implementations.

Several Kconfig options control the set of features that are enabled, allowing some control over features and memory usage:

- `CONFIG_CBPRINTF_FULL_INTEGRAL` or `CONFIG_CBPRINTF_REduced_INTEGRAL`
- `CONFIG_CBPRINTF_FP_SUPPORT`
- `CONFIG_CBPRINTF_FP_A_SUPPORT`
- `CONFIG_CBPRINTF_FP_ALWAYS_A`
- `CONFIG_CBPRINTF_N_SPECIFIER`

`CONFIG_CBPRINTF_LIBC_SUBSTS` can be used to provide functions that behave like standard libc functions but use the selected `cbprintf` formatter rather than pulling in another formatter from libc.

In addition `CONFIG_CBPRINTF_NANO` can be used to revert back to the very space-optimized but limited formatter used for `printf()` before this capability was added.

4.5.1 Cbprintf Packaging

Typically, strings are formatted synchronously when a function from `printf` family is called. However, there are cases when it is beneficial that formatting is deferred. In that case, a state (format string and arguments) must be captured. Such state forms a self-contained package which contains format string and arguments. Additionally, package may contain copies of strings which are part of a format string (format string or any `%s` argument). Package primary content resembles `va_list` stack frame thus standard formatting functions are used to process a package. Since package contains data which is processed as `va_list` frame, strict alignment must be maintained. Due to required padding, size of the package depends on alignment. When package is copied, it should be copied to a memory block with the same alignment as origin.

Package can have following variants:

- **Self-contained** - non read-only strings appended to the package. String can be formatted from such package as long as there is access to read-only string locations. Package may contain information where read-only strings are located within the package. That information can be used to convert packet to fully self-contained package.

- **Fully self-contained** - all strings are appended to the package. String can be formatted from such package without any external data.

- **Transient** - only arguments are stored. Package contain information where pointers to non read-only strings are located within the package. Optionally, it may contain read-only string location information. String can be formatted from such package as long as non read-only strings are still valid and read-only strings are accessible. Alternatively, package can be converted to `self-contained` package or `fully self-contained` if information about read-only string locations is present in the package.
Package can be created using two methods:

- runtime - using `cbprintf_package()` or `cbvprintf_package()`. This method scans format string and based on detected format specifiers builds the package.
- static - types of arguments are detected at compile time by the preprocessor and package is created as simple assignments to a provided memory. This method is significantly faster than runtime (more than 15 times) but has following limitations: requires `_Generic` keyword (C11 feature) to be supported by the compiler and cannot distinguish between `%p` and `%s` if char pointer is used. It treats all (unsigned) char pointers as `%s` thus it will attempt to append string to a package. It can be handled correctly during conversion from `transient` package to `self-contained` package using `CBPRINTF_PACKAGE_CONVERT_PTR_CHECK` flag. However, it requires access to the format string and it is not always possible thus it is recommended to cast char pointers used for `%p` to `void*`. There is a logging warning generated by `cbprintf_package_convert()` called with `CBPRINTF_PACKAGE_CONVERT_PTR_CHECK` flag when char pointer is used with `%p`.

Several Kconfig options control behavior of the packaging:

- `CONFIG_CBPRINTF_PACKAGE_LONGDOUBLE`
- `CONFIG_CBPRINTF_STATIC_PACKAGE_CHECK_ALIGNMENT`

**Cbprintf package conversion**

It is possible to convert package to a variant which contains more information, e.g `transient` package can be converted to `self-contained`. Conversion to fully `self-contained` package is possible if `CBPRINTF_PACKAGE_ADD_RO_STR_POS` flag was used when package was created.

`cbprintf_package_copy()` is used to calculate space needed for the new package and to copy and convert a package.

**Cbprintf package format**

Format of the package contains paddings which are platform specific. Package consists of header which contains size of package (excluding appended strings) and number of appended strings. It is followed by the arguments which contains alignment paddings and resembles `va_list` stack frame. It is followed by data associated with character pointer arguments used by the string which are not appended to the string (but may be appended later by `cbprintf_package_convert()`). Finally, package, optionally, contains appended strings. Each string contains 1 byte header which contains index of the location where address argument is stored. During packaging address is set to null and before string formatting it is updated to point to the current string location within the package. Updating address argument must happen just before string formatting since address changes whenever package is copied.

</tbody>
</table>

**Warning:** If 	exttt{CONFIG_MINIMAL_LIBC} is selected in combination with 	exttt{CONFIG_CBPRINTF_NANO} formatting with C standard library functions like \texttt{printf} or \texttt{snprintf} is limited. Among other things the \texttt{%n} specifier, most format flags, precision control, and floating point are not supported.

Limitations and recommendations

- C11 \_Generic support is required by the compiler to use static (fast) packaging.
- It is recommended to cast any character pointer used with \texttt{%p} format specifier to other pointer type (e.g. \texttt{void *}). If format string is not accessible then only static packaging is possible and it will append all detected strings. Character pointer used for \texttt{%p} will be considered as string pointer. Copying from unexpected location can have serious consequences (e.g., memory fault or security violation).

4.5.2 API Reference

\texttt{group cbprintf\_apis}

**Defines**

\texttt{CBPRINTF\_PACKAGE\_ALIGNMENT}

Required alignment of the buffer used for packaging.

\texttt{CBPRINTF\_MUST\_RUNTIME\_PACKAGE(flags, ...)}

Determine if string must be packaged in run time.

Static packaging can be applied if size of the package can be determined at compile time. In general, package size can be determined at compile time if there are no string arguments which might be copied into package body if they are considered transient.
Note: By default any char pointers are considered to be pointing at transient strings. This can be narrowed down to non const pointers by using \texttt{CBPRINTF\_PACKAGE\_CONST\_CHAR\_RO}.

**Parameters**

- \ldots – String with arguments.
- \texttt{flags} – option flags. See Package flags.

**Return values**

- 1 – if string must be packaged in run time.
- 0 – string can be statically packaged.

\texttt{CBPRINTF\_STATIC\_PACKAGE}(packaged, inlen, outlen, align_offset, flags, \ldots)

Statically package string.

Build string package from formatted string. It assumes that formatted string is in the read only memory.

If \_\_Generic is not supported then runtime packaging is performed.

**Parameters**

- \texttt{packaged} – pointer to where the packaged data can be stored. Pass a null pointer to skip packaging but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. It must be aligned to the size of the longest argument. It is recommended to use \texttt{CBPRINTF\_PACKAGE\_ALIGNMENT} for alignment.
- \texttt{inlen} – set to the number of bytes available at \texttt{packaged}. If \texttt{packaged} is NULL the value is ignored.
- \texttt{outlen} – variable updated to the number of bytes required to completely store the packed information. If input buffer was too small it is set to -ENOSPC.
- \texttt{align_offset} – input buffer alignment offset in bytes. Where offset 0 means that buffer is aligned to \texttt{CBPRINTF\_PACKAGE\_ALIGNMENT}. Xtensa requires that \texttt{packaged} is aligned to \texttt{CBPRINTF\_PACKAGE\_ALIGNMENT} so it must be multiply of \texttt{CBPRINTF\_PACKAGE\_ALIGNMENT} or 0.
- \texttt{flags} – option flags. See Package flags.
- \ldots – formatted string with arguments. Format string must be constant.

**Typedefs**

typedef int (*cbprintf\_cb)()

Signature for a cbprintf callback function.

This function expects two parameters:

- \texttt{c} a character to output. The output behavior should be as if this was cast to an unsigned char.
- \texttt{ctx} a pointer to an object that provides context for the output operation.

The declaration does not specify the parameter types. This allows a function like \texttt{fputc} to be used without requiring all context pointers to be to a FILE object.
Return
the value of `c` cast to an unsigned char then back to int, or a negative error code
that will be returned from `cbprintf()`.

typedef int (*cbprintf_convert_cb)(const void *buf, size_t len, void *ctx)
Signature for a cbprintf multibyte callback function.
	nreturn Amount of copied data or negative error code.

Param `buf`
data.

Param `len`
data length.

Param `ctx`
a pointer to an object that provides context for the operation.

typedef int (*cbvprintf_external_formatter_func)(cbprintf_cb out, void *ctx, const char *fmt, va_list ap)
Signature for a external formatter function identical to cbvprintf.

This function expects the following parameters:

Param `out`
the function used to emit each generated character.

Param `ctx`
a pointer to an object that provides context for the external formatter.

Param `fmt`
a standard ISO C format string with characters and conversion specifications.

Param `ap`
captured stack arguments corresponding to the conversion specifications found
within `fmt`.

Return
vprintf like return values: the number of characters printed, or a negative error
value returned from external formatter.

Functions

int cbprintf_package(void *packaged, size_t len, uint32_t flags, const char *format, ...)
Capture state required to output formatted data later.

Like `cbprintf()` but instead of processing the arguments and emitting the formatted results
immediately all arguments are captured so this can be done in a different context, e.g. when
the output function can block.

In addition to the values extracted from arguments this will ensure that copies are made of the
necessary portions of any string parameters that are not confirmed to be stored in read-only
memory (hence assumed to be safe to refer to directly later).

Parameters

• `packaged` – pointer to where the packaged data can be stored. Pass a null
pointer to store nothing but still calculate the total space required. The data
stored here is relocatable, that is it can be moved to another contiguous block
of memory. However, under condition that alignment is maintained. It must be
aligned to at least the size of a pointer.
• `len` – this must be set to the number of bytes available at `packaged` if it is not null. If `packaged` is null then it indicates hypothetical buffer alignment offset in bytes compared to `CBPRINTF_PACKAGE_ALIGNMENT` alignment. Buffer alignment offset impacts returned size of the package. Xtensa requires that buffer is always aligned to `CBPRINTF_PACKAGE_ALIGNMENT` so it must be multiply of `CBPRINTF_PACKAGE_ALIGNMENT` or 0 when `packaged` is null.

• `flags` – option flags. See Package flags.

• `format` – a standard ISO C format string with characters and conversion specifications.

• `...` – arguments corresponding to the conversion specifications found within `format`.

**Return values**

• `nonnegative` – the number of bytes successfully stored at `packaged`. This will not exceed `len`.

• `-EINVAL` – if `format` is not acceptable

• `-EFAULT` – if `packaged` alignment is not acceptable

• `-ENOSPC` – if `packaged` was not null and the space required to store exceed `len`.

```c
int cbvprintf_package(void *packaged, size_t len, uint32_t flags, const char *format, va_list ap)
```

Capture state required to output formatted data later.

Like `cbprintf()` but instead of processing the arguments and emitting the formatted results immediately all arguments are captured so this can be done in a different context, e.g. when the output function can block.

In addition to the values extracted from arguments this will ensure that copies are made of the necessary portions of any string parameters that are not confirmed to be stored in read-only memory (hence assumed to be safe to refer to directly later).

**Parameters**

• `packaged` – pointer to where the packaged data can be stored. Pass a null pointer to store nothing but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. The pointer must be aligned to a multiple of the largest element in the argument list.

• `len` – this must be set to the number of bytes available at `packaged`. Ignored if `packaged` is NULL.

• `flags` – option flags. See Package flags.

• `format` – a standard ISO C format string with characters and conversion specifications.

• `ap` – captured stack arguments corresponding to the conversion specifications found within `format`.

**Return values**

• `nonnegative` – the number of bytes successfully stored at `packaged`. This will not exceed `len`.

• `-EINVAL` – if `format` is not acceptable

• `-EFAULT` – if `packaged` was not null and the space required to store exceed `len`.

```c
int cbprintf_package_convert(void *in_packaged, size_t in_len, cbprintf_convert_cb cb, void *ctx, uint32_t flags, uint16_t *strl, size_t strl_len)
```

4.5. Formatted Output 635
Convert a package.

Converting may include appending strings used in the package to the package body. If input package was created with CBPRINTF_PACKAGE_ADD_RO_STR_POS or CBPRINTF_PACKAGE_ADD_RW_STR_POS, it contains information where strings are located within the package. This information can be used to copy strings during the conversion.

\texttt{cb} is called with portions of the output package. At the end of the conversion \texttt{cb} is called with null buffer.

**Parameters**

- \texttt{in\_packaged} – Input package.
- \texttt{in\_len} – Input package length. If 0 package length will be retrieved from the \texttt{in\_packaged}
- \texttt{cb} – callback called with portions of the converted package. If null only length of the output package is calculated.
- \texttt{ctx} – Context provided to the \texttt{cb}.
- \texttt{flags} – Flags. See Package flags..
- \texttt{strl} – [inout] if \texttt{packaged} is null, it is a pointer to the array where \texttt{strl\_len} first string lengths will is stored. If \texttt{packaged} is not null, it contains lengths of first \texttt{strl\_len} strings. It can be used to optimize copying so that string length is calculated only once (at length calculation phase when \texttt{packaged} is null.)
- \texttt{strl\_len} – Number of elements in \texttt{strl} array.

**Return values**

- Positive – output package size.
- \texttt{-ENOSPC} – if \texttt{packaged} was not null and the space required to store exceed \texttt{len}.

\begin{verbatim}
static inline int cbprintf_package_copy(void *in_packaged, size_t in_len, void *packaged, size_t len, uint32_t flags, uint16_t *strl, size_t strl_len)
\end{verbatim}

Copy package with optional appending of strings.

\texttt{cbprintf\_package\_convert} is used to convert and store converted package in the new location.

**Parameters**

- \texttt{in\_packaged} – Input package.
- \texttt{in\_len} – Input package length. If 0 package length will be retrieved from the \texttt{in\_packaged}
- \texttt{packaged} – [out] Output package. If null only length of the output package is calculated.
- \texttt{len} – Available space in the location pointed by \texttt{packaged}. Not used when \texttt{packaged} is null.
- \texttt{flags} – Flags. See Package flags..
- \texttt{strl} – [inout] if \texttt{packaged} is null, it is a pointer to the array where \texttt{strl\_len} first string lengths will is stored. If \texttt{packaged} is not null, it contains lengths of first \texttt{strl\_len} strings. It can be used to optimize copying so that string length is calculated only once (at length calculation phase when \texttt{packaged} is null.)
- \texttt{strl\_len} – Number of elements in \texttt{strl} array.

**Return values**

- Positive – Output package size.
- \texttt{-ENOSPC} – if \texttt{packaged} was not null and the space required to store exceed \texttt{len}. 

636 Chapter 4. OS Services
static inline int cbprintf_fsc_package(void *in_packaged, size_t in_len, void *packaged, size_t len)

Convert package to fully self-contained (fsc) package.

Package may not be self contain since strings by default are stored by address. Package may be partially self-contained when transient (not read only) strings are appended to the package. Such package can be decoded only when there is an access to read-only strings.

Fully self-contained has (fsc) contains all strings used in the package. A package can be converted to fsc package if it was create with CBPRINTF_PACKAGE_ADD_RO_STR_POS flag. Such package will contain necessary data to find read only strings in the package and copy them into the package body.

Parameters

• in_packaged – pointer to original package created with CBPRINTF_PACKAGE_ADD_RO_STR_POS.
• in_len – in_packaged length.
• packaged – pointer to location where fully self-contained version of the input package will be written. Pass a null pointer to calculate space required.
• len – must be set to the number of bytes available at packaged. Not used if packaged is null.

Return values

• nonegative – the number of bytes successfully stored at packaged. This will not exceed len. If packaged is null, calculated length.
• -ENOSPC – if packaged was not null and the space required to store exceed len.
• -EINVAL – if in_packaged is null.

int cbprintf_external(cbprintf_cb out, cbprintf_external_formatter_func formatter, void *ctx, void *packaged)

Generate the output for a previously captured format operation using an external formatter.

Note: Memory indicated by packaged will be modified in a non-destructive way, meaning that it could still be reused with this function again.

Parameters

• out – the function used to emit each generated character.
• formatter – external formatter function.
• ctx – a pointer to an object that provides context for the external formatter.
• packaged – the data required to generate the formatted output, as captured by cbprintf_package() or cbvprintf_package(). The alignment requirement on this data is the same as when it was initially created.

Returns

printf like return values: the number of characters printed, or a negative error value returned from external formatter.

int cbprintf(cbprintf_cb out, *ctx, const char *format, ...)

*printf-like output through a callback.

This is essentially printf() except the output is generated character-by-character using the provided out function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.
All formatting specifiers of C99 are recognized, and most are supported if the functionality is enabled.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

**Parameters**
- `out` – the function used to emit each generated character.
- `ctx` – context provided when invoking `out`.
- `format` – a standard ISO C format string with characters and conversion specifications.
- `...` – arguments corresponding to the conversion specifications found within `format`.

**Returns**
the number of characters printed, or a negative error value returned from invoking `out`.

```c
static inline int cbvprintf(cbprintf_cb out, void *ctx, const char *format, va_list ap)
```

varargs-aware `printf-like output through a callback.

This is essentially `vsprintf()` except the output is generated character-by-character using the provided `out` function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

**Parameters**
- `out` – the function used to emit each generated character.
- `ctx` – context provided when invoking `out`.
- `format` – a standard ISO C format string with characters and conversion specifications.
- `ap` – a reference to the values to be converted.

**Returns**
the number of characters generated, or a negative error value returned from invoking `out`.

```c
static inline int cbvprintf_tagged_args(cbprintf_cb out, void *ctx, const char *format, va_list ap)
```

varargs-aware `printf-like output through a callback with tagged arguments.

This is essentially `vsprintf()` except the output is generated character-by-character using the provided `out` function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.

Note that the argument list `ap` are tagged.
Note: This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

Note: The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

**Parameters**

- `out` – the function used to emit each generated character.
- `ctx` – context provided when invoking `out`.
- `format` – a standard ISO C format string with characters and conversion specifications.
- `ap` – a reference to the values to be converted.

**Returns**

the number of characters generated, or a negative error value returned from invoking `out`.

static inline int cbpprintf (cbprintf_cb out, void *ctx, void *packaged)

Generate the output for a previously captured format operation.

Note: Memory indicated by `packaged` will be modified in a non-destructive way, meaning that it could still be reused with this function again.

**Parameters**

- `out` – the function used to emit each generated character.
- `ctx` – context provided when invoking `out`.
- `packaged` – the data required to generate the formatted output, as captured by `cbprintf_package()` or `cbvprintf_package()`. The alignment requirement on this data is the same as when it was initially created.

**Returns**

the number of characters printed, or a negative error value returned from invoking `out`.

```c
int fprintfcb(FILE *stream, const char *format, ...)
```

fprintf using Zephyrs cbprintf infrastructure.

return The number of characters printed.

Note: This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

Note: The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

**Parameters**

- `stream` – the stream to which the output should be written.
• format – a standard ISO C format string with characters and conversion specifications.
• ... – arguments corresponding to the conversion specifications found within format.

```c
int vfprintfcb(FILE *stream, const char *format, va_list ap)
vfprintf using Zephyrs cbprintf infrastructure.
```

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

### Parameters
- stream – the stream to which the output should be written.
- format – a standard ISO C format string with characters and conversion specifications.
- ap – a reference to the values to be converted.

### Returns
The number of characters printed.

```c
int printfcb(const char *format, ...)
printf using Zephyrs cbprintf infrastructure.
```

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

```
Parameters
• format – a standard ISO C format string with characters and conversion specifications.
• ... – arguments corresponding to the conversion specifications found within format.

Returns
The number of characters printed.
```

```c
int vprintfcb(const char *format, va_list ap)
vprintf using Zephyrs cbprintf infrastructure.
```

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.
Parameters

- format – a standard ISO C format string with characters and conversion specifications.
- ap – a reference to the values to be converted.

Returns
The number of characters printed.

```c
int snprintfcb(char *str, size_t size, const char *format, ...)
```

snprintf using Zephyrs cbprintf infrastructure.

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

Parameters

- str – where the formatted content should be written
- size – maximum number of characters for the formatted output, including the terminating null byte.
- format – a standard ISO C format string with characters and conversion specifications.
- ... – arguments corresponding to the conversion specifications found within format.

Returns
The number of characters that would have been written to str, excluding the terminating null byte. This is greater than the number actually written if size is too small.

```c
int vsnprintfcb(char *str, size_t size, const char *format, va_list ap)
```

vsnprintf using Zephyrs cbprintf infrastructure.

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

Parameters

- str – where the formatted content should be written
- size – maximum number of characters for the formatted output, including the terminating null byte.
- format – a standard ISO C format string with characters and conversion specifications.
- ap – a reference to the values to be converted.
Returns

The number of characters that would have been written to `str`, excluding the terminating null byte. This is greater than the number actually written if `size` is too small.

## 4.6 Interprocessor Communication (IPC)

### 4.6.1 IPC service

The IPC service API provides an interface to exchange data between two domains or CPUs.

**Overview**

An IPC service communication channel consists of one instance and one or several endpoints associated with the instance.

An instance is the external representation of a physical communication channel between two domains or CPUs. The actual implementation and internal representation of the instance is peculiar to each backend.

An individual instance is not used to send data between domains/CPUs. To send and receive the data, the user must create (register) an endpoint in the instance. This allows for the connection of the two domains of interest.

It is possible to have zero or multiple endpoints for one single instance, possibly with different priorities, and to use each to exchange data. Endpoint prioritization and multi-instance ability highly depend on the backend used.

The endpoint is an entity the user must use to send and receive data between two domains (connected by the instance). An endpoint is always associated to an instance.

The creation of the instances is left to the backend, usually at init time. The registration of the endpoints is left to the user, usually at run time.

The API does not mandate a way for the backend to create instances but it is strongly recommended to use the devicetree to retrieve the configuration parameters for an instance. Currently, each backend defines its own DT-compatible configuration that is used to configure the interface at boot time.

The following usage scenarios are supported:

- Simple data exchange.
- Data exchange using the no-copy API.

**Simple data exchange**

To send data between domains or CPUs, an endpoint must be registered onto an instance.
See the following example:

```c
#include <zephyr/include/ipc_service.h>

static void bound_cb(void *priv)
{
    /* Endpoint bounded */
}

static void recv_cb(const void *data, size_t len, void *priv)
{
    /* Data received */
}

static struct ipc_ept_cfg ept0_cfg = {
    .name = "ept0",
    .cb = {
        .bound = bound_cb,
        .received = recv_cb,
    },
};

int main(void)
{
    const struct device *inst0;
    struct ipc_ept ept0;
    int ret;

    inst0 = DEVICE_DT_GET(DT_NODELABEL(ipc0));
    ret = ipc_service_open_instance(inst0);
    ret = ipc_service_register_endpoint(inst0, &ept0, &ept0_cfg);

    /* Wait for endpoint bound (bound_cb called) */

    unsigned char message[] = "hello world";
    ret = ipc_service_send(&ept0, &message, sizeof(message));
}
```

### Data exchange using the no-copy API

If the backend supports the no-copy API you can use it to directly write and read to and from shared memory regions.

See the following example:

```c
#include <zephyr/include/ipc_service.h>
#include <stdint.h>
#include <string.h>

static struct ipc_ept ept0;

static void bound_cb(void *priv)
```

(continues on next page)
static void recv_cb_nocopy(const void *data, size_t len, void *priv)
{
    int ret;
    ret = ipc_service_hold_rx_buffer(&ept0, (void *)data);
    /* Process directly or put the buffer somewhere else and release. */
    ret = ipc_service_release_rx_buffer(&ept0, (void *)data);
}

static struct ipc_ept_cfg ept0_cfg = {
    .name = "ept0",
    .cb = {
        .bound = bound_cb,
        .received = recv_cb,
    },
};

int main(void)
{
    const struct device *inst0;
    int ret;
    inst0 = DEVICE_DT_GET(DT_NODELABEL(ipc0));
    ret = ipc_service_open_instance(inst0);
    ret = ipc_service_register_endpoint(inst0, &ept0, &ept0_cfg);
    /* Wait for endpoint bound (bound_cb called) */
    void *data;
    unsigned char message[] = "hello world";
    uint32_t len = sizeof(message);
    ret = ipc_service_get_tx_buffer(&ept0, &data, &len, K_FOREVER);
    memcpy(data, message, len);
    ret = ipc_service_send_nocopy(&ept0, data, sizeof(message));
}

Backends  The requirements needed for implementing backends give flexibility to the IPC service. These allow for the addition of dedicated backends having only a subsets of features for specific use cases.

The backend must support at least the following:

- The init-time creation of instances.
- The run-time registration of an endpoint in an instance.

Additionally, the backend can also support the following:

- The run-time deregistration of an endpoint from the instance.
- The run-time closing of an instance.
- The no-copy API.
Each backend can have its own limitations and features that make the backend unique and dedicated to a specific use case. The IPC service API can be used with multiple backends simultaneously, combining the pros and cons of each backend.

**ICMsg backend**  The inter core messaging backend (ICMsg) is a lighter alternative to the heavier RPMsg static v rings backend. It offers a minimal feature set in a small memory footprint. The ICMsg backend is build on top of Single Producer Single Consumer Packet Buffer.

**Overview**  The ICMsg backend uses shared memory and MBOX devices for exchanging data. Shared memory is used to store the data, MBOX devices are used to signal that the data has been written. The backend supports the registration of a single endpoint on a single instance. If the application requires more than one communication channel, you must define multiple instances, each having its own dedicated endpoint.

**Configuration**  The backend is configured via devicetree. When configuring the backend, do the following:

- Define two memory regions and assign them to tx-region and rx-region of an instance. Ensure that the memory regions used for data exchange are unique (not overlapping any other region) and accessible by both domains (or CPUs).
- Define MBOX devices which are used to send the signal that informs the other domain (or CPU) that data has been written. Ensure that the other domain (or CPU) is able to receive the signal.

See the following configuration example for one of the instances:

```yaml
reserved-memory {
  tx: memory@20070000 {
    reg = <0x20070000 0x0800>;
  };
  rx: memory@20078000 {
    reg = <0x20078000 0x0800>;
  };

  ipc {
    ipc0: ipc0 {
      compatible = "zephyr,ipc-icmsg";
      tx-region = <&tx>;
      rx-region = <&rx>;
      mboxes = <&mbox 0>, <&mbox 1>;
      mbox-names = "tx", "rx";
      status = "okay";
    };
  };
}
```

You must provide a similar configuration for the other side of the communication (domain or CPU) but you must swap the MBOX channels and memory regions (tx-region and rx-region).

**Bonding**  When the endpoint is registered, the following happens on each domain (or CPU) connected through the IPC instance:

1. The domain (or CPU) writes a magic number to its tx-region of the shared memory. It then sends a signal to the other domain or CPU, informing that the data has been written. It then checks, regardless of the signal from the other side being received or not, if the magic number is already in its
If the magic number is not yet in the rx-region, the domain (or CPU) waits to receive the signal from the other side of the communication to finish the bonding process, and informs the application by calling `ipc_service_cb.bound`.

Since the ICMsg backend performs the first read from rx-region, regardless of the signaling mechanism, the shared memory areas must be cleared with zeroes before any side of the communication uses them.

**Samples**
- `ipc_icmsg_sample`

**API Reference**

**IPC service API**

```c
#include <zephyr/device.h>

__BEGIN_DECLS

/* Open an instance. */

int ipc_service_open_instance(const struct device *instance)
{
  return Kinesis::open_ipc_service_instance(instance);
}

/* Close an instance. */

int ipc_service_close_instance(const struct device *instance)
{
  return Kinesis::close_ipc_service_instance(instance);
}

__END_DECLS
```

**Functions**

### `ipc_service_open_instance`

\[ \text{Open an instance.} \]

Function to be used to open an instance before being able to register a new endpoint on it.

**Parameters**
- `instance` - [in] Instance to open.

**Return values**
- `-EINVAL` - when instance configuration is invalid.
- `-EIO` - when no backend is registered.
- `-EAGAIN` - when the instance is already opened (or being opened).
- `0` - on success or when not implemented on the backend (not needed).
- `other` - errno codes depending on the implementation of the backend.

### `ipc_service_close_instance`

\[ \text{Close an instance.} \]

Function to be used to close an instance. All endpoints must be deregistered using `ipc_service_deregister_endpoint` before this is called.

**Parameters**
- `instance` - [in] Instance to close.

**Return values**
- `-EINVAL` - when instance configuration is invalid.
- `-EIO` - when no backend is registered.
- `-EAGAIN` - when the instance is not already opened.
- `-EBUSY` - when an endpoint exists that hasn't been deregistered
- `0` - on success or when not implemented on the backend (not needed).
- `other` - errno codes depending on the implementation of the backend.
int ipc_service_register_endpoint(const struct device *instance, struct ipc_ept *ept, const struct ipc_ept_cfg *cfg)

Register IPC endpoint onto an instance.

Registers IPC endpoint onto an instance to enable communication with a remote device.
The same function registers endpoints for both host and remote devices.

**Note:** Keep the variable pointed by `cfg` alive when endpoint is in use.

**Parameters**
- `instance` – [in] Instance to register the endpoint onto.

**Return values**
- `-EIO` – when no backend is registered.
- `-EINVAL` – when instance, endpoint or configuration is invalid.
- `-EBUSY` – when the instance is busy.
- `0` – on success.
- `other` – errno codes depending on the implementation of the backend.

int ipc_service_deregister_endpoint(struct ipc_ept *ept)

Deregister an IPC endpoint from its instance.

Deregisters an IPC endpoint from its instance.
The same function deregisters endpoints for both host and remote devices.

**Parameters**

**Return values**
- `-EIO` – when no backend is registered.
- `-EINVAL` – when instance or endpoint is invalid.
- `-ENOENT` – when the endpoint is not registered with the instance.
- `-EBUSY` – when the instance is busy.
- `0` – on success.
- `other` – errno codes depending on the implementation of the backend.

int ipc_service_send(struct ipc_ept *ept, const void *data, size_t len)

Send data using given IPC endpoint.

**Parameters**
- `data` – [in] Pointer to the buffer to send.
- `len` – [in] Number of bytes to send.

**Return values**
- `-EIO` – when no backend is registered or send hook is missing from backend.
- `-EINVAL` – when instance or endpoint is invalid.
- ENOENT – when the endpoint is not registered with the instance.
- EBADMSG – when the data is invalid (i.e. invalid data format, invalid length, ...)
- EBUSY – when the instance is busy.
- ENOMEM – when no memory / buffers are available.

bytes – number of bytes sent.
other – errno codes depending on the implementation of the backend.

int ipc_service_get_tx_buffer_size(struct ipc_ept *ept)

Get the TX buffer size.

Get the maximal size of a buffer which can be obtained by \texttt{ipc_service_get_tx_buffer}

\textbf{Parameters}

\begin{itemize}
  \item \texttt{ept} – [in] Registered endpoint by \texttt{ipc_service_register_endpoint}.
\end{itemize}

\textbf{Return values}

\begin{itemize}
  \item -EIO – when no backend is registered or send hook is missing from backend.
  \item -EINVAL – when instance or endpoint is invalid.
  \item -ENOENT – when the endpoint is not registered with the instance.
  \item -ENOTSUP – when the operation is not supported by backend.
  \item \texttt{size} – TX buffer size on success.
  \item other – errno codes depending on the implementation of the backend.
\end{itemize}

int ipc_service_get_tx_buffer(struct ipc_ept *ept, void **data, uint32_t *size, k_timeout_t wait)

Get an empty TX buffer to be sent using \texttt{ipc_service_send_nocopy}.

This function can be called to get an empty TX buffer so that the application can directly put its data into the sending buffer without copy from an application buffer.

It is the application responsibility to correctly fill the allocated TX buffer with data and passing correct parameters to \texttt{ipc_service_send_nocopy} function to perform data no-copy-send mechanism.

The size parameter can be used to request a buffer with a certain size:

- if the size can be accommodated the function returns no errors and the buffer is allocated
- if the requested size is too big, the function returns -ENOMEM and the the buffer is not allocated.
- if the requested size is ‘0’ the buffer is allocated with the maximum allowed size.

In all the cases on return the size parameter contains the maximum size for the returned buffer.

When the function returns no errors, the buffer is intended as allocated and it is released under two conditions: (1) when sending the buffer using \texttt{ipc_service_send_nocopy} (and in this case the buffer is automatically released by the backend), (2) when using \texttt{ipc_service_drop_tx_buffer} on a buffer not sent.

\textbf{Parameters}

\begin{itemize}
  \item \texttt{ept} – [in] Registered endpoint by \texttt{ipc_service_register_endpoint}.
  \item \texttt{data} – [out] Pointer to the empty TX buffer.
  \item \texttt{size} – [inout] Pointer to store the requested TX buffer size. If the function returns -ENOMEM, this parameter returns the maximum allowed size.
\end{itemize}
• `wait` – [in] Timeout waiting for an available TX buffer.

**Return values**

• `-EIO` – when no backend is registered or send hook is missing from backend.
• `-EINVAL` – when instance or endpoint is invalid.
• `-ENOTENT` – when the endpoint is not registered with the instance.
• `-ENOTSUP` – when the operation or the timeout is not supported by backend.
• `-ENOBUFS` – when there are no TX buffers available.
• `-EALREADY` – when a buffer was already claimed and not yet released.
• `-ENOMEM` – when the requested size is too big (and the size parameter contains the maximum allowed size).
• `0` – on success.
• `other` – errno codes depending on the implementation of the backend.

```c
int ipc_service_drop_tx_buffer(struct ipc_ept *ept, const void *data)
```

Drop and release a TX buffer. It is possible to drop only TX buffers obtained by using `ipc_service_get_tx_buffer`.

**Parameters**

• `ept` – [in] Registered endpoint by `ipc_service_register_endpoint`.
• `data` – [in] Pointer to the TX buffer.

**Return values**

• `-EIO` – when no backend is registered or send hook is missing from backend.
• `-EINVAL` – when instance or endpoint is invalid.
• `-ENOTENT` – when the endpoint is not registered with the instance.
• `-ENOTSUP` – when this is not supported by backend.
• `-EALREADY` – when the buffer was already dropped.
• `-ENXIO` – when the buffer was not obtained using `ipc_service_get_tx_buffer`
• `0` – on success.
• `other` – errno codes depending on the implementation of the backend.

```c
int ipc_service_send_nocopy(struct ipc_ept *ept, const void *data, size_t len)
```

Send data in a TX buffer reserved by `ipc_service_get_tx_buffer` using the given IPC endpoint. This is equivalent to `ipc_service_send` but in this case the TX buffer has been obtained by using `ipc_service_get_tx_buffer`.

The application has to take the responsibility for getting the TX buffer using `ipc_service_get_tx_buffer` and filling the TX buffer with the data.

After the `ipc_service_send_nocopy` function is issued the TX buffer is no more owned by the sending task and must not be touched anymore unless the function fails and returns an error.

If this function returns an error, `ipc_service_drop_tx_buffer` can be used to drop the TX buffer.

**Parameters**

• `ept` – [in] Registered endpoint by `ipc_service_register_endpoint`.
• `data` – [in] Pointer to the buffer to send obtained by `ipc_service_get_tx_buffer`.
• `len` – [in] Number of bytes to send.
Return values

- **-EIO** – when no backend is registered or send hook is missing from backend.
- **-EINVAL** – when instance or endpoint is invalid.
- **-ENOENT** – when the endpoint is not registered with the instance.
- **-EBADMSG** – when the data is invalid (i.e. invalid data format, invalid length, ...)
- **-EBUSY** – when the instance is busy.
- **bytes** – number of bytes sent.
- **other** – errno codes depending on the implementation of the backend.

```c
int ipc_service_hold_rx_buffer(struct ipc_ept *ept, void *data)
```

Holds the RX buffer for usage outside the receive callback.

Calling this function prevents the receive buffer from being released back to the pool of shmem buffers. This function can be called in the receive callback when the user does not want to copy the message out in the callback itself.

After the message is processed, the application must release the buffer using the `ipc_service_release_rx_buffer` function.

Parameters

- **ept** – [in] Registered endpoint by `ipc_service_register_endpoint`.
- **data** – [in] Pointer to the RX buffer to release.

Return values

- **-EIO** – when no backend is registered or release hook is missing from backend.
- **-EINVAL** – when instance or endpoint is invalid.
- **-ENOENT** – when the endpoint is not registered with the instance.
- **-EALREADY** – when the buffer data has been hold already.
- **-ENOTSUP** – when this is not supported by backend.
- **0** – on success.
- **other** – errno codes depending on the implementation of the backend.

```c
int ipc_service_release_rx_buffer(struct ipc_ept *ept, void *data)
```

Release the RX buffer for future reuse.

When supported by the backend, this function can be called after the received message has been processed and the buffer can be marked as reusable again.

It is possible to release only RX buffers on which `ipc_service_hold_rx_buffer` was previously used.

Parameters

- **ept** – [in] Registered endpoint by `ipc_service_register_endpoint`.
- **data** – [in] Pointer to the RX buffer to release.

Return values

- **-EIO** – when no backend is registered or release hook is missing from backend.
- **-EINVAL** – when instance or endpoint is invalid.
- **-ENOENT** – when the endpoint is not registered with the instance.
- **-EALREADY** – when the buffer data has been already released.
- `ENOTSUP` – when this is not supported by backend.
- `ENXIO` – when the buffer was not hold before using `ipc_service_hold_rx_buffer`
- 0 – on success.
- `other` – errno codes depending on the implementation of the backend.

```c
struct ipc_service_cb
#include <ipc_service.h>  // Event callback structure.
```

It is registered during endpoint registration. This structure is part of the endpoint configuration.

**Public Members**

```c
void (*bound)(void *priv)
    Bind was successful.
    This callback is called when the endpoint binding is successful.
    **Param priv**
    [in] Private user data.
```

```c
void (*received)(const void *data, size_t len, void *priv)
    New packet arrived.
    This callback is called when new data is received.
    **Note:** When `ipc_service_hold_rx_buffer` is not used, the data buffer is to be considered released and available again only when this callback returns.
    **Param data**
    [in] Pointer to data buffer.
    **Param len**
    [in] Length of data.
    **Param priv**
    [in] Private user data.
```

```c
void (*error)(const char *message, void *priv)
    An error occurred.
    **Param message**
    **Param priv**
    [in] Private user data.
```

```c
struct ipc_ept
#include <ipc_service.h>  // Endpoint instance.
```

Token is not important for user of the API. It is implemented in a specific backend.

**Public Members**

```c
const struct device *instance
    Instance this endpoint belongs to.
```

4.6. Interprocessor Communication (IPC)
void *token
    Backend-specific token used to identify an endpoint in an instance.

struct ipc_ept_cfg
    #include <ipc_service.h> Endpoint configuration structure.

Public Members

const char *name
    Name of the endpoint.

int prio
    Endpoint priority. If the backend supports priorities.

struct ipc_service_cb cb
    Event callback structure.

void *priv
    Private user data.

IPC service backend API

group ipc_service_backend
    IPC service backend.

struct ipc_service_backend
    #include <ipc_service_backend.h> IPC backend configuration structure.
    This structure is used for configuration backend during registration.

Public Members

int (*open_instance)(const struct device *instance)
    Pointer to the function that will be used to open an instance.

    Param instance
        [in] Instance pointer.

    Retval -EALREADY
        when the instance is already opened.

    Retval 0
        on success

    Retval other
        errno codes depending on the implementation of the backend.

int (*close_instance)(const struct device *instance)
    Pointer to the function that will be used to close an instance.

    Param instance
        [in] Instance pointer.

    Retval -EALREADY
        when the instance is not already initiated.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*send)(const struct device *instance, void *token, const void *data, size_t len)
Pointer to the function that will be used to send data to the endpoint.

Param instance
[in] Instance pointer.

Param token

Param data
[in] Pointer to the buffer to send.

Param len
[in] Number of bytes to send.
Retval -EINVAL
when instance is invalid.
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -EBADMSG
when the message is invalid.
Retval -EBUSY
when the instance is busy or not ready.
Retval -ENOMEM
when no memory / buffers are available.

Retval bytes
number of bytes sent.
Retval other
errno codes depending on the implementation of the backend.

int (*register_endpoint)(const struct device *instance, void **token, const struct ipc_ept_cfg *cfg)
Pointer to the function that will be used to register endpoints.

Param instance
[in] Instance to register the endpoint onto.

Param token
[out] Backend-specific token.

Param cfg
[in] Endpoint configuration.
Retval -EINVAL
when the endpoint configuration or instance is invalid.
Retval -EBUSY
when the instance is busy or not ready.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*deregister_endpoint)(const struct device *instance, void *token)
Pointer to the function that will be used to deregister endpoints.

Param instance
[in] Instance from which to deregister the endpoint.

Param token
Retval -EINVAL
when the endpoint configuration or instance is invalid.
Retval -ENOENT
  when the endpoint is not registered with the instance.
Retval -EBUSY
  when the instance is busy or not ready.
Retval 0
  on success
Retval other
  errno codes depending on the implementation of the backend.

int (*get_tx_buffer_size)(const struct device *instance, void *token)

  Pointer to the function that will return the TX buffer size.

  Param instance
    [in] Instance pointer.

  Param token

  Retval -EINVAL
    when instance is invalid.

  Retval -ENOENT
    when the endpoint is not registered with the instance.

  Retval -ENOTSUP
    when the operation is not supported.

  Retval size
    TX buffer size on success.

  Retval other
    errno codes depending on the implementation of the backend.

int (*get_tx_buffer)(const struct device *instance, void *token, void **data, uint32_t *len, k_timeout_t *wait)

  Pointer to the function that will return an empty TX buffer.

  Param instance
    [in] Instance pointer.

  Param token

  Param data
    [out] Pointer to the empty TX buffer.

  Param len
    [inout] Pointer to store the TX buffer size.

  Param wait
    [in] Timeout waiting for an available TX buffer.

  Retval -EINVAL
    when instance is invalid.

  Retval -ENOENT
    when the endpoint is not registered with the instance.

  Retval -ENOTSUP
    when the operation or the timeout is not supported.

  Retval -ENOBUFFS
    when there are no TX buffers available.

  Retval -EALREADY
    when a buffer was already claimed and not yet released.

  Retval -ENOMEM
    when the requested size is too big (and the size parameter contains the maximum allowed size).

  Retval 0
    on success

  Retval other
    errno codes depending on the implementation of the backend.

int (*drop_tx_buffer)(const struct device *instance, void *token, const void *data)
Pointer to the function that will drop a TX buffer.

**Param instance**
[in] Instance pointer.

**Param token**

**Param data**
[in] Pointer to the TX buffer.

**Retval**
- EINVAL when instance is invalid.
- ENOENT when the endpoint is not registered with the instance.
- ENOTSUP when this function is not supported.
- EALREADY when the buffer was already dropped.
- 0 on success
- other errno codes depending on the implementation of the backend.

```c
int (*send_nocopy)(const struct device *instance, void *token, const void *data, size_t len)
```

Pointer to the function that will be used to send data to the endpoint when the TX buffer has been obtained using `ipc_service_get_tx_buffer`.

**Param instance**
[in] Instance pointer.

**Param token**

**Param data**
[in] Pointer to the buffer to send.

**Param len**
[in] Number of bytes to send.

**Retval**
- EINVAL when instance is invalid.
- ENOENT when the endpoint is not registered with the instance.
- EBADMSG when the data is invalid (i.e. invalid data format, invalid length, ...)
- EBUSY when the instance is busy or not ready.
- bytes number of bytes sent.
- other errno codes depending on the implementation of the backend.

```c
int (*hold_rx_buffer)(const struct device *instance, void *token, void *data)
```

Pointer to the function that will hold the RX buffer.

**Param instance**
[in] Instance pointer.

**Param token**

**Param data**
[in] Pointer to the RX buffer to hold.

**Retval**
- EINVAL when instance is invalid.
- ENOENT when the endpoint is not registered with the instance.
Retval -EALREADY
when the buffer data has been already hold.
Retval -ENOTSUP
when this function is not supported.
Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

int (*release_rx_buffer)(const struct device *instance, void *token, void *data)

Pointer to the function that will release the RX buffer.

Param instance
[in] Instance pointer.

Param token

Param data
[in] Pointer to the RX buffer to release.

Retval -EINVAL
when instance is invalid.

Retval -ENOENT
when the endpoint is not registered with the instance.

Retval -EALREADY
when the buffer data has been already released.

Retval -ENOTSUP
when this function is not supported.

Retval 0
on success
Retval other
errno codes depending on the implementation of the backend.

4.7 Logging
The logging API provides a common interface to process messages issued by developers. Messages are passed through a frontend and are then processed by active backends. Custom frontend and backends can be used if needed.

Summary of the logging features:

- Deferred logging reduces the time needed to log a message by shifting time consuming operations to a known context instead of processing and sending the log message when called.
- Multiple backends supported (up to 9 backends).
- Custom frontend support. It can work together with backends.
- Compile time filtering on module level.
- Run time filtering independent for each backend.
- Additional run time filtering on module instance level.
- Timestamping with user provided function. Timestamp can have 32 or 64 bits.
- Dedicated API for dumping data.
- Dedicated API for handling transient strings.
- Panic support - in panic mode logging switches to blocking, synchronous processing.
- Printk support - printk message can be redirected to the logging.
- Design ready for multi-domain/multi-processor system.
- Support for logging floating point variables and long long arguments.
- Built-in copying of transient strings used as arguments.
- Support for multi-domain logging.

Logging API is highly configurable at compile time as well as at run time. Using Kconfig options (see [Global Kconfig Options](#)) logs can be gradually removed from compilation to reduce image size and execution time when logs are not needed. During compilation logs can be filtered out on module basis and severity level.

Logs can also be compiled in but filtered on run time using dedicate API. Run time filtering is independent for each backend and each source of log messages. Source of log messages can be a module or specific instance of the module.

There are four severity levels available in the system: error, warning, info and debug. For each severity level the logging API ([include/zephyr/logging/log.h](#)) has set of dedicated macros. Logger API also has macros for logging data.

For each level following set of macros are available:

- **LOG_X** for standard printf-like messages, e.g. `LOG_ERR`.
- **LOG_HEXDUMP_X** for dumping data, e.g. `LOG_HEXDUMP_WRN`.

---

4.7. Logging
• LOG_INST_X for standard printf-like message associated with the particular instance, e.g. LOG_INST_INF.

• LOG_INST_HEXDUMP_X for dumping data associated with the particular instance, e.g. LOG_HEXDUMP_INST_dbg

There are two configuration categories: configurations per module and global configuration. When logging is enabled globally, it works for modules. However, modules can disable logging locally. Every module can specify its own logging level. The module must define the LOG_LEVEL macro before using the API. Unless a global override is set, the module logging level will be honored. The global override can only increase the logging level. It cannot be used to lower module logging levels that were previously set higher. It is also possible to globally limit logs by providing maximal severity level present in the system, where maximal means lowest severity (e.g. if maximal level in the system is set to info, it means that errors, warnings and info levels are present but debug messages are excluded).

Each module which is using the logging must specify its unique name and register itself to the logging. If module consists of more than one file, registration is performed in one file but each file must define a module name.

Logger's default frontend is designed to be thread safe and minimizes time needed to log the message. Time consuming operations like string formatting or access to the transport are not performed by default when logging API is called. When logging API is called a message is created and added to the list. Dedicated, configurable buffer for pool of log messages is used. There are 2 types of messages: standard and hexdump. Each message contain source ID (module or instance ID and domain ID which might be used for multiprocessor systems), timestamp and severity level. Standard message contains pointer to the string and arguments. Hexdump message contains copied data and string.

4.7.1 Global Kconfig Options

These options can be found in the following path subsys/logging/Kconfig.

CONFIG_LOG: Global switch, turns on/off the logging.

Mode of operations:

CONFIG_LOG_MODE_DEFERRED: Deferred mode.

CONFIG_LOG_MODE_IMMEDIATE: Immediate (synchronous) mode.

CONFIG_LOG_MODE_MINIMAL: Minimal footprint mode.

Filtering options:

CONFIG_LOG_RUNTIME_FILTERING: Enables runtime reconfiguration of the filtering.

CONFIG_LOG_DEFAULT_LEVEL: Default level, sets the logging level used by modules that are not setting their own logging level.

CONFIG_LOG_OVERRIDE_LEVEL: It overrides module logging level when it is not set of set lower than the override value.

CONFIG_LOG_MAX_LEVEL: Maximal (lowest severity) level which is compiled in.

Processing options:

CONFIG_LOG_MODE_OVERFLOW: When new message cannot be allocated, oldest one are discarded.

CONFIG_LOG_BLOCK_IN_THREAD: If enabled and new log message cannot be allocated thread context will block for up to CONFIG_LOG_BLOCK_IN_THREAD_TIMEOUT_MS or until log message is allocated.

CONFIG_LOG_PRINTK: Redirect printk calls to the logging.

CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD: When number of buffered log messages reaches the threshold dedicated thread (see log_thread_set()) is waken up. If CONFIG_LOG_PROCESS_THREAD is enabled then this threshold is used by the internal thread.

CONFIG_LOG_PROCESS_THREAD: When enabled, logging thread is created which handles log processing.
CONFIG_LOG_PROCESS_THREAD_STARTUP_DELAY_MS: Delay in milliseconds after which logging thread is started.

CONFIG_LOG_BUFFER_SIZE: Number of bytes dedicated for the circular packet buffer.

CONFIG_LOG_FRONTEND: Direct logs to a custom frontend.

CONFIG_LOG_FRONTEND_ONLY: No backends are used when messages go to frontend.

CONFIG_LOG_TIMESTAMP_64BIT: 64 bit timestamp.

Formatting options:

CONFIG_LOG_FUNC_NAME_PREFIX_ERR: Prepend standard ERROR log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_WRN: Prepend standard WARNING log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_INF: Prepend standard INFO log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_DBG: Prepend standard DEBUG log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_BACKEND_SHOW_COLOR: Enables coloring of errors (red) and warnings (yellow).

CONFIG_LOG_BACKEND_FORMAT_TIMESTAMP: If enabled timestamp is formatted to \texttt{hh:mm:ss:mmm,uuu}. Otherwise is printed in raw format.

Backend options:

CONFIG_LOG_BACKEND_UART: Enabled built-in UART backend.

### 4.7.2 Usage

Logging in a module

In order to use logging in the module, a unique name of a module must be specified and module must be registered using \texttt{LOG_MODULE_REGISTER}. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (\texttt{CONFIG_LOG_DEFAULT_LEVEL}) is used if custom log level is not provided.

\begin{verbatim}
#include <zephyr/logging/log.h>
LOG_MODULE_REGISTER(foo, CONFIG_FOO_LOG_LEVEL);
\end{verbatim}

If the module consists of multiple files, then \texttt{LOG_MODULE_REGISTER()} should appear in exactly one of them. Each other file should use \texttt{LOG_MODULE_DECLARE} to declare its membership in the module. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (\texttt{CONFIG_LOG_DEFAULT_LEVEL}) is used if custom log level is not provided.

\begin{verbatim}
#include <zephyr/logging/log.h>
/* In all files comprising the module but one */
LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);
\end{verbatim}

In order to use logging API in a function implemented in a header file \texttt{LOG_MODULE_DECLARE} macro must be used in the function body before logging API is called. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (\texttt{CONFIG_LOG_DEFAULT_LEVEL}) is used if custom log level is not provided.

\begin{verbatim}
#include <zephyr/logging/log.h>

static inline void foo(void)
\end{verbatim}

(continues on next page)
{  
    LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);
    LOG_INF("foo");
}

Dedicated Kconfig template (subsys/logging/Kconfig.template.log_config) can be used to create local log level configuration.

Example below presents usage of the template. As a result CONFIG_FOO_LOG_LEVEL will be generated:

module = FOO
module-str = foo
source "subsys/logging/Kconfig.template.log_config"

Logging in a module instance

In case of modules which are multi-instance and instances are widely used across the system enabling logs will lead to flooding. Logger provide the tools which can be used to provide filtering on instance level rather than module level. In that case logging can be enabled for particular instance.

In order to use instance level filtering following steps must be performed:

• a pointer to specific logging structure is declared in instance structure. LOG_INSTANCE_PTR_DECLARE is used for that.

    #include <zephyr/logging/log_instance.h>

    struct foo_object {
        LOG_INSTANCE_PTR_DECLARE(log);
        uint32_t id;
    }

• module must provide macro for instantiation. In that macro, logging instance is registered and log instance pointer is initialized in the object structure.

    #define FOO_OBJECT_DEFINE(_name)   
        LOG_INSTANCE_REGISTER(foo, _name, CONFIG_FOO_LOG_LEVEL) \ 
        struct foo_object _name = { \ 
            LOG_INSTANCE_PTR_INIT(log, foo, _name) \ 
        }

Note that when logging is disabled logging instance and pointer to that instance are not created.

In order to use the instance logging API in a source file, a compile-time log level must be set using LOG_LEVEL_SET.

LOG_LEVEL_SET(CONFIG_FOO_LOG_LEVEL);

void foo_init(foo_object *f) {
    LOG_INST_INF(f->log, "Initialized.");
}

In order to use the instance logging API in a header file, a compile-time log level must be set using LOG_LEVEL_SET.

660 Chapter 4. OS Services
Controlling the logging

By default, logging processing in deferred mode is handled internally by the dedicated task which starts automatically. However, it might not be available if multithreading is disabled. It can also be disabled by unsetting `CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD`. In that case, logging can be controlled using API defined in `include/zephyr/logging/log_ctrl.h`. Logging must be initialized before it can be used. Optionally, user can provide function which returns timestamp value. If not provided, `k_cycle_get` or `k_cycle_get_32` is used for timestamping. `log_process()` function is used to trigger processing of one log message (if pending). Function returns true if there is more messages pending. However, it is recommended to use macro wrappers (`LOG_INIT` and `LOG_PROCESS`) which handles case when logging is disabled.

Following snippet shows how logging can be processed in simple forever loop.

```c
#include <zephyr/log_ctrl.h>

void main(void)
{
    LOG_INIT();
    /* If multithreading is enabled provide thread id to the logging. */
    log_thread_set(k_current_get());

    while (true) {
        if (LOG_PROCESS() == false) {
            /* sleep */
        }
    }
}
```

If logs are processed from a thread (user or internal) then it is possible to enable a feature which will wake up processing thread when certain amount of log messages are buffered (see `CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD`).

### 4.7.3 Logging panic

In case of error condition system usually can no longer rely on scheduler or interrupts. In that situation deferred log message processing is not an option. Logger controlling API provides a function for entering into panic mode (`log_panic()`) which should be called in such situation.

When `log_panic()` is called, `_panic_` notification is sent to all active backends. Once all backends are notified, all buffered messages are flushed. Since that moment all logs are processed in a blocking way.

### 4.7.4 Printk

Typically, logging and `printk()` is using the same output for which they compete. This can lead to issues if the output does not support preemption but also it may result in the corrupted output because logging data is interleaved with printk data. However, it is possible to redirect printk messages to the logging subsystem by enabling `CONFIG_LOG_PRINTK`. In that case, printk entries are treated as log messages with
level 0 (they cannot be disabled). When enabled, logging manages the output so there is no interleaving. However, in the deferred mode it changes the behavior of the printk because output is delayed until logging thread processes the data. CONFIG_LOG_PRINTK is by default enabled.

4.7.5 Architecture

Logging consists of 3 main parts:

- Frontend
- Core
- Backends

Log message is generated by a source of logging which can be a module or instance of a module.

Default Frontend

Default frontend is engaged when logging API is called in a source of logging (e.g. `LOG_INF`) and is responsible for filtering a message (compile and run time), allocating buffer for the message, creating the message and committing that message. Since logging API can be called in an interrupt, frontend is optimized to log the message as fast as possible.

Log message: Log message contains message descriptor (source, domain and level), timestamp, formatted string details (see Cbprintf Packaging) and optional data. Log messages are stored in a continuous block of memory. Memory is allocated from a circular packet buffer (Multi Producer Single Consumer Packet Buffer). It has few consequences:

- Each message is self-contained, continuous block of memory thus it is suited for copying the message (e.g. for offline processing).
- Messages must be sequentially freed. Backend processing is synchronous. Backend can make a copy for deferred processing.

Log message has following format:

<table>
<thead>
<tr>
<th>Message Header</th>
<th>2 bits: MPSC packet buffer header</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1 bit: Trace/Log message flag</td>
</tr>
<tr>
<td></td>
<td>3 bits: Domain ID</td>
</tr>
<tr>
<td></td>
<td>3 bits: Level</td>
</tr>
<tr>
<td></td>
<td>10 bits: Cbprintf Package Length</td>
</tr>
<tr>
<td></td>
<td>12 bits: Data length</td>
</tr>
<tr>
<td></td>
<td>1 bit: Reserved</td>
</tr>
<tr>
<td></td>
<td>pointer: Pointer to the source descriptor</td>
</tr>
<tr>
<td></td>
<td>32 or 64 bits: Timestamp</td>
</tr>
<tr>
<td></td>
<td>Optional padding</td>
</tr>
</tbody>
</table>

Cbprintf package (optional)  
Header  
Arguments  
Appended strings  
Hexdump data (optional)  
Alignment padding (optional)

1 Depending on the platform and the timestamp size fields may be swapped.  
2 It may be required for cbprintf package alignment
Log message allocation It may happen that frontend cannot allocate a message. It happens if system is generating more log messages than it can process in certain time frame. There are two strategies to handle that case:

- No overflow - new log is dropped if space for a message cannot be allocated.
- Overflow - oldest pending messages are freed, until new message can be allocated. Enabled by CONFIG_LOG_MODE_OVERFLOW. Note that it degrades performance thus it is recommended to adjust buffer size and amount of enabled logs to limit dropping.

Run-time filtering If run-time filtering is enabled, then for each source of logging a filter structure in RAM is declared. Such filter is using 32 bits divided into ten 3 bit slots. Except slot 0, each slot stores current filter for one backend in the system. Slot 0 (bits 0-2) is used to aggregate maximal filter setting for given source of logging. Aggregate slot determines if log message is created for given entry since it indicates if there is at least one backend expecting that log entry. Backend slots are examined when message is processed by the core to determine if message is accepted by the given backend. Contrary to compile time filtering, binary footprint is increased because logs are compiled in.

In the example below backend 1 is set to receive errors (slot 1) and backend 2 up to info level (slot 2). Slots 3-9 are not used. Aggregated filter (slot 0) is set to info level and up to this level message from that particular source will be buffered.

```
<table>
<thead>
<tr>
<th>slot 0</th>
<th>slot 1</th>
<th>slot 2</th>
<th>slot 3</th>
<th>...</th>
<th>slot 9</th>
</tr>
</thead>
<tbody>
<tr>
<td>INF</td>
<td>ERR</td>
<td>INF</td>
<td>OFF</td>
<td>...</td>
<td>OFF</td>
</tr>
</tbody>
</table>
```

Custom Frontend

Custom frontend is enabled using CONFIG_LOG_FRONTEND. Logs are directed to functions declared in include/zephyr/logging/log_frontend.h. If option CONFIG_LOG_FRONTEND_ONLY is enabled then log message is not created and no backend is handled. Otherwise, custom frontend can coexist with backends.

Logging strings

String arguments are handled by Cbprintf Packaging. See Limitations and recommendations for limitations and recommendations.

Multi-domain support

More complex systems can consist of multiple domains where each domain is an independent binary. Examples of domains are a core in a multicore SoC or one of the binaries (Secure or Nonsecure) on an ARM TrustZone core.

Tracing and debugging on a multi-domain system is more complex and requires an efficient logging system. Two approaches can be used to structure this logging system:

- Log inside each domain independently. This option is not always possible as it requires that each domain has an available backend (for example, UART). This approach can also be troublesome to use and not scalable, as logs are presented on independent outputs.
- Use a multi-domain logging system where log messages from each domain end up in one root domain, where they are processed exactly as in a single domain case. In this approach, log messages are passed between domains using a connection between domains created from the backend on one side and linked to the other.

The Log link is an interface introduced in this multi-domain approach. The Log link is responsible for receiving any log message from another domain, creating a copy, and putting that local log message copy (including remote data) into the message queue. This specific log link implementation
matches the complementary backend implementation to allow log messages exchange and logger control like configuring filtering, getting log source names, and so on.

There are three types of domains in a multi-domain system:

- The end domain has the logging core implementation and a cross-domain backend. It can also have other backends in parallel.
- The relay domain has one or more links to other domains but does not have backends that output logs to the user. It has a cross-domain backend either to another relay or to the root domain.
- The root domain has one or multiple links and a backend that outputs logs to the user.

See the following image for an example of a multi-domain setup:

![Fig. 4.1: Multi-domain example](image)

In this architecture, a link can handle multiple domains. For example, let's consider an SoC with two ARM Cortex-M33 cores with TrustZone: cores A and B (see Fig. 4.1). There are four domains in the system, as each core has both a Secure and a Nonsecure domain. If core A nonsecure (A_NS) is the root domain, it has two links: one to core A secure (A_NS-A_S) and one to core B nonsecure (A_NS-B_NS). B_NS domain has one link, to core B secure B_NS-B_S), and a backend to A_NS.

Since in all instances there is a standard logging subsystem, it is always possible to have multiple backends and simultaneously output messages to them. An example of this is shown on Fig. 4.1 as a dotted UART backend on the B_NS domain.

**Domain ID** The source of each log message can be identified by the following fields in the header: source_id and domain_id.

The value assigned to the domain_id is relative. Whenever a domain creates a log message, it sets its domain_id to 0. When a message crosses the domain, domain_id changes as it is increased by the link offset. The link offset is assigned during the initialization, where the logger core is iterating over all the registered links and assigned offsets.

The first link has the offset set to 1. The following offset equals the previous link offset plus the number of domains in the previous link.

The following example is shown on Fig. 4.2, where the assigned domain_ids are shown for each domain:

Let's consider a log message created on the B_S domain:
1. Initially, it has its `domain_id` set to 0.
2. When the `B_NS-B_S` link receives the message, it increases the `domain_id` to 1 by adding the `B_NS-B_S` offset.
3. The message is passed to `A_NS`.
4. When the `A_NS-B_NS` link receives the message, it adds the offset (2) to the `domain_id`. The message ends up with the `domain_id` set to 3, which uniquely identifies the message originator.

**Cross-domain log message**  In most cases, the address space of each domain is unique, and one domain cannot access directly the data in another domain. For this reason, the backend can partially process the message before it is passed to another domain. Partial processing can include converting a string package to a **fully self-contained** version (copying read-only strings to the package body).

Each domain can have a different timestamp source in terms of frequency and offset. Logging does not perform any timestamp conversion.

**Runtime filtering**  In the single-domain case, each log source has a dedicated variable with runtime filtering for each backend in the system. In the multi-domain case, the originator of the log message is not aware of the number of backends in the root domain.

As such, to filter logs in multiple domains, each source requires a runtime filtering setting in each domain on the way to the root domain. As the number of sources in other domains is not known during the compilation, the runtime filtering of remote sources must use dynamically allocated memory (one word per source). When a backend in the root domain changes the filtering of the module from a remote domain, the local filter is updated. After the update, the aggregated filter (the maximum from all the local backends) is checked and, if changed, the remote domain is informed about this change. With this approach, the runtime filtering works identically in both multi-domain and single-domain scenarios.

**Message ordering**  Logging does not provide any mechanism for synchronizing timestamps across multiple domains:

- If domains have different timestamp sources, messages will be processed in the order of arrival to the buffer in the root domain.
• If domains have the same timestamp source or if there is an out-of-bound mechanism that recalculates timestamps, there are 2 options:
  – Messages are processed as they arrive in the buffer in the root domain. Messages are unordered but they can be sorted by the host as the timestamp indicates the time of the message generation.
  – Links have dedicated buffers. During processing, the head of each buffer is checked and the oldest message is processed first.

With this approach, it is possible to maintain the order of the messages at the cost of a sub-optimal memory utilization (since the buffer is not shared) and increased processing latency (see `CONFIG_LOG_PROCESSING_LATENCY_US`).

Logging backends

Logging backends are registered using `LOG_BACKEND_DEFINE`. The macro creates an instance in the dedicated memory section. Backends can be dynamically enabled (`log_backend_enable()`) and disabled. When `Run-time filtering` is enabled, `log_filter_set()` can be used to dynamically change filtering of a module logs for given backend. Module is identified by source ID and domain ID. Source ID can be retrieved if source name is known by iterating through all registered sources.

Logging supports up to 9 concurrent backends. Log message is passed to the each backend in processing phase. Additionally, backend is notified when logging enter panic mode with `log_backend_panic()`. On that call backend should switch to synchronous, interrupt-less operation or shut down itself if that is not supported. Occasionally, logging may inform backend about number of dropped messages with `log_backend_dropped()`. Message processing API is version specific.

`log_backend_msg2_process()` is used for processing message. It is common for standard and hexdump messages because log message hold string with arguments and data. It is also common for deferred and immediate logging.

Message formatting

Logging provides set of function that can be used by the backend to format a message. Helper functions are available in `include/zephyr/logging/log_output.h`.

Example message formatted using `log_output_msg2_process()`.

```
[00:00:00.000,274] <info> sample_instance.inst1: logging message
```

Dictionary-based Logging

Dictionary-based logging, instead of human readable texts, outputs the log messages in binary format. This binary format encodes arguments to formatted strings in their native storage formats which can be more compact than their text equivalents. For statically defined strings (including the format strings and any string arguments), references to the ELF file are encoded instead of the whole strings. A dictionary created at build time contains the mappings between these references and the actual strings. This allows the offline parser to obtain the strings from the dictionary to parse the log messages. This binary format allows a more compact representation of log messages in certain scenarios. However, this requires the use of an offline parser and is not as intuitive to use as text-based log messages.

Note that `long double` is not supported by Python's `struct` module. Therefore, log messages with `long double` will not display the correct values.

Configuration

Here are kconfig options related to dictionary-based logging:

- `CONFIG_LOG_DICTIONARY_SUPPORT` enables dictionary-based logging support. This should be selected by the backends which require it.
• The UART backend can be used for dictionary-based logging. These are additional config for the UART backend:
  – CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX tells the UART backend to output hexadecimal characters for dictionary based logging. This is useful when the log data needs to be captured manually via terminals and consoles.
  – CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_BIN tells the UART backend to output binary data.

Usage When dictionary-based logging is enabled via enabling related logging backends, a JSON database file, named log_dictionary.json, will be created in the build directory. This database file contains information for the parser to correctly parse the log data. Note that this database file only works with the same build, and cannot be used for any other builds.

To use the log parser:

```
./scripts/logging/dictionary/log_parser.py <build dir>/log_dictionary.json <log data file>
```

The parser takes two required arguments, where the first one is the full path to the JSON database file, and the second part is the file containing log data. Add an optional argument --hex to the end if the log data file contains hexadecimal characters (e.g. when CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX=y). This tells the parser to convert the hexadecimal characters to binary before parsing.

Please refer to logging_dictionary_sample on how to use the log parser.

4.7.6 Recommendations

The are following recommendations:

• Enable CONFIG_LOG_SPEED to slightly speed up deferred logging at the cost of slight increase in memory footprint.

• Compiler with C11 _Generic keyword support is recommended. Logging performance is significantly degraded without it. See Cprintf Packaging.

• It is recommended to cast pointer to const char * when it is used with %s format specifier and it points to a constant string.

• It is recommended to cast pointer to char * when it is used with %s format specifier and it points to a transient string.

• It is recommended to cast character pointer to non character pointer (e.g., void *) when it is used with %p format specifier.

```c
LOG_WRN("%s", str);
LOG_WRN("%p", (void *)str);
```

4.7.7 Benchmark

Benchmark numbers from tests/subsys/logging/log_benchmark performed on qemu_x86. It is a rough comparison to give a general overview.
### Benchmark details

#### 4.7.8 Stack usage

When logging is enabled it impacts stack usage of the context that uses logging API. If stack is optimized it may lead to stack overflow. Stack usage depends on mode and optimization. It also significantly varies between platforms. In general, when CONFIG_LOG_MODE_DEFERRED is used stack usage is smaller since logging is limited to creating and storing log message. When CONFIG_LOG_MODE_IMMEDIATE is used then log message is processed by the backend which includes string formatting. In case of that mode, stack usage will depend on which backends are used.

The `tests/subsys/logging/log_stack` test is used to characterize stack usage depending on mode, optimization and platform used. Test is using only the default backend.

Some of the platforms characterization for log message with two integer arguments listed below:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Deferred</th>
<th>Deferred (no optimization)</th>
<th>Immediate</th>
<th>Immediate (no optimization)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARM Cortex-M3</td>
<td>40</td>
<td>152</td>
<td>412</td>
<td>783</td>
</tr>
<tr>
<td>x86</td>
<td>12</td>
<td>224</td>
<td>388</td>
<td>796</td>

#### 4.7.9 API Reference

**Logger API**

```c
#include <log_api.h>

#define LOG_ERR(...) 
        /* Writes an ERROR level message to the log. */ 
        /* It’s meant to report severe errors, such as those from which it’s not possible to recover. */
```

---

3 CONFIG_LOG_SPEED enabled.
4 Number of log messages with various number of arguments that fits in 2048 bytes dedicated for logging.
5 Logging subsystem memory footprint in `tests/subsys/logging/log_benchmark` where filtering and formatting features are not used.
6 Logging subsystem memory footprint in `samples/subsys/logging/logger`.
7 Average size of a log message (excluding string) with 2 arguments on Cortex M3
Parameters

• . . . – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_WRN(...)

Writes a WARNING level message to the log.
It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters

• . . . – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INF(...)

Writes an INFO level message to the log.
It's meant to write generic user oriented messages.

Parameters

• . . . – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_DBG(...)

Writes a DEBUG level message to the log.
It's meant to write developer oriented information.

Parameters

• . . . – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_PRINTK(...)

Unconditionally print raw log message.
The result is same as if printk was used but it goes through logging infrastructure thus utilizes logging mode, e.g. deferred mode.

Parameters

• . . . – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_RAW(...)

Unconditionally print raw log message.
Provided string is printed as is without appending any characters (e.g., color or newline).

Parameters

• . . . – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_ERR(_log_inst, ...)

Writes an ERROR level message associated with the instance to the log.
Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to report severe errors, such as those from which it's not possible to recover.

Parameters

• _log_inst – Pointer to the log structure associated with the instance.

• . . . – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.
LOG_INST_WRN(_log_inst, ...)  
Writes a WARNING level message associated with the instance to the log.
Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters
• _log_inst – Pointer to the log structure associated with the instance.
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_INF(_log_inst, ...)  
Writes an INFO level message associated with the instance to the log.
Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to write generic user oriented messages.

Parameters
• _log_inst – Pointer to the log structure associated with the instance.
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_DBG(_log_inst, ...)  
Writes a DEBUG level message associated with the instance to the log.
Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to write developer oriented information.

Parameters
• _log_inst – Pointer to the log structure associated with the instance.
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_HEXDump_ERR(_data, _length, _str)  
Writes an ERROR level hexdump message to the log.
It's meant to report severe errors, such as those from which it's not possible to recover.

Parameters
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_HEXDump_WRN(_data, _length, _str)  
Writes a WARNING level message to the log.
It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.
LOG_HEXDUMP_INF(_data, _length, _str)
  Writes an INFO level message to the log.
  It’s meant to write generic user oriented messages.

  Parameters
  • _data – Pointer to the data to be logged.
  • _length – Length of data (in bytes).
  • _str – Persistent, raw string.

LOG_HEXDUMP_DBG(_data, _length, _str)
  Writes a DEBUG level message to the log.
  It’s meant to write developer oriented information.

  Parameters
  • _data – Pointer to the data to be logged.
  • _length – Length of data (in bytes).
  • _str – Persistent, raw string.

LOG_INST_HEXDUMP_ERR(_log_inst, _data, _length, _str)
  Writes an ERROR hexdump message associated with the instance to the log.
  Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>_<instance_name>). It’s meant to report severe errors, such as those from which it’s not possible to recover.

  Parameters
  • _log_inst – Pointer to the log structure associated with the instance.
  • _data – Pointer to the data to be logged.
  • _length – Length of data (in bytes).
  • _str – Persistent, raw string.

LOG_INST_HEXDUMP_WRN(_log_inst, _data, _length, _str)
  Writes a WARNING level hexdump message associated with the instance to the log.
  It’s meant to register messages related to unusual situations that are not necessarily errors.

  Parameters
  • _log_inst – Pointer to the log structure associated with the instance.
  • _data – Pointer to the data to be logged.
  • _length – Length of data (in bytes).
  • _str – Persistent, raw string.

LOG_INST_HEXDUMP_INF(_log_inst, _data, _length, _str)
  Writes an INFO level hexdump message associated with the instance to the log.
  It’s meant to write generic user oriented messages.

  Parameters
  • _log_inst – Pointer to the log structure associated with the instance.
  • _data – Pointer to the data to be logged.
  • _length – Length of data (in bytes).
  • _str – Persistent, raw string.
LOG_INST.HEXDUMP_DBG(_log_inst, _data, _length, _str)

Writes a DEBUG level hexdump message associated with the instance to the log.

It's meant to write developer oriented information.

**Parameters**

- `_log_inst` – Pointer to the log structure associated with the instance.
- `_data` – Pointer to the data to be logged.
- `_length` – Length of data (in bytes).
- `_str` – Persistent, raw string.

LOG_MODULE_REGISTER(...)  
Create module-specific state and register the module with Logger.

This macro normally must be used after including `<zephyr/logging/log.h>` to complete the initialization of the module.

Module registration can be skipped in two cases:

- The module consists of more than one file, and another file invokes this macro.  
  *(LOG_MODULE_DECLARE() should be used instead in all of the module's other files.)*  
- Instance logging is used and there is no need to create module entry.  In that case  
  LOG_LEVEL_SET() should be used to set log level used within the file.

Macro accepts one or two parameters:

- module name
- optional log level. If not provided then default log level is used in the file.

Example usage:

- `LOG_MODULE_REGISTER(foo, CONFIG_FOO_LOG_LEVEL)`
- `LOG_MODULE_REGISTER(foo)`  

**See also:**

*LOG_MODULE_DECLARE*

---

**Note:** The module's state is defined, and the module is registered, only if LOG_LEVEL for  
the current source file is non-zero or it is not defined and CONFIG_LOG_DEFAULT_LEVEL is non-zero. In other cases, this macro has no effect.

---

LOG_MODULE_DECLARE(...)  
Macro for declaring a log module (not registering it).

Modules which are split up over multiple files must have exactly one file use  
LOG_MODULE_REGISTER() to create module-specific state and register the module with the  
logger core.

The other files in the module should use this macro instead to declare that same state. (Othe-  
wise, LOG_INF() etc. will not be able to refer to module-specific state variables.)

Macro accepts one or two parameters:

- module name
- optional log level. If not provided then default log level is used in the file.

Example usage:
• `LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL)`
• `LOG_MODULE_DECLARE(foo)`

**See also:**

`LOG_MODULE_REGISTER`

---

**Note:** The module's state is declared only if LOG_LEVEL for the current source file is non-zero or it is not defined and CONFIG_LOG_DEFAULT_LEVEL is non-zero. In other cases, this macro has no effect.

`LOG_LEVEL_SET(level)`

Macro for setting log level in the file or function where instance logging API is used.

**Parameters**

- `level` – Level used in file or in function.

**Logger control**

`group log_ctrl`

Logger control API.

**Defines**

- `LOG_CORE_INIT()`
- `LOG_INIT()`
- `LOG_PANIC()`
- `LOG_PROCESS()`

**Typedefs**

typedef `log_timestamp_t (*log_timestamp_get_t)(void)`

**Functions**

- `void log_core_init(void)`
  Function system initialization of the logger.
  Function is called during start up to allow logging before user can explicitly initialize the logger.
- `void log_init(void)`
  Function for user initialization of the logger.
void log_thread_set(k_tid_t process_tid)
Function for providing thread which is processing logs.
See CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD.

Note: Function has asserts and has no effect when CONFIG_LOG_PROCESS_THREAD is set.

Parameters
• process_tid – Process thread id. Used to wake up the thread.

int log_set_timestamp_func(log_timestamp_get_t timestamp_getter, uint32_t freq)
Function for providing timestamp function.

Parameters
• timestamp_getter – Timestamp function.
• freq – Timestamping frequency.

Returns
0 on success or error.

void log_panic(void)
Switch the logger subsystem to the panic mode.

Returns immediately if the logger is already in the panic mode.

On panic the logger subsystem informs all backends about panic mode. Backends must switch to blocking mode or halt. All pending logs are flushed after switching to panic mode. In panic mode, all log messages must be processed in the context of the call.

bool log_process(void)
Process one pending log message.

Return values
• true – There is more messages pending to be processed.
• false – No messages pending.

uint32_t log_buffered_cnt(void)
Return number of buffered log messages.

Returns
Number of currently buffered log messages.

uint32_t log_src_cnt_get(uint32_t domain_id)
Get number of independent logger sources (modules and instances)

Parameters
• domain_id – Domain ID.

Returns
Number of sources.

const char *log_source_name_get(uint32_t domain_id, uint32_t source_id)
Get name of the source (module or instance).

Parameters
• domain_id – Domain ID.
• source_id – Source ID.
Returns
Source name or NULL if invalid arguments.

static inline uint8_t log_domains_count(void)
Return number of domains present in the system.
There will be at least one local domain.

Returns
Number of domains.

const char *log_domain_name_get(uint32_t domain_id)
Get name of the domain.

Parameters
• domain_id – Domain ID.

Returns
Domain name.

int log_source_id_get(const char *name)
Function for finding source ID based on source name.

Parameters
• name – Source name

Returns
Source ID or negative number when source ID is not found.

uint32_t log_filter_get(struct log_backend const *const backend, uint32_t domain_id, int16_t source_id, bool runtime)
Get source filter for the provided backend.

Parameters
• backend – Backend instance.
• domain_id – ID of the domain.
• source_id – Source (module or instance) ID.
• runtime – True for runtime filter or false for compiled in.

Returns
Severity level.

uint32_t log_filter_set(struct log_backend const *const backend, uint32_t domain_id, int16_t source_id, uint32_t level)
Set filter on given source for the provided backend.

Parameters
• backend – Backend instance. NULL for all backends.
• domain_id – ID of the domain.
• source_id – Source (module or instance) ID.
• level – Severity level.

Returns
Actual level set which may be limited by compiled level. If filter was set for all backends then maximal level that was set is returned.

void log_backend_enable(struct log_backend const *const backend, void *ctx, uint32_t level)
Enable backend with initial maximum filtering level.

Parameters
• `backend` – Backend instance.
• `ctx` – User context.
• `level` – Severity level.

```c
void log_backend_disable(const log_backend *const backend)
```
Disable backend.

**Parameters**

• `backend` – Backend instance.

```c
const struct log_backend *
log_backend_get_by_name(const char *backend_name)
```
Get backend by name.

**Parameters**

• `backend_name` – [in] Name of the backend as defined by the LOG_BACKEND_DEFINE.

**Return values**

Pointer – to the backend instance if found, NULL if backend is not found.

```c
const struct log_backend *
log_format_set_all_active_backends(size_t log_type)
```
Sets logging format for all active backends.

**Parameters**

• `log_type` – Log format.

**Return values**

Pointer – to the last backend that failed, NULL for success.

```c
uint32_t log_get_strdup_pool_current_utilization(void)
```
Get current number of allocated buffers for string duplicates.

```c
uint32_t log_get_strdup_pool_utilization(void)
```
Get maximal number of simultaneously allocated buffers for string duplicates.

Value can be used to determine pool size.

```c
uint32_t log_get_strdup_longest_string(void)
```
Get length of the longest string duplicated.

Value can be used to determine buffer size in the string duplicates pool.

```c
static inline bool log_data_pending(void)
```
Check if there is pending data to be processed by the logging subsystem.

Function can be used to determine if all logs have been flushed. Function returns false when deferred mode is not enabled.

**Return values**

• `true` – There is pending data.
• `false` – No pending data to process.

```c
int log_set_tag(const char *tag)
```
Configure tag used to prefix each message.

**Parameters**

• `tag` – Tag.

**Return values**

• `0` – on successful operation.
• `-ENOTSUP` – if feature is disabled.
-ENOMEM – if string is longer than the buffer capacity. Tag will be trimmed.

```c
int log_mem_get_usage(uint32_t *buf_size, uint32_t *usage)
Get current memory usage.
```

**Parameters**

- `buf_size` – [out] Capacity of the buffer used for storing log messages.
- `usage` – [out] Number of bytes currently containing pending log messages.

**Return values**

- EINVAL – if logging mode does not use the buffer.
- 0 – successfully collected usage data.

```c
int log_mem_get_max_usage(uint32_t *max)
Get maximum memory usage.
```

Requires CONFIG_LOG_MEM_UTILIZATION option.

**Parameters**

- `max` – [out] Maximum number of bytes used for pending log messages.

**Return values**

- EINVAL – if logging mode does not use the buffer.
- ENOTSUP – if instrumentation is not enabled. not been enabled.
- 0 – successfully collected usage data.

### Log message

**group log_msg**

Log message API.

**Defines**

LOG_MSG2_GENERIC_HDR

**Functions**

```c
static inline uint32_t log_msg_get_total_wlen(const struct log_msg_desc desc)
Get total length (in 32 bit words) of a log message.
```

**Parameters**

- `desc` – Log message descriptor.

**Returns**

Length.

```c
static inline uint32_t log_msg_generic_get_wlen(const union mpsc_pbuf_generic *item)
Get length of the log item.
```

**Parameters**

- `item` – Item.

**Returns**

Length in 32 bit words.
static inline uint8_t log_msg_get_domain(struct log_msg *msg)
    Get log message domain ID.

    **Parameters**
    
    • msg – Log message.

    **Returns**
    Domain ID

static inline uint8_t log_msg_get_level(struct log_msg *msg)
    Get log message level.

    **Parameters**
    
    • msg – Log message.

    **Returns**
    Log level.

static inline const void *log_msg_get_source(struct log_msg *msg)
    Get message source data.

    **Parameters**
    
    • msg – Log message.

    **Returns**
    Pointer to the source data.

static inline log_timestamp_t log_msg_get_timestamp(struct log_msg *msg)
    Get timestamp.

    **Parameters**
    
    • msg – Log message.

    **Returns**
    Timestamp.

static inline uint8_t *log_msg_get_data(struct log_msg *msg, size_t *len)
    Get data buffer.

    **Parameters**
    
    • msg – log message.
    • len – location where data length is written.

    **Returns**
    pointer to the data buffer.

static inline uint8_t *log_msg_get_package(struct log_msg *msg, size_t *len)
    Get string package.

    **Parameters**
    
    • msg – log message.
    • len – location where string package length is written.

    **Returns**
    pointer to the package.

struct log_msg_desc
# include <log_msg.h>

union log_msg_source
# include <log_msg.h>
Public Members

const struct log_source_const_data *fixed

struct log_source_dynamic_data *dynamic

void *raw

struct log_msg_hdr
#include <log_msg.h>

struct log_msg
#include <log_msg.h>

struct log_msg_generic_hdr
#include <log_msg.h>

union log_msg_generic
#include <log_msg.h>

Public Members

union mpsc_pbuf_generic buf

struct log_msg_generic_hdr generic

struct log_msg log

Logger backend interface

group log_backend
Logger backend interface.

Defines

LOG_BACKEND_DEFINE(_name, _api, _autostart, ...)
Macro for creating a logger backend instance.

Parameters

• _name – Name of the backend instance.
• _api – Logger backend API.
• _autostart – If true backend is initialized and activated together with the logger subsystem.
• ... – Optional context.

4.7. Logging
Enums

enum log_backend_evt
   Backend events.
   Values:

   enumerator LOG_BACKEND_EVT_PROCESS_THREAD_DONE
      Event when process thread finishes processing.
      This event is emitted when the process thread finishes processing pending log messages.

      Note: This is not emitted when there are no pending log messages being processed.

      Note: Deferred mode only.

   enumerator LOG_BACKEND_EVT_MAX
      Maximum number of backend events.

Functions

static inline void log_backend_init(const struct log_backend *const backend)
   Initialize or initiate the logging backend.
   If backend initialization takes longer time it could block logging thread if backend is autostarted. That is because all backends are initialized in the context of the logging thread. In that case, backend shall provide function for polling for readiness (log_backend_is_ready).

   Parameters
   • backend – [in] Pointer to the backend instance.

static inline int log_backend_is_ready(const struct log_backend *const backend)
   Poll for backend readiness.
   If backend is ready immediately after initialization then backend may not provide this function.

   Parameters
   • backend – [in] Pointer to the backend instance.

   Return values
   • 0 – if backend is ready.
   • -EBUSY – if backend is not yet ready.

static inline void log_backend_msg_process(const struct log_backend *const backend,
                                           union log_msg_generic *msg)
   Process message.
   Function is used in deferred and immediate mode. On return, message content is processed by the backend and memory can be freed.

   Parameters
   • backend – [in] Pointer to the backend instance.
   • msg – [in] Pointer to message with log entry.
static inline void log_backend_dropped(const struct log_backend *const backend, uint32_t cnt)
    Notify backend about dropped log messages.
    Function is optional.

    Parameters
    • backend – [in] Pointer to the backend instance.
    • cnt – [in] Number of dropped logs since last notification.

static inline void log_backend_panic(const struct log_backend *const backend)
    Reconfigure backend to panic mode.

    Parameters
    • backend – [in] Pointer to the backend instance.

static inline void log_backend_id_set(const struct log_backend *const backend, uint8_t id)
    Set backend id.

    Note: It is used internally by the logger.

    Parameters
    • backend – Pointer to the backend instance.
    • id – ID.

static inline uint8_t log_backend_id_get(const struct log_backend *const backend)
    Get backend id.

    Note: It is used internally by the logger.

    Parameters
    • backend – [in] Pointer to the backend instance.

static inline const struct log_backend *log_backend_get(uint32_t idx)
    Get backend.

    Parameters
    • idx – [in] Pointer to the backend instance.

    Returns
    Id.

static inline int log_backend_count_get(void)
    Get number of backends.

    Returns
    Number of backends.

static inline void log_backend_activate(const struct log_backend *const backend, void *ctx)
    Activate backend.

    Parameters
    • backend – [in] Pointer to the backend instance.
• ctx – [in] User context.

static inline void log_backend_deactivate(const struct log_backend *const backend)
    Deactivate backend.

Parameters
• backend – [in] Pointer to the backend instance.

static inline bool log_backend_is_active(const struct log_backend *const backend)
    Check state of the backend.

Parameters
• backend – [in] Pointer to the backend instance.

Returns
True if backend is active, false otherwise.

static inline int log_backend_format_set(const struct log_backend *backend, uint32_t log_type)
    Set logging format.

Parameters
• backend – Pointer to the backend instance.
• log_type – Log format.

Return values
• -ENOTSUP – If the backend does not support changing format types.
• -EINVAL – If the input is invalid.
• 0 – for success.

static inline void log_backend_notify(const struct log_backend *const backend, enum log_backend_evt event, union log_backend_evt_arg *arg)
    Notify a backend of an event.

Parameters
• backend – Pointer to the backend instance.
• event – Event to be notified.
• arg – Pointer to the argument(s).

union log_backend_evt_arg
    #include <log_backend.h> Argument(s) for backend events.

Public Members

void *raw
    Unspecified argument(s).

struct log_backend_api
    #include <log_backend.h> Logger backend API.

struct log_backend_control_block
    #include <log_backend.h> Logger backend control block.

struct log_backend
    #include <log_backend.h> Logger backend structure.
Logger output formatting

`group log_output`

Log output API.

**Unnamed Group**

`void log_custom_output_msg_process(const struct log_output *log_output, struct log_msg *msg, uint32_t flags)`

Custom logging output formatting.

Process log messages from an external output function set with `log_custom_output_msg_set`.

Function is using provided context with the buffer and output function to process formatted string and output the data.

**Parameters**

- `log_output` – Pointer to the log output instance.
- `msg` – Log message.
- `flags` – Optional flags.

`void log_custom_output_msg_set(log_format_func_t format)`

Set the formatting log function that will be applied with LOG_OUTPUT_CUSTOM.

**Parameters**

- `format` – Pointer to the external formatter function

**Defines**

LOG_OUTPUT_TEXT

Supported backend logging format types for use with `log_format_set()` API to switch log format at runtime.

LOG_OUTPUT_SYST

LOG_OUTPUT_DICT

LOG_OUTPUT_CUSTOM

LOG_OUTPUT_DEFINE(_name, _func, _buf, _size)

Create `log_output` instance.

**Parameters**

- `_name` – Instance name.
- `_func` – Function for processing output data.
- `_buf` – Pointer to the output buffer.
- `_size` – Size of the output buffer.
**Typedefs**

```c
typedef int (*log_output_func_t)(uint8_t *buf, size_t size, void *ctx)
Prototype of the function processing output data.
```

**Note:** If the log output function cannot process all of the data, it is its responsibility to mark them as dropped or discarded by returning the corresponding number of bytes dropped or discarded to the caller.

- **Param buf**
  The buffer data.
- **Param size**
  The buffer size.
- **Param ctx**
  User context.
- **Return**
  Number of bytes processed, dropped or discarded.

```c
typedef void (*log_format_func_t)(const struct log_output *output, struct log_msg *msg, uint32_t flags)
Typedef of the function pointer table “format_table”.
```

- **Param output**
  Pointer to `log_output` struct.
- **Param msg**
  Pointer to `log_msg` struct.
- **Param flags**
  Flags used for text formatting options.
- **Return**
  Function pointer based on Kconfigs defined for backends.

**Functions**

```c
log_format_func_t log_format_func_t_get(uint32_t log_type)
Declaration of the get routine for function pointer table format_table.
```

```c
void log_output_msg_process(const struct log_output *log_output, struct log_msg *msg, uint32_t flags)
Process log messages v2 to readable strings.
Function is using provided context with the buffer and output function to process formatted string and output the data.
```

- **Parameters**
  - `log_output` – Pointer to the log output instance.
  - `msg` – Log message.
  - `flags` – Optional flags. See Log output formatting flags.
void log_output_process(const struct log_output *log_output, log_timestamp_t timestamp, const char *domain, const char *source, uint8_t level, const uint8_t *package, const uint8_t *data, size_t data_len, uint32_t flags)

Process input data to a readable string.

Parameters

- `log_output` – Pointer to the log output instance.
- `timestamp` – Timestamp.
- `domain` – Domain name string. Can be NULL.
- `source` – Source name string. Can be NULL.
- `level` – Criticality level.
- `package` – Cbprintf package with a logging message string.
- `data` – Data passed to hexdump API. Can be NULL.
- `data_len` – Data length.
- `flags` – Formatting flags. See Log output formatting flags.

void log_output_msg_syst_process(const struct log_output *log_output, struct log_msg *msg, uint32_t flags)

Process log messages v2 to SYS-T format.

Function is using provided context with the buffer and output function to process formatted string and output the data in sys-t log output format.

Parameters

- `log_output` – Pointer to the log output instance.
- `msg` – Log message.
- `flags` – Optional flags. See Log output formatting flags.

void log_output_dropped_process(const struct log_output *output, uint32_t cnt)

Process dropped messages indication.

Function prints error message indicating lost log messages.

Parameters

- `output` – Pointer to the log output instance.
- `cnt` – Number of dropped messages.

void log_output_flush(const struct log_output *output)

Flush output buffer.

Parameters

- `output` – Pointer to the log output instance.

static inline void log_output_ctx_set(const struct log_output *output, void *ctx)

Function for setting user context passed to the output function.

Parameters

- `output` – Pointer to the log output instance.
- `ctx` – User context.

static inline void log_output_hostname_set(const struct log_output *output, const char *hostname)

Function for setting hostname of this device.
Parameters

- output – Pointer to the log output instance.
- hostname – Hostname of this device

void log_output_timestamp_freq_set(uint32_t freq)
Set timestamp frequency.

Parameters

- freq – Frequency in Hz.

uint64_t log_output_timestamp_to_us(uint32_t timestamp)
Convert timestamp of the message to us.

Parameters

- timestamp – Message timestamp

Returns

Timestamp value in us.

struct log_output_control_block
#include <log_output.h>

struct log_output
#include <log_output.h> Log_output instance structure.

4.8 Tracing

4.8.1 Overview

The tracing feature provides hooks that permits you to collect data from your application and allows tools running on a host to visualize the inner-working of the kernel and various subsystems.

Every system has application-specific events to trace out. Historically, that has implied:

1. Determining the application-specific payload,
2. Choosing suitable serialization-format,
3. Writing the on-target serialization code,
4. Deciding on and writing the I/O transport mechanics,
5. Writing the PC-side deserializer/parser,
6. Writing custom ad-hoc tools for filtering and presentation.

An application can use one of the existing formats or define a custom format by overriding the macros declared in include/zephyr/tracing/tracing.h.

Different formats, transports and host tools are available and supported in Zephyr.

In fact, I/O varies greatly from system to system. Therefore, it is instructive to create a taxonomy for I/O types when we must ensure the interface between payload/format (Top Layer) and the transport mechanics (bottom Layer) is generic and efficient enough to model these. See the I/O taxonomy section below.
4.8.2 Serialization Formats

Common Trace Format (CTF) Support

Common Trace Format, CTF, is an open format and language to describe trace formats. This enables tool reuse, of which line-textual (babeltrace) and graphical (TraceCompass) variants already exist.

CTF should look familiar to C programmers but adds stronger typing. See CTF - A Flexible, High-performance Binary Trace Format.

CTF allows us to formally describe application specific payload and the serialization format, which enables common infrastructure for host tools and parsers and tools for filtering and presentation.

A Generic Interface  In CTF, an event is serialized to a packet containing one or more fields. As seen from I/O taxonomy section below, a bottom layer may:

- perform actions at transaction-start (e.g. mutex-lock),
- process each field in some way (e.g. sync-push emit, concat, enqueue to thread-bound FIFO),
- perform actions at transaction-stop (e.g. mutex-release, emit of concat buffer).

CTF Top-Layer Example The CTF_EVENT macro will serialize each argument to a field:

```c
/* Example for illustration */
static inline void ctf_top_foo(uint32_t thread_id, ctf_bounded_string_t name)
{
    CTF_EVENT(
        CTF_LITERAL(uint8_t, 42),
        thread_id,
        name,
        "hello, I was emitted from function: ",
        __func__ /* __func__ is standard since C99 */
    );
}
```

How to serialize and emit fields as well as handling alignment, can be done internally and statically at compile-time in the bottom-layer.

The CTF top layer is enabled using the configuration option CONFIG_TRACING_CTF and can be used with the different transport backends both in synchronous and asynchronous modes.

SEGGER SystemView Support

Zephyr provides built-in support for SEGGER SystemView that can be enabled in any application for platforms that have the required hardware support.

The payload and format used with SystemView is custom to the application and relies on RTT as a transport. Newer versions of SystemView support other transports, for example UART or using snapshot mode (both still not supported in Zephyr).

To enable tracing support with SEGGER SystemView add the configuration option CONFIG_SEGGER_SYSTEMVIEW to your project configuration file and set it to y. For example, this can be added to the synchronization_sample to visualize fast switching between threads. SystemView can also be used for post-mortem tracing, which can be enabled with CONFIG_SEGGER_SYSVIEW_POST_MORTEM_MODE. In this mode, a debugger can be attached after the system has crashed using west attach after which the latest data from the internal RAM buffer can be loaded into SystemView.
Recent versions of SEGGER SystemView come with an API translation table for Zephyr which is incomplete and does not match the current level of support available in Zephyr. To use the latest Zephyr API description table, copy the file available in the tree to your local configuration directory to override the builtin table:

```bash
# On Linux and MacOS
cp ZEPHYR_BASE/subsys/tracing/sysview/SYSVIEW_Zephyr.txt ~/.config/SEGGER/
```

User-Defined Tracing

This tracing format allows the user to define functions to perform any work desired when a task is switched in or out, when an interrupt is entered or exited, and when the cpu is idle.

Examples include:
- simple toggling of GPIO for external scope tracing while minimizing extra cpu load
- generating/outputting trace data in a non-standard or proprietary format that can not be supported by the other tracing systems

The following functions can be defined by the user:
- `void sys_trace_thread_create_user(struct k_thread *thread)`
- `void sys_trace_thread_abort_user(struct k_thread *thread)`
- `void sys_trace_thread_suspend_user(struct k_thread *thread)`
- `void sys_trace_thread_resume_user(struct k_thread *thread)`
- `void sys_trace_thread_name_set_user(struct k_thread *thread)`
- `void sys_trace_thread_switched_in_user(struct k_thread *thread)`
- `void sys_trace_thread_switched_out_user(struct k_thread *thread)`
- `void sys_trace_thread_info_user(struct k_thread *thread)`
- `void sys_trace_thread_sched_ready_user(struct k_thread *thread)`
- `void sys_trace_thread_pend_user(struct k_thread *thread)`
- `void sys_trace_thread_priority_set_user(struct k_thread *thread)`
k_thread *thread, int prio) - void sys_trace_isr_enter_user(int nested_interrupts) - void
sys_trace_isr_exit_user(int nested_interrupts) - void sys_trace_idle_user()

Enable this format with the CONFIG_TRACING_USER option.

4.8.3 Transport Backends

The following backends are currently supported:

- UART
- USB
- File (Using native posix port)
- RTT (With SystemView)
- RAM (buffer to be retrieved by a debugger)

4.8.4 Using Tracing

The sample samples/subsys/tracing demonstrates tracing with different formats and backends.

To get started, the simplest way is to use the CTF format with the native_posix port, build the sample as follows:

Using west:

```
w west build -b native_posix samples/subsys/tracing -- -DCONF_FILE=prj_native_posix_ctf.conf
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=native_posix -DCONF_FILE=prj_native_posix_ctf.conf
   samples/subsys/tracing

# Now run ninja on the generated build system:
ninja -Cbuild
```

You can then run the resulting binary with the option -trace-file to generate the tracing data:

```
mkdir data
cp $ZEPHYR_BASE/subsys/tracing/ctf/tsdl/metadata data/
cp $ZEPHYR_BASE/subsys/tracing/ctf/tsdl/metadata data/
./build/zephyr/zephyr.exe -trace-file=data/channel0_0
```

The resulting CTF output can be visualized using babeltrace or TraceCompass by pointing the tool to the data directory with the metadata and trace files.

Using RAM backend

For devices that do not have available I/O for tracing such as USB or UART but have enough RAM to collect trace data, the ram backend can be enabled with configuration CONFIG_TRACING_BACKEND_RAM. Adjust CONFIG_RAM_TRACING_BUFFER_SIZE to be able to record enough traces for your needs. Then thanks to a runtime debugger such as gdb this buffer can be fetched from the target to an host computer:

```
(gdb) dump binary memory data/channel0_0 <ram_tracing_start> <ram_tracing_end>
```

The resulting channel0_0 file have to be placed in a directory with the metadata file like the other backend.
4.8.5 Visualisation Tools

TraceCompass

TraceCompass is an open source tool that visualizes CTF events such as thread scheduling and interrupts, and is helpful to find unintended interactions and resource conflicts on complex systems. See also the presentation by Ericsson, Advanced Trouble-shooting Of Real-time Systems.

4.8.6 Future LTTng Inspiration

Currently, the top-layer provided here is quite simple and bare-bones, and needlessly copied from Zephyr’s Segger SystemView debug module.

For an OS like Zephyr, it would make sense to draw inspiration from Linux’s LTTng and change the top-layer to serialize to the same format. Doing this would enable direct reuse of TraceCompass’ canned analyses for Linux. Alternatively, LTTng-analyses in TraceCompass could be customized to Zephyr. It is ongoing work to enable TraceCompass visibility of Zephyr in a target-agnostic and open source way.

I/O Taxonomy

- Atomic Push/Produce/Write/Enqueue:
  - synchronous:
    means data-transmission has completed with the return of the call.
  - asynchronous:
    means data-transmission is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - buffered:
    means data-transmissions are copied and grouped together to form a larger ones. Usually for amortizing overhead (burst dequeue) or jitter-mitigation (steady dequeue).

Examples:

- sync unbuffered
  E.g. PIO via GPIOs having steady stream, no extra FIFO memory needed. Low jitter but may be less efficient (can’t amortize the overhead of writing).

- sync buffered
  E.g. fwrite() or enqueuing into FIFO. Blockingly burst the FIFO when its buffer-waterlevel exceeds threshold. Jitter due to bursts may lead to missed deadlines.

- async unbuffered
  E.g. DMA, or zero-copying in shared memory. Be careful of data hazards, race conditions, etc!

- async buffered
  E.g. enqueuing into FIFO.

- Atomic Pull/Consume/Read/Dequeue:
  - synchronous:
    means data-reception has completed with the return of the call.
  - asynchronous:
    means data-reception is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - buffered:
    means data is copied-in in larger chunks than request-size. Usually for amortizing wait-time.
Examples:

- **sync unbuffered**
  E.g. Blocking read-call, `fread()` or SPI-read, zero-copying in shared memory.

- **sync buffered**
  E.g. Blocking read-call with caching applied. Makes sense if read pattern exhibits
  spatial locality.

- **async unbuffered**
  E.g. zero-copying in shared memory. Be careful of data hazards, race conditions, etc!

- **async buffered**
  E.g. `aio_read()` or DMA.

Unfortunately, I/O may not be atomic and may, therefore, require locking. Locking may not be needed if
multiple independent channels are available.

- **The system has non-atomic write and one shared channel**
  E.g. UART. Locking required.
  
  ```
  lock(); emit(a); emit(b); emit(c); release();
  ```

- **The system has non-atomic write but many channels**
  E.g. Multi-UART. Lock-free if the bottom-layer maps each Zephyr thread+ISR to its own
  channel, thus alleviating races as each thread is sequentially consistent with itself.
  
  ```
  emit(a,thread_id); emit(b,thread_id); emit(c,thread_id);
  ```

- **The system has atomic write but one shared channel**
  E.g. native_posix or board with DMA. May or may not need locking.
  
  ```
  emit(a ## b ## c); /* Concat to buffer */
  lock(); emit(a); emit(b); emit(c); release(); /* No extra mem */
  ```

- **The system has atomic write and many channels**
  E.g. native_posix or board with multi-channel DMA. Lock-free.
  
  ```
  emit(a ## b ## c, thread_id);
  ```

### 4.8.7 Object tracking

The kernel can also maintain lists of objects that can be used to track their usage. Currently, the following
lists can be enabled:

```
struct k_timer * _track_list_k_timer;
struct k_mem_slab * _track_list_k_mem_slab;
struct k_sem * _track_list_k_sem;
struct k_mutex * _track_list_k_mutex;
struct k_stack * _track_list_k_stack;
struct k_msgq * _track_list_k_msgq;
struct k_mbox * _track_list_k_mbox;
struct k_pipe * _track_list_k_pipe;
struct k_queue * _track_list_k_queue;
```

Those global variables are the head of each list - they can be traversed with the help of macro
`SYS_PORT_TRACK_NEXT`. For instance, to traverse all initialized mutexes, one can write:

```
struct k_mutex * cur = _track_list_k_mutex;
while (cur != NULL) {
    /* Do something */
}
```

(continues on next page)
To enable object tracking, enable `CONFIG_TRACING_OBJECT_TRACKING`. Note that each list can be enabled or disabled via their tracing configuration. For example, to disable tracking of semaphores, one can disable `CONFIG_TRACING_SEMAPHORE`.

Object tracking is behind tracing configuration as it currently leverages tracing infrastructure to perform the tracking.

### 4.8.8 API

**Common**

**group subsys_tracing_apis**
Tracing APIs.

**Functions**

```c
void sys_trace_isr_enter(void)
Called when entering an ISR.

void sys_trace_isr_exit(void)
Called when exiting an ISR.

void sys_trace_isr_exit_to_scheduler(void)
Called when exiting an ISR and switching to scheduler.

void sys_trace_idle(void)
Called when the cpu enters the idle state.
```

**Threads**

**group subsys_tracing_apis_thread**
Thread Tracing APIs.

**Defines**

```c
sys_port_trace_k_thread_foreach_enter()
Called when entering a k_thread_foreach call.

sys_port_trace_k_thread_foreach_exit()
Called when exiting a k_thread_foreach call.

sys_port_trace_k_thread_foreach_unlocked_enter()
Called when entering a k_thread_foreach_unlocked.

sys_port_trace_k_thread_foreach_unlocked_exit()
Called when exiting a k_thread_foreach_unlocked.
```
sys_port_trace_k_thread_create(new_thread)
Trace creating a Thread.

Parameters
• new_thread – Thread object

sys_port_trace_k_thread_user_mode_enter()
Trace Thread entering user mode.

sys_port_trace_k_thread_join_enter(thread, timeout)
Called when entering a k_thread_join.

Parameters
• thread – Thread object
• timeout – Timeout period

sys_port_trace_k_thread_join_blocking(thread, timeout)
Called when k_thread_join blocks.

Parameters
• thread – Thread object
• timeout – Timeout period

sys_port_trace_k_thread_join_exit(thread, timeout, ret)
Called when exiting k_thread_join.

Parameters
• thread – Thread object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_thread_sleep_enter(timeout)
Called when entering k_thread_sleep.

Parameters
• timeout – Timeout period

sys_port_trace_k_thread_sleep_exit(timeout, ret)
Called when exiting k_thread_sleep.

Parameters
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_thread_msleep_enter(ms)
Called when entering k_thread_msleep.

Parameters
• ms – Duration in milliseconds

sys_port_trace_k_thread_msleep_exit(ms, ret)
Called when exiting k_thread_msleep.

Parameters
• ms – Duration in milliseconds
• ret – Return value
sys_port_trace_k_thread_usleep_enter(us)
    Called when entering k_thread_usleep.

    **Parameters**
    - us – Duration in microseconds

sys_port_trace_k_thread_usleep_exit(us, ret)
    Called when exiting k_thread_usleep.

    **Parameters**
    - us – Duration in microseconds
    - ret – Return value

sys_port_trace_k_thread_busy_wait_enter(usec_to_wait)
    Called when entering k_thread_busy_wait.

    **Parameters**
    - usec_to_wait – Duration in microseconds

sys_port_trace_k_thread_busy_wait_exit(usec_to_wait)
    Called when exiting k_thread_busy_wait.

    **Parameters**
    - usec_to_wait – Duration in microseconds

sys_port_trace_k_thread_yield()
    Called when a thread yields.

sys_port_trace_k_thread_wakeup(thread)
    Called when a thread wakes up.

    **Parameters**
    - thread – Thread object

sys_port_trace_k_thread_start(thread)
    Called when a thread is started.

    **Parameters**
    - thread – Thread object

sys_port_trace_k_thread_abort(thread)
    Called when a thread is being aborted.

    **Parameters**
    - thread – Thread object

sys_port_trace_k_thread_abort_enter(thread)
    Called when a thread enters the k_thread_abort routine.

    **Parameters**
    - thread – Thread object

sys_port_trace_k_thread_abort_exit(thread)
    Called when a thread exits the k_thread_abort routine.

    **Parameters**
    - thread – Thread object
sys_port_trace_k_thread_priority_set(thread)
   Called when setting priority of a thread.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_suspend_enter(thread)
   Called when a thread enters the k_thread_suspend function.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_suspend_exit(thread)
   Called when a thread exits the k_thread_suspend function.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_resume_enter(thread)
   Called when a thread enters the resume from suspension function.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_resume_exit(thread)
   Called when a thread exits the resumed from suspension function.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_sched_lock()
   Called when the thread scheduler is locked.

sys_port_trace_k_thread_sched_unlock()
   Called when the thread scheduler is unlocked.

sys_port_trace_k_thread_name_set(thread, ret)
   Called when a thread name is set.

   Parameters
   • thread – Thread object
   • ret – Return value

sys_port_trace_k_thread_switched_out()
   Called before a thread has been selected to run.

sys_port_trace_k_thread_switched_in()
   Called after a thread has been selected to run.

sys_port_trace_k_thread_ready(thread)
   Called when a thread is ready to run.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_pend(thread)
   Called when a thread is pending.

   Parameters
   • thread – Thread object
sys_port_trace_k_thread_info(thread)
   Provide information about specific thread.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_sched_wakeup(thread)
   Trace implicit thread wakeup invocation by the scheduler.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_sched_abort(thread)
   Trace implicit thread abort invocation by the scheduler.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_sched_priority_set(thread, prio)
   Trace implicit thread set priority invocation by the scheduler.

   Parameters
   • thread – Thread object
   • prio – Thread priority

sys_port_trace_k_thread_sched_ready(thread)
   Trace implicit thread ready invocation by the scheduler.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_sched_pend(thread)
   Trace implicit thread pend invocation by the scheduler.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_sched_resume(thread)
   Trace implicit thread resume invocation by the scheduler.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_sched_suspend(thread)
   Trace implicit thread suspend invocation by the scheduler.

   Parameters
   • thread – Thread object

Work Queues

group subsys_tracing_apis_work
   Work Tracing APIs.
Defines

sys_port_trace_k_work_init(work)
    Trace initialisation of a Work structure.

    Parameters
    • work – Work structure

sys_port_trace_k_work_submit_to_queue_enter(queue, work)
    Trace submit work to work queue call entry.

    Parameters
    • queue – Work queue structure
    • work – Work structure

sys_port_trace_k_work_submit_to_queue_exit(queue, work, ret)
    Trace submit work to work queue call exit.

    Parameters
    • queue – Work queue structure
    • work – Work structure
    • ret – Return value

sys_port_trace_k_work_submit_enter(work)
    Trace submit work to system work queue call entry.

    Parameters
    • work – Work structure

sys_port_trace_k_work_submit_exit(work, ret)
    Trace submit work to system work queue call exit.

    Parameters
    • work – Work structure
    • ret – Return value

sys_port_trace_k_work_flush_enter(work)
    Trace flush work call entry.

    Parameters
    • work – Work structure

sys_port_trace_k_work_flush_blocking(work, timeout)
    Trace flush work call blocking.

    Parameters
    • work – Work structure
    • timeout – Timeout period

sys_port_trace_k_work_flush_exit(work, ret)
    Trace flush work call exit.

    Parameters
    • work – Work structure
    • ret – Return value
sys_port_trace_k_work_cancel_enter(work)
Trace cancel work call entry.

**Parameters**
- **work** – Work structure

sys_port_trace_k_work_cancel_exit(work, ret)
Trace cancel work call exit.

**Parameters**
- **work** – Work structure
- **ret** – Return value

sys_port_trace_k_work_cancel_sync_enter(work, sync)
Trace cancel sync work call entry.

**Parameters**
- **work** – Work structure
- **sync** – Sync object

sys_port_trace_k_work_cancel_sync_blocking(work, sync)
Trace cancel sync work call blocking.

**Parameters**
- **work** – Work structure
- **sync** – Sync object

sys_port_trace_k_work_cancel_sync_exit(work, sync, ret)
Trace cancel sync work call exit.

**Parameters**
- **work** – Work structure
- **sync** – Sync object
- **ret** – Return value

Poll

**group** subsys_tracingapis_poll
Poll Tracing APIs.

**Defines**

sys_port_trace_k_poll_api_event_init(event)
Trace initialisation of a Poll Event.

**Parameters**
- **event** – Poll Event

sys_port_trace_k_poll_api_poll_enter(events)
Trace Polling call start.

**Parameters**
- **events** – Poll Events
sys_port_trace_k_poll_api_poll_exit(events, ret)
  Trace Polling call outcome.
  **Parameters**
  - events – Poll Events
  - ret – Return value

sys_port_trace_k_poll_api_signal_init(signal)
  Trace initialisation of a Poll Signal.
  **Parameters**
  - signal – Poll Signal

sys_port_trace_k_poll_api_signal_reset(signal)
  Trace resetting of Poll Signal.
  **Parameters**
  - signal – Poll Signal

sys_port_trace_k_poll_api_signal_check(signal)
  Trace checking of Poll Signal.
  **Parameters**
  - signal – Poll Signal

sys_port_trace_k_poll_api_signal_raise(signal, ret)
  Trace raising of Poll Signal.
  **Parameters**
  - signal – Poll Signal
  - ret – Return value

**Semaphore**

group subsys_tracing_apis_sem
  Semaphore Tracing APIs.

**Defines**

sys_port_trace_k_sem_init(sem, ret)
  Trace initialisation of a Semaphore.
  **Parameters**
  - sem – Semaphore object
  - ret – Return value

sys_port_trace_k_sem_give_enter(sem)
  Trace giving a Semaphore entry.
  **Parameters**
  - sem – Semaphore object
sys_port_trace_k_sem_give_exit(sem)
  Trace giving a Semaphore exit.

  Parameters
  • sem – Semaphore object

sys_port_trace_k_sem_take_enter(sem, timeout)
  Trace taking a Semaphore attempt start.

  Parameters
  • sem – Semaphore object
  • timeout – Timeout period

sys_port_trace_k_sem_take_blocking(sem, timeout)
  Trace taking a Semaphore attempt blocking.

  Parameters
  • sem – Semaphore object
  • timeout – Timeout period

sys_port_trace_k_sem_take_exit(sem, timeout, ret)
  Trace taking a Semaphore attempt outcome.

  Parameters
  • sem – Semaphore object
  • timeout – Timeout period
  • ret – Return value

sys_port_trace_k_sem_reset(sem)
  Trace resetting a Semaphore.

  Parameters
  • sem – Semaphore object

Mutex

`group subsys_tracing_apis_mutex`

Mutex Tracing APIs.

Defines

sys_port_trace_k_mutex_init(mutex, ret)
  Trace initialization of Mutex.

  Parameters
  • mutex – Mutex object
  • ret – Return value

sys_port_trace_k_mutex_lock_enter(mutex, timeout)
  Trace Mutex lock attempt start.

  Parameters
  • mutex – Mutex object
timeout – Timeout period

\texttt{sys\_port\_trace\_k\_mutex\_lock\_blocking(mutex, timeout)}

Trace Mutex lock attempt blocking.

**Parameters**

- \texttt{mutex} – Mutex object
- \texttt{timeout} – Timeout period

\texttt{sys\_port\_trace\_k\_mutex\_lock\_exit(mutex, timeout, ret)}

Trace Mutex lock attempt outcome.

**Parameters**

- \texttt{mutex} – Mutex object
- \texttt{timeout} – Timeout period
- \texttt{ret} – Return value

\texttt{sys\_port\_trace\_k\_mutex\_unlock\_enter(mutex)}

Trace Mutex unlock entry.

**Parameters**

- \texttt{mutex} – Mutex object

\texttt{sys\_port\_trace\_k\_mutex\_unlock\_exit(mutex, ret)}

Trace Mutex unlock exit.

**Condition Variables**

**group** subsys\_tracing\_apis\_condvar

Conditional Variable Tracing APIs.

**Defines**

\texttt{sys\_port\_trace\_k\_condvar\_init(condvar, ret)}

Trace initialization of Conditional Variable.

**Parameters**

- \texttt{condvar} – Conditional Variable object
- \texttt{ret} – Return value

\texttt{sys\_port\_trace\_k\_condvar\_signal\_enter(condvar)}

Trace Conditional Variable signaling start.

**Parameters**

- \texttt{condvar} – Conditional Variable object

\texttt{sys\_port\_trace\_k\_condvar\_signal\_blocking(condvar, timeout)}

Trace Conditional Variable signaling blocking.

**Parameters**

- \texttt{condvar} – Conditional Variable object
- \texttt{timeout} – Timeout period

4.8. Tracing
sys_port_trace_k_condvar_signal_exit(condvar, ret)
  Trace Conditional Variable signaling outcome.
  
  **Parameters**
  - condvar – Conditional Variable object
  - ret – Return value

sys_port_trace_k_condvar_broadcast_enter(condvar)
  Trace Conditional Variable broadcast enter.
  
  **Parameters**
  - condvar – Conditional Variable object

sys_port_trace_k_condvar_broadcast_exit(condvar, ret)
  Trace Conditional Variable broadcast exit.
  
  **Parameters**
  - condvar – Conditional Variable object
  - ret – Return value

sys_port_trace_k_condvar_wait_enter(condvar)
  Trace Conditional Variable wait enter.
  
  **Parameters**
  - condvar – Conditional Variable object

sys_port_trace_k_condvar_wait_exit(condvar, ret)
  Trace Conditional Variable wait exit.
  
  **Parameters**
  - condvar – Conditional Variable object
  - ret – Return value

**Queues**

group subsys_tracing_apis_queue
  Queue Tracing APIs.

**Defines**

sys_port_trace_k_queue_init(queue)
  Trace initialization of Queue.
  
  **Parameters**
  - queue – Queue object

sys_port_trace_k_queue_cancel_wait(queue)
  Trace Queue cancel wait.
  
  **Parameters**
  - queue – Queue object
sys_port_trace_k_queue_queue_insert_enter(queue, alloc)
Trace Queue insert attempt entry.

Parameters
- queue – Queue object
- alloc – Allocation flag

sys_port_trace_k_queue_queue_insert_blocking(queue, alloc, timeout)
Trace Queue insert attempt blocking.

Parameters
- queue – Queue object
- alloc – Allocation flag
- timeout – Timeout period

sys_port_trace_k_queue_queue_insert_exit(queue, alloc, ret)
Trace Queue insert attempt outcome.

Parameters
- queue – Queue object
- alloc – Allocation flag
- ret – Return value

sys_port_trace_k_queue_append_enter(queue)
Trace Queue append enter.

Parameters
- queue – Queue object

sys_port_trace_k_queue_append_exit(queue)
Trace Queue append exit.

Parameters
- queue – Queue object

sys_port_trace_k_queue_alloc_append_enter(queue)
Trace Queue alloc append enter.

Parameters
- queue – Queue object

sys_port_trace_k_queue_alloc_append_exit(queue, ret)
Trace Queue alloc append exit.

Parameters
- queue – Queue object
- ret – Return value

sys_port_trace_k_queue_prepend_enter(queue)
Trace Queue prepend enter.

Parameters
- queue – Queue object

4.8. Tracing
sys_port_trace_k_queue_prepend_exit(queue)
   Trace Queue prepend exit.
   **Parameters**
   - queue – Queue object

sys_port_trace_k_queue_alloc_prepend_enter(queue)
   Trace Queue alloc prepend enter.
   **Parameters**
   - queue – Queue object

sys_port_trace_k_queue_alloc_prepend_exit(queue, ret)
   Trace Queue alloc prepend exit.
   **Parameters**
   - queue – Queue object
   - ret – Return value

sys_port_trace_k_queue_insert_enter(queue)
   Trace Queue insert attempt entry.
   **Parameters**
   - queue – Queue object

sys_port_trace_k_queue_insert_blocking(queue, timeout)
   Trace Queue insert attempt blocking.
   **Parameters**
   - queue – Queue object
   - timeout – Timeout period

sys_port_trace_k_queue_insert_exit(queue)
   Trace Queue insert attempt exit.
   **Parameters**
   - queue – Queue object

sys_port_trace_k_queue_append_list_enter(queue)
   Trace Queue append list enter.
   **Parameters**
   - queue – Queue object

sys_port_trace_k_queue_append_list_exit(queue, ret)
   Trace Queue append list exit.
   **Parameters**
   - queue – Queue object
   - ret – Return value

sys_port_trace_k_queue_merge_slist_enter(queue)
   Trace Queue merge slist enter.
   **Parameters**
   - queue – Queue object
sys_port_trace_k_queue_merge_slist_exit(queue, ret)
Trace Queue merge slist exit.

Parameters
• queue – Queue object
• ret – Return value

docs_port_trace_k_queue_get_enter(queue, timeout)
Trace Queue get attempt enter.

Parameters
• queue – Queue object
• timeout – Timeout period

docs_port_trace_k_queue_get_blocking(queue, timeout)
Trace Queue get attempt blockings.

Parameters
• queue – Queue object
• timeout – Timeout period

docs_port_trace_k_queue_get_exit(queue, timeout, ret)
Trace Queue get attempt outcome.

Parameters
• queue – Queue object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_queue_remove_enter(queue)
Trace Queue remove enter.

Parameters
• queue – Queue object

sys_port_trace_k_queue_remove_exit(queue, ret)
Trace Queue remove exit.

Parameters
• queue – Queue object
• ret – Return value

sys_port_trace_k_queue_unique_append_enter(queue)
Trace Queue unique append enter.

Parameters
• queue – Queue object

sys_port_trace_k_queue_unique_append_exit(queue, ret)
Trace Queue unique append exit.

Parameters
• queue – Queue object
• ret – Return value
sys_port_trace_k_queue.Peek head.

Parameters

- queue – Queue object
- ret – Return value

sys_port_trace_k_queue.Peek tail.

Parameters

- queue – Queue object
- ret – Return value

FIFO

group subsystem_tracingApis_fifo

FIFO Tracing APIs.

Defines

sys_port_trace_k_fifo.init.enter(fifo)

Trace initialization of FIFO Queue entry.

Parameters

- fifo – FIFO object

sys_port_trace_k_fifo.init.exit(fifo)

Trace initialization of FIFO Queue exit.

Parameters

- fifo – FIFO object

sys_port_trace_k_fifo.cancel.wait.enter(fifo)

Trace FIFO Queue cancel wait entry.

Parameters

- fifo – FIFO object

sys_port_trace_k_fifo.cancel.wait.exit(fifo)

Trace FIFO Queue cancel wait exit.

Parameters

- fifo – FIFO object

sys_port_trace_k_fifo.put.enter(fifo, data)

Trace FIFO Queue put entry.

Parameters

- fifo – FIFO object
- data – Data item
sys_port_trace_k_fifo_put_exit(fifo, data)
Trace FIFO Queue put exit.

**Parameters**
- fifo – FIFO object
- data – Data item

sys_port_trace_k_fifo_alloc_put_enter(fifo, data)
Trace FIFO Queue alloc put entry.

**Parameters**
- fifo – FIFO object
- data – Data item

sys_port_trace_k_fifo_alloc_put_exit(fifo, data, ret)
Trace FIFO Queue alloc put exit.

**Parameters**
- fifo – FIFO object
- data – Data item
- ret – Return value

sys_port_trace_k_fifo_put_list_enter(fifo, head, tail)
Trace FIFO Queue put list entry.

**Parameters**
- fifo – FIFO object
- head – First ll-node
- tail – Last ll-node

sys_port_trace_k_fifo_put_list_exit(fifo, head, tail)
Trace FIFO Queue put list exit.

**Parameters**
- fifo – FIFO object
- head – First ll-node
- tail – Last ll-node

sys_port_trace_k_fifo_alloc_put_slist_enter(fifo, list)
Trace FIFO Queue put slist entry.

**Parameters**
- fifo – FIFO object
- list – Syslist object

sys_port_trace_k_fifo_alloc_put_slist_exit(fifo, list)
Trace FIFO Queue put slist exit.

**Parameters**
- fifo – FIFO object
- list – Syslist object
sys_port_trace_k_fifo_get_enter(fifo, timeout)
Trace FIFO Queue get entry.

Parameters
• fifo – FIFO object
• timeout – Timeout period

sys_port_trace_k_fifo_get_exit(fifo, timeout, ret)
Trace FIFO Queue get exit.

Parameters
• fifo – FIFO object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_fifo_peek_head_entry(fifo)
Trace FIFO Queue peek head entry.

Parameters
• fifo – FIFO object

sys_port_trace_k_fifo_peek_head_exit(fifo, ret)
Trace FIFO Queue peek head exit.

Parameters
• fifo – FIFO object
• ret – Return value

sys_port_trace_k_fifo_peek_tail_entry(fifo)
Trace FIFO Queue peek tail entry.

Parameters
• fifo – FIFO object

sys_port_trace_k_fifo_peek_tail_exit(fifo, ret)
Trace FIFO Queue peek tail exit.

Parameters
• fifo – FIFO object
• ret – Return value

LIFO

group subsys_tracingApis_lifo
LIFO Tracing APIs.

Defines

sys_port_trace_k_lifo_init_enter(lifo)
Trace initialization of LIFO Queue entry.

Parameters
• lifo – LIFO object
sys_port_trace_k_lifo_init_exit(lifo)
Trace initialization of LIFO Queue exit.

Parameters
• lifo – LIFO object

sys_port_trace_k_lifo_put_enter(lifo, data)
Trace LIFO Queue put entry.

Parameters
• lifo – LIFO object
• data – Data item

sys_port_trace_k_lifo_put_exit(lifo, data)
Trace LIFO Queue put exit.

Parameters
• lifo – LIFO object
• data – Data item

sys_port_trace_k_lifo_alloc_put_enter(lifo, data)
Trace LIFO Queue alloc put entry.

Parameters
• lifo – LIFO object
• data – Data item

sys_port_trace_k_lifo_alloc_put_exit(lifo, data, ret)
Trace LIFO Queue alloc put exit.

Parameters
• lifo – LIFO object
• data – Data item
• ret – Return value

sys_port_trace_k_lifo_get_enter(lifo, timeout)
Trace LIFO Queue get entry.

Parameters
• lifo – LIFO object
• timeout – Timeout period

sys_port_trace_k_lifo_get_exit(lifo, timeout, ret)
Trace LIFO Queue get exit.

Parameters
• lifo – LIFO object
• timeout – Timeout period
• ret – Return value

Stacks

/group subsys_tracingapis_stack
Stack Tracing APIs.
Defines

sys_port_trace_k_stack_init(stack)
Trace initialization of Stack.

Parameters
  * stack – Stack object

sys_port_trace_k_stack_alloc_init_enter(stack)
Trace Stack alloc init attempt entry.

Parameters
  * stack – Stack object

sys_port_trace_k_stack_alloc_init_exit(stack, ret)
Trace Stack alloc init outcome.

Parameters
  * stack – Stack object
  * ret – Return value

sys_port_trace_k_stack_cleanup_enter(stack)
Trace Stack cleanup attempt entry.

Parameters
  * stack – Stack object

sys_port_trace_k_stack_cleanup_exit(stack, ret)
Trace Stack cleanup outcome.

Parameters
  * stack – Stack object
  * ret – Return value

sys_port_trace_k_stack_push_enter(stack)
Trace Stack push attempt entry.

Parameters
  * stack – Stack object

sys_port_trace_k_stack_push_exit(stack, ret)
Trace Stack push attempt outcome.

Parameters
  * stack – Stack object
  * ret – Return value

sys_port_trace_k_stack_pop_enter(stack, timeout)
Trace Stack pop attempt entry.

Parameters
  * stack – Stack object
  * timeout – Timeout period
sys_port_trace_k_stack_pop_blocking(stack, timeout)
Trace Stack pop attempt blocking.

Parameters
• stack – Stack object
• timeout – Timeout period

sys_port_trace_k_stack_pop_exit(stack, timeout, ret)
Trace Stack pop attempt outcome.

Parameters
• stack – Stack object
• timeout – Timeout period
• ret – Return value

Message Queues

group subsys_tracing_apis_msgq
Message Queue Tracing APIs.

Defines

sys_port_trace_k_msgq_init(msgq)
Trace initialization of Message Queue.

Parameters
• msgq – Message Queue object

sys_port_trace_k_msgq_alloc_init_enter(msgq)
Trace Message Queue alloc init attempt entry.

Parameters
• msgq – Message Queue object

sys_port_trace_k_msgq_alloc_init_exit(msgq, ret)
Trace Message Queue alloc init attempt outcome.

Parameters
• msgq – Message Queue object
• ret – Return value

sys_port_trace_k_msgq_cleanup_enter(msgq)
Trace Message Queue cleanup attempt entry.

Parameters
• msgq – Message Queue object

sys_port_trace_k_msgq_cleanup_exit(msgq, ret)
Trace Message Queue cleanup attempt outcome.

Parameters
• msgq – Message Queue object
• ret – Return value
sys_port_trace_k_msgq_put_enter(msgq, timeout)
   Trace Message Queue put attempt entry.

Parameters
   • msgq – Message Queue object
   • timeout – Timeout period

sys_port_trace_k_msgq_put_blocking(msgq, timeout)
   Trace Message Queue put attempt blocking.

Parameters
   • msgq – Message Queue object
   • timeout – Timeout period

sys_port_trace_k_msgq_put_exit(msgq, timeout, ret)
   Trace Message Queue put attempt outcome.

Parameters
   • msgq – Message Queue object
   • timeout – Timeout period
   • ret – Return value

sys_port_trace_k_msgq_get_enter(msgq, timeout)
   Trace Message Queue get attempt entry.

Parameters
   • msgq – Message Queue object
   • timeout – Timeout period

sys_port_trace_k_msgq_get_blocking(msgq, timeout)
   Trace Message Queue get attempt blockings.

Parameters
   • msgq – Message Queue object
   • timeout – Timeout period

sys_port_trace_k_msgq_get_exit(msgq, timeout, ret)
   Trace Message Queue get attempt outcome.

Parameters
   • msgq – Message Queue object
   • timeout – Timeout period
   • ret – Return value

sys_port_trace_k_msgq_peek(msgq, ret)
   Trace Message Queue peek.

Parameters
   • msgq – Message Queue object
   • ret – Return value

sys_port_trace_k_msgq_purge(msgq)
   Trace Message Queue purge.

Parameters
   • msgq – Message Queue object
Mailbox

group subsys_tracing.Apis_mbox
Mailbox Tracing APIs.

Defines

sys_port_trace_k_mbox_init(mbox)
Trace initialization of Mailbox.

Parameters
• mbox – Mailbox object

sys_port_trace_k_mbox_message_put_enter(mbox, timeout)
Trace Mailbox message put attempt entry.

Parameters
• mbox – Mailbox object
• timeout – Timeout period

sys_port_trace_k_mbox_message_put_blocking(mbox, timeout)
Trace Mailbox message put attempt blocking.

Parameters
• mbox – Mailbox object
• timeout – Timeout period

sys_port_trace_k_mbox_message_put_exit(mbox, timeout, ret)
Trace Mailbox message put attempt outcome.

Parameters
• mbox – Mailbox object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_mbox_put_enter(mbox, timeout)
Trace Mailbox put attempt entry.

Parameters
• mbox – Mailbox object
• timeout – Timeout period

sys_port_trace_k_mbox_put_exit(mbox, timeout, ret)
Trace Mailbox put attempt blocking.

Parameters
• mbox – Mailbox object
• timeout – Timeout period
• ret – Return value
sys_port_trace_k_mbox_async_put_enter(mbox, sem)
Trace Mailbox async put entry.

Parameters
• mbox – Mailbox object
• sem – Semaphore object

sys_port_trace_k_mbox_async_put_exit(mbox, sem)
Trace Mailbox async put exit.

Parameters
• mbox – Mailbox object
• sem – Semaphore object

sys_port_trace_k_mbox_get_enter(mbox, timeout)
Trace Mailbox get attempt entry.

Parameters
• mbox – Mailbox entry
• timeout – Timeout period

sys_port_trace_k_mbox_get_blocking(mbox, timeout)
Trace Mailbox get attempt blocking.

Parameters
• mbox – Mailbox entry
• timeout – Timeout period

sys_port_trace_k_mbox_get_exit(mbox, timeout, ret)
Trace Mailbox get attempt outcome.

Parameters
• mbox – Mailbox entry
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_mbox_data_get(rx_msg)
Trace Mailbox data get.

rx_msg Receive Message object

Pipes

group subsys_tracing.Apis_pipe
Pipe Tracing APIs.

Defines

sys_port_trace_k_pipe_init(pipe)
Trace initialization of Pipe.

Parameters
• pipe – Pipe object
sys_port_trace_k_pipe_cleanup_enter(pipe)
  Trace Pipe cleanup entry.

  Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_cleanup_exit(pipe, ret)
  Trace Pipe cleanup exit.

  Parameters
  • pipe – Pipe object
  • ret – Return value

sys_port_trace_k_pipe_alloc_init_enter(pipe)
  Trace Pipe alloc init entry.

  Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_alloc_init_exit(pipe, ret)
  Trace Pipe alloc init exit.

  Parameters
  • pipe – Pipe object
  • ret – Return value

sys_port_trace_k_pipe_flush_enter(pipe)
  Trace Pipe flush entry.

  Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_flush_exit(pipe)
  Trace Pipe flush exit.

  Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_buffer_flush_enter(pipe)
  Trace Pipe buffer flush entry.

  Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_buffer_flush_exit(pipe)
  Trace Pipe buffer flush exit.

  Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_put_enter(pipe, timeout)
  Trace Pipe put attempt entry.

  Parameters
  • pipe – Pipe object
  • timeout – Timeout period
sys_port_trace_k_pipe_put_blocking(pipe, timeout)
Trace Pipe put attempt blocking.

Parameters
• pipe – Pipe object
• timeout – Timeout period

sys_port_trace_k_pipe_put_exit(pipe, timeout, ret)
Trace Pipe put attempt outcome.

Parameters
• pipe – Pipe object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_pipe_get_enter(pipe, timeout)
Trace Pipe get attempt entry.

Parameters
• pipe – Pipe object
• timeout – Timeout period

sys_port_trace_k_pipe_get_blocking(pipe, timeout)
Trace Pipe get attempt blocking.

Parameters
• pipe – Pipe object
• timeout – Timeout period

sys_port_trace_k_pipe_get_exit(pipe, timeout, ret)
Trace Pipe get attempt outcome.

Parameters
• pipe – Pipe object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_pipe_block_put_enter(pipe, sem)
Trace Pipe block put enter.

Parameters
• pipe – Pipe object
• sem – Semaphore object

sys_port_trace_k_pipe_block_put_exit(pipe, sem)
Trace Pipe block put exit.

Parameters
• pipe – Pipe object
• sem – Semaphore object
Heaps

group subsys_tracing.Apis_heap

Heap Tracing APIs.

Defines

sys_port_trace_k_heap_init(h)

Trace initialization of Heap.

Parameters
• h – Heap object

sys_port_trace_k_heapAligned_alloc_enter(h, timeout)

Trace Heap aligned alloc attempt entry.

Parameters
• h – Heap object
• timeout – Timeout period

sys_port_trace_k_heapAligned_alloc_blocking(h, timeout)

Trace Heap align alloc attempt blocking.

Parameters
• h – Heap object
• timeout – Timeout period

sys_port_trace_k_heapAligned_alloc_exit(h, timeout, ret)

Trace Heap align alloc attempt outcome.

Parameters
• h – Heap object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_heap_alloc enter(h, timeout)

Trace Heap alloc enter.

Parameters
• h – Heap object
• timeout – Timeout period

sys_port_trace_k_heap_alloc exit(h, timeout, ret)

Trace Heap alloc exit.

Parameters
• h – Heap object
• timeout – Timeout period
• ret – Return value
sys_port_trace_k_heap_free(h)
Trace Heap free.

Parameters
• h – Heap object

sys_port_trace_k_heap_sys_k_aligned_alloc_enter(heap)
Trace System Heap aligned alloc enter.

Parameters
• heap – Heap object

sys_port_trace_k_heap_sys_k_aligned_alloc_exit(heap, ret)
Trace System Heap aligned alloc exit.

Parameters
• heap – Heap object
• ret – Return value

sys_port_trace_k_heap_sys_k_malloc_enter(heap)
Trace System Heap aligned alloc enter.

Parameters
• heap – Heap object

sys_port_trace_k_heap_sys_k_malloc_exit(heap, ret)
Trace System Heap aligned alloc exit.

Parameters
• heap – Heap object
• ret – Return value

sys_port_trace_k_heap_sys_k_free_enter(heap, heap_ref)
Trace System Heap free entry.

Parameters
• heap – Heap object
• heap_ref – Heap reference

sys_port_trace_k_heap_sys_k_free_exit(heap, heap_ref)
Trace System Heap free exit.

Parameters
• heap – Heap object
• heap_ref – Heap reference

sys_port_trace_k_heap_sys_k_calloc_enter(heap)
Trace System heap calloc enter.

Parameters
• heap –

sys_port_trace_k_heap_sys_k_calloc_exit(heap, ret)
Trace System heap calloc exit.

Parameters
• heap – Heap object
• ret – Return value
Memory Slabs

`group subsys_tracing_apis_mslab`
Memory Slab Tracing APIs.

**Defines**

`sys_port_trace_k_mem_slab_init(slab, rc)`
Trace initialization of Memory Slab.

**Parameters**
- `slab` – Memory Slab object
- `rc` – Return value

`sys_port_trace_k_mem_slab_alloc_enter(slab, timeout)`
Trace Memory Slab alloc attempt entry.

**Parameters**
- `slab` – Memory Slab object
- `timeout` – Timeout period

`sys_port_trace_k_mem_slab_alloc_blocking(slab, timeout)`
Trace Memory Slab alloc attempt blocking.

**Parameters**
- `slab` – Memory Slab object
- `timeout` – Timeout period

`sys_port_trace_k_mem_slab_alloc_exit(slab, timeout, ret)`
Trace Memory Slab alloc attempt outcome.

**Parameters**
- `slab` – Memory Slab object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mem_slab_free_enter(slab)`
Trace Memory Slab free entry.

**Parameters**
- `slab` – Memory Slab object

`sys_port_trace_k_mem_slab_free_exit(slab)`
Trace Memory Slab free exit.

**Parameters**
- `slab` – Memory Slab object

Timers

`group subsys_tracing_apis_timer`
Timer Tracing APIs.
Defines

```c
sys_port_trace_k_timer_init(timer)
    Trace initialization of Timer.

Parameters
    • timer – Timer object
```

```c
sys_port_trace_k_timer_start(timer, duration, period)
    Trace Timer start.

Parameters
    • timer – Timer object
    • duration – Timer duration
    • period – Timer period
```

```c
sys_port_trace_k_timer_stop(timer)
    Trace Timer stop.

Parameters
    • timer – Timer object
```

```c
sys_port_trace_k_timer_status_sync_enter(timer)
    Trace Timer status sync entry.

Parameters
    • timer – Timer object
```

```c
sys_port_trace_k_timer_status_sync_blocking(timer, timeout)
    Trace Timer Status sync blocking.

Parameters
    • timer – Timer object
    • timeout – Timeout period
```

```c
sys_port_trace_k_timer_status_sync_exit(timer, result)
    Trace Time Status sync outcome.

Parameters
    • timer – Timer object
    • result – Return value
```

Object tracking

```c
group subsys_tracing_object_tracking
    Object tracking.
```

Object tracking provides lists to kernel objects, so their existence and current status can be tracked. The following global variables are the heads of available lists:

```c
• _track_list_k_timer
• _track_list_k_mem_slab
• _track_list_k_sem
• _track_list_k_mutex
```
• _track_list_k_stack
• _track_list_k_msgq
• _track_list_k_mbox
• _track_list_k_pipe
• _track_list_k_queue

Defines

SYS_PORT_TRACK_NEXT(list)
Gets node's next element in an object tracking list.

Parameters

• list – Node to get next element from.

Syscalls

group subsys_tracing_apis_syscall
Syscall Tracing APIs.

Defines

sys_port_trace_syscall_enter(id, name, ...)
Trace syscall entry.

Parameters

• id – Syscall ID (as defined in the generated syscall_list.h)
• name – Syscall name as a token (ex: k_thread_create)
• ... – Other parameters passed to the syscall

sys_port_trace_syscall_exit(id, name, ...)
Trace syscall exit.

Parameters

• id – Syscall ID (as defined in the generated syscall_list.h)
• name – Syscall name as a token (ex: k_thread_create)
• ... – Other parameters passed to the syscall, if the syscall has a return, the return value is the last parameter in the list

4.9 Resource Management

There are various situations where it's necessary to coordinate resource use at runtime among multiple clients. These include power rails, clocks, other peripherals, and binary device power management. The complexity of properly managing multiple consumers of a device in a multithreaded system, especially when transitions may be asynchronous, suggests that a shared implementation is desirable.

Zephyr provides managers for several coordination policies. These managers are embedded into services that use them for specific functions.
4.9.1 On-Off Manager

An on-off manager supports an arbitrary number of clients of a service which has a binary state. Example applications are power rails, clocks, and binary device power management.

The manager has the following properties:

- The stable states are off, on, and error. The service always begins in the off state. The service may also be in a transition to a given state.
- The core operations are request (add a dependency) and release (remove a dependency). Supporting operations are reset (to clear an error state) and cancel (to reclaim client data from an in-progress transition). The service manages the state based on calls to functions that initiate these operations.
- The service transitions from off to on when first client request is received.
- The service transitions from on to off when last client release is received.
- Each service configuration provides functions that implement the transition from off to on, from on to off, and optionally from an error state to off. Transitions must be invokable from both thread and interrupt context.
- The request and reset operations are asynchronous using Asynchronous Notifications. Both operations may be cancelled, but cancellation has no effect on the in-progress transition.
- Requests to turn on may be queued while a transition to off is in progress: when the service has turned off successfully it will be immediately turned on again (where context allows) and waiting clients notified when the start completes.

Requests are reference counted, but not tracked. That means clients are responsible for recording whether their requests were accepted, and for initiating a release only if they have previously successfully completed a request. Improper use of the API can cause an active client to be shut out, and the manager does not maintain a record of specific clients that have been granted a request.

Failures in executing a transition are recorded and inhibit further requests or releases until the manager is reset. Pending requests are notified (and cancelled) when errors are discovered.

Transition operation completion notifications are provided through Asynchronous Notifications.

Clients and other components interested in tracking all service state changes, including when a service begins turning off or enters an error state, can be informed of state transitions by registering a monitor with onoff_monitor_register(). Notification of changes are provided before issuing completion notifications associated with the new state.

Note: A generic API may be implemented by multiple drivers where the common case is asynchronous. The on-off client structure may be an appropriate solution for the generic API. Where drivers that can guarantee synchronous context-independent transitions a driver may use onoff_sync_service and its supporting API rather than onoff_manager, with only a small reduction in functionality (primarily no support for the monitor API).

defines group resource_mgmt_onoff_apis
ONOFF_FLAG_ERROR
Flag indicating an error state.
Error states are cleared using onoff_reset().

ONOFF_FLAG_ONOFF

ONOFF_FLAG_TRANSITION

ONOFF_STATE_MASK
Mask used to isolate bits defining the service state.
Mask a value with this then test for ONOFF_FLAG_ERROR to determine whether the machine has an unfixed error, or compare against ONOFF_STATE_ON, ONOFF_STATE_OFF, ONOFF_STATE_TO_ON, ONOFF_STATE_TO_OFF, or ONOFF_STATE_RESETTING.

ONOFF_STATE_OFF
Value exposed by ONOFF_STATE_MASK when service is off.

ONOFF_STATE_ON
Value exposed by ONOFF_STATE_MASK when service is on.

ONOFF_STATE_ERROR
Value exposed by ONOFF_STATE_MASK when the service is in an error state (and not in the process of resetting its state).

ONOFF_STATE_TO_ON
Value exposed by ONOFF_STATE_MASK when service is transitioning to on.

ONOFF_STATE_TO_OFF
Value exposed by ONOFF_STATE_MASK when service is transitioning to off.

ONOFF_STATE_RESETTING
Value exposed by ONOFF_STATE_MASK when service is in the process of resetting.

ONOFF_TRANSITIONS_INITIALIZER(_start, _stop, _reset)
Initializer for a onoff_transitions object.

Parameters
• _start – a function used to transition from off to on state.
• _stop – a function used to transition from on to off state.
• _reset – a function used to clear errors and force the service to an off state. Can be null.

ONOFF_MANAGER_INITIALIZER(_transitions)

ONOFF_CLIENT_EXTENSION_POS
Identify region of sys_notify flags available for containing services.
Bits of the flags field of the sys_notify structure contained within the queued_operation structure at and above this position may be used by extensions to the onoff_client structure.
These bits are intended for use by containing service implementations to record client-specific information and are subject to other conditions of use specified on the sys_notify API.
Typedefs

typedef void (\*onoff_notify_fn)(struct onoff_manager *mgr, int res)

Signature used to notify an on-off manager that a transition has completed.

Functions of this type are passed to service-specific transition functions to be used to report
the completion of the operation. The functions may be invoked from any context.

**Param mgr**
the manager for which transition was requested.

**Param res**
the result of the transition. This shall be non-negative on success, or a negative
error code. If an error is indicated the service shall enter an error state.

typedef void (\*onoff_transition_fn)(struct onoff_manager *mgr, onoff_notify_fn notify)

Signature used by service implementations to effect a transition.

Service definitions use two required function pointers of this type to be notified that a transi-
tion is required, and a third optional one to reset the service when it is in an error state.
The start function will be called only from the off state.
The stop function will be called only from the on state.
The reset function (where supported) will be called only when onoff_has_error() returns true.

**Note:** All transitions functions must be isr-ok.

**Param mgr**
the manager for which transition was requested.

**Param notify**
the function to be invoked when the transition has completed. If the transition is
synchronous, notify shall be invoked by the implementation before the transition
function returns. Otherwise the implementation shall capture this parameter and
invoke it when the transition completes.

typedef void (\*onoff_client_callback)(struct onoff_manager *mgr, struct onoff_client *cli,
uint32_t state, int res)

Signature used to notify an on-off service client of the completion of an operation.

These functions may be invoked from any context including pre-kernel, ISR, or cooperative or
pre-emptible threads. Compatible functions must be isr-ok and not sleep.

**Param mgr**
the manager for which the operation was initiated. This may be null if the on-off
service uses synchronous transitions.

**Param cli**
the client structure passed to the function that initiated the operation.

**Param state**
the state of the machine at the time of completion, restricted by
ONOFF_STATE_MASK. ONOFF_FLAG_ERROR must be checked independently of
whether res is negative as a machine error may indicate that all future operations
except onoff_reset() will fail.

**Param res**
the result of the operation. Expected values are service-specific, but the value
shall be non-negative if the operation succeeded, and negative if the operation failed. If res is negative ONOFF_FLAG_ERROR will be set in state, but if res is non-negative ONOFF_FLAG_ERROR may still be set in state.

typedef void (*onoff_monitor_callback)(struct onoff_manager *mgr, struct onoff_monitor *mon, uint32_t state, int res)

Signature used to notify a monitor of an onoff service of errors or completion of a state transition.

This is similar to onoff_client_callback but provides information about all transitions, not just ones associated with a specific client. Monitor callbacks are invoked before any completion notifications associated with the state change are made.

These functions may be invoked from any context including pre-kernel, ISR, or cooperative or pre-emptible threads. Compatible functions must be isr-ok and not sleep.

The callback is permitted to unregister itself from the manager, but must not register or unregister any other monitors.

Param mgr
the manager for which a transition has completed.

Param mon
the monitor instance through which this notification arrived.

Param state
the state of the machine at the time of completion, restricted by ONOFF_STATE_MASK. All valid states may be observed.

Param res
the result of the operation. Expected values are service- and state-specific, but the value shall be non-negative if the operation succeeded, and negative if the operation failed.

Functions

int onoff_manager_init(struct onoff_manager *mgr, const struct onoff_transitions *transitions)
Initialize an on-off service to off state.

This function must be invoked exactly once per service instance, by the infrastructure that provides the service, and before any other on-off service API is invoked on the service.

This function should never be invoked by clients of an on-off service.

Parameters

• mgr – the manager definition object to be initialized.
• transitions – pointer to a structure providing transition functions. The referenced object must persist as long as the manager can be referenced.

Return values

• 0 – on success
• -EINVAL – if start, stop, or flags are invalid

static inline bool onoff_has_error(const struct onoff_manager *mgr)
Test whether an on-off service has recorded an error.

This function can be used to determine whether the service has recorded an error. Errors may be cleared by invoking onoff_reset().

This is an unlocked convenience function suitable for use only when it is known that no other process might invoke an operation that transitions the service between an error and non-error state.
Returns
true if and only if the service has an uncleared error.

```c
int onoff_request(struct onoff_manager *mgr, struct onoff_client *cli)
```
Request a reservation to use an on-off service.

The return value indicates the success or failure of an attempt to initiate an operation to request the resource be made available. If initiation of the operation succeeds the result of the request operation is provided through the configured client notification method, possibly before this call returns.

Note that the call to this function may succeed in a case where the actual request fails. Always check the operation completion result.

**Parameters**
- `mgr` – the manager that will be used.
- `cli` – a non-null pointer to client state providing instructions on synchronous expectations and how to notify the client when the request completes. Behavior is undefined if client passes a pointer object associated with an incomplete service operation.

**Return values**
- non-negative – the observed state of the machine at the time the request was processed, if successful.
- -EIO – if service has recorded an error.
- -EINVAL – if the parameters are invalid.
- -EAGAIN – if the reference count would overflow.

```c
int onoff_release(struct onoff_manager *mgr)
```
Release a reserved use of an on-off service.

This synchronously releases the caller's previous request. If the last request is released the manager will initiate a transition to off, which can be observed by registering an `onoff_monitor`.

**Note:** Behavior is undefined if this is not paired with a preceding `onoff_request()` call that completed successfully.

**Parameters**
- `mgr` – the manager for which a request was successful.

**Return values**
- non-negative – the observed state (ONOFF_STATE_ON) of the machine at the time of the release, if the release succeeds.
- -EIO – if service has recorded an error.
- -ENOTSUP – if the machine is not in a state that permits release.

```c
int onoff_cancel(struct onoff_manager *mgr, struct onoff_client *cli)
```
Attempt to cancel an in-progress client operation.

It may be that a client has initiated an operation but needs to shut down before the operation has completed. For example, when a request was made and the need is no longer present.

Cancelling is supported only for `onoff_request()` and `onoff_reset()` operations, and is a synchronous operation. Be aware that any transition that was initiated on behalf of the client will continue to progress to completion: it is only notification of transition completion that
may be eliminated. If there are no active requests when a transition to on completes the manager will initiate a transition to off.

Client notification does not occur for cancelled operations.

**Parameters**
- `mgr` – the manager for which an operation is to be cancelled.
- `cli` – a pointer to the same client state that was provided when the operation to be cancelled was issued.

**Return values**
- `non-negative` – the observed state of the machine at the time of the cancellation, if the cancellation succeeds. On successful cancellation ownership of `cli` reverts to the client.
- `-EINVAL` – if the parameters are invalid.
- `-EALREADY` – if `cli` was not a record of an uncompleted notification at the time the cancellation was processed. This likely indicates that the operation and client notification had already completed.

```c
static inline int onoff_cancel_or_release(struct onoff_manager *mgr, struct onoff_client *cli)
```

Helper function to safely cancel a request.

Some applications may want to issue requests on an asynchronous event (such as connection to a USB bus) and to release on a paired event (such as loss of connection to a USB bus). Applications cannot precisely determine that an in-progress request is still pending without using `onoff_monitor` and carefully avoiding race conditions.

This function is a helper that attempts to cancel the operation and issues a release if cancellation fails because the request was completed. This synchronously ensures that ownership of the client data reverts to the client so is available for a future request.

**Parameters**
- `mgr` – the manager for which an operation is to be cancelled.
- `cli` – a pointer to the same client state that was provided when `onoff_request()` was invoked. Behavior is undefined if this is a pointer to client data associated with an `onoff_reset()` request.

**Return values**
- `ONOFF_STATE_TO_ON` – if the cancellation occurred before the transition completed.
- `ONOFF_STATE_ON` – if the cancellation occurred after the transition completed.
- `-EINVAL` – if the parameters are invalid.
- `negative` – other errors produced by `onoff_release()`.

```c
int onoff_reset(struct onoff_manager *mgr, struct onoff_client *cli)
```

Clear errors on an on-off service and reset it to its off state.

A service can only be reset when it is in an error state as indicated by `onoff_has_error()`.

The return value indicates the success or failure of an attempt to initiate an operation to reset the resource. If initiation of the operation succeeds the result of the reset operation itself is provided through the configured client notification method, possibly before this call returns. Multiple clients may request a reset; all are notified when it is complete.

Note that the call to this function may succeed in a case where the actual reset fails. Always check the operation completion result.
Due to the conditions on state transition all incomplete asynchronous operations will have been informed of the error when it occurred. There need be no concern about dangling requests left after a reset completes.

Parameters
- `mgr` – the manager to be reset.
- `cli` – pointer to client state, including instructions on how to notify the client when reset completes. Behavior is undefined if cli references an object associated with an incomplete service operation.

Return values
- non-negative – the observed state of the machine at the time of the reset, if the reset succeeds.
- -ENOTSUP – if reset is not supported by the service.
- -EINVAL – if the parameters are invalid.
- -EALREADY – if the service does not have a recorded error.

```c
int onoff_monitor_register(struct onoff_manager *mgr, struct onoff_monitor *mon)
```
Add a monitor of state changes for a manager.

Parameters
- `mgr` – the manager for which a state changes are to be monitored.
- `mon` – a linkable node providing a non-null callback to be invoked on state changes.

Returns
non-negative on successful addition, or a negative error code.

```c
int onoff_monitor_unregister(struct onoff_manager *mgr, struct onoff_monitor *mon)
```
Remove a monitor of state changes from a manager.

Parameters
- `mgr` – the manager for which a state changes are to be monitored.
- `mon` – a linkable node providing the callback to be invoked on state changes.

Returns
non-negative on successful removal, or a negative error code.

```c
int onoff_sync_lock(struct onoff_sync_service *srv, k_spinlock_key_t *keyp)
```
Lock a synchronous onoff service and provide its state.

Note: If an error state is returned it is the caller's responsibility to decide whether to preserve it (finalize with the same error state) or clear the error (finalize with a non-error result).

Parameters
- `srv` – pointer to the synchronous service state.
- `keyp` – pointer to where the lock key should be stored.

Returns
negative if the service is in an error state, otherwise the number of active requests at the time the lock was taken. The lock is held on return regardless of whether a negative state is returned.
int onoff_sync_finalize(struct onoff_sync_service *srv, k_spinlock_key_t key, struct onoff_client *cli, int res, bool on)

Process the completion of a transition in a synchronous service and release lock.

This function updates the service state on the res and on parameters then releases the lock. If cli is not null it finalizes the client notification using res.

If the service was in an error state when locked, and res is non-negative when finalized, the count is reset to zero before completing finalization.

Parameters

- srv – pointer to the synchronous service state
- key – the key returned by the preceding invocation of onoff_sync_lock().
- cli – pointer to the onoff client through which completion information is returned. If a null pointer is passed only the state of the service is updated. For compatibility with the behavior of callbacks used with the manager API cli must be null when on is false (the manager does not support callbacks when turning off devices).
- res – the result of the transition. A negative value places the service into an error state. A non-negative value increments or decrements the reference count as specified by on.
- on – Only when res is non-negative, the service reference count will be incremented if on is true, and decremented if on is false.

Returns

negative if the service is left or put into an error state, otherwise the number of active requests at the time the lock was released.

struct onoff_transitions

#include <onoff.h> On-off service transition functions.

struct onoff_manager

#include <onoff.h> State associated with an on-off manager.

No fields in this structure are intended for use by service providers or clients. The state is to be initialized once, using onoff_manager_init(), when the service provider is initialized. In case of error it may be reset through the onoff_reset() API.

struct onoff_client

#include <onoff.h> State associated with a client of an on-off service.

Objects of this type are allocated by a client, which is responsible for zero-initializing the node field and invoking the appropriate sys_notify init function to configure notification.

Control of the object content transfers to the service provider when a pointer to the object is passed to any on-off manager function. While the service provider controls the object the client must not change any object fields. Control reverts to the client concurrent with release of the owned sys_notify structure, or when indicated by an onoff_cancel() return value.

After control has reverted to the client the notify field must be reinitialized for the next operation.

Public Members

struct sys_notify notify

Notification configuration.
struct onoff_monitor

#include <onoff.h> Registration state for notifications of onoff service transitions.

Any given onoff_monitor structure can be associated with at most one onoff_manager instance.

Public Members

onoff_monitor_callback callback

Callback to be invoked on state change.

This must not be null.

struct onoff_sync_service

#include <onoff.h> State used when a driver uses the on-off service API for synchronous operations.

This is useful when a subsystem API uses the on-off API to support asynchronous operations but the transitions required by a particular driver are isr-ok and not sleep. It serves as a substitute for onoff_manager, with locking and persisted state updates supported by onoff_sync_lock() and onoff_sync_finalize().

4.10 Modbus

Modbus is an industrial messaging protocol. The protocol is specified for different types of networks or buses. Zephyr OS implementation supports communication over serial line and may be used with different physical interfaces, like RS485 or RS232. TCP support is not implemented directly, but there are helper functions to realize TCP support according to the application's needs.

Modbus communication is based on client/server model. Only one client may be present on the bus. Client can communicate with several server devices. Server devices themselves are passive and must not send requests or unsolicited responses. Services requested by the client are specified by function codes (FCxx), and can be found in the specification or documentation of the API below.

Zephyr RTOS implementation supports both client and server roles.

More information about Modbus and Modbus RTU can be found on the website MODBUS Protocol Specifications.

4.10.1 Samples

modbus-rtu-server-sample and modbus-rtu-client-sample give the possibility to try out RTU server and RTU client implementation with an evaluation board.

modbus-tcp-server-sample is a simple Modbus TCP server.

modbus-gateway-sample is an example how to build a TCP to serial line gateway with Zephyr OS.

4.10.2 API Reference

group modbus

MODBUS transport protocol API.
**Defines**

MODBUS_MBAP_LENGTH
Length of MBAP Header

MODBUS_MBAP_AND_FC_LENGTH
Length of MBAP Header plus function code

**Typedefs**

typedef int (*modbus_raw_cb_t)(const int iface, const struct modbus_adu *adu, void *user_data)
ADU raw callback function signature.

- **Param iface**
  Modbus RTU interface index

- **Param adu**
  Pointer to the RAW ADU struct to send

- **Param user_data**
  Pointer to the user data

- **Retval 0**
  If transfer was successful

**Enums**

class modbus_mode
Modbus interface mode.

**Values:**

class enumerator MODBUS_MODE_RTU
  Modbus over serial line RTU mode

class enumerator MODBUS_MODE_ASCII
  Modbus over serial line ASCII mode

class enumerator MODBUS_MODE_RAW
  Modbus raw ADU mode

**Functions**

int modbus_read_coils(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint8_t *const coil_tbl, const uint16_t num_coils)
Coil read (FC01)
Sends a Modbus message to read the status of coils from a server.

**Parameters**

- **iface** – Modbus interface index
- **unit_id** – Modbus unit ID of the server
• start_addr – Coil starting address

• coil_tbl – Pointer to an array of bytes containing the value of the coils read. The format is:

<table>
<thead>
<tr>
<th>MSB</th>
<th>LSB</th>
</tr>
</thead>
<tbody>
<tr>
<td>B7</td>
<td>B6</td>
</tr>
<tr>
<td>B5</td>
<td>B4</td>
</tr>
<tr>
<td>B3</td>
<td>B2</td>
</tr>
<tr>
<td>B1</td>
<td>B0</td>
</tr>
</tbody>
</table>

| coil_tbl[0] | #8 #7 | #1 |
| coil_tbl[1] | #16 #15 | #9 |
| :           | :     | :  |

Note that the array that will be receiving the coil values must be greater than or equal to: \((\text{num\_coils} - 1) / 8 + 1\)

• num_coils – Quantity of coils to read

Return values

0 – If the function was successful

```c
int modbus_read_dinputs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint8_t *const di_tbl, const uint16_t num_di)
```

Read discrete inputs (FC02)

Sends a Modbus message to read the status of discrete inputs from a server.

Parameters

• iface – Modbus interface index

• unit_id – Modbus unit ID of the server

• start_addr – Discrete input starting address

• di_tbl – Pointer to an array that will receive the state of the discrete inputs. The format of the array is as follows:

<table>
<thead>
<tr>
<th>MSB</th>
<th>LSB</th>
</tr>
</thead>
<tbody>
<tr>
<td>B7</td>
<td>B6</td>
</tr>
<tr>
<td>B5</td>
<td>B4</td>
</tr>
<tr>
<td>B3</td>
<td>B2</td>
</tr>
<tr>
<td>B1</td>
<td>B0</td>
</tr>
</tbody>
</table>

| di_tbl[0] | #8 #7 | #1 |
| di_tbl[1] | #16 #15 | #9 |
| :           | :     | :  |

Note that the array that will be receiving the discrete input values must be greater than or equal to: \((\text{num\_di} - 1) / 8 + 1\)

• num_di – Quantity of discrete inputs to read

Return values

0 – If the function was successful

```c
int modbus_read_holding_regs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint16_t *const reg_buf, const uint16_t num_regs)
```

Read holding registers (FC03)

Sends a Modbus message to read the value of holding registers from a server.

Parameters

• iface – Modbus interface index

• unit_id – Modbus unit ID of the server

• start_addr – Register starting address
• `reg_buf` – Is a pointer to an array that will receive the current values of the holding registers from the server. The array pointed to by `reg_buf` needs to be able to hold at least `num_regs` entries.

• `num_regs` – Quantity of registers to read

**Return values**

- `0` – If the function was successful

```c
int modbus_read_input_regs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint16_t *const reg_buf, const uint16_t num_regs)
```

Read input registers (FC04)

Sends a Modbus message to read the value of input registers from a server.

**Parameters**

- `iface` – Modbus interface index
- `unit_id` – Modbus unit ID of the server
- `start_addr` – Register starting address
- `reg_buf` – Is a pointer to an array that will receive the current value of the holding registers from the server. The array pointed to by `reg_buf` needs to be able to hold at least `num_regs` entries.
- `num_regs` – Quantity of registers to read

**Return values**

- `0` – If the function was successful

```c
int modbus_write_coil(const int iface, const uint8_t unit_id, const uint16_t coil_addr, const bool coil_state)
```

Write single coil (FC05)

Sends a Modbus message to write the value of single coil to a server.

**Parameters**

- `iface` – Modbus interface index
- `unit_id` – Modbus unit ID of the server
- `coil_addr` – Coils starting address
- `coil_state` – Is the desired state of the coil

**Return values**

- `0` – If the function was successful

```c
int modbus_write_holding_reg(const int iface, const uint8_t unit_id, const uint16_t start_addr, const uint16_t reg_val)
```

Write single holding register (FC06)

Sends a Modbus message to write the value of single holding register to a server unit.

**Parameters**

- `iface` – Modbus interface index
- `unit_id` – Modbus unit ID of the server
- `start_addr` – Coils starting address
- `reg_val` – Desired value of the holding register

**Return values**

- `0` – If the function was successful
int modbus_request_diagnostic(const int iface, const uint8_t unit_id, const uint16_t sfunc, const uint16_t data, uint16_t *const data_out)

Read diagnostic (FC08)
Sends a Modbus message to perform a diagnostic function of a server unit.

Parameters
- iface – Modbus interface index
- unit_id – Modbus unit ID of the server
- sfunc – Diagnostic sub-function code
- data – Sub-function data
- data_out – Pointer to the data value

Return values
0 – If the function was successful

int modbus_write_coils(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint8_t *const coil_tbl, const uint16_t num_coils)

Write coils (FC15)
Sends a Modbus message to write to coils on a server unit.

Parameters
- iface – Modbus interface index
- unit_id – Modbus unit ID of the server
- start_addr – Coils starting address
- coil_tbl – Pointer to an array of bytes containing the value of the coils to write. The format is:
<table>
<thead>
<tr>
<th>MSB</th>
<th>LSB</th>
</tr>
</thead>
<tbody>
<tr>
<td>B7</td>
<td>B0</td>
</tr>
<tr>
<td>B6</td>
<td>B1</td>
</tr>
<tr>
<td>B5</td>
<td>B2</td>
</tr>
<tr>
<td>B4</td>
<td>B3</td>
</tr>
</tbody>
</table>

Note that the array that will be receiving the coil values must be greater than or equal to: (num_coils - 1) / 8 + 1
- num_coils – Quantity of coils to write

Return values
0 – If the function was successful

int modbus_write_holding_regs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint16_t *const reg_buf, const uint16_t num_regs)

Write holding registers (FC16)
Sends a Modbus message to write to integer holding registers to a server unit.

Parameters
- iface – Modbus interface index
- unit_id – Modbus unit ID of the server
- start_addr – Register starting address
• **reg_buf** – Is a pointer to an array containing the value of the holding registers to write. Note that the array containing the register values must be greater than or equal to ‘num_regs’

• **num_regs** – Quantity of registers to write

**Return values**

0 – If the function was successful

```c
int modbus_read_holding_regs_fp(const int iface, const uint8_t unit_id, const uint16_t start_addr, float *const reg_buf, const uint16_t num_regs)
```

Read floating-point holding registers (FC03)

Sends a Modbus message to read the value of floating-point holding registers from a server unit.

**Parameters**

• **iface** – Modbus interface index

• **unit_id** – Modbus unit ID of the server

• **start_addr** – Register starting address

• **reg_buf** – Is a pointer to an array that will receive the current values of the holding registers from the server. The array pointed to by ‘reg_buf’ needs to be able to hold at least ‘num_regs’ entries.

• **num_regs** – Quantity of registers to read

**Return values**

0 – If the function was successful

```c
int modbus_write_holding_regs_fp(const int iface, const uint8_t unit_id, const uint16_t start_addr, float *const reg_buf, const uint16_t num_regs)
```

Write floating-point holding registers (FC16)

Sends a Modbus message to write to floating-point holding registers to a server unit.

**Parameters**

• **iface** – Modbus interface index

• **unit_id** – Modbus unit ID of the server

• **start_addr** – Register starting address

• **reg_buf** – Is a pointer to an array containing the value of the holding registers to write. Note that the array containing the register values must be greater than or equal to ‘num_regs’

• **num_regs** – Quantity of registers to write

**Return values**

0 – If the function was successful

```c
int modbus_iface_get_by_name(const char *iface_name)
```

Get Modbus interface index according to interface name.

If there is more than one interface, it can be used to clearly identify interfaces in the application.

**Parameters**

• **iface_name** – Modbus interface name

**Return values**

Modbus – interface index or negative error value.
int modbus_init_server(const int iface, struct modbus_iface_param *param)
Configure Modbus Interface as raw ADU server.

Parameters
• iface – Modbus RTU interface index
• param – Configuration parameter of the server interface

Return values
0 – If the function was successful

int modbus_init_client(const int iface, struct modbus_iface_param *param)
Configure Modbus Interface as raw ADU client.

Parameters
• iface – Modbus RTU interface index
• param – Configuration parameter of the client interface

Return values
0 – If the function was successful

int modbus_disable(const uint8_t iface)
Disable Modbus Interface.

This function is called to disable Modbus interface.

Parameters
• iface – Modbus interface index

Return values
0 – If the function was successful

int modbus_raw_submit_rx(const int iface, const struct modbus_adu *adu)
Submit raw ADU.

Parameters
• iface – Modbus RTU interface index
• adu – Pointer to the RAW ADU struct that is received

Return values
0 – If transfer was successful

void modbus_raw_put_header(const struct modbus_adu *adu, uint8_t *header)
Put MBAP header into a buffer.

Parameters
• adu – Pointer to the RAW ADU struct
• header – Pointer to the buffer in which MBAP header will be placed.

void modbus_raw_get_header(struct modbus_adu *adu, const uint8_t *header)
Get MBAP header from a buffer.

Parameters
• adu – Pointer to the RAW ADU struct
• header – Pointer to the buffer containing MBAP header

void modbus_raw_set_server_failure(struct modbus_adu *adu)
Set Server Device Failure exception.

This function modifies ADU passed by the pointer.
int modbus_raw_backend_txn(const int iface, struct modbus_adu *adu)

Use interface as backend to send and receive ADU.

This function overwrites ADU passed by the pointer and generates exception responses if backend interface is misconfigured or target device is unreachable.

Parameters

• iface – Modbus client interface index

• adu – Pointer to the RAW ADU struct

Return values

0 – If transfer was successful

#include <modbus.h>

Frame struct used internally and for raw ADU support.

Public Members

uint16_t trans_id
Transaction Identifier

uint16_t proto_id
Protocol Identifier

uint16_t length
Length of the data only (not the length of unit ID + PDU)

struct modbus_iface_param
#include <modbus.h> User parameter structure to configure Modbus interface as client or server.

Public Members

enum modbus_mode mode
   Mode of the interface

uint32_t rx_timeout
   Amount of time client will wait for a response from the server.

struct modbus_serial_param serial
   Serial support parameter of the interface

struct modbus_raw_cb rawcb
   Pointer to raw ADU callback function
```

4.11 Asynchronous Notifications

Zephyr APIs often include async functions where an operation is initiated and the application needs to be informed when it completes, and whether it succeeded. Using \texttt{k.poll()} is often a good method, but some application architectures may be more suited to a callback notification, and operations like enabling clocks and power rails may need to be invoked before kernel functions are available so a busy-wait for completion may be needed.

This API is intended to be embedded within specific subsystems such as \textit{On-Off Manager} and other APIs that support async transactions. The subsystem wrappers are responsible for extracting operation-specific data from requests that include a notification element, and for invoking callbacks with the parameters required by the API.

A limitation is that this API is not suitable for \textit{System Calls} because:

- \texttt{sys.notify} is not a kernel object;
- copying the notification content from userspace will break use of \texttt{CONTAINER_OF} in the implementing function;
- neither the spin-wait nor callback notification methods can be accepted from userspace callers.

Where a notification is required for an asynchronous operation invoked from a user mode thread the subsystem or driver should provide a syscall API that uses \texttt{k.poll.signal} for notification.

4.11.1 API Reference

\texttt{group sys_notify_apis}
Typedefs

typedef void (*sys_notify_generic_callback)()

Generic signature used to notify of result completion by callback.

Functions with this role may be invoked from any context including pre-kernel, ISR, or co-op-
erative or pre-emptible threads. Compatible functions must be isr-ok and not sleep.

Parameters that should generally be passed to such functions include:

- a pointer to a specific client request structure, i.e. the one that contains the sys_notify
  structure.
- the result of the operation, either as passed to sys_notify_finalize() or extracted afterwards
  using sys_notify_fetch_result(). Expected values are service-specific, but the value shall be
  non-negative if the operation succeeded, and negative if the operation failed.

Functions

static inline uint32_t sys_notify_get_method(const struct sys_notify *notify)

int sys_notify_validate(struct sys_notify *notify)

Validate and initialize the notify structure.

This should be invoked at the start of any service-specific configuration validation. It ensures
that the basic asynchronous notification configuration is consistent, and clears the result.

Note that this function does not validate extension bits (zeroed by async notify API init func-
tions like sys_notify_init_callback()). It may fail to recognize that an uninitialized structure
has been passed because only method bits of flags are tested against method settings. To
reduce the chance of accepting an uninitialized operation service validation of structures that
contain an sys_notify instance should confirm that the extension bits are set or cleared as
expected.

Return values

- 0 – on successful validation and reinitialization
- -EINVAL – if the configuration is not valid.

sys_notify_generic_callback sys_notify_finalize(struct sys_notify *notify, int res)

Record and signal the operation completion.

Parameters

- notify – pointer to the notification state structure.
- res – the result of the operation. Expected values are service-specific, but the
  value shall be non-negative if the operation succeeded, and negative if the
  operation failed.

Returns

If the notification is to be done by callback this returns the generic version of the
function to be invoked. The caller must immediately invoke that function with
whatever arguments are expected by the callback. If notification is by spin-wait
or signal, the notification has been completed by the point this function returns,
and a null pointer is returned.

static inline int sys_notify_fetch_result(const struct sys_notify *notify, int *result)

Check for and read the result of an asynchronous operation.

Parameters
• notify – pointer to the object used to specify asynchronous function behavior
  and store completion information.
• result – pointer to storage for the result of the operation. The result is stored
  only if the operation has completed.

Return values
• 0 – if the operation has completed.
• -EAGAIN – if the operation has not completed.

static inline void sys_notify_init_spinwait(struct sys_notify *notify)
Initialize a notify object for spin-wait notification.
Clients that use this initialization receive no asynchronous notification, and instead must pe-
riodically check for completion using sys_notify_fetch_result().
On completion of the operation the client object must be reinitialized before it can be re-used.

Parameters
• notify – pointer to the notification configuration object.

static inline void sys_notify_init_signal(struct sys_notify *notify, struct k_poll_signal *sigp)
Initialize a notify object for (k_poll) signal notification.
Clients that use this initialization will be notified of the completion of operations through the
provided signal.
On completion of the operation the client object must be reinitialized before it can be re-used.

Note: This capability is available only when CONFIG_POLL is selected.

Parameters
• notify – pointer to the notification configuration object.
• sigp – pointer to the signal to use for notification. The value must not be null.
  The signal must be reset before the client object is passed to the on-off service
  API.

static inline void sys_notify_init_callback(struct sys_notify *notify, sys_notify_generic_callback handler)
Initialize a notify object for callback notification.
Clients that use this initialization will be notified of the completion of operations through the
provided callback. Note that callbacks may be invoked from various contexts depending on
the specific service; see sys_notify_generic_callback.
On completion of the operation the client object must be reinitialized before it can be re-used.

Parameters
• notify – pointer to the notification configuration object.
• handler – a function pointer to use for notification.

static inline bool sys_notify_uses_callback(const struct sys_notify *notify)
Detect whether a particular notification uses a callback.

The generic handler does not capture the signature expected by the callback, and the transla-
tion to a service-specific callback must be provided by the service. This check allows abstracted
services to reject callback notification requests when the service doesn’t provide a translation
function.
Returns

true if and only if a callback is to be used for notification.

struct sys_notify
#include <notify.h> State associated with notification for an asynchronous operation.

Objects of this type are allocated by a client, which must use an initialization function (e.g. sys_notify_init_signal()) to configure them. Generally the structure is a member of a service-specific client structure, such as onoff_client.

Control of the containing object transfers to the service provider when a pointer to the object is passed to a service function that is documented to take control of the object, such as onoff_service_request(). While the service provider controls the object the client must not change any object fields. Control reverts to the client:

- if the call to the service API returns an error;
- when operation completion is posted. This may occur before the call to the service API returns.

Operation completion is technically posted when the flags field is updated so that sys_notify_fetch_result() returns success. This will happen before the signal is posted or callback is invoked. Note that although the manager will no longer reference the sys_notify object past this point, the containing object may have state that will be referenced within the callback. Where callbacks are used control of the containing object does not revert to the client until the callback has been invoked. (Re-use within the callback is explicitly permitted.)

After control has reverted to the client the notify object must be reinitialized for the next operation.

The content of this structure is not public API to clients: all configuration and inspection should be done with functions like sys_notify_init_callback() and sys_notify_fetch_result(). However, services that use this structure may access certain fields directly.

4.12 Power Management

Zephyr RTOS power management subsystem provides several means for a system integrator to implement power management support that can take full advantage of the power saving features of SOCs.

4.12.1 Overview

The interfaces and APIs provided by the power management subsystem are designed to be architecture and SOC independent. This enables power management implementations to be easily adapted to different SOCs and architectures.
The architecture and SOC independence is achieved by separating the core infrastructure and the SOC specific implementations. The SOC specific implementations are abstracted to the application and the OS using hardware abstraction layers.

The power management features are classified into the following categories.

- System Power Management
- Device Power Management

### 4.12.2 System Power Management

The kernel enters the idle state when it has nothing to schedule. If enabled via the `CONFIG_PM` Kconfig option, the Power Management Subsystem can put an idle system in one of the supported power states, based on the selected power management policy and the duration of the idle time allotted by the kernel.

It is an application responsibility to set up a wake up event. A wake up event will typically be an interrupt triggered by one of the SoC peripheral modules such as a SysTick, RTC, counter, or GPIO. Depending on the power mode entered, only some SoC peripheral modules may be active and can be used as a wake up source.

The following diagram describes system power management:

- samples/subsys/pm/device_pm/
- tests/subsys/pm/power_mgmt/
- tests/subsys/pm/power_mgmt_soc/
- tests/subsys/pm/power_states_api/

**Power States**

The power management subsystem contains a set of states based on power consumption and context retention.

The list of available power states is defined by `pm_state`. In general power states with higher indexes will offer greater power savings and have higher wake latencies.

**Power Management Policies**

The power management subsystem supports the following power management policies:

- Residency based
- Application defined

The policy manager is responsible for informing the power subsystem which power state the system should transition to based on states defined by the platform and other constraints such as a list of allowed states.

More details on the states definition can be found in the zephyr, power-state binding documentation.

**Residency** The power management system enters the power state which offers the highest power savings, and with a minimum residency value (see zephyr, power-state) less than or equal to the scheduled system idle time duration.

This policy also accounts for the time necessary to become active again. The core logic used by this policy to select the best power state is:

```c
if (time_to_next_scheduled_event >= (state.min_residency_us + state.exit_latency)) {
    return state
}
```

**Application** The application defines the power management policy by implementing the `pm_policy_next_state()` function. In this policy the application is free to decide which power state the system should transition to based on the remaining time for the next scheduled timeout.

An example of an application that defines its own policy can be found in tests/subsys/pm/power_mgmt/.

**Policy and Power States** The power management subsystem allows different Zephyr components and applications to configure the policy manager to block system from transitioning into certain power states. This can be used by devices when executing tasks in background to prevent the system from going to a specific state where it would lose context.
4.12.3 Device Power Management

Introduction

Device power management (PM) on Zephyr is a feature that enables devices to save energy when they are not being used. This feature can be enabled by setting `CONFIG_PM_DEVICE` to y. When this option is selected, device drivers implementing power management will be able to take advantage of the device power management subsystem.

Zephyr supports two types of device power management:

- Device Runtime Power Management
- System Power Management

Device Runtime Power Management

In this method, the application or any component that deals with devices directly and has the best knowledge of their use, performs the device power management. This saves power if some devices that are not in use can be turned off or put in power saving mode. This method allows saving power even when the CPU is active. The components that use the devices need to be power aware and should be able to make decisions related to managing device power.

When using this type of device power management, the kernel can change CPU power states quickly when `pm_system_suspend()` gets called. This is because it does not need to spend time doing device power management if the devices are already put in the appropriate power state by the application or component managing the devices.

For more information, see Device Runtime Power Management.

System Power Management

When using this type, device power management is mostly done inside `pm_system_suspend()` along with entering a CPU or SOC power state.

If a decision to enter a CPU lower power state is made, the power management subsystem will suspend devices before changing state. The subsystem takes care of suspending devices following their initialization order, ensuring that possible dependencies between them are satisfied. As soon as the CPU wakes up from a sleep state, devices are resumed in the opposite order that they were suspended.

**Note:** When using System Power Management, device transitions can be run from the idle thread. As functions in this context cannot block, transitions that intend to use blocking APIs must check whether they can do so with `k_can_yield()`.

This type of device power management can be useful when the application is not power aware and does not implement runtime device power management. Though, Device Runtime Power Management is the preferred option for device power management.

**Note:** When using this type of device power management, the CPU will only enter a low power state only if no device is in the middle of a hardware transaction that cannot be interrupted.

**Note:** This type of device power management is disabled when `CONFIG_PM_DEVICE_RUNTIME_EXCLUSIVE` is set to y (that is the default value when `CONFIG_PM_DEVICE_RUNTIME` is enabled).
Device Power Management States

The power management subsystem defines device states in `pm_device_state`. This type is used to track power states of a particular device. It is important to emphasize that, although the state is tracked by the subsystem, it is the responsibility of each device driver to handle device actions( `pm_device_action` ) which change device state.

Each `pm_device_action` have a direct an unambiguous relationship with a `pm_device_state`.

As mentioned above, device drivers do not directly change between these states. This is entirely done by the power management subsystem. Instead, drivers are responsible for implementing any hardware-specific tasks needed to handle state changes.

Device Model with Power Management Support

Drivers initialize devices using macros. See `Device Driver Model` for details on how these macros are used. A driver which implements device power management support must provide these macros with arguments that describe its power management implementation.

Use `PM_DEVICE_DEFINE` or `PM_DEVICE_DT_DEFINE` to define the power management resources required by a driver. These macros allocate the driver-specific state which is required by the power management subsystem.

Drivers can use `PM_DEVICE_GET` or `PM_DEVICE_DT_GET` to get a pointer to this state. These pointers should be passed to `DEVICE_DEFINE` or `DEVICE_DT_DEFINE` to initialize the power management field in each device.

Here is some example code showing how to implement device power management support in a device driver.

```c
#define DT_DRV_COMPAT dummy_device

static int dummy_driver_pm_action(const struct device *dev,      
enum pm_device_action *action)
{
    switch (action) {
(continues on next page)```
case PM_DEVICE_ACTION_SUSPEND:
    /* suspend the device */
    ...
    break;
case PM_DEVICE_ACTION_RESUME:
    /* resume the device */
    ...
    break;
case PM_DEVICE_ACTION_TURN_ON:
    /* powered on the device, used when the power
     * domain this device belongs is resumed.
     */
    ...
    break;
case PM_DEVICE_ACTION_TURN_OFF:
    /* power off the device, used when the power
     * domain this device belongs is suspended.
     */
    ...
    break;
default:
    return -ENOTSUP;
}

return 0;

PM_DEVICE_DT_INST_DEFINE(0, dummy_driver_pm_action);

DEVICE_DT_INST_DEFINE(0, &dummy_init,
    PM_DEVICE_DT_INST_GET(0), NULL, NULL, POST_KERNEL,
    CONFIG_KERNEL_INIT_PRIORITY_DEFAULT, NULL);

Busy Status Indication

When the system is idle and the SoC is going to sleep, the power management subsystem can suspend
devices, as described in System Power Management. This can cause device hardware to lose some states.
Suspending a device which is in the middle of a hardware transaction, such as writing to a flash memory,
may lead to undefined behavior or inconsistent states. This API guards such transactions by indicating
to the kernel that the device is in the middle of an operation and should not be suspended.

When pm_device_busy_set() is called, the device is marked as busy and the system will not do power
management on it. After the device is no longer doing an operation and can be suspended, it should call
pm_device_busy_clear().

Wakeup capability

Some devices are capable of waking the system up from a sleep state. When a device has
such capability, applications can enable or disable this feature on a device dynamically using
pm_device_wakeup_enable().

This property can be set on device declaring the property "wakeup-source" in the device node in device-
tree. For example, this devicetree fragment sets the gpio0 device as a "wakeup" source:
By default, “wakeup” capable devices do not have this functionality enabled during the device initialization. Applications can enable this functionality later calling `pm_device_wakeup_enable()`.

Note: This property is only used by the system power management to identify devices that should not be suspended. It is responsibility of driver or the application to do any additional configuration required by the device to support it.

Power Domain

Power domain on Zephyr is represented as a regular device. The power management subsystem ensures that a domain is resumed before and suspended after devices using it. For more details, see Power Domain.

4.12.4 Device Runtime Power Management

Introduction

The device runtime power management (PM) framework is an active power management mechanism which reduces the overall system power consumption by suspending the devices which are idle or not used independently of the system state. It can be enabled by setting `CONFIG_PM_DEVICE_RUNTIME`. In this model the device driver is responsible to indicate when it needs the device and when it does not. This information is used to determine when to suspend or resume a device based on usage count.

When device runtime power management is enabled on a device, its state will be initially set to a `PM_DEVICE_STATE_SUSPENDED` indicating it is not used. On the first device request, it will be resumed and so put into the `PM_DEVICE_STATE_ACTIVE` state. The device will remain in this state until it is no longer used. At this point, the device will be suspended until the next device request. If the suspension is performed synchronously the device will be immediately put into the `PM_DEVICE_STATE_SUSPENDED` state, whereas if it is performed asynchronously, it will be put into the `PM_DEVICE_STATE_SUSPENDING` state first and then into the `PM_DEVICE_STATE_SUSPENDED` state when the action is run.

The device runtime power management framework has been designed to minimize devices power consumption with minimal application work. Device drivers are responsible for indicating when they need the device to be operational and when they do not. Therefore, applications can not manually suspend or resume a device. An application can, however, decide when to disable or enable runtime power management for a device. This can be useful, for example, if an application wants a particular device to be always active.

Design principles

When runtime PM is enabled on a device it will no longer be resumed or suspended during system power transitions. Instead, the device is fully responsible to indicate when it needs a device and when it does not. The device runtime PM API uses reference counting to keep track of device’s usage. This allows
the API to determine when a device needs to be resumed or suspended. The API uses the `get` and `put` terminology to indicate when a device is needed or not, respectively. This mechanism plays a key role when we account for device dependencies. For example, if a bus device is used by multiple sensors, we can keep the bus active until the last sensor has finished using it.

**Note:** As of today, the device runtime power management API does not manage device dependencies. This effectively means that, if a device depends on other devices to operate (e.g., a sensor may depend on a bus device), the bus will be resumed and suspended on every transaction. In general, it is more efficient to keep parent devices active when their children are used, since the children may perform multiple transactions in a short period of time. Until this feature is added, devices can manually `get` or `put` their dependencies.

The `pm_device_runtime_get()` function can be used by a device driver to indicate it needs the device to be active or operational. This function will increase device usage count and resume the device if necessary. Similarly, the `pm_device_runtime_put()` function can be used to indicate that the device is no longer needed. This function will decrease the device usage count and suspend the device if necessary. It is worth to note that in both cases, the operation is carried out synchronously. The sequence diagram shown in Fig. 4.5 illustrates how a device can use this API and the expected sequence of events.

The synchronous model is as simple as it gets. However, it may introduce unnecessary delays since the application will not get the operation result until the device is suspended (in case device is no longer used). It will likely not be a problem if the operation is fast, e.g., a register toggle. However, the situation will not be the same if suspension involves sending packets through a slow bus. For this reason the device drivers can also make use of the `pm_device_runtime_put_async()` function. This function will schedule the suspend operation, again, if device is no longer used. The suspension will then be carried out when the system work queue gets the chance to run. The sequence diagram in Fig. 4.6 illustrates this scenario.

PM_DEVICE_ACTION_SUSPEND

Fig. 4.6: Asynchronous operation on a single device

Chapter 4. OS Services
Implementation guidelines

In a first place, a device driver needs to implement the PM action callback used by the PM subsystem to suspend or resume devices.

```c
static int mydev_pm_action(const struct device *dev, enum pm_device_action *action)
{
    switch (action) {
    case PM_DEVICE_ACTION_SUSPEND:
        /* suspend the device */
        ...
        break;
    case PM_DEVICE_ACTION_RESUME:
        /* resume the device */
        ...
        break;
    default:
        return -ENOTSUP;
    }
    return 0;
}
```

The PM action callback calls are serialized by the PM subsystem, therefore, no special synchronization is required.

To enable device runtime power management on a device, the driver needs to call `pm_device_runtime_enable()` at initialization time. Note that this function will suspend the device if its state is `PM_DEVICE_STATE_ACTIVE`. In case the device is physically suspended, the init function should call `pm_device_init_suspended()` before calling `pm_device_runtime_enable()`.

```c
/* device driver initialization function */
static int mydev_init(const struct device *dev)
{
    int ret;
    ...

    /* OPTIONAL: mark device as suspended if it is physically suspended */
    pm_device_init_suspended(dev);

    /* enable device runtime power management */
    ret = pm_device_runtime_enable(dev);
    if ((ret < 0) && (ret != -ENOSYS)) {
        return ret;
    }
}
```

Assuming an example device driver that implements an operation API call, the `get` and `put` operations could be carried out as follows:

```c
static int mydev_operation(const struct device *dev)
{
    int ret;

    /* "get" device (increases usage count, resumes device if suspended) */
    ret = pm_device_runtime_get(dev);
    if (ret < 0) {
        return ret;
    }
}
```

(continues on next page)
In case the suspend operation is slow, the device driver can use the asynchronous API:

```c
static int mydev_operation(const struct device *dev)
{
    int ret;

    /* "get" device (increases usage count, resumes device if suspended) */
    ret = pm_device_runtime_get(dev);
    if (ret < 0) {
        return ret;
    }

    /* do something with the device */
    ...

    /* "put" device (decreases usage count, schedule suspend if no more users) */
    return pm_device_runtime_put_async(dev);
}
```

4.12.5 Power Domain

Introduction

The Zephyr power domain abstraction is designed to support groupings of devices powered by a common source to be notified of power source state changes in a generic fashion. Application code that is using device A does not need to know that device B is on the same power domain and should also be configured into a low power state.

Power domains are optional on Zephyr, to enable this feature the option `CONFIG_PM_DEVICE_POWER_DOMAIN` has to be set.

When a power domain turns itself on or off, it is the responsibility of the power domain to notify all devices using it through their power management callback called with `PM_DEVICE_ACTION_TURN_ON` or `PM_DEVICE_ACTION_TURN_OFF` respectively. This work flow is illustrated in the diagram bellow.

**Internal Power Domains**  Most of the devices in an SoC have independent power control that can be turned on or off to reduce power consumption. But there is a significant amount of static current leakage that can't be controlled only using device power management. To solve this problem, SoCs normally are divided into several regions grouping devices that are generally used together, so that an unused region can be completely powered off to eliminate this leakage. These regions are called “power domains”, can be present in a hierarchy and can be nested.

**External Power Domains**  Devices external to a SoC can be powered from sources other than the main power source of the SoC. These external sources are typically a switch, a regulator, or a dedicated power IC. Multiple devices can be powered from the same source, and this grouping of devices is typically called a “power domain”.

754 Chapter 4. OS Services
Power Management

Placing devices on power domains can be done for a variety of reasons, including to enable devices with high power consumption in low power mode to be completely turned off when not in use.

**Implementation guidelines**

In a first place, a device that acts as a power domain needs to declare compatible with `power-domain`.

Taking the **Power domain work flow** as example, the following code defines a domain called `gpio_domain`.

```c
static int mydomain_pm_action(const struct device *dev, enum pm_device_action *action)
{
    switch (action) {
        case PM_DEVICE_ACTION_RESUME:
            /* resume the domain */
            ...
            /* notify children domain is now powered */
            pm_device_children_action_run(dev, PM_DEVICE_ACTION_TURN_ON, NULL);
            break;
        case PM_DEVICE_ACTION_SUSPEND:
            /* notify children domain is going down */
            pm_device_children_action_run(dev, PM_DEVICE_ACTION_TURN_OFF, NULL);
            /* suspend the domain */
            ...
            break;
        case PM_DEVICE_ACTION_TURN_ON:
            /* turn on the domain (e.g. setup control pins to disabled) */
            ...
            break;
        case PM_DEVICE_ACTION_TURN_OFF:
            /* turn off the domain (e.g. reset control pins to default state) */
            ...
            break;
    }
}
```

(continues on next page)
default:
    return -ENOTSUP;
}

return 0;
}

Devices belonging to this device can be declared referring it in the power-domain node's property. The example below declares devices gpio0 and gpio1 belonging to domain gpio_domain.

```
&gpio0 {
    compatible = "zephyr,gpio-emul";
    gpio-controller;
    power-domain = <&gpio_domain>;
};

&gpio1 {
    compatible = "zephyr,gpio-emul";
    gpio-controller;
    power-domain = <&gpio_domain>;
};
```

All devices under a domain will be notified when the domain changes state. These notifications are sent as actions in the device PM action callback and can be used by them to do any additional work required. They can safely be ignored though.

```
static int mydev_pm_action(const struct device *dev,
    enum pm_device_action *action)
{
    switch (action) {
    case PM_DEVICE_ACTION_SUSPEND:
        /* suspend the device */
        ...
        break;
    case PM_DEVICE_ACTION_RESUME:
        /* resume the device */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_ON:
        /* configure the device into low power mode */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_OFF:
        /* prepare the device for power down */
        ...
        break;
    default:
        return -ENOTSUP;
    }

    return 0;
}
```

**Note:** It is responsibility of driver or the application to set the domain as “wakeup” source if a device depending on it is used as “wakeup” source.
4.12.6 Power Management

System PM APIs

group subsys_pm_sys

System Power Management API.

Functions

bool pm_state_force(uint8_t cpu, const struct pm_state_info *info)

Force usage of given power state.

This function overrides decision made by PM policy forcing usage of given power state upon
next entry of the idle thread.

Note: This function can only run in thread context

Parameters

• cpu – CPU index.
• info – Power state which should be used in the ongoing suspend operation.

void pm_notifier_register(struct pm_notifier *notifier)

Register a power management notifier.

Register the given notifier from the power management notification list.

Parameters

• notifier – pm_notifier object to be registered.

int pm_notifier_unregister(struct pm_notifier *notifier)

Unregister a power management notifier.

Remove the given notifier from the power management notification list. After that this object
callbacks will not be called.

Parameters

• notifier – pm_notifier object to be unregistered.

Returns

0 if the notifier was successfully removed, a negative value otherwise.

const struct pm_state_info *pm_state_next_get(uint8_t cpu)

Gets the next power state that will be used.

This function returns the next power state that will be used by the SoC.

Parameters

• cpu – CPU index.

Returns

next pm_state_info that will be used
struct pm_notifier
#include <pm.h> Power management notifier struct

This struct contains callbacks that are called when the target enters and exits power states. As currently implemented the entry callback is invoked when transitioning from PM_STATE_ACTIVE to another state, and the exit callback is invoked when transitioning from a non-active state to PM_STATE_ACTIVE. This behavior may change in the future.

Note: These callbacks can be called from the ISR of the event that caused the kernel exit from idling.

Note: It is not allowed to call pm_notifier_unregister or pm_notifier_register from these callbacks because they are called with the spin locked in those functions.

Public Members

void (*state_entry)(enum pm_state state)
Application defined function for doing any target specific operations for power state entry.

void (*state_exit)(enum pm_state state)
Application defined function for doing any target specific operations for power state exit.

States

group subsys_pm_states
System Power Management States.

Defines

PM_STATE_INFO_DT_INIT(node_id)
Initializer for struct pm_state_info given a DT node identifier with zephyr,power-state compatible.

Parameters
• node_id – A node identifier with compatible zephyr,power-state

PM_STATE_DT_INIT(node_id)
Initializer for enum pm_state given a DT node identifier with zephyr,power-state compatible.

Parameters
• node_id – A node identifier with compatible zephyr,power-state

DT_NUM_CPU_POWER_STATES(node_id)
Obtain number of CPU power states supported by the given CPU node identifier.

Parameters
• node_id – A CPU node identifier.

Returns
Number of supported CPU power states.
PM_STATE_INFO_LIST_FROM_DT_CPU(node_id)
Initialize an array of struct pm_state_info with information from all the states present in the given CPU node identifier.

Example devicetree fragment:

cpus {
    ...
    cpu0: cpu@0 {
        device_type = "cpu";
        ...
        cpu-power-states = <&state0 &state1>;
    };
    ...
}

power-states {
    state0: state0 {
        compatible = "zephyr,power-state";
        power-state-name = "suspend-to-idle";
        min-residency-us = <10000>;
        exit-latency-us = <100>;
    };

    state1: state1 {
        compatible = "zephyr,power-state";
        power-state-name = "suspend-to-ram";
        min-residency-us = <50000>;
        exit-latency-us = <500>;
    };
}

Example usage:

const struct pm_state_info states[] =
    PM_STATE_INFO_LIST_FROM_DT_CPU(DT_NODELABEL(cpu0));

Parameters

• node_id – A CPU node identifier.

PM_STATE_LIST_FROM_DT_CPU(node_id)
Initialize an array of struct pm_state with information from all the states present in the given CPU node identifier.

Example devicetree fragment:

cpus {
    ...
    cpu0: cpu@0 {
        device_type = "cpu";
        ...
        cpu-power-states = <&state0 &state1>;
    };
    ...
}
Example usage:

```c
const enum pm_state states[] = PM_STATE_LIST_FROM_DT_CPU(DT_NODELABEL(cpu0));
```

**Parameters**

- `node_id` – A CPU node identifier.

**Enums**

enum pm_state

Power management state

**Values:**

enumerator PM_STATE_ACTIVE

Runtime active state.

The system is fully powered and active.

---

**Note:** This state is correlated with ACPI G0/S0 state

enumerator PM_STATE_RUNTIME_IDLE

Runtime idle state.

Runtime idle is a system sleep state in which all of the cores enter deepest possible idle state and wait for interrupts, no requirements for the devices, leaving them at the states where they are.

---

**Note:** This state is correlated with ACPI S0ix state
Suspend to idle state.
The system goes through a normal platform suspend where it puts all of the cores in deepest possible idle state and may put peripherals into low-power states. No operating state is lost (i.e., the CPU core does not lose execution context), so the system can go back to where it left off easily enough.

**Note:** This state is correlated with ACPI S1 state

Standby state.
In addition to putting peripherals into low-power states all non-boot CPUs are powered off. It should allow more energy to be saved relative to suspend to idle, but the resume latency will generally be greater than for that state. But it should be the same state with suspend to idle state on uniprocessor system.

**Note:** This state is correlated with ACPI S2 state

Suspend to ram state.
This state offers significant energy savings by powering off as much of the system as possible, where memory should be placed into the self-refresh mode to retain its contents. The state of devices and CPUs is saved and held in memory, and it may require some boot-strapping code in ROM to resume the system from it.

**Note:** This state is correlated with ACPI S3 state

Suspend to disk state.
This state offers significant energy savings by powering off as much of the system as possible, including the memory. The contents of memory are written to disk or other non-volatile storage, and on resume it’s read back into memory with the help of boot-strapping code, restores the system to the same point of execution where it went to suspend to disk.

**Note:** This state is correlated with ACPI S4 state

Soft off state.
This state consumes a minimal amount of power and requires a large latency in order to return to runtime active state. The contents of system (CPU and memory) will not be preserved, so the system will be restarted as if from initial power-up and kernel boot.

**Note:** This state is correlated with ACPI G2/S5 state
enumerator PM_STATE_COUNT
    Number of power management states (internal use)

Functions

uint8_t pm_state_cpu_get_all(uint8_t cpu, const struct pm_state_info **states)
    Obtain information about all supported states by a CPU.

Parameters

• cpu – CPU index.
• states – Where to store the list of supported states.

Returns
    Number of supported states.

struct pm_state_info
    #include <state.h> Information about a power management state

Public Members

uint8_t substate_id
    Some platforms have multiple states that map to one Zephyr power state. This property allows the platform distinguish them. e.g:

    power-states {
        state0: state0 {
            compatible = "zephyr,power-state";
            power-state-name = "suspend-to-idle";
            substate-id = <1>;
            min-residency-us = <10000>;
            exit-latency-us = <100>;
        };
        state1: state1 {
            compatible = "zephyr,power-state";
            power-state-name = "suspend-to-idle";
            substate-id = <2>;
            min-residency-us = <20000>;
            exit-latency-us = <200>;
        };
    }

uint32_t min_residency_us
    Minimum residency duration in microseconds. It is the minimum time for a given idle state to be worthwhile energywise.

    Note: 0 means that this property is not available for this state.

uint32_t exit_latency_us
Worst case latency in microseconds required to exit the idle state.

**Note:** 0 means that this property is not available for this state.

**Policy**

*group subsys_pm_sys_policy*

System Power Management Policy API.

**Defines**

**PM_ALL_SUBSTATES**

Special value for 'all substates'.

**Typedefs**

typedef void (*pm_policy_latency_changed_cb_t)(int32_t latency)

Callback to notify when maximum latency changes.

**Param latency**

New maximum latency. Positive value represents latency in microseconds. SYS_FOREVER_US value lifts the latency constraint. Other values are forbidden.

**Functions**

def pm_policy_state_lock_get(enum pm_state state, uint8_t substate_id)

Increase a power state lock counter.

A power state will not be allowed on the first call of pm_policy_state_lock_get(). Subsequent calls will just increase a reference count, thus meaning this API can be safely used concurrently. A state will be allowed again after pm_policy_state_lock_put() is called as many times as pm_policy_state_lock_get().

Note that the PM_STATE_ACTIVE state is always allowed, so calling this API with PM_STATE_ACTIVE will have no effect.

**See also:**

*pm_policy_state_lock_put()*

**Parameters**

- **state** – Power state.
- **substate_id** – Power substate ID. Use PM_ALL_SUBSTATES to affect all the substates in the given power state.
void pm_policy_state_lock_put(enum pm_state state, uint8_t substate_id)
Decrease a power state lock counter.

See also:

pm_policy_state_lock_get()

Parameters

• state – Power state.
• substate_id – Power substate ID. Use PM_ALL_SUBSTATES to affect all the
substates in the given power state.

bool pm_policy_state_lock_is_active(enum pm_state state, uint8_t substate_id)
Check if a power state lock is active (not allowed).

Parameters

• state – Power state.
• substate_id – Power substate ID. Use PM_ALL_SUBSTATES to affect all the
substates in the given power state.

Return values

• true – if power state lock is active.
• false – if power state lock is not active.

void pm_policy_latency_request_add(struct pm_policy_latency_request *req, uint32_t value)
Add a new latency requirement.

The system will not enter any power state that would make the system to exceed the given
latency value.

Parameters

• req – Latency request.
• value – Maximum allowed latency in microseconds.

void pm_policy_latency_request_update(struct pm_policy_latency_request *req, uint32_t value)
Update a latency requirement.

Parameters

• req – Latency request.
• value – New maximum allowed latency in microseconds.

void pm_policy_latency_request_remove(struct pm_policy_latency_request *req)
Remove a latency requirement.

Parameters

• req – Latency request.

void pm_policy_latency_changed_subscribe(struct pm_policy_latency_subscription *req,
  pm_policy_latency_changed_cb_t cb)
Subscribe to maximum latency changes.

Parameters

• req – Subscription request.
• cb – Callback function (NULL to disable).
void pm_policy_latency_changed_unsubscribe(struct pm_policy_latency_subscription *req)
Unsubscribe to maximum latency changes.

Parameters
• req – Subscription request.

struct pm_policy_latency_subscription
#include <policy.h> Latency change subscription.

Public Members

pm_policy_latency_changed_cb_t cb
Notification callback.

struct pm_policy_latency_request
#include <policy.h> Latency request.

Public Members

uint32_t value
Request value.

Hooks

group subsys_pm_sys_hooks
System Power Management Hooks.

Functions

void pm_state_set(enum pm_state state, uint8_t substate_id)
Put processor into a power state.
This function implements the SoC specific details necessary to put the processor into available power states.

Parameters
• state – Power state.
• substate_id – Power substate id.

void pm_state_exit_post_ops(enum pm_state state, uint8_t substate_id)
Do any SoC or architecture specific post ops after sleep state exits.
This function is a place holder to do any operations that may be needed to be done after sleep state exits. Currently it enables interrupts after resuming from sleep state. In future, the enabling of interrupts may be moved into the kernel.

Parameters
• state – Power state.
• substate_id – Power substate id.
Device PM APIs

```c
PM_DEVICE_DEFINE(dev_id, pm_action_cb)
Define device PM resources for the given device name.
```

See also:

```
PM_DEVICE_DT_DEFINE, PM_DEVICE_DT_INST_DEFINE
```

**Note:** This macro is a no-op if `CONFIG_PM_DEVICE` is not enabled.

**Parameters**

- `dev_id` – Device id.
- `pm_action_cb` – PM control callback.

```
PM_DEVICE_DEFINE(node_id, pm_action_cb)
Define device PM resources for the given node identifier.
```

See also:

```
PM_DEVICE_DT_INST_DEFINE, PM_DEVICE_DEFINE
```

**Note:** This macro is a no-op if `CONFIG_PM_DEVICE` is not enabled.

**Parameters**

- `node_id` – Node identifier.
- `pm_action_cb` – PM control callback.

```
PM_DEVICE_DEFINE_INST_DEFINE(idx, pm_action_cb)
Define device PM resources for the given instance.
```

See also:

```
PM_DEVICE_DT_DEFINE, PM_DEVICE_DEFINE
```

**Note:** This macro is a no-op if `CONFIG_PM_DEVICE` is not enabled.

**Parameters**

- `idx` – Instance index.
- `pm_action_cb` – PM control callback.
PM_DEVICE_GET(dev_id)
Obtain a reference to the device PM resources for the given device.

Parameters
• dev_id – Device id.

Returns
Reference to the device PM resources (NULL if device CONFIG_PM_DEVICE is disabled).

PM_DEVICE_DT_GET(node_id)
Obtain a reference to the device PM resources for the given node.

Parameters
• node_id – Node identifier.

Returns
Reference to the device PM resources (NULL if device CONFIG_PM_DEVICE is disabled).

PM_DEVICE_DT_INST_GET(idx)
Obtain a reference to the device PM resources for the given instance.

Parameters
• idx – Instance index.

Returns
Reference to the device PM resources (NULL if device CONFIG_PM_DEVICE is disabled).

Typedefs

typedef int (*pm_device_action_cb_t)(const struct device *dev, enum pm_device_action action)
Device PM action callback.

Param dev
Device instance.

Param action
Requested action.

Retval 0
If successful.

Retval -ENOTSUP
If the requested action is not supported.

Retval Errno
Other negative errno on failure.

typedef bool (*pm_device_action_failed_cb_t)(const struct device *dev, int err)
Device PM action failed callback.

Param dev
Device that failed the action.

Param err
Return code of action failure.

Return
True to continue iteration, false to halt iteration.
**Enums**

enum pm_device_state

Device power states.

*Values:*

enumerator PM_DEVICE_STATE_ACTIVE

Device is in active or regular state.

enumerator PM_DEVICE_STATE_SUSPENDED

Device is suspended.

**Note:** Device context may be lost.

enumerator PM_DEVICE_STATE_SUSPENDING

Device is being suspended.

enumerator PM_DEVICE_STATE_OFF

Device is turned off (power removed).

**Note:** Device context is lost.

enum pm_device_action

Device PM actions.

*Values:*

enumerator PM_DEVICE_ACTION_SUSPEND

Suspend.

enumerator PM_DEVICE_ACTION_RESUME

Resume.

enumerator PM_DEVICE_ACTION_TURN_OFF

Turn off.

**Note:** Action triggered only by a power domain.

enumerator PM_DEVICE_ACTION_TURN_ON

Turn on.

**Note:** Action triggered only by a power domain.

**Functions**
const char *pm_device_state_str(enum pm_device_state state)
Get name of device PM state.

Parameters
• state – State id which name should be returned

int pm_device_action_run(const struct device *dev, enum pm_device_action action)
Run a pm action on a device.
This function calls the device PM control callback so that the device does the necessary operations to execute the given action.

Parameters
• dev – Device instance.
• action – Device pm action.

Return values
• 0 – If successful.
• -ENOTSUP – If requested state is not supported.
• -EALREADY – If device is already at the requested state.
• -EBUSY – If device is changing its state.
• -ENOSYS – If device does not support PM.
• -EPERM – If device has power state locked.
• Errno – Other negative errno on failure.

void pm_device_children_action_run(const struct device *dev, enum pm_device_action action, pm_device_action_failed_cb_t failure_cb)
Run a pm action on all children of a device.
This function calls all child devices PM control callback so that the device does the necessary operations to execute the given action.

Parameters
• dev – Device instance.
• action – Device pm action.
• failure_cb – Function to call if a child fails the action, can be NULL.

int pm_device_state_get(const struct device *dev, enum pm_device_state *state)
Obtain the power state of a device.

Parameters
• dev – Device instance.
• state – Pointer where device power state will be stored.

Return values
• 0 – If successful.
• -ENOSYS – If device does not implement power management.

static inline void pm_device_init_suspended(const struct device *dev)
Initialize a device state to PM_DEVICE_STATE_SUSPENDED.
By default device state is initialized to PM_DEVICE_STATE_ACTIVE. However in order to save power some drivers may choose to only initialize the device to the suspended state, or actively put the device into the suspended state. This function can therefore be used to notify the PM subsystem that the device is in PM_DEVICE_STATE_SUSPENDED instead of the default.
Parameters

- `dev` – Device instance.

static inline void pm_device_init_off(const struct device *dev)

Initialize a device state to `PM_DEVICE_STATE_OFF`.

By default device state is initialized to `PM_DEVICE_STATE_ACTIVE`. In general, this makes sense because the device initialization function will resume and configure a device, leaving it operational. However, when power domains are enabled, the device may be connected to a switchable power source, in which case it won't be powered at boot. This function can therefore be used to notify the PM subsystem that the device is in `PM_DEVICE_STATE_OFF` instead of the default.

Parameters

- `dev` – Device instance.

void pm_device_busy_set(const struct device *dev)

Mark a device as busy.

Devices marked as busy will not be suspended when the system goes into low-power states. This can be useful if, for example, the device is in the middle of a transaction.

See also:

`pm_device_busy_clear()`

Parameters

- `dev` – Device instance.

void pm_device_busy_clear(const struct device *dev)

Clear a device busy status.

See also:

`pm_device_busy_set()`

Parameters

- `dev` – Device instance.

bool pm_device_is_any_busy(void)

Check if any device is busy.

Return values

- `false` – If no device is busy
- `true` – If one or more devices are busy

bool pm_device_is_busy(const struct device *dev)

Check if a device is busy.

Parameters

- `dev` – Device instance.

Return values

- `false` – If the device is not busy
- `true` – If the device is busy
bool pm_device_wakeup_enable(const struct device *dev, bool enable)
Enable or disable a device as a wake up source.

A device marked as a wake up source will not be suspended when the system goes into low-power modes, thus allowing to use it as a wake up source for the system.

Parameters
- dev – Device instance.
- enable – true to enable or false to disable

Return values
- true – If the wakeup source was successfully enabled.
- false – If the wakeup source was not successfully enabled.

bool pm_device_wakeup_is_enabled(const struct device *dev)
Check if a device is enabled as a wake up source.

Parameters
- dev – Device instance.

Return values
- true – if the wakeup source is enabled.
- false – if the wakeup source is not enabled.

bool pm_device_wakeup_is_capable(const struct device *dev)
Check if a device is wake up capable.

Parameters
- dev – Device instance.

Return values
- true – If the device is wake up capable.
- false – If the device is not wake up capable.

void pm_device_state_lock(const struct device *dev)
Lock current device state.

This function locks the current device power state. Once locked the device power state will not be changed by system power management or device runtime power management until unlocked.

See also:
- pm_device_state_unlock

Note: The given device should not have device runtime enabled.

Parameters
- dev – Device instance.

void pm_device_state_unlock(const struct device *dev)
Unlock the current device state.

Unlocks a previously locked device pm.
See also:

`pm_device_state_lock`

**Parameters**

- `dev` – Device instance.

```c
bool pm_device_state_is_locked(const struct device *dev)
```

Check if the device pm is locked.

**Parameters**

- `dev` – Device instance.

**Return values**

- `true` – If device is locked.
- `false` – If device is not locked.

```c
bool pm_device_on_power_domain(const struct device *dev)
```

Check if the device is on a switchable power domain.

**Parameters**

- `dev` – Device instance.

**Return values**

- `true` – If device is on a switchable power domain.
- `false` – If device is not on a switchable power domain.

```c
int pm_device_power_domain_add(const struct device *dev, const struct device *domain)
```

Add a device to a power domain.

This function adds a device to a given power domain.

**Parameters**

- `dev` – Device to be added to the power domain.
- `domain` – Power domain.

**Return values**

- `0` – If successful.
- `-EALREADY` – If device is already part of the power domain.
- `-ENOSYS` – If the application was built without power domain support.
- `-ENOSPC` – If there is no space available in the power domain to add the device.

```c
int pm_device_power_domain_remove(const struct device *dev, const struct device *domain)
```

Remove a device from a power domain.

This function removes a device from a given power domain.

**Parameters**

- `dev` – Device to be removed from the power domain.
- `domain` – Power domain.

**Return values**

- `0` – If successful.
- `-ENOSYS` – If the application was built without power domain support.
- `-ENOTENT` – If device is not in the given domain.
bool pm_device_is_powered(const struct device *dev)
Check if the device is currently powered.

Parameters
• dev – Device instance.

Return values
• true – If device is currently powered
• false – If device is not currently powered

struct pm_device
#include <device.h> Device PM info.

Public Members

const struct device *dev
Pointer to the device

struct k_mutex lock
Lock to synchronize the get/put operations

uint32_t usage
Device usage count

struct k_work_delayable work
Work object for asynchronous calls

struct k_condvar condvar
Event conditional var to listen to the sync request events

enum pm_device_state state
Device power state

pm_device_action_cb_t action_cb
Device PM action callback

Device Runtime PM APIs

group subsys_pm_device_runtime
Device Runtime Power Management API.

Functions

int pm_device_runtime_enable(const struct device *dev)
Enable device runtime PM.
This function will enable runtime PM on the given device. If the device is in
PMDEVICESTATEACTIVE state, the device will be suspended.
See also:

\texttt{pm_device_init_suspended()}

\textbf{Function properties (list may not be complete)}

\texttt{pre-kernel-ok}

\textbf{Parameters}

- \texttt{dev} – Device instance.

\textbf{Return values}

- \texttt{0} – If the device runtime PM is enabled successfully.
- \texttt{-EPERM} – If device has power state locked.
- \texttt{-ENOTSUP} – If the device does not support PM.
- \texttt{-ENOSYS} – If the functionality is not available.
- \texttt{-errno} – Other negative \texttt{errno}, result of suspending the device.

\begin{verbatim}
int pm_device_runtime_disable(const struct device *dev)
\end{verbatim}

Disable device runtime PM.
If the device is currently suspended it will be resumed.

\textbf{Function properties (list may not be complete)}

\texttt{pre-kernel-ok}

\textbf{Parameters}

- \texttt{dev} – Device instance.

\textbf{Return values}

- \texttt{0} – If the device runtime PM is disabled successfully.
- \texttt{-ENOTSUP} – If the device does not support PM.
- \texttt{-ENOSYS} – If the functionality is not available.
- \texttt{-errno} – Other negative \texttt{errno}, result of resuming the device.

\begin{verbatim}
int pm_device_runtime_get(const struct device *dev)
\end{verbatim}

Resume a device based on usage count.
This function will resume the device if the device is suspended (usage count equal to 0). In case of a resume failure, usage count and device state will be left unchanged. In all other cases, usage count will be incremented.

If the device is still being suspended as a result of calling \texttt{pm_device_runtime_put_async()}, this function will wait for the operation to finish to then resume the device.

\textbf{Function properties (list may not be complete)}

\texttt{pre-kernel-ok}

\textbf{Parameters}

- \texttt{dev} – Device instance.

\textbf{Return values}

- \texttt{0} – If it succeeds. In case device runtime PM is not enabled or not available this function will be a no-op and will also return 0.
• -ENOTSUP – If the device does not support PM.
• -errno – Other negative errno, result of the PM action callback.

```c
int pm_device_runtime_put(const struct device *dev)
```

Suspend a device based on usage count.

This function will suspend the device if the device is no longer required (usage count equal to 0). In case of suspend failure, usage count and device state will be left unchanged. In all other cases, usage count will be decremented (down to 0).

**See also:**

`pm_device_runtime_put_async()`

**Function properties (list may not be complete)**

`pre-kernel-ok`

**Parameters**

• `dev` – Device instance.

**Return values**

• 0 – If it succeeds. In case device runtime PM is not enabled or not available this function will be a no-op and will also return 0.
• -ENOTSUP – If the device does not support PM.
• -EALREADY – If device is already suspended (can only happen if get/put calls are unbalanced).
• -errno – Other negative errno, result of the action callback.

```c
int pm_device_runtime_put_async(const struct device *dev)
```

Suspend a device based on usage count (asynchronously).

This function will schedule the device suspension if the device is no longer required (usage count equal to 0). In all other cases, usage count will be decremented (down to 0).

**See also:**

`pm_device_runtime_put()`

**Function properties (list may not be complete)**

`pre-kernel-ok, async`

**Note:** Asynchronous operations are not supported when in pre-kernel mode. In this case, the function will be blocking (equivalent to `pm_device_runtime_put()`).

**Parameters**

• `dev` – Device instance.

**Return values**

• 0 – If it succeeds. In case device runtime PM is not enabled or not available this function will be a no-op and will also return 0.
• -ENOTSUP – If the device does not support PM.
bool pm_device_runtime_is_enabled(const struct device *dev)
Check if device runtime is enabled for a given device.

See also:

pm_device_runtime_enable()

Function properties (list may not be complete)
pre-kernel-ok

Parameters
• dev – Device instance.

Return values
• true – If device has device runtime PM enabled.
• false – If the device has device runtime PM disabled.

4.13 OS Abstraction

OS abstraction layers (OSAL) provide wrapper function APIs that encapsulate common system functions offered by any operating system. These APIs make it easier and quicker to develop for, and port code to multiple software and hardware platforms.

These sections describe the software and hardware abstraction layers supported by the Zephyr RTOS.

4.13.1 POSIX Support

The Portable Operating System Interface (POSIX) is a family of standards specified by the IEEE Computer Society for maintaining compatibility between operating systems. Zephyr implements a subset of the embedded profiles PSE51 and PSE52, and BSD Sockets API.

With the POSIX support available in Zephyr, an existing POSIX compliant application can be ported to run on the Zephyr kernel, and therefore leverage Zephyr features and functionality. Additionally, a library designed for use with POSIX threading compatible operating systems can be ported to Zephyr kernel based applications with minimal or no changes.

The POSIX API subset is an increasingly popular OSAL (operating system abstraction layer) for IoT and embedded applications, as can be seen in Zephyr, AWS:FreeRTOS, TI-RTOS, and NuttX.

Benefits of POSIX support in Zephyr include:
• Offering a familiar API to non-embedded programmers, especially from Linux
• Enabling reuse (portability) of existing libraries based on POSIX APIs
• Providing an efficient API subset appropriate for small (MCU) embedded systems

System Overview

Units of Functionality  The system profile is defined in terms of component profiles that specify Units of Functionality that can be combined to realize the application platform. A Unit of Functionality is a defined set of services which can be implemented. If implemented, the standard prescribes that all services in the Unit must be implemented.
A Minimal Realtime System Profile implementation must support the following Units of Functionality as defined in IEEE Std. 1003.1 (also referred to as POSIX.1-2017).

**Table 4.4: Units of Functionality**

<table>
<thead>
<tr>
<th>Requirements</th>
<th>Supported</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>POSIX_C_LANG_JUMP</td>
<td></td>
<td></td>

<tr>
<td>XSI_THREADS_EXT</td>
<td>yes</td>
<td></td>
</tr>
</tbody>
</table>

**Option Requirements**  An implementation supporting the Minimal Realtime System Profile must support the POSIX.1 Option Requirements which are defined in the standard. Options Requirements are used for further sub-profiling within the units of functionality: they further define the functional behavior of the system service (normally adding extra functionality). Depending on the profile to which the POSIX implementation complies, parameters and/or the precise functionality of certain services may differ.

The following list shows the option requirements that are implemented in Zephyr.
## Units of Functionality

This section describes the Units of Functionality (fixed sets of interfaces) which are implemented (partially or completely) in Zephyr. Please refer to the standard for a full description of each listed interface.

### POSIX_THREADS_BASE

The basic assumption in this profile is that the system consists of a single (implicit) process with multiple threads. Therefore, the standard requires all basic thread services, except those related to multiple processes.

#### Table 4.6: POSIX_THREADS_BASE

### 4.13.2 CMSIS RTOS v1

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v1, please refer [http://www.keil.com/pack/doc/CMSIS/RTOS/html/index.html](http://www.keil.com/pack/doc/CMSIS/RTOS/html/index.html)
4.13.3 CMSIS RTOS v2

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v2, please refer to the CMSIS-RTOS2 Documentation.

Features not supported in Zephyr implementation

**Kernel**
- `osKernelGetState`, `osKernelSuspend`, `osKernelResume`, `osKernelInitialize` and `osKernelStart` are not supported.

**Mutex**
- `osMutexPrioInherit` is supported by default and is not configurable, you cannot select/unselect this attribute.
- `osMutexRecursive` is also supported by default. If this attribute is not set, an error is thrown when the same thread tries to acquire it the second time.
- `osMutexRobust` is not supported in Zephyr.

Return values not supported in the Zephyr implementation

- `osKernelUnlock`, `osKernelLock`, `osKernelRestoreLock`
- `osError` (Unspecified error) is not supported.
- `osSemaphoreDelete`
- `osErrorResource` (the semaphore specified by parameter semaphore_id is in an invalid semaphore state) is not supported.
- `osMutexDelete`
- `osErrorResource` (mutex specified by parameter mutex_id is in an invalid mutex state) is not supported.
- `osTimerDelete`
- `osErrorResource` (the timer specified by parameter timer_id is in an invalid timer state) is not supported.
- `osMessageQueueReset`
- `osErrorResource` (the message queue specified by parameter msgq_id is in an invalid message queue state) is not supported.
- `osMessageQueueDelete`
- `osErrorResource` (the message queue specified by parameter msgq_id is in an invalid message queue state) is not supported.
- `osMemoryPoolFree`
- `osErrorResource` (the memory pool specified by parameter mp_id is in an invalid memory pool state) is not supported.
- `osMemoryPoolDelete`
- `osErrorResource` (the memory pool specified by parameter mp_id is in an invalid memory pool state) is not supported.
- `osEventFlagsSet`, `osEventFlagsClear`
- `osFlagsErrorUnknown` (Unspecified error) and `osFlagsErrorResource` (Event flags object specified by parameter ef_id is not ready to be used) are not supported.
- `osEventFlagsDelete`
- `osErrorParameter` (the value of the parameter ef_id is incorrect) is not supported.
osThreadFlagsSet
  osFlagsErrorUnknown (Unspecified error) and osFlagsErrorResource (Thread specified by parameter thread_id is not active to receive flags) are not supported.

osThreadFlagsClear
  osFlagsErrorResource (Running thread is not active to receive flags) is not supported.

osDelayUntil
  osParameter (the time cannot be handled) is not supported.

4.14 Shell

- Overview
  - Connecting to Segger RTT via TCP (on macOS, for example)
- Commands
  - Creating commands
  - Dictionary commands
  - Commands execution
  - Built-in commands
- Tab Feature
- History Feature
- Wildcards Feature
- Meta Keys Feature
- Getopt Feature
- Obscured Input Feature
- Shell Logger Backend Feature
- Usage
- API Reference

4.14.1 Overview

This module allows you to create and handle a shell with a user-defined command set. You can use it in examples where more than simple button or LED user interaction is required. This module is a Unix-like shell with these features:

- Support for multiple instances.
- Advanced cooperation with the Logging.
- Support for static and dynamic commands.
- Support for dictionary commands.
- Smart command completion with the Tab key.
- Built-in commands: clear, shell, colors, echo, history and resize.
- Viewing recently executed commands using keys: ↑ ↓ or meta keys.
• Support for ANSI escape codes: VT100 and \texttt{ESC[n~} for cursor control and color printing.
• Support for editing multiline commands.
• Built-in handler to display help for the commands.
• Support for wildcards: * and ?.
• Support for meta keys.
• Support for getopt and getopt\_long.
• Kconfig configuration to optimize memory usage.

\textbf{Note:} Some of these features have a significant impact on RAM and flash usage, but many can be disabled when not needed. To default to options which favor reduced RAM and flash requirements instead of features, you should enable CONFIG\_SHELL\_MINIMAL and selectively enable just the features you want.

The module can be connected to any transport for command input and output. At this point, the following transport layers are implemented:

• Segger RTT
• SMP
• Telnet
• UART
• USB
• DUMMY - not a physical transport layer.

\textbf{Connecting to Segger RTT via TCP (on macOS, for example)}

On macOS JLinkRTTClient won’t let you enter input. Instead, please use following procedure:

• Open up a first Terminal window and enter:

\begin{verbatim}
JLinkRTTLogger -Device NRF52840\_XXAA -RTTChannel 1 -if SWD -Speed 4000 ~/rtt.log
\end{verbatim}

(change device if required)

• Open up a second Terminal window and enter:

\begin{verbatim}
nc localhost 19021
\end{verbatim}

• Now you should have a network connection to RTT that will let you enter input to the shell.

\textbf{4.14.2 Commands}

Shell commands are organized in a tree structure and grouped into the following types:

• Root command (level 0): Gathered and alphabetically sorted in a dedicated memory section.
• Static subcommand (level > 0): Number and syntax must be known during compile time. Created in the software module.
• Dynamic subcommand (level > 0): Number and syntax does not need to be known during compile time. Created in the software module.
Creating commands

Use the following macros for adding shell commands:

- **SHELL_CMD_REGISTER** - Create root command. All root commands must have different name.
- **SHELL_COND_CMD_REGISTER** - Conditionally (if compile time flag is set) create root command. All root commands must have different name.
- **SHELL_CMD_ARG_REGISTER** - Create root command with arguments. All root commands must have different name.
- **SHELL_COND_CMD_ARG_REGISTER** - Conditionally (if compile time flag is set) create root command with arguments. All root commands must have different name.
- **SHELL_CMD** - Initialize a command.
- **SHELL_COND_CMD** - Initialize a command if compile time flag is set.
- **SHELL_EXPR_CMD** - Initialize a command if compile time expression is non-zero.
- **SHELL_CMD_ARG** - Initialize a command with arguments.
- **SHELL_COND_CMD_ARG** - Initialize a command with arguments if compile time flag is set.
- **SHELL_EXPR_CMD_ARG** - Initialize a command with arguments if compile time expression is non-zero.
- **SHELL_STATIC_SUBCMD_SET_CREATE** - Create a static subcommands array.
- **SHELL_SUBCMD_DICT_SET_CREATE** - Create a dictionary subcommands array.
- **SHELL_DYNAMIC_CMD_CREATE** - Create a dynamic subcommands array.

Commands can be created in any file in the system that includes `include/zephyr/shell/shell.h`. All created commands are available for all shell instances.

**Static commands**  
Example code demonstrating how to create a root command with static subcommands.

```c
/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
    SHELL_CMD(params, NULL, "Print params command.", cmd_demo_params),
    SHELL_CMD(ping, NULL, "Ping command.", cmd_demo_ping),
    SHELL_SUBCMD_SET_END
);
/* Creating root (level 0) command "demo" */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);
```

Example implementation can be found under following location: `samples/subsys/shell/shell_module/src/main.c`.  

---

**4.14. Shell**  
787
Dictionary commands

This is a special kind of static commands. Dictionary commands can be used every time you want to use a pair: (string <-> corresponding data) in a command handler. The string is usually a verbal description of a given data. The idea is to use the string as a command syntax that can be prompted by the shell and corresponding data can be used to process the command.

Let's use an example. Suppose you created a command to set an ADC gain. It is a perfect place where a dictionary can be used. The dictionary would be a set of pairs: (string: gain_value, int: value) where int value could be used with the ADC driver API.

Abstract code for this task would look like this:

```c
static int gain_cmd_handler(const struct shell *shell, size_t argc, char **argv, void *data)
{
    int gain;

    // data is a value corresponding to called command syntax */
    gain = (int)data;
    adc_set_gain(gain);

    shell_print(shell, "ADC gain set to: %s\n"
               "Value send to ADC driver: %d",
               argv[0],
               gain);

    return 0;
}
```

SHELL_SUBCMD_DICT_SET_CREATE(sub_gain, gain_cmd_handler,
      (gain_1, 1), (gain_2, 2), (gain_1_2, 3), (gain_1_4, 4)
    );
SHELL_CMD_REGISTER(gain, &sub_gain, "Set ADC gain", NULL);

This is how it would look like in the shell:

```
uart:--$ gain ga
    gain_1  gain_2  gain_1_2  gain_1_4
uart:--$ gain gain_1
      ADC gain set to: gain_1
      Value send to ADC driver: 1
uart:--$ gain gain_2
      ADC gain set to: gain_2
      Value send to ADC driver: 2
uart:--$ gain gain_1_2
      ADC gain set to: gain_1_2
      Value send to ADC driver: 3
uart:--$ gain gain_1_4
      ADC gain set to: gain_1_4
      Value send to ADC driver: 4
uart:--$
```

Dynamic commands  Example code demonstrating how to create a root command with static and dynamic subcommands. At the beginning dynamic command list is empty. New commands can be added by typing:
dynamic add <new_dynamic_command>

Newly added commands can be prompted or autocompleted with the Tab key.

```c
/* Buffer for 10 dynamic commands */
static char dynamic_cmd_buffer[10][50];

/* commands counter */
static uint8_t dynamic_cmd_cnt;

/* Function returning command dynamically created * in dynamic_cmd_buffer. */
static void dynamic_cmd_get(size_t idx, struct shell_static_entry *entry)
{
    if (idx < dynamic_cmd_cnt) {
        entry->syntax = dynamic_cmd_buffer[idx];
        entry->handler = NULL;
        entry->subcmd = NULL;
        entry->help = "Show dynamic command name."
    } else {
        /* if there are no more dynamic commands available * syntax must be set to NULL. */
        entry->syntax = NULL;
    }
}

SHELL_DYNAMIC_CMD_CREATE(m_sub_dynamic_set, dynamic_cmd_get);
SHELL_STATIC_SUBCMD_SET_CREATE(m_sub_dynamic, 
    SHELL_CMD(add, NULL, "Add new command to dynamic_cmd_buffer and" 
        " sort them alphabetically.", cmd_dynamic_add),
    SHELL_CMD(execute, &m_sub_dynamic_set, 
        "Execute a command.", cmd_dynamic_execute),
    SHELL_CMD(remove, &m_sub_dynamic_set, 
        "Remove a command from dynamic_cmd_buffer.", 
        cmd_dynamic_remove),
    SHELL_CMD(show, NULL, 
        "Show all commands in dynamic_cmd_buffer.", 
        cmd_dynamic_show),
```

(continues on next page)
Example implementation can be found under following location: samples/subsys/shell/shell_module/src/dynamic_cmd.c.

Commands execution

Each command or subcommand may have a handler. The shell executes the handler that is found deepest in the command tree and further subcommands (without a handler) are passed as arguments. Characters within parentheses are treated as one argument. If shell won't find a handler it will display an error message.

Commands can be also executed from a user application using any active backend and a function `shell_execute_cmd()`, as shown in this example:

```c
void main(void)
{
    /* Below code will execute "clear" command on a DUMMY backend */
    shell_execute_cmd(NULL, "clear");

    /* Below code will execute "shell colors off" command on * an UART backend */
    shell_execute_cmd(shell_backend_uart_get_ptr(), "shell colors off");
}
```

Enable the DUMMY backend by setting the Kconfig `CONFIG_SHELL_BACKEND_DUMMY` option.

Command handler  Simple command handler implementation:

```c
static int cmd_handler(const struct shell *shell, size_t argc, char **argv)
{
    ARG_UNUSED(argc);
    ARG_UNUSED(argv);

    shell_fprintf(shell, SHELL_INFO, "Print info message\n");
    shell_print(shell, "Print simple text.");
    shell_warn(shell, "Print warning text.");
    shell_error(shell, "Print error text.");

    return 0;
}
```

Function `shell_fprintf()` or the shell print macros: `shell_print`, `shell_info`, `shell_warn` and `shell_error` can be used from the command handler or from threads, but not from an interrupt context. Instead, interrupt handlers should use `Logging` for printing.
Command help Every user-defined command or subcommand can have its own help description. The help for commands and subcommands can be created with respective macros: `SHELL_CMD_REGISTER`, `SHELL_CMD_ARG_REGISTER`, `SHELL_CMD`, and `SHELL_CMD_ARG`.

Shell prints this help message when you call a command or subcommand with `-h` or `--help` parameter.

Parent commands In the subcommand handler, you can access both the parameters passed to commands or the parent commands, depending on how you index `argv`.

- When indexing `argv` with positive numbers, you can access the parameters.
- When indexing `argv` with negative numbers, you can access the parent commands.
- The subcommand to which the handler belongs has the `argv` index of 0.

```c
static int cmd_handler(const struct shell *shell, size_t argc, char **argv)
{
    ARG_UNUSED(argc);

    /* If it is a subcommand handler parent command syntax can be found using argv[-1]. */
    shell_print(shell, "This command has a parent command: \%s", argv[-1]);

    /* Print this command syntax */
    shell_print(shell, "This command syntax is: \%s", argv[0]);

    /* Print first argument */
    return 0;
}
```

Built-in commands

These commands are activated by `CONFIG_SHELL_CMDS` set to `y`.

- `clear` - Clears the screen.
- `history` - Shows the recently entered commands.
- `resize` - Must be executed when terminal width is different than 80 characters or after each change of terminal width. It ensures proper multiline text display and ←, →, End, Home keys handling. Currently this command works only with UART flow control switched on. It can be also called with a subcommand:
  - `default` - Shell will send terminal width = 80 to the terminal and assume successful delivery. These command needs extra activation: `CONFIG_SHELL_CMDS_RESIZE` set to `y`.
- `select` - It can be used to set new root command. Exit to main command tree is with alt+r. This command needs extra activation: `CONFIG_SHELL_CMDS_SELECT` set to `y`.
- `shell` - Root command with useful shell-related subcommands like:
  - `echo` - Toggles shell echo.
  - `colors` - Toggles colored syntax. This might be helpful in case of Bluetooth shell to limit the amount of transferred bytes.
  - `stats` - Shows shell statistics.
4.14.3 Tab Feature

The Tab button can be used to suggest commands or subcommands. This feature is enabled by CONFIG_SHELL_TAB set to y. It can also be used for partial or complete auto-completion of commands. This feature is activated by CONFIG_SHELL_TAB_AUTOCOMPLETION set to y. When user starts writing a command and presses the Tab button then the shell will do one of 3 possible things:

- Autocomplete the command.
- Prompts available commands and if possible partly completes the command.
- Will not do anything if there are no available or matching commands.

4.14.4 History Feature

This feature enables commands history in the shell. It is activated by: CONFIG_SHELL_HISTORY set to y. History can be accessed using keys: ↑ + or Ctrl + n and Ctrl + p if meta keys are active. Number of commands that can be stored depends on size of CONFIG_SHELL_HISTORY_BUFFER parameter.

4.14.5 Wildcards Feature

The shell module can handle wildcards. Wildcards are interpreted correctly when expanded command and its subcommands do not have a handler. For example, if you want to set logging level to err for the app and app_test modules you can execute the following command:

```
log enable err a*
```

This feature is activated by CONFIG_SHELL_WILDCARD set to y.
### 4.14.6 Meta Keys Feature

The shell module supports the following meta keys:

<table>
<thead>
<tr>
<th>Meta keys</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl + a</td>
<td>Moves the cursor to the beginning of the line.</td>
</tr>
<tr>
<td>Ctrl + b</td>
<td>Moves the cursor backward one character.</td>
</tr>
<tr>
<td>Ctrl + c</td>
<td>Preserves the last command on the screen and starts a new command in a new line.</td>
</tr>
<tr>
<td>Ctrl + d</td>
<td>Deletes the character under the cursor.</td>
</tr>
<tr>
<td>Ctrl + e</td>
<td>Moves the cursor to the end of the line.</td>
</tr>
<tr>
<td>Ctrl + f</td>
<td>Moves the cursor forward one character.</td>
</tr>
<tr>
<td>Ctrl + k</td>
<td>Deletes from the cursor to the end of the line.</td>
</tr>
<tr>
<td>Ctrl + l</td>
<td>Clears the screen and leaves the currently typed command at the top of the screen.</td>
</tr>
<tr>
<td>Ctrl + n</td>
<td>Moves in history to next entry.</td>
</tr>
<tr>
<td>Ctrl + p</td>
<td>Moves in history to previous entry.</td>
</tr>
<tr>
<td>Ctrl + u</td>
<td>Clears the currently typed command.</td>
</tr>
<tr>
<td>Ctrl + w</td>
<td>Removes the word or part of the word to the left of the cursor. Words separated by period instead of space are treated as one word.</td>
</tr>
<tr>
<td>Alt + b</td>
<td>Moves the cursor backward one word.</td>
</tr>
<tr>
<td>Alt + f</td>
<td>Moves the cursor forward one word.</td>
</tr>
</tbody>
</table>

This feature is activated by `CONFIG_SHELL_METAKEYS` set to y.

### 4.14.7 Getopt Feature

Some shell users apart from subcommands might need to use options as well. The arguments string, looking for supported options. Typically, this task is accomplished by the `getopt` family functions.

For this purpose shell supports the getopt and getopt_long libraries available in the FreeBSD project. This feature is activated by: `CONFIG_GETOPT` set to y and `CONFIG_GETOPT_LONG` set to y.

This feature can be used in thread safe as well as non thread safe manner. The former is full compatible with regular getopt usage while the latter a bit differs.

An example non-thread safe usage:

```c
char *cvalue = NULL;
while ((char c = getopt(argc, argv, "abhc:")) != -1) {
    switch (c) {
    case 'c':
        cvalue = optarg;
        break;
    default:
        break;
    }
}
```

An example thread safe usage:

```c
char *cvalue = NULL;
struct getopt_state *state;
while ((char c = getopt(argc, argv, "abhc:")) != -1) {
    state = getopt_state_get();
    switch (c) {
```

(continues on next page)
Thread safe getopt functionality is activated by CONFIG_SHELL_GETOPT set to y.

### 4.14.8 Obscured Input Feature

With the obscured input feature, the shell can be used for implementing a login prompt or other user interaction whereby the characters the user types should not be revealed on screen, such as when entering a password.

Once the obscured input has been accepted, it is normally desired to return the shell to normal operation. Such runtime control is possible with the `shell_obscure_set` function.

An example of login and logout commands using this feature is located in `samples/subsys/shell/shell_module/src/main.c` and the config file `samples/subsys/shell/shell_module/prj_login.conf`.

This feature is activated upon startup by `CONFIG_SHELL_START_OBSCURED` set to y. With this set either way, the option can still be controlled later at runtime. `CONFIG_SHELL_CMDS_SELECT` is useful to prevent entry of any other command besides a login command, by means of the `shell_set_root_cmd` function. Likewise, `CONFIG_SHELL_PROMPT_UART` allows you to set the prompt upon startup, but it can be changed later with the `shell_prompt_change` function.

### 4.14.9 Shell Logger Backend Feature

Shell instance can act as the Logging backend. Shell ensures that log messages are correctly multiplexed with shell output. Log messages from logger thread are enqueued and processed in the shell thread. Logger thread will block for configurable amount of time if queue is full, blocking logger thread context for that time. Oldest log message is removed from the queue after timeout and new message is enqueued.

Use the `shell stats show` command to retrieve number of log messages dropped by the shell instance. Log queue size and timeout are `SHELL_DEFINE` arguments.

This feature is activated by: `CONFIG_SHELL_LOG_BACKEND` set to y.

**Warning:** Enqueuing timeout must be set carefully when multiple backends are used in the system. The shell instance could have a slow transport or could block, for example, by a UART with hardware flow control. If timeout is set too high, the logger thread could be blocked and impact other logger backends.

**Warning:** As the shell is a complex logger backend, it can not output logs if the application crashes before the shell thread is running. In this situation, you can enable one of the simple logging backends instead, such as UART (CONFIG_LOG_BACKEND_UART) or RTT (CONFIG_LOG_BACKEND_RTT), which are available earlier during system initialization.

### 4.14.10 Usage

To create a new shell instance user needs to activate requested backend using menuconfig.
The following code shows a simple use case of this library:

```c
void main(void)
{
}

static int cmd_demo_ping(const struct shell *shell, size_t argc,
    char **argv)
{
    ARG_UNUSED(argc);
    ARG_UNUSED(argv);
    shell_print(shell, "pong");
    return 0;
}

static int cmd_demo_params(const struct shell *shell, size_t argc,
    char **argv)
{
    int cnt;

    shell_print(shell, "argc = %d", argc);
    for (cnt = 0; cnt < argc; cnt++) {
        shell_print(shell, " argv[%d] = %s", cnt, argv[cnt]);
    }
    return 0;
}

/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
    SHELL_CMD(params, NULL, "Print params command.", cmd_demo_params),
    SHELL_CMD(ping, NULL, "Ping command.", cmd_demo_ping),
    SHELL_SUBCMD_SET_END
);
/* Creating root (level 0) command "demo" without a handler */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);

/* Creating root (level 0) command "version" */
SHELL_CMD_REGISTER(version, NULL, "Show kernel version", cmd_version);
```

Users may use the Tab key to complete a command/subcommand or to see the available subcommands for the currently entered command level. For example, when the cursor is positioned at the beginning of the command line and the Tab key is pressed, the user will see all root (level 0) commands:

```
clear demo shell history log resize version
```

**Note:** To view the subcommands that are available for a specific command, you must first type a space after this command and then hit Tab.

These commands are registered by various modules, for example:

- clear, shell, history, and resize are built-in commands which have been registered by `subsys/shell/shell.c`
- demo and version have been registered in example code above by `main.c`
- log has been registered by `subsys/logging/log_cmds.c`
Then, if a user types a `demo` command and presses the Tab key, the shell will only print the subcommands registered for this command:

```
params ping
```

## 4.14.11 API Reference

### group shell_api

Shell API.

#### Defines

`SHELL_CMD_ARG_REGISTER(syntax, subcmd, help, handler, mandatory, optional)`

Macro for defining and adding a root command (level 0) with required number of arguments.

**Note:** Each root command shall have unique syntax. If a command will be called with wrong number of arguments shell will print an error message and command handler will not be called.

**Parameters**

- `mandatory` – [in] Number of mandatory arguments including command name.

`SHELL_COND_CMD_ARG_REGISTER(flag, syntax, subcmd, help, handler, mandatory, optional)`

Macro for defining and adding a conditional root command (level 0) with required number of arguments.

Macro can be used to create a command which can be conditionally present. It is and alternative to #ifdefs around command registration and command handler. If command is disabled handler and subcommands are removed from the application.

**See also:**

`SHELL_CMD_ARG_REGISTER` for details.

**Parameters**

- `flag` – [in] Compile time flag. Command is present only if flag exists and equals 1.
- `mandatory` – [in] Number of mandatory arguments including command name.
SHELL_CMD_REGISTER(syntax, subcmd, help, handler)
Macro for defining and adding a root command (level 0) with arguments.

Note: All root commands must have different name.

Parameters

• syntax – [in] Command syntax (for example: history).
• subcmd – [in] Pointer to a subcommands array.
• help – [in] Pointer to a command help string.
• handler – [in] Pointer to a function handler.

SHELL_COND_CMD_REGISTER(flag, syntax, subcmd, help, handler)
Macro for defining and adding a conditional root command (level 0) with arguments.

See also:
SHELL_COND_CMD_ARG_REGISTER.

Parameters

• flag – [in] Compile time flag. Command is present only if flag exists and equals 1.
• syntax – [in] Command syntax (for example: history).
• subcmd – [in] Pointer to a subcommands array.
• help – [in] Pointer to a command help string.
• handler – [in] Pointer to a function handler.

SHELL_STATIC_SUBCMD_SET_CREATE(name, ...)
Macro for creating a subcommand set. It must be used outside of any function body.

Example usage: SHELL_STATIC_SUBCMD_SET_CREATE( foo, SHELL_CMD(abc, ...), SHELL_CMD(def, ...), SHELL_SUBCMD_SET_END )

Parameters

• name – [in] Name of the subcommand set.
• ... – [in] List of commands created with SHELL_CMD_ARG or or SHELL_CMD

SHELL_SUBCMD_SET_CREATE(_name, _parent)
Create set of subcommands.

Commands to this set are added using SHELL_SUBCMD_ADD and SHELL_SUBCMD_COND_ADD. Commands can be added from multiple files.

Parameters

• _name – [in] Name of the set. _name is used to refer the set in the parent command.
• _parent – [in] Set of comma separated parent commands in parenthesis, e.g. (foo_cmd) if subcommands are for the root command “foo_cmd”.

4.14. Shell
SHELL_SUBCMD_COND_ADD(_flag, _parent, _syntax, _subcmd, _help, _handler, _mand, _opt)
Conditionally add command to the set of subcommands.
Add command to the set created with SHELL_SUBCMD_SET_CREATE.

**Note:** The name of the section is formed as concatenation of number of parent commands, names of all parent commands and own syntax. Number of parent commands is added to ensure that section prefix is unique. Without it subcommands of (foo) and (foo, cmd1) would mix.

**Parameters**

- `_flag` – [in] Compile time flag. Command is present only if flag exists and equals 1.
- `_handler` – [in] Pointer to a function handler.
- `_mand` – [in] Number of mandatory arguments including command name.

SHELL_SUBCMD_ADD(_parent, _syntax, _subcmd, _help, _handler, _mand, _opt)
Add command to the set of subcommands.
Add command to the set created with SHELL_SUBCMD_SET_CREATE.

**Parameters**

- `_handler` – [in] Pointer to a function handler.
- `_mand` – [in] Number of mandatory arguments including command name.

SHELL_SUBCMD_SET_END
Define ending subcommands set.

SHELL_DYNAMIC_CMD_CREATE(name, get)
Macro for creating a dynamic entry.

**Parameters**

- `name` – [in] Name of the dynamic entry.
- `get` – [in] Pointer to the function returning dynamic commands array
**SHELL_CMD_ARG**(*syntax*, *subcmd*, *help*, *handler*, *mand*, *opt*)

Initializes a shell command with arguments.

**Note:** If a command will be called with wrong number of arguments shell will print an error message and command handler will not be called.

**Parameters**

- **syntax** – [in] Command syntax (for example: *history*).
- **subcmd** – [in] Pointer to a subcommands array.
- **help** – [in] Pointer to a command help string.
- **handler** – [in] Pointer to a function handler.
- **mand** – [in] Number of mandatory arguments including command name.
- **opt** – [in] Number of optional arguments.

**SHELL_COND_CMD_ARG**(*flag*, *syntax*, *subcmd*, *help*, *handler*, *mand*, *opt*)

Initializes a conditional shell command with arguments.

**See also:**

**SHELL_CMD_ARG**. Based on the flag, creates a valid entry or an empty command which is ignored by the *shell*. It is an alternative to #ifdefs around command registration and command handler. However, empty structure is present in the flash even if command is disabled (subcommands and handler are removed). Macro internally handles case if flag is not defined so flag must be provided without any wrapper, e.g.: **SHELL_COND_CMD_ARG**(CONFIG_FOO, . . . )

**Parameters**

- **flag** – [in] Compile time flag. Command is present only if flag exists and equals 1.
- **syntax** – [in] Command syntax (for example: *history*).
- **subcmd** – [in] Pointer to a subcommands array.
- **help** – [in] Pointer to a command help string.
- **handler** – [in] Pointer to a function handler.
- **mand** – [in] Number of mandatory arguments including command name.
- **opt** – [in] Number of optional arguments.

**SHELL_EXPR_CMD_ARG**(_expr_, _syntax_, _subcmd_, _help_, _handler_, _mand_, _opt_)

Initializes a conditional shell command with arguments if expression gives non-zero result at compile time.

**See also:**

**SHELL_CMD_ARG**. Based on the expression, creates a valid entry or an empty command which is ignored by the *shell*. It should be used instead of **SHELL_COND_CMD_ARG** if condition is not a single configuration flag, e.g.: **SHELL_EXPR_CMD_ARG**(IS_ENABLED(CONFIG_FOO) && IS_ENABLED(CONFIG_FOO_SETTING_1), . . . )

**Parameters**
• _syntax – [in] Command syntax (for example: history).
• _subcmd – [in] Pointer to a subcommands array.
• _help – [in] Pointer to a command help string.
• _handler – [in] Pointer to a function handler.
• _mand – [in] Number of mandatory arguments including command name.
• _opt – [in] Number of optional arguments.

SHELL_CMD(_syntax, _subcmd, _help, _handler)
Initializes a shell command.

Parameters
• _syntax – [in] Command syntax (for example: history).
• _subcmd – [in] Pointer to a subcommands array.
• _help – [in] Pointer to a command help string.
• _handler – [in] Pointer to a function handler.

SHELL_COND_CMD(_flag, _syntax, _subcmd, _help, _handler)
Initializes a conditional shell command.

See also:
SHELL_COND_CMD_ARG.

Parameters
• _flag – [in] Compile time flag. Command is present only if flag exists and equals 1.
• _syntax – [in] Command syntax (for example: history).
• _subcmd – [in] Pointer to a subcommands array.
• _help – [in] Pointer to a command help string.
• _handler – [in] Pointer to a function handler.

SHELL_EXPR_CMD(_expr, _syntax, _subcmd, _help, _handler)
Initializes shell command if expression gives non-zero result at compile time.

See also:
SHELL_EXPR_CMD_ARG.

Parameters
• _expr – [in] Compile time expression. Command is present only if expression is non-zero.
• _syntax – [in] Command syntax (for example: history).
• _subcmd – [in] Pointer to a subcommands array.
• _help – [in] Pointer to a command help string.
• _handler – [in] Pointer to a function handler.
SHELL_CMD_DICT_CREATE(_data, _handler)

SHELL_SUBCMD_DICT_SET_CREATE(_name, _handler, ...)

Initializes shell dictionary commands.

This is a special kind of static commands. Dictionary commands can be used every time you want to use a pair: (string <-> corresponding data) in a command handler. The string is usually a verbal description of a given data. The idea is to use the string as a command syntax that can be prompted by the shell and corresponding data can be used to process the command.

Example usage: static int my_handler(const struct shell *shell,
size_t argc, char **argv, void *data) { int val = (int)data;

See also:

shell_dict_cmd_handler

shell_print(shell, “(%s, %d)”, argv[0], val); return 0; }

SHELL_SUBCMD_DICT_SET_CREATE(sub_dict_cmds, my_handler, (value_0, 0), (value_1, 1), (value_2, 2), (value_3, 3) ); SHELL_CMD_REGISTER(dictionary, &sub_dict_cmds, NULL, NULL);

Parameters

• _name – [in] Name of the dictionary subcommand set
• ... – [in] Dictionary pairs: (command_syntax, value). Value will be passed to the _handler as user data.

SHELL_DEFAULT_BACKEND_CONFIG_FLAGS

SHELL_DEFINE(_name, _prompt, _transport_iface, _log_queue_size, _log_timeout, _shell_flag)

Macro for defining a shell instance.

Parameters

• _name – [in] Instance name.
• _prompt – [in] Shell default prompt string.
• _transport_iface – [in] Pointer to the transport interface.
• _log_queue_size – [in] Logger processing queue size.
• _log_timeout – [in] Logger thread timeout in milliseconds on full log queue. If queue is full logger thread is blocked for given amount of time before log message is dropped.
• _shell_flag – [in] Shell output newline sequence.

SHELL_NORMAL

Terminal default text color for shell_fprintf function.

SHELL_INFO

Green text color for shell_fprintf function.

SHELL_OPTION

Cyan text color for shell_fprintf function.
SHELL_WARNING
Yellow text color for shell_printf function.

SHELL_ERROR
Red text color for shell_printf function.

shell_info(_sh, _ft, ...)
Print info message to the shell.
See shell_printf.

Parameters
• _sh – [in] Pointer to the shell instance.
• ... – [in] List of parameters to print.

shell_print(_sh, _ft, ...)
Print normal message to the shell.
See shell_printf.

Parameters
• _sh – [in] Pointer to the shell instance.
• ... – [in] List of parameters to print.

shell_warn(_sh, _ft, ...)
Print warning message to the shell.
See shell_printf.

Parameters
• _sh – [in] Pointer to the shell instance.
• ... – [in] List of parameters to print.

shell_error(_sh, _ft, ...)
Print error message to the shell.
See shell_printf.

Parameters
• _sh – [in] Pointer to the shell instance.
• ... – [in] List of parameters to print.

SHELL_CMD_HELP_PRINTED

Typedefs
typedef void (*shell_dynamic_get)(size_t idx, struct shell_static_entry *entry)

Shell dynamic command descriptor.

Function shall fill the received shell static entry structure with requested (idx) dynamic subcommand data. If there is more than one dynamic subcommand available, the function shall ensure that the returned commands: entry->syntax are sorted in alphabetical order. If idx exceeds the available dynamic subcommands, the function must write to entry->syntax NULL value. This will indicate to the shell module that there are no more dynamic commands to read.

typedef int (*shell_cmd_handler)(const struct shell *shell, size_t argc, char **argv)

Shell command handler prototype.

**Param shell**
Shell instance.

**Param argc**
Arguments count.

**Param argv**
Arguments.

**Retval 0**
Successful command execution.

**Retval 1**
Help printed and command not executed.

**Retval -EINVAL**
Argument validation failed.

**Retval -ENOEXEC**
Command not executed.

typedef int (*shell_dict_cmd_handler)(const struct shell *shell, size_t argc, char **argv, void *data)

Shell dictionary command handler prototype.

**Param shell**
Shell instance.

**Param argc**
Arguments count.

**Param argv**
Arguments.

**Param data**
Pointer to the user data.

**Retval 0**
Successful command execution.

**Retval 1**
Help printed and command not executed.

**Retval -EINVAL**
Argument validation failed.

**Retval -ENOEXEC**
Command not executed.

typedef void (*shell_transport_handler_t)(enum shell_transport_evt evt, void *context)
typedef void (*shell_uninit_cb_t)(const struct shell *shell, int res)

typedef void (*shell_bypass_cb_t)(const struct shell *shell, uint8_t *data, size_t len)
   Bypass callback.
   
   **Param shell**
   Shell instance.

   **Param data**
   Raw data from transport.

   **Param len**
   Data length.

** Enums **

** enum shell_receive_state **

** Values:**

enumerator SHELL_RECEIVE_DEFAULT

enumerator SHELL_RECEIVE_ESC

enumerator SHELL_RECEIVE_ESC_SEQ

enumerator SHELL_RECEIVE_TILDE_EXP

** enum shell_state **

** Values:**

enumerator SHELL_STATE_UNINITIALIZED

enumerator SHELL_STATE_INITIALIZED

enumerator SHELL_STATE_ACTIVE

enumerator SHELL_STATE_PANIC_MODE_ACTIVE
   Panic activated.

enumerator SHELL_STATE_PANIC_MODE_INACTIVE
   Panic requested, not supported.

** enum shell_transport_evt **

** Shell transport event. **

** Values:**

enumerator SHELL_TRANSPORT_EVT_RX_RDY
enumerator SHELL_TRANSPORT_EVT_TX_RDY

enum shell_signal
Values:

enumerator SHELL_SIGNAL_RXRDY
enumerator SHELL_SIGNAL_LOG_MSG
enumerator SHELL_SIGNAL_KILL
enumerator SHELL_SIGNAL_TXDONE
enumerator SHELL_SIGNALS

enum shell_flag
Flags for setting shell output newline sequence.
Values:

enumerator SHELL_FLAG_CRLF_DEFAULT = (1 << 0)
enumerator SHELL_FLAG_OLF_CRLF = (1 << 1)

Functions

custom struct device *shell_device_lookup(size_t idx, const char *prefix)
Get by index a device that matches.
This can be used, for example, to identify I2C_1 as the second I2C device.
Devices that failed to initialize or do not have a non-empty name are excluded from the
candidates for a match.

Parameters
• idx – the device number starting from zero.
• prefix – optional name prefix used to restrict candidate devices. Indexing is
done relative to devices with names that start with this text. Pass null if no
prefix match is required.

int shell_init(const struct shell *shell, const void *transport_config, struct
shell_backend_config_flags cfg_flags, bool log_backend, uint32_t init_log_level)
Function for initializing a transport layer and internal shell state.

Parameters
• shell – [in] Pointer to shell instance.
• cfg_flags – [in] Initial backend configuration flags. Shell will copy this data.
• log_backend – If true, the console will be used as logger backend.
• init_log_level – [in] Default severity level for the logger.
Returns
Standard error code.

void shell_uninit(const struct shell *shell, shell_uninit_cb_t cb)
Uninitializes the transport layer and the internal shell state.

Parameters
• shell – Pointer to shell instance.
• cb – Callback called when uninitialization is completed.

int shell_start(const struct shell *shell)
Function for starting shell processing.

Parameters
• shell – Pointer to the shell instance.

Returns
Standard error code.

int shell_stop(const struct shell *shell)
Function for stopping shell processing.

Parameters
• shell – Pointer to shell instance.

Returns
Standard error code.

void shell_fprintf(const struct shell *shell, enum shell_vt100_color color, const char *fmt, ...)
printf-like function which sends formatted data stream to the shell.
This function can be used from the command handler or from threads, but not from an interrupt context.

Parameters
• shell – [in] Pointer to the shell instance.
• color – [in] Printed text color.
• ... – [in] List of parameters to print.

void shell_vfprintf(const struct shell *shell, enum shell_vt100_color color, const char *fmt, va_list args)
vprintf-like function which sends formatted data stream to the shell.
This function can be used from the command handler or from threads, but not from an interrupt context. It is similar to shell_fprintf() but takes a va_list instead of variable arguments.

Parameters
• shell – [in] Pointer to the shell instance.
• color – [in] Printed text color.
• args – [in] List of parameters to print.

void shell_hexdump_line(const struct shell *shell, unsigned int offset, const uint8_t *data, size_t len)
Print a line of data in hexadecimal format.
Each line shows the offset, bytes and then ASCII representation.
For example:
00008010: 20 25 00 20 2f 48 00 08 80 05 00 20 af 46 00 | %. /H.. . . . .F. |

Parameters
- \texttt{shell} – [in] Pointer to the shell instance.
- \texttt{offset} – [in] Offset to show for this line.
- \texttt{data} – [in] Pointer to data.
- \texttt{len} – [in] Length of data.

\begin{verbatim}
void shell_hexdump(const struct shell *shell, const uint8_t *data, size_t len)
Print data in hexadecimal format.
\end{verbatim}

Parameters
- \texttt{shell} – [in] Pointer to the shell instance.
- \texttt{data} – [in] Pointer to data.
- \texttt{len} – [in] Length of data.

\begin{verbatim}
void shell_process(const struct shell *shell)
Process function, which should be executed when data is ready in the transport interface. To
be used if shell thread is disabled.
\end{verbatim}

Parameters
- \texttt{shell} – [in] Pointer to the shell instance.

\begin{verbatim}
int shell_prompt_change(const struct shell *shell, const char *prompt)
Change displayed shell prompt.
\end{verbatim}

Parameters
- \texttt{shell} – [in] Pointer to the shell instance.

Returns
0 Success.

Returns
-EINVAL Pointer to new prompt is not correct.

\begin{verbatim}
void shell_help(const struct shell *shell)
Prints the current command help.
Function will print a help string with: the currently entered command and subcommands (if
they exist).
\end{verbatim}

Parameters
- \texttt{shell} – [in] Pointer to the shell instance.

\begin{verbatim}
int shell_execute_cmd(const struct shell *shell, const char *cmd)
Execute command.
Pass command line to shell to execute.
Note: This by no means makes any of the commands a stable interface, so this function should
only be used for debugging/diagnostic.
This function must not be called from shell command context!
\end{verbatim}

Parameters
- \texttt{shell} – [in] Pointer to the shell instance. It can be NULL when the
  CONFIG_SHELL_BACKEND_DUMMY option is enabled.
• cmd – [in] Command to be executed.

Returns
Result of the execution

int shell_set_root_cmd(const char *cmd)
Set root command for all shell instances.
It allows setting from the code the root command. It is an equivalent of calling select command with one of the root commands as the argument (e.g “select log”) except it sets command for all shell instances.

Parameters
• cmd – String with one of the root commands or null pointer to reset.

Return values
• 0 – if root command is set.
• -EINVAL – if invalid root command is provided.

void shell_set_bypass(const struct shell *shell, shell_bypass_cb_t bypass)
Set bypass callback.
Bypass callback is called whenever data is received. Shell is bypassed and data is passed directly to the callback. Use null to disable bypass functionality.

Parameters
• shell – [in] Pointer to the shell instance.
• bypass – [in] Bypass callback or null to disable.

bool shell_ready(const struct shell *sh)
Get shell readiness to execute commands.

Parameters
• sh – [in] Pointer to the shell instance.

Return values
• true – Shell backend is ready to execute commands.
• false – Shell backend is not initialized or not started.

int shell_insert_mode_set(const struct shell *shell, bool val)
Allow application to control text insert mode. Value is modified atomically and the previous value is returned.

Parameters
• shell – [in] Pointer to the shell instance.
• val – [in] Insert mode.

Return values
• 0 – or 1: previous value
• -EINVAL – if shell is NULL.

int shell_use_colors_set(const struct shell *shell, bool val)
Allow application to control whether terminal output uses colored syntax. Value is modified atomically and the previous value is returned.

Parameters
• shell – [in] Pointer to the shell instance.
• val – [in] Color mode.
Return values

- 0 – or 1: previous value
- -EINVAL – if shell is NULL.

int shell_echo_set(const struct shell *shell, bool val)

Allow application to control whether user input is echoed back. Value is modified atomically and the previous value is returned.

Parameters

- shell – [in] Pointer to the shell instance.

Return values

- 0 – or 1: previous value
- -EINVAL – if shell is NULL.

int shell_obscure_set(const struct shell *shell, bool obscure)

Allow application to control whether user input is obscured with asterisks. Useful for implementing passwords. Value is modified atomically and the previous value is returned.

Parameters

- shell – [in] Pointer to the shell instance.

Return values

- 0 – or 1: previous value
- -EINVAL – if shell is NULL.

int shell_mode_delete_set(const struct shell *shell, bool val)

Allow application to control whether the delete key backspaces or deletes. Value is modified atomically and the previous value is returned.

Parameters

- shell – [in] Pointer to the shell instance.

Return values

- 0 – or 1: previous value
- -EINVAL – if shell is NULL.

Variables

const struct log_backend_api log_backend_shell_api

union shell_cmd_entry

#include <shell.h> Shell command descriptor.

Public Members
shell_dynamic_get  dynamic_get
< Pointer to function returning dynamic commands. Pointer to array of static commands.

const struct shell_static_entry *entry

struct shell_static_args
#include <shell.h>

Public Members

uint8_t mandatory
   Number of mandatory arguments.

uint8_t optional
   Number of optional arguments.

struct shell_static_entry
#include <shell.h>

Public Members

const char *syntax
   Command syntax strings.

const char *help
   Command help string.

const union shell_cmd_entry *subcmd
   Pointer to subcommand.

shell_cmd_handler handler
   Command handler.

struct shell_static_args args
   Command arguments.

struct shell_transport_api
#include <shell.h> Unified shell transport interface.

Public Members

int (*init)(const struct shell_transport *transport, const void *config,
shell_transport_handler_t evt_handler, void *context)
   Function for initializing the shell transport interface.
   
   Param transport
      [in] Pointer to the transfer instance.
Param config
  [in] Pointer to instance configuration.

Param evt_handler

Param context
  [in] Pointer to the context passed to event handler.

Return
  Standard error code.

int (*uninit)(const struct shell_transport *transport)
Function for uninitializing the shell transport interface.
  Param transport
    [in] Pointer to the transfer instance.
  Return
    Standard error code.

int (*enable)(const struct shell_transport *transport, bool blocking_tx)
Function for enabling transport in given TX mode.
  Function can be used to reconfigure TX to work in blocking mode.
  Param transport
    Pointer to the transfer instance.
  Param blocking_tx
    If true, the transport TX is enabled in blocking mode.
  Return
    NRF_SUCCESS on successful enabling, error otherwise (also if not supported).

int (*write)(const struct shell_transport *transport, const void *data, size_t length, size_t *cnt)
Function for writing data to the transport interface.
  Param transport
    [in] Pointer to the transfer instance.
  Param data
    [in] Pointer to the source buffer.
  Param length
    [in] Source buffer length.
  Param cnt
    [out] Pointer to the sent bytes counter.
  Return
    Standard error code.

int (*read)(const struct shell_transport *transport, void *data, size_t length, size_t *cnt)
Function for reading data from the transport interface.
  Param p_transport
    [in] Pointer to the transfer instance.
  Param p_data
    [in] Pointer to the destination buffer.
  Param length
    [in] Destination buffer length.
  Param cnt
    [out] Pointer to the received bytes counter.
  Return
    Standard error code.

void (*update)(const struct shell_transport *transport)
Function called in shell thread loop.
Can be used for backend operations that require longer execution time

**Param transport**

[in] Pointer to the transfer instance.

```c
struct shell_transport
#include <shell.h>
```

```c
struct shell_stats
#include <shell.h> Shell statistics structure.

Public Members

atomic_t log_lost_cnt
Lost log counter.

struct shell_backend_config_flags
#include <shell.h>

Public Members

uint32_t insert_mode
Controls insert mode for text introduction

uint32_t echo
Controls shell echo

uint32_t obscure
If echo on, print asterisk instead

uint32_t mode_delete
Operation mode of backspace key

uint32_t use_colors
Controls colored syntax

uint32_t use_vt100
Controls VT100 commands usage in shell

struct shell_backend_ctx_flags
#include <shell.h>

Public Members

uint32_t processing
Shell is executing process function
uint32_t history_exit
    Request to exit history mode

uint32_t last_nl
    Last received new line character

uint32_t cmd_ctx
    Shell is executing command

uint32_t print_noinit
    Print request from not initialized shell

uint32_t sync_mode
    Shell in synchronous mode

union shell_backend_cfg
    #include <shell.h>

Public Members

atomic_t value

struct shell_backend_config_flags flags

union shell_backend_ctx
    #include <shell.h>

Public Members

uint32_t value

struct shell_backend_ctx_flags flags

struct shell_ctx
    #include <shell.h> Shell instance context.

Public Members

const char *prompt
    Shell current prompt.

enum shell_state state
    Internal module state.
enum **shell_receive_state** receive_state

Escape sequence indicator. Currently executed command.

const struct **shell_static_entry** *selected_cmd

VT100 color and cursor position, terminal width.

struct shell_vt100_ctx vt100_ctx

Callback called from shell thread context when unitialization is completed just before aborting shell thread.

**shell_uninit_cb_t** uninit_cb

When bypass is set, all incoming data is passed to the callback.

uint16_t cmd_buff_len

Command length.

uint16_t cmd_buff_pos

Command buffer cursor position.

uint16_t cmd_tmp_buff_len

Command length in tmp buffer. Command input buffer.

char cmd_buff[0]

Command temporary buffer.

char temp_buff[0]

Printf buffer size.

struct *k_poll_signal* signals[SHELL_SIGNALS]

Events that should be used only internally by shell thread. Event for SHELL_SIGNAL_TXDONE is initialized but unused.

struct shell

#include <shell.h> Shell instance internals.

**Public Members**

const char *default_prompt

shell default prompt.

const struct **shell_transport** *iface

Transport interface.

struct **shell_ctx** *ctx

Internal context.
4.15 Settings

The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. A variety of storage implementations are provided behind a common API using FCB, NVS, or a file system. These different implementations give the application developer flexibility to select an appropriate storage medium, and even change it later as needs change. This subsystem is used by various Zephyr components and can be used simultaneously by user applications.

Settings items are stored as key-value pair strings. By convention, the keys can be organized by the package and subtree defining the key, for example the key `id/serial` would define the `serial` configuration element for the package `id`.

Convenience routines are provided for converting a key value to and from a string type.

For an example of the settings subsystem refer to the sample.

**Note:** As of Zephyr release 2.1 the recommended backend for non-filesystem storage is **NVS**.

4.15.1 Handlers

Settings handlers for subtree implement a set of handler functions. These are registered using a call to `settings_register()`.

- **h_get**
  This gets called when asking for a settings element value by its name using `settings_runtime_get()` from the runtime backend.

- **h_set**
  This gets called when the value is loaded from persisted storage with `settings_load()`, or when using `settings_runtime_set()` from the runtime backend.

- **h_commit**
  This gets called after the settings have been loaded in full. Sometimes you don’t want an individual setting value to take effect right away, for example if there are multiple settings which are interdependent.

- **h_export**
  This gets called to write all current settings. This happens when `settings_save()` tries to save the settings or transfer to any user-implemented back-end.

4.15.2 Backends

Backends are meant to load and save data to/from setting handlers, and implement a set of handler functions. These are registered using a call to `settings_src_register()` for backends that can load data, and/or `settings_dst_register()` for backends that can save data. The current implementation allows for multiple source backends but only a single destination backend.

- **csi_load**
  This gets called when loading values from persistent storage using `settings_load()`.

- **csi_save**
  This gets called when saving a single setting to persistent storage using `settings_save_one()`.

- **csi_save_start**
  This gets called when starting a save of all current settings using `settings_save()`.

- **csi_save_end**
  This gets called after having saved of all current settings using `settings_save()`.
4.15.3 Zephyr Storage Backends

Zephyr has three storage backends: a Flash Circular Buffer (CONFIG_SETTINGS_FCB), a file in the filesystem (CONFIG_SETTINGS_FILE), or non-volatile storage (CONFIG_SETTINGS_NVS).

You can declare multiple sources for settings; settings from all of these are restored when settings_load() is called.

There can be only one target for writing settings; this is where data is stored when you call settings_save(), or settings_save_one().

FCB read target is registered using settings_fcb_src(), and write target using settings_fcb_dst(). As a side-effect, settings_fcb_src() initializes the FCB area, so it must be called before calling settings_fcb_dst(). File read target is registered using settings_file_src(), and write target by using settings_file_dst(). Non-volatile storage read target is registered using settings_nvs_src(), and write target by using settings_nvs_dst().

4.15.4 Storage Location

The FCB and non-volatile storage (NVS) backends both look for a fixed partition with label “storage” by default. A different partition can be selected by setting the zephyr,settings-partition property of the chosen node in the devicetree.

The file path used by the file backend to store settings is selected via the option CONFIG_SETTINGS_FILE_PATH.

4.15.5 Loading data from persisted storage

A call to settings_load() uses an h_set implementation to load settings data from storage to volatile memory. After all data is loaded, the h_commit handler is issued, signalling the application that the settings were successfully retrieved.

Technically FCB and file backends may store some history of the entities. This means that the newest data entity is stored after any older existing data entities. Starting with Zephyr 2.1, the back-end must filter out all old entities and call the callback with only the newest entity.

4.15.6 Storing data to persistent storage

A call to settings_save_one() uses a backend implementation to store settings data to the storage medium. A call to settings_save() uses an h_export implementation to store different data in one operation using settings_save_one(). A key need to be covered by a h_export only if it is supposed to be stored by settings_save() call.

For both FCB and file back-end only storage requests with data which changes most actual key’s value are stored, therefore there is no need to check whether a value changed by the application. Such a storage mechanism implies that storage can contain multiple value assignments for a key, while only the last is the current value for the key.

Garbage collection

When storage becomes full (FCB) or consumes too much space (file), the backend removes non-recent key-value pairs records and unnecessary key-delete records.
4.15.7 Secure domain settings

Currently settings doesn’t provide scheme of being secure, and non-secure configuration storage simultaneously for the same instance. It is recommended that secure domain uses its own settings instance and it might provide data for non-secure domain using dedicated interface if needed (case dependent).

4.15.8 Example: Device Configuration

This is a simple example, where the settings handler only implements h_set and h_export. h_set is called when the value is restored from storage (or when set initially), and h_export is used to write the value to storage thanks to storage_func(). The user can also implement some other export functionality, for example, writing to the shell console).

```c
#define DEFAULT_FOO_VAL_VALUE 1

static int8 foo_val = DEFAULT_FOO_VAL_VALUE;

static int foo_settings_set(const char *name, size_t len,
                            settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) && !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }
        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            /* key-value pair was properly read.
             * rc contains value length.
             */
            return 0;
        }
        /* read-out error */
    }
    /* read-out error */
    return rc;
}

static int foo_settings_export(int (*storage_func)(const char *name,
                                                    const void *value,
                                                    size_t val_len))
{
    return storage_func("foo/bar", &foo_val, sizeof(foo_val));
}

struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set,
    .h_export = foo_settings_export
};
```
4.15.9 Example: Persist Runtime State

This is a simple example showing how to persist runtime state. In this example, only h_set is defined, which is used when restoring value from persisted storage.

In this example, the main function increments foo_val, and then persists the latest number. When the system restarts, the application calls settings_load() while initializing, and foo_val will continue counting up from where it was before restart.

```c
#include <zephyr/kernel.h>
#include <zephyr/sys/reboot.h>
#include <zephyr/settings/settings.h>
#include <zephyr/sys/printk.h>
#include <inttypes.h>

#define DEFAULT_FOO_VAL_VALUE 0

static uint8_t foo_val = DEFAULT_FOO_VAL_VALUE;

static int foo_settings_set(const char *name, size_t len,
    settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) && !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }

        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            return 0;
        }
    }

    return rc;
}

struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set
};

void main(void)
{
    settings_subsys_init();
    settings_register(&my_conf);
    settings_load();

    foo_val++;
    settings_save_one("foo/bar", &foo_val, sizeof(foo_val));

    printk("foo: %d\n", foo_val);
}
```

(continues on next page)
4.15.10 Example: Custom Backend Implementation

This is a simple example showing how to register a simple custom backend handler (CONFIG_SETTINGS_CUSTOM).

```c
static int settings_custom_load(struct settings_store *cs)
{
  //...
}

static int settings_custom_save(struct settings_store *cs, const char *name,
                                const char *value, size_t val_len)
{
  //...
}

/* custom backend interface */
static struct settings_store_itf settings_custom_itf = {
  .csi_load = settings_custom_load,
  .csi_save = settings_custom_save,
};

/* custom backend node */
static struct settings_store settings_custom_store = {
  .cs_itf = &settings_custom_itf
}

int settings_backend_init(void)
{
  /* register custom backend */
  settings_dst_register(&settings_custom_store);
  settings_src_register(&settings_custom_store);
  return 0;
}
```

4.15.11 API Reference

The Settings subsystem APIs are provided by settings.h:

**API for general settings usage**

`group settings`

**Defines**

```
SETTINGS_MAX_DIR_DEPTH
```
SETTINGS_MAX_NAME_LEN

SETTINGS_MAX_VAL_LEN

SETTINGS_NAME_SEPARATOR

SETTINGS_NAME_END

SETTINGS_EXTRA_LEN

SETTINGS_STATIC_HANDLER_DEFINE(_hname, _tree, _get, _set, _commit, _export)

Define a static handler for settings items

This creates a variable *hname prepended by settings_handler.*

Parameters

- _hname – handler name
- _tree – subtree name
- _get – get routine (can be NULL)
- _set – set routine (can be NULL)
- _commit – commit routine (can be NULL)
- _export – export routine (can be NULL)

Typedefs

typedef ssize_t (*settings_read_cb)(void *cb_arg, void *data, size_t len)

Function used to read the data from the settings storage in h_set handler implementations.

- **Param cb_arg**
  - [in] arguments for the read function. Appropriate cb_arg is transferred to h_set handler implementation by the backend.

- **Param data**
  - [out] the destination buffer

- **Param len**
  - [in] length of read

Return

- positive: Number of bytes read, 0: key-value pair is deleted. On error returns -ERRNO code.

typedef int (*settings_load_direct_cb)(const char *key, size_t len, settings_read_cb read_cb, void *cb_arg, void *param)

Callback function used for direct loading. Used by settings_load_subtree_direct function.

- **Param key**
  - [in] the name with skipped part that was used as name in handler registration

- **Param len**
  - [in] the size of the data found in the backend.
**Param read_cb**

[in] function provided to read the data from the backend.

**Param cb_arg**

[inout] arguments for the read function provided by the backend.

**Param param**

[inout] parameter given to the `settings_load_subtree_direct` function.

**Return**

When nonzero value is returned, further subtree searching is stopped.

### Functions

```c
int settings_subsys_init(void)
```

Initialization of settings and backend

Can be called at application startup. In case the backend is a FS Remember to call it after the FS was mounted. For FCB backend it can be called without such a restriction.

**Returns**

0 on success, non-zero on failure.

```c
int settings_register(struct settings_handler *cf)
```

Register a handler for settings items stored in RAM.

**Parameters**

- `cf` – Structure containing registration info.

**Returns**

0 on success, non-zero on failure.

```c
int settings_load(void)
```

Load serialized items from registered persistence sources. Handlers for serialized item subtrees registered earlier will be called for encountered values.

**Returns**

0 on success, non-zero on failure.

```c
int settings_load_subtree(const char *subtree)
```

Load limited set of serialized items from registered persistence sources. Handlers for serialized item subtrees registered earlier will be called for encountered values that belong to the subtree.

**Parameters**

- `subtree` – [in] name of the subtree to be loaded.

**Returns**

0 on success, non-zero on failure.

```c
int settings_load_subtree_direct(const char *subtree, settings_load_direct_cb cb, void *param)
```

Load limited set of serialized items using given callback.

This function bypasses the normal data workflow in settings module. All the settings values that are found are passed to the given callback.

**Note:** This function does not call commit function. It works as a blocking function, so it is up to the user to call any kind of commit function when this operation ends.

**Parameters**
Zephyr Project Documentation, Release 3.2.99

- **subtree** – [in] subtree name of the subtree to be loaded.
- **cb** – [in] pointer to the callback function.
- **param** – [inout] parameter to be passed when callback function is called.

**Returns**
0 on success, non-zero on failure.

```c
int settings_save(void)
```
Save currently running serialized items. All serialized items which are different from currently persisted values will be saved.

**Returns**
0 on success, non-zero on failure.

```c
int settings_save_one(const char *name, const void *value, size_t val_len)
```
Write a single serialized value to persisted storage (if it has changed value).

**Parameters**
- **name** – Name/key of the settings item.
- **value** – Pointer to the value of the settings item. This value will be transferred to the `settings_handler::h_export` handler implementation.
- **val_len** – Length of the value.

**Returns**
0 on success, non-zero on failure.

```c
int settings_delete(const char *name)
```
Delete a single serialized in persisted storage.

Deleting an existing key-value pair in the settings mean to set its value to NULL.

**Parameters**
- **name** – Name/key of the settings item.

**Returns**
0 on success, non-zero on failure.

```c
int settings_commit(void)
```
Call commit for all settings handler. This should apply all settings which has been set, but not applied yet.

**Returns**
0 on success, non-zero on failure.

```c
int settings_commit_subtree(const char *subtree)
```
Call commit for settings handler that belong to subtree. This should apply all settings which has been set, but not applied yet.

**Parameters**
- **subtree** – [in] name of the subtree to be committed.

**Returns**
0 on success, non-zero on failure.

```c
struct settings_handler
```
#include <settings.h> Config handlers for subtree implement a set of handler functions. These are registered using a call to `settings_register`.  

Chapter 4. OS Services
Public Members

const char *name
  Name of subtree.

int (*h_get)(const char *key, char *val, int val_len_max)
  Get values handler of settings items identified by keyword names.
  Parameters:
  • key[in] the name with skipped part that was used as name in handler registration
  • val[out] buffer to receive value.
  • val_len_max[in] size of that buffer.
  Return: length of data read on success, negative on failure.

int (*h_set)(const char *key, size_t len, settings_read_cb read_cb, void *cb_arg)
  Set value handler of settings items identified by keyword names.
  Parameters:
  • key[in] the name with skipped part that was used as name in handler registration
  • len[in] the size of the data found in the backend.
  • read_cb[in] function provided to read the data from the backend.
  • cb_arg[in] arguments for the read function provided by the backend.
  Return: 0 on success, non-zero on failure.

int (*h_commit)(void)
  This handler gets called after settings has been loaded in full. User might use it to apply
  setting to the application.
  Return: 0 on success, non-zero on failure.

int (*h_export)(int (*export_func)(const char *name, const void *val, size_t val_len))
  This gets called to dump all current settings items.
  This happens when settings_save tries to save the settings. Parameters:
  • export_func: the pointer to the internal function which appends a single key-value
    pair to persisted settings. Don’t store duplicated value. The name is subtree/key
    string, val is the string with value.
  Return: 0 on success, non-zero on failure.

Remark
The User might limit a implementations of handler to serving only one keyword at one
  call - what will impose limit to get/set values using full subtree/key name.

sys_snod_t node
  Linked list node info for module internal usage.

struct settings_handler_static
  #include <settings.h> Config handlers without the node element, used for static handlers.
  These are registered using a call to SETTINGS_STATIC_HANDLER_DEFINE().

4.15. Settings 823
Public Members

const char *name
Name of subtree.

int (*h_get)(const char *key, char *val, int val_len_max)
Get values handler of settings items identified by keyword names.
Parameters:
• key[in] the name with skipped part that was used as name in handler registration
• val[out] buffer to receive value.
• val_len_max[in] size of that buffer.
Return: length of data read on success, negative on failure.

int (*h_set)(const char *key, size_t len, settings_read_cb read_cb, void *cb_arg)
Set value handler of settings items identified by keyword names.
Parameters:
• key[in] the name with skipped part that was used as name in handler registration
• len[in] the size of the data found in the backend.
• read_cb[in] function provided to read the data from the backend.
• cb_arg[in] arguments for the read function provided by the backend.
Return: 0 on success, non-zero on failure.

int (*h_commit)(void)
This handler gets called after settings has been loaded in full. User might use it to apply setting to the application.

int (*h_export)(int (*export_func)(const char *name, const void *val, size_t val_len))
This gets called to dump all current settings items.
This happens when settings_save tries to save the settings. Parameters:
• export_func: the pointer to the internal function which appends a single key-value pair to persisted settings. Don't store duplicated value. The name is subtree/key string, val is the string with value.

Remark
The User might limit a implementations of handler to serving only one keyword at one call - what will impose limit to get/set values using full subtree/key name.

API for key-name processing

group settings_name_proc
API for const name processing.

Functions
int settings_name_steq(const char *name, const char *key, const char **next)
Compared the start of name with a key

Some examples: settings_name_steq("bt/btmesh/iv", "b", &next) returns 1, next="t/btmesh/iv" settings_name_steq("bt/btmesh/iv", "bt", &next) returns 1, next="bmesh/iv" settings_name_steq("bt/btmesh/iv", "bt/", &next) returns 0, next=NULL settings_name_steq("bt/btmesh/iv", "bta", &next) returns 0, next=NULL

REMARK: This routine could be simplified if the settings_handler names would include a separator at the end.

Parameters
• name – [in] in string format
• key – [in] comparison string
• next – [out] pointer to remaining of name, when the remaining part starts with a separator the separator is removed from next

Returns
0: no match 1: match, next can be used to check if match is full

int settings_name_next(const char *name, const char **next)
determine the number of characters before the first separator

Parameters
• name – [in] in string format
• next – [out] pointer to remaining of name (excluding separator)

Returns
index of the first separator, in case no separator was found this is the size of name

API for runtime settings manipulation

group settings_rt
API for runtime settings.

Functions

int settings_runtime_set(const char *name, const void *data, size_t len)
Set a value with a specific key to a module handler.

Parameters
• name – Key in string format.
• data – Binary value.
• len – Value length in bytes.

Returns
0 on success, non-zero on failure.

int settings_runtime_get(const char *name, void *data, size_t len)
Get a value corresponding to a key from a module handler.

Parameters
• name – Key in string format.
• data – Returned binary value.
• len – requested value length in bytes.

Returns
length of data read on success, negative on failure.

int settings_runtime_commit(const char *name)
Apply settings in a module handler.

Parameters
• name – Key in string format.

Returns
0 on success, non-zero on failure.

API of backend interface

group settings_backend
settings

Functions

void settings_src_register(struct settings_store *cs)
Register a backend handler acting as source.

Parameters
• cs – Backend handler node containing handler information.

void settings_dst_register(struct settings_store *cs)
Register a backend handler acting as destination.

Parameters
• cs – Backend handler node containing handler information.

struct settings_handler_* settings_parse_and_lookup(const char *name, const char **next)
Parses a key to an array of elements and locate corresponding module handler.

Parameters
• name – [in] in string format
• next – [out] remaining of name after matched handler

Returns
settings_handler_static on success, NULL on failure.

int settings_call_set_handler(const char *name, size_t len, settings_read_cb read_cb, void
read_cb_arg, const struct settings_load_arg *load_arg)
Calls settings handler.

Parameters
• name – [in] The name of the data found in the backend.
• len – [in] The size of the data found in the backend.
• read_cb – [in] Function provided to read the data from the backend.
• read_cb_arg – [inout] Arguments for the read function provided by the back-end.
**Returns**

0 or negative error code

```c
struct settings_store

#include <settings.h> Backend handler node for storage handling.
```

**Public Members**

```c
sys_snnode_t cs_next
  Linked list node info for internal usage.

const struct settings_store_itf *cs_itf
  Backend handler structure.
```

```c
struct settings_load_arg

#include <settings.h> Arguments for data loading. Holds all parameters that changes the way data should be loaded from backend.
```

**Public Members**

```c
const char *subtree
  Name of the subtree to be loaded.
  If NULL, all values would be loaded.

settings_load_direct_cb cb
  Pointer to the callback function.
  If NULL then matching registered function would be used.

void *param
  Parameter for callback function.
  Parameter to be passed to the callback function.
```

```c
struct settings_store_itf

#include <settings.h> Backend handler functions. Sources are registered using a call to settings_src_register. Destinations are registered using a call to settings_dst_register.
```

**Public Members**

```c
int (*csi_load)(struct settings_store *cs, const struct settings_load_arg *arg)
  Loads values from storage limited to subtree defined by subtree.

Parameters:
  • cs - Corresponding backend handler node,
  • arg - Structure that holds additional data for data loading.
```

**Note:** Backend is expected not to provide duplicates of the entities. It means that if the backend does not contain any functionality to really delete old keys, it has to filter out old entities and call load callback only on the final entity.
int (*csi_save_start)(struct settings_store *cs)
    Handler called before an export operation.
    Parameters:
    • cs - Corresponding backend handler node

int (*csi_save)(struct settings_store *cs, const char *name, const char *value, size_t val_len)
    Save a single key-value pair to storage.
    Parameters:
    • cs - Corresponding backend handler node
    • name - Key in string format
    • value - Binary value
    • val_len - Length of value in bytes.

int (*csi_save_end)(struct settings_store *cs)
    Handler called after an export operation.
    Parameters:
    • cs - Corresponding backend handler node

4.16 State Machine Framework

4.16.1 Overview

The State Machine Framework (SMF) is an application agnostic framework that provides an easy way for developers to integrate state machines into their application. The framework can be added to any project by enabling the CONFIG_SMF option.

4.16.2 State Creation

A state is represented by three functions, where one function implements the Entry actions, another function implements the Run actions, and the last function implements the Exit actions. The prototype for these functions is as follows: void funct(void *obj), where the obj parameter is a user defined structure that has the state machine context, struct smf_ctx, as its first member. For example:

```c
struct user_object {
    struct smf_ctx ctx;
    /* All User Defined Data Follows */
};
```

The struct smf_ctx member must be first because the state machine framework’s functions casts the user defined object to the struct smf_ctx type with the following macro: SMF_CTX(o)

For example instead of doing this (struct smf_ctx *)&user_obj, you could use SMF_CTX(&user_obj).

By default, a state can have no ancestor states, resulting in a flat state machine. But to enable the creation of a hierarchical state machine, the CONFIG_SMFANCESTOR_SUPPORT option must be enabled.

The following macro can be used for easy state creation:

```
    • SMF_CREATE_STATE Create a state
```

**NOTE:** The SMF_CREATE_STATE macro takes an additional parameter when CONFIG_SMFANCESTOR_SUPPORT is enabled.
4.16.3  State Machine Creation

A state machine is created by defining a table of states that's indexed by an enum. For example, the following creates three flat states:

```c
enum demo_state { S0, S1, S2 };

const struct smf_state demo_states[] = {
    [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit),
    [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit),
    [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit)
};
```

And this example creates three hierarchical states:

```c
enum demo_state { S0, S1, S2 };

const struct smf_state demo_states[] = {
    [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, parent_s0),
    [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit, parent_s12),
    [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit, parent_s12)
};
```

To set the initial state, the `smf_set_initial` function should be called. It has the following prototype:

```c
void smf_set_initial(smf_ctx *ctx, smf_state *state)
```

To transition from one state to another, the `smf_set_state` function is used and it has the following prototype:

```c
void smf_set_state(smf_ctx *ctx, smf_state *state)
```

**NOTE:** While the state machine is running, `smf_set_state` should only be called from the Entry and Run functions. Calling `smf_set_state` from the Exit functions doesn't make sense and will generate a warning.

4.16.4  State Machine Execution

To run the state machine, the `smf_run_state` function should be called in some application dependent way. An application should cease calling `smf_run_state` if it returns a non-zero value. The function has the following prototype:

```c
int32_t smf_run_state(smf_ctx *ctx)
```

4.16.5  State Machine Termination

To terminate the state machine, the `smf_terminate` function should be called. It can be called from the entry, run, or exit action. The function takes a non-zero user defined value that's returned by the `smf_run_state` function. The function has the following prototype:

```c
void smf_terminate(smf_ctx *ctx, int32_t val)
```

4.16.6  Flat State Machine Example

This example turns the following state diagram into code using the SMF, where the initial state is S0.

Code:

```c
#include <zephyr/smf.h>

/* Forward declaration of state table */
static const struct smf_state demo_states[];
```

(continues on next page)
/* List of demo states */
enum demo_state { S0, S1, S2 };

/* User defined object */
struct s_object {
    /* This must be first */
    struct smf_ctx ctx;

    /* Other state specific data add here */
} s_obj;

/* State S0 */
static void s0_entry(void *o) {
    /* Do something */
}
static void s0_run(void *o) {
    smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
}
static void s0_exit(void *o) {
    /* Do something */
}

/* State S1 */
static void s1_run(void *o) {
    /* Do something */
}

/* State S2 */
static void s2_entry(void *o) {
    /* Do something */
}
static void s2_run(void *o) {
    /* Do something */
}

(continued from previous page)
### 4.16.7 Hierarchical State Machine Example

This example turns the following state diagram into code using the SMF, where S0 and S1 share a parent state and S0 is the initial state.

**Code:**

```c
#include <zephyr/smf.h>
```

(continues on next page)
Fig. 4.10: Hierarchical state machine diagram

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
enum demo_state { PARENT, S0, S1, S2 };

/* User defined object */
struct s_object {
    /* This must be first */
    struct smf_ctx ctx;

    /* Other state specific data add here */
} s_obj;

/* Parent State */
static void parent_entry(void *o)
{
    /* Do something */
}
static void parent_exit(void *o)
{
    /* Do something */
}

/* State S0 */
static void s0_run(void *o)
{

(continues on next page)
When designing hierarchical state machines, the following should be considered:

- Ancestor entry actions are executed before the sibling entry actions. For example, the parent_entry function is called before the s0_entry function.

- Transitioning from one sibling to another with a shared ancestry does not re-execute the ancestor's entry action or execute the exit action. For example, the parent_entry function is not called when transitioning from S0 to S1, nor is the parent_exit function called.

- Ancestor exit actions are executed after the sibling exit actions. For example, the s1_exit function is called before the parent_exit function is called.

- The parent_run function only executes if the child_run function returns without transitioning to another state, i.e. calling smf_set_state.
4.16.8 Event Driven State Machine Example

Events are not explicitly part of the State Machine Framework but an event driven state machine can be implemented using Zephyr Events.

Figure 4.11: Event driven state machine diagram

Code:

```c
#include <zephyr/kernel.h>
#include <zephyr/drivers/gpio.h>
#include <zephyr/smf.h>

#define SW0_NODE DT_ALIAS(sw0)

/* List of events */
#define EVENT_BTN_PRESS BIT(0)

static const struct gpio_dt_spec button =
    GPIO_DT_SPEC_GET_OR(SW0_NODE, gpios, {0});

static struct gpio_callback button_cb_data;

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
enum demo_state { S0, S1 };

/* User defined object */
struct s_object {
    /* This must be first */
    struct smf_ctx ctx;

    /* Events */
    struct k_event smf_event;
};
```

(continues on next page)
int32_t events;
 *
 */ Other state specific data add here */
} s_obj;

/* State S0 */
static void s0_entry(void *o)
{
    printk("STATE0\n");
}

static void s0_run(void *o)
{
    struct s_object *s = (struct s_object *)o;
    /* Change states on Button Press Event */
    if (s->events & EVENT_BTN_PRESS) {
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
    }
}

/* State S1 */
static void s1_entry(void *o)
{
    printk("STATE1\n");
}

static void s1_run(void *o)
{
    struct s_object *s = (struct s_object *)o;
    /* Change states on Button Press Event */
    if (s->events & EVENT_BTN_PRESS) {
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
    }
}

/* Populate state table */
static const struct smf_state demo_states[] = {
    [S0] = SMF_CREATE_STATE(s0_entry, s0_run, NULL),
    [S1] = SMF_CREATE_STATE(s1_entry, s1_run, NULL),
};

void button_pressed(const struct device *dev,
    struct gpio_callback *cb, uint32_t pins)
{
    /* Generate Button Press Event */
    k_event_post(&s_obj.smf_event, EVENT_BTN_PRESS);
}

void main(void)
{
    int ret;
    if (!device_is_ready(button.port)) {
        printk("Error: button device %s is not ready\n",}
button.port->name);
    return;
}

ret = gpio_pin_configure_dt(&button, GPIO_INPUT);
if (ret != 0) {
    printk("Error %d: failed to configure %s pin %d\n",
           ret, button.port->name, button.pin);
    return;
}

ret = gpio_pin_interrupt_configure_dt(&button,
                                       GPIO_INT_EDGE_TO_ACTIVE);
if (ret != 0) {
    printk("Error %d: failed to configure interrupt on %s pin %d\n",
            ret, button.port->name, button.pin);
    return;
}

gpio_init_callback(&button_cb_data, button_pressed, BIT(button.pin));
gpio_add_callback(button.port, &button_cb_data);

/* Initialize the event */
k_event_init(&s_obj.smf_event);

/* Set initial state */
smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

/* Run the state machine */
while(1) {
    /* Block until an event is detected */
    s_obj.events = k_event_wait(&s_obj.smf_event,
                                 EVENT_BTN_PRESS, true, K_FOREVER);

    /* State machine terminates if a non-zero value is returned */
    ret = smf_run_state(SMF_CTX(&s_obj));
    if (ret) {
        /* handle return code and terminate state machine */
        break;
    }
}

4.17 Storage

4.17.1 Non-Volatile Storage (NVS)

Elements, represented as id-data pairs, are stored in flash using a FIFO-managed circular buffer. The flash area is divided into sectors. Elements are appended to a sector until storage space in the sector is exhausted. Then a new sector in the flash area is prepared for use (erased). Before erasing the sector it is checked that identifier - data pairs exist in the sectors in use, if not the id-data pair is copied.

The id is a 16-bit unsigned number. NVS ensures that for each used id there is at least one id-data pair stored in flash at all time.
NVS allows storage of binary blobs, strings, integers, longs, and any combination of these. Each element is stored in flash as metadata (8 byte) and data. The metadata is written in a table starting from the end of an nvs sector, the data is written one after the other from the start of the sector. The metadata consists of: id, data offset in sector, data length, part (unused) and a crc.

A write of data to nvs always starts with writing the data, followed by a write of the metadata. Data that is written in flash without metadata is ignored during initialization.

During initialization NVS will verify the data stored in flash, if it encounters an error it will ignore any data with missing/incorrect metadata.

NVS checks the id-data pair before writing data to flash. If the id-data pair is unchanged no write to flash is performed.

To protect the flash area against frequent erases it is important that there is sufficient free space. NVS has a protection mechanism to avoid getting in an endless loop of flash page erases when there is limited free space. When such a loop is detected NVS returns that there is no more space available.

For NVS the file system is declared as:

```c
static struct nvs_fs fs = {
    .flash_device = NVS_FLASH_DEVICE,
    .sector_size = NVS_SECTOR_SIZE,
    .sector_count = NVS_SECTOR_COUNT,
    .offset = NVS_STORAGE_OFFSET,
};
```

where

- `NVS_FLASH_DEVICE` is a reference to the flash device that will be used. The device needs to be operational.
- `NVS_SECTOR_SIZE` is the sector size, it has to be a multiple of the flash erase page size and a power of 2.
- `NVS_SECTOR_COUNT` is the number of sectors, it is at least 2, one sector is always kept empty to allow copying of existing data.
- `NVS_STORAGE_OFFSET` is the offset of the storage area in flash.

**Flash wear**

When writing data to flash a study of the flash wear is important. Flash has a limited life which is determined by the number of times flash can be erased. Flash is erased one page at a time and the pagesize is determined by the hardware. As an example a nRF51822 device has a pagesize of 1024 bytes and each page can be erased about 20,000 times.

**Calculating expected device lifetime** Suppose we use a 4 bytes state variable that is changed every minute and needs to be restored after reboot. NVS has been defined with a sector_size equal to the pagesize (1024 bytes) and 2 sectors have been defined.

Each write of the state variable requires 12 bytes of flash storage: 8 bytes for the metadata and 4 bytes for the data. When storing the data the first sector will be full after 1024/12 = 85.33 minutes. After another 85.33 minutes, the second sector is full. When this happens, because we're using only two sectors, the first sector will be used for storage and will be erased after 171 minutes of system time. With the expected device life of 20,000 writes, with two sectors writing every 171 minutes, the device should last about 171 * 20,000 minutes, or about 6.5 years.

More generally then, with

- $NS$ as the number of storage requests per minute,
- $DS$ as the data size in bytes,
• SECTOR_SIZE in bytes, and
  • PAGE_ERASES as the number of times the page can be erased,
the expected device life (in minutes) can be calculated as:

\[
\text{SECTOR\_COUNT} \times \text{SECTOR\_SIZE} \times \text{PAGE\_ERASES} \div (\text{NS} \times (\text{DS+8})) \text{ minutes}
\]

From this formula it is also clear what to do in case the expected life is too short: increase SECTOR\_COUNT or SECTOR\_SIZE.

Flash write block size migration

It is possible that during a DFU process, the flash driver used by the NVS changes the supported minimal write block size. The NVS in-flash image will stay compatible unless the physical ATE size changes. Especially, migration between 1,2,4,8-bytes write block sizes is allowed.

Sample

A sample of how NVS can be used is supplied in samples/subsys/nvs.

Troubleshooting

MPU fault while using NVS, or -ETIMEDOUT error returned
NVS can use the internal flash of the SoC. While the MPU is enabled, the flash driver requires MPU RWX access to flash memory, configured using CONFIG_MPU_ALLOW_FLASH_WRITE. If this option is disabled, the NVS application will get an MPU fault if it references the internal SoC flash and it’s the only thread running. In a multi-threaded application, another thread might intercept the fault and the NVS API will return an -ETIMEDOUT error.

API Reference

The NVS subsystem APIs are provided by nvs.h:

group nvs_data_structures
  Non-volatile Storage Data Structures.

struct nvs_fs
  #include <nvs.h> Non-volatile Storage File system structure.

  Param offset
  File system offset in flash

  Param ate_wra
  Allocation table entry write address. Addresses are stored as uint32_t: high 2 bytes correspond to the sector, low 2 bytes are the offset in the sector

  Param data_wra
  Data write address

  Param sector_size
  File system is split into sectors, each sector must be multiple of pagesize

  Param sector_count
  Number of sectors in the file systems

  Param ready
  Flag indicating if the filesystem is initialized
Param nvs_lock
Mutex

Param flash_device
Flash Device runtime structure

Param flash_parameters
Flash memory parameters structure

group nvs_high_level_api
Non-volatile Storage APIs.

Functions

int nvs_mount(struct nvs_fs *fs)
nvs_mount
Mount a NVS file system onto the flash device specified in fs.

Parameters
• fs – Pointer to file system

Return values
• 0 – Success
• -ERRNO – errno code if error

int nvs_clear(struct nvs_fs *fs)
nvs_clear
Clears the NVS file system from flash.

Parameters
• fs – Pointer to file system

Return values
• 0 – Success
• -ERRNO – errno code if error

ssize_t nvs_write(struct nvs_fs *fs, uint16_t id, const void *data, size_t len)
nvs_write
Write an entry to the file system.

Parameters
• fs – Pointer to file system
• id – Id of the entry to be written
• data – Pointer to the data to be written
• len – Number of bytes to be written

Returns
Number of bytes written. On success, it will be equal to the number of bytes requested to be written. When a rewrite of the same data already stored is attempted, nothing is written to flash, thus 0 is returned. On error, returns negative value of errno.h defined error codes.
int nvs_delete(struct nvs_fs *fs, uint16_t id)
    nvs_delete
Delete an entry from the file system

Parameters
• fs – Pointer to file system
• id – Id of the entry to be deleted

Return values
• 0 – Success
• -ENOMEM – errno code if error

ssize_t nvs_read(struct nvs_fs *fs, uint16_t id, void *data, size_t len)
    nvs_read
Read an entry from the file system.

Parameters
• fs – Pointer to file system
• id – Id of the entry to be read
• data – Pointer to data buffer
• len – Number of bytes to be read

Returns
Number of bytes read. On success, it will be equal to the number of bytes requested to be read. When the return value is larger than the number of bytes requested to read this indicates not all bytes were read, and more data is available. On error, returns negative value of errno.h defined error codes.

ssize_t nvs_read_hist(struct nvs_fs *fs, uint16_t id, void *data, size_t len, uint16_t cnt)
    nvs_read_hist
Read a history entry from the file system.

Parameters
• fs – Pointer to file system
• id – Id of the entry to be read
• data – Pointer to data buffer
• len – Number of bytes to be read
• cnt – History counter: 0: latest entry, 1: one before latest ...

Returns
Number of bytes read. On success, it will be equal to the number of bytes requested to be read. When the return value is larger than the number of bytes requested to read this indicates not all bytes were read, and more data is available. On error, returns negative value of errno.h defined error codes.

ssize_t nvs_calc_free_space(struct nvs_fs *fs)
    nvs_calc_free_space
Calculate the available free space in the file system.

Parameters
• fs – Pointer to file system
Returns
Number of bytes free. On success, it will be equal to the number of bytes that can still be written to the file system. Calculating the free space is a time consuming operation, especially on spi flash. On error, returns negative value of errno.h defined error codes.

4.17.2 Disk Access

Overview
The disk access API provides access to storage devices.

SD Card support
Zephyr has support for some SD card controllers and support for interfacing SD cards via SPI. These drivers use disk driver interface and a file system can access the SD cards via disk access API. Both standard and high-capacity SD cards are supported.

Note: The system does not support inserting or removing cards while the system is running. The cards must be present at boot and must not be removed. This may be fixed in future releases.

FAT filesystems are not power safe so the filesystem may become corrupted if power is lost or if the card is removed.

SD Memory Card subsystem Zephyr supports SD memory cards via the disk driver API, or via the SDMMC subsystem. This subsystem can be used transparently via the disk driver API, but also supports direct block level access to cards. The SDMMC subsystem interacts with the sd host controller api to communicate with attached SD cards.

SD Card support via SPI Example devicetree fragment below shows how to add SD card node to spi1 interface. Example uses pin PA27 for chip select, and runs the SPI bus at 24 MHz once the SD card has been initialized:

```c
&spi1 {
    status = "okay";
    cs-gpios = <&porta 27 GPIO_ACTIVE_LOW>;

    sdhc0: sdhc00 {
        compatible = "zephyr,sdhc-spi-slot";
        reg = <0>;
        status = "okay";
        mmc {
            compatible = "zephyr,sdmmc-disk";
            status = "okay";
        };
        spi-max-frequency = <24000000>;
    };
}
```

The SD card will be automatically detected and initialized by the filesystem driver when the board boots.

To read and write files and directories, see the File Systems in include/zephyr/fs/fs.h such as fs_open(), fs_read(), and fs_write().
Emulated block device on flash partition support

Zephyr flashdisk driver makes it possible to use flash memory partition as a block device. The flashdisk instances are defined in devicetree:

```c
/ {
    msc_disk0 {
        compatible = "zephyr,flash-disk";
        partition = <&storage_partition>;
        disk-name = "NAND";
        cache-size = <4096>;
    }
};
```

The cache size specified in `zephyr,flash-disk` node should be equal to backing partition minimum erasable block size.

Disk Access API Configuration Options

Related configuration options:

- CONFIG_DISK_ACCESS

API Reference

**group** disk_access_interface

Disk Access APIs.

**Functions**

`int disk_access_init(const char *pdrv)`

perform any initialization

This call is made by the consumer before doing any IO calls so that the disk or the backing device can do any initialization.

**Parameters**

- `pdrv` – [in] Disk name

**Returns**

0 on success, negative errno code on fail

`int disk_access_status(const char *pdrv)`

Get the status of disk.

This call is used to get the status of the disk

**Parameters**

- `pdrv` – [in] Disk name

**Returns**

DISK_STATUS_OK or other DISK_STATUS_*s

`int disk_access_read(const char *pdrv, uint8_t *data_buf, uint32_t start_sector, uint32_t num sector)`

read data from disk

Function to read data from disk to a memory buffer.
Parameters

• pdrv – [in] Disk name
• data_buf – [in] Pointer to the memory buffer to put data.
• start_sector – [in] Start disk sector to read from
• num_sector – [in] Number of disk sectors to read

Returns
0 on success, negative errno code on fail

int disk_access_write(const char *pdrv, const uint8_t *data_buf, uint32_t start_sector, uint32_t num_sector)

write data to disk
Function write data from memory buffer to disk.

Parameters

• pdrv – [in] Disk name
• data_buf – [in] Pointer to the memory buffer
• start_sector – [in] Start disk sector to write to
• num_sector – [in] Number of disk sectors to write

Returns
0 on success, negative errno code on fail

int disk_access_ioctl(const char *pdrv, uint8_t cmd, void *buff)

Get/Configure disk parameters.
Function to get disk parameters and make any special device requests.

Parameters

• pdrv – [in] Disk name
• cmd – [in] DISK_IOCTL_* code describing the request
• buff – [in] Command data buffer

Returns
0 on success, negative errno code on fail

Disk Driver Configuration Options

### 4.17.3 Flash map

The `<storage/flash_map.h>` API allows accessing information about device flash partitions via `flash_area` structures.

Each `flash_area` describes a flash partition. The API provides access to a “flash map”, which contains predefined flash areas accessible via globally unique ID numbers. The map is created from “fixed-partition” compatible entries in DTS file. Users may also create `flash_area` objects at runtime for application-specific purposes.

This documentation uses “flash area” when referencing single “fixed-partition” entities.

The `flash_area` contains a pointer to a `device`, which can be used to access the flash device an area is placed on directly with the `flash API`. Each flash area is characterized by a device it is placed on, offset from the beginning of the device and size on the device. An additional identifier parameter is used by the `flash_area_open()` function to find flash area in flash map.

The `flash_map.h` API provides functions for operating on a `flash_area`. The main examples are `flash_area_read()` and `flash_area_write()`. These functions are basically wrappers around the flash API with additional offset and size checks, to limit flash operations to a predefined area.

Most `<storage/flash_map.h>` API functions require a `flash_area` object pointer characterizing the flash area they will be working on. There are two possible methods to obtain such a pointer:

- obtain it using `flash_area_open();`
- defining a `flash_area` type object, which requires providing a valid `device` object pointer with offset and size of the area within the flash device.

`flash_area_open()` uses numeric identifiers to search flash map for `flash_area` objects and returns, if found, a pointer to an object representing area with given ID. The ID number for a flash area can be obtained from a fixed-partition DTS node label using `FIXED_PARTITION_ID();` these labels are obtained from the devicetree as described below.

**Relationship with Devicetree**

The `flash_map.h` API uses data generated from the `Devicetree API`, in particular its `Fixed flash partitions`. Zephyr additionally has some partitioning conventions used for `Device Firmware Upgrade` via the MCU-boot bootloader, as well as defining partitions usable by `file systems` or other nonvolatile `storage`. 
Here is an example devicetree fragment which uses fixed flash partitions for both MCUboot and a storage partition. Some details were left out for clarity.

/ {
    soc {
        flashctrl: flash-controller@deadbeef {
            flash0: flash@0 {
                compatible = "soc-nv-flash";
                reg = <0x0 0x100000>;

                partitions {
                    compatible = "fixed-partitions";
                    #address-cells = <0x1>;
                    #size-cells = <0x1>;

                    boot_partition: partition@0 {
                        reg = <0x0 0x10000>;
                        read-only;
                    }

                    storage_partition: partition@1e000 {
                        reg = <0x1e000 0x2000>;
                    }

                    slot0_partition: partition@20000 {
                        reg = <0x20000 0x60000>;
                    }

                    slot1_partition: partition@80000 {
                        reg = <0x80000 0x60000>;
                    }

                    scratch_partition: partition@e0000 {
                        reg = <0xe0000 0x20000>;
                    }
                }
            }
        }
    }
};

Partition offset shall be expressed in relation to the flash memory beginning address, to which the partition belongs to.

The `boot_partition`, `slot0_partition`, `slot1_partition`, and `scratch_partition` node labels are defined for MCUboot, though not all MCUboot configurations require all of them to be defined. See the MCUboot documentation for more details.

The `storage_partition` node is defined for use by a file system or other nonvolatile storage API.

Numeric flash area ID is obtained by passing DTS node label to `FIXED_PARTITION_ID()`; for example to obtain ID number for `slot0_partition`, user would invoke `FIXED_PARTITION_ID(slot0_partition)`.

All `FIXED_PARTITION_` macros take DTS node labels as partition identifiers.

Users do not have to obtain a `flash_area` object pointer using `flash_map_open()` to get information on flash area size, offset or device, if such area is defined in DTS file. Knowing the DTS node label of an area, users may use `FIXED_PARTITION_OFFSET()``, `FIXED_PARTITION_SIZE()` or `FIXED_PARTITION_DEVICE()` respectively to obtain such information directly from DTS node definition. For example to obtain offset of `storage_partition` it is enough to invoke `FIXED_PARTITION_OFFSET(storage_partition)`.

Below example shows how to obtain a `flash_area` object pointer using `flash_area_open()` and DTS node label:
struct flash_area *my_area;
int err = flash_area_open(FIXED_PARTITION_ID(slot0_partition), &my_area);

if (err != 0) {
    handle_the_error(err);
} else {
    flash_area_read(my_area, ...);
}

API Reference

group flash_area_api
    Abstraction over flash partitions/areas and their drivers.

Defines

SOC_FLASH_0_ID
    Provided for compatibility with MCUboot
SPI_FLASH_0_ID
    Provided for compatibility with MCUboot
FLASH_AREA_LABEL_EXISTS(label)
FLASH_AREA_LABEL_STR(lbl)
FLASH_AREA_ID(label)
FLASH_AREA_OFFSET(label)
FLASH_AREA_SIZE(label)
FIXED_PARTITION_EXISTS(label)
    Returns non-0 value if fixed-partition of given DTS node label exists.

Parameters
    • label – DTS node label

Returns
    non-0 if fixed-partition node exists and is enabled; 0 if node does not exist, is not enabled or is not fixed-partition.

FIXED_PARTITION_ID(label)
    Get flash area ID from fixed-partition DTS node label

Parameters
    • label – DTS node label of a partition

Returns
    flash area ID

FIXED_PARTITION_OFFSET(label)
    Get fixed-partition offset from DTS node label

Parameters
    • label – DTS node label of a partition
**Returns**

fixed-partition offset, as defined for the partition in DTS.

**FIXED_PARTITION_SIZE**<br>
Get fixed-partition size for DTS node label

**Parameters**

- label – DTS node label

**Returns**

fixed-partition offset, as defined for the partition in DTS.

**FLASH_AREA_DEVICE**<br>
Get device pointer for device the area/partition resides on

**Parameters**

- label – DTS node label of a partition

**Returns**

const struct device type pointer

**FIXED_PARTITION_DEVICE**<br>
Get device pointer for device the area/partition resides on

**Parameters**

- label – DTS node label of a partition

**Returns**

Pointer to a device.

**Typedefs**

typedef void (*flash_area_cb_t)(const struct flash_area *fa, void *user_data)<br>
Flash map iteration callback

**Param fa**
flash area

**Param user_data**
User supplied data

**Functions**

int flash_area_open(uint8_t id, const struct flash_area **fa)<br>
Retrieve partitions flash area from the flash_map.<br>
Function Retrieves flash_area from flash_map for given partition.

**Parameters**

- fa – [out] Pointer which has to reference flash_area. If ID is unknown, it will be NULL on output.

**Returns**

0 on success, -EACCES if the flash_map is not available, -ENOENT if ID is unknown, -ENODEV if there is no driver attached to the area.
void flash_area_close(const struct flash_area *fa)

Close flash_area.

Reserved for future usage and external projects compatibility reason. Currently is NOP.

Parameters

• fa – [in] Flash area to be closed.

int flash_area_read(const struct flash_area *fa, off_t off, void *dst, size_t len)

Read flash area data.

Read data from flash area. Area readout boundaries are asserted before read request. API has the same limitation regard read-block alignment and size as wrapped flash driver.

Parameters

• fa – [in] Flash area
• off – [in] Offset relative from beginning of flash area to read
• dst – [out] Buffer to store read data
• len – [in] Number of bytes to read

Returns

0 on success, negative errno code on fail.

int flash_area_write(const struct flash_area *fa, off_t off, const void *src, size_t len)

Write data to flash area.

Write data to flash area. Area write boundaries are asserted before write request. API has the same limitation regard write-block alignment and size as wrapped flash driver.

Parameters

• fa – [in] Flash area
• off – [in] Offset relative from beginning of flash area to read
• src – [out] Buffer with data to be written
• len – [in] Number of bytes to write

Returns

0 on success, negative errno code on fail.

int flash_area_erase(const struct flash_area *fa, off_t off, size_t len)

Erase flash area.

Erase given flash area range. Area boundaries are asserted before erase request. API has the same limitation regard erase-block alignment and size as wrapped flash driver.

Parameters

• fa – [in] Flash area
• off – [in] Offset relative from beginning of flash area.
• len – [in] Number of bytes to be erase

Returns

0 on success, negative errno code on fail.

uint32_t flash_area_align(const struct flash_area *fa)

Get write block size of the flash area.

Currently write block size might be treated as read block size, although most of drivers supports unaligned readout.

Parameters
• **fa** – [in] Flash area

**Returns**
Alignment restriction for flash writes in [B].

```c
int flash_area_get_sectors(int fa_id, uint32_t *count, struct flash_sector *sectors)
```

Retrieve info about sectors within the area.

**Parameters**
- **fa_id** – [in] Given flash area ID
- **sectors** – [out] buffer for sectors data
- **count** – [inout] On input Capacity of sectors, on output number of sectors Retrieved.

**Returns**
0 on success, negative errno code on fail. Especially returns -ENOMEM if There are too many flash pages on the flash_area to fit in the array.

```c
void flash_area_foreach(flash_area_cb_t user_cb, void *user_data)
```

Iterate over flash map

**Parameters**
- **user_cb** – User callback
- **user_data** – User supplied data

```c
int flash_area_has_driver(const struct flash_area *fa)
```

Check whether given flash area has supporting flash driver in the system.

**Parameters**
- **fa** – [in] Flash area.

**Returns**
1 On success. -ENODEV if no driver match.

```c
const struct device *flash_area_get_device(const struct flash_area *fa)
```

Get driver for given flash area.

**Parameters**
- **fa** – Flash area.

**Returns**
device driver.

```c
uint8_t flash_area_erased_val(const struct flash_area *fa)
```

Get the value expected to be read when accessing any erased flash byte. This API is compatible with the MCUBoot's porting layer.

**Parameters**
- **fa** – Flash area.

**Returns**
Byte value of erase memory.

```c
struct flash_area
```

*include <flash_map.h>* Flash partition.

This structure represents a fixed-size partition on a flash device. Each partition contains one or more flash sectors.
Public Members

uint8_t fa_id
    ID number

uint8_t fa_device_id
    Provided for compatibility with MCUboot

off_t fa_off
    Start offset from the beginning of the flash device

size_t fa_size
    Total size

const struct device *fa_dev
    Backing flash device

struct flash_sector
    #include <flash_map.h> Structure for transfer flash sector boundaries.
    This template is used for presentation of flash memory structure. It consumes much less RAM than flash_area

Public Members

off_t fs_off
    Sector offset from the beginning of the flash device

size_t fs_size
    Sector size in bytes

4.17.4 Flash Image

The flash image API as part of the Device Firmware Upgrade (DFU) subsystem provides an abstraction on top of Flash Stream to simplify writing firmware image chunks to flash.

API Reference

group flash_img_api
    Abstraction layer to write firmware images to flash.

Functions

int flash_img_init_id(struct flash_img_context *ctx, uint8_t area_id)
    Initialize context needed for writing the image to the flash.

Parameters
    • ctx – context to be initialized
• area_id – flash area id of partition where the image should be written

Returns
0 on success, negative errno code on fail

int flash_img_init(struct flash_img_context *ctx)
Initialize context needed for writing the image to the flash.

Parameters
• ctx – context to be initialized

Returns
0 on success, negative errno code on fail

size_t flash_img_bytes_written(struct flash_img_context *ctx)
Read number of bytes of the image written to the flash.

Parameters
• ctx – context

Returns
Number of bytes written to the image flash.

int flash_img_buffered_write(struct flash_img_context *ctx, const uint8_t *data, size_t len, bool flush)
Process input buffers to be written to the image slot 1. flash memory in single blocks. Will store remainder between calls.

A final call to this function with flush set to true will write out the remaining block buffer to flash. Since flash is written to in blocks, the contents of flash from the last byte written up to the next multiple of CONFIG_IMG_BLOCK_BUF_SIZE is padded with 0xff.

Parameters
• ctx – context
• data – data to write
• len – Number of bytes to write
• flush – when true this forces any buffered data to be written to flash

Returns
0 on success, negative errno code on fail

int flash_img_check(struct flash_img_context *ctx, const struct flash_img_check *fic, uint8_t area_id)
Verify flash memory length bytes integrity from a flash area. The start point is indicated by an offset value.

The function is enabled via CONFIG_IMG_ENABLE_IMAGE_CHECK Kconfig options.

Parameters
• ctx – [in] context.
• fic – [in] flash img check data.
• area_id – [in] flash area id of partition where the image should be verified.

Returns
0 on success, negative errno code on fail

#include <flash_img.h>
struct flash_img_check

#include <flash_img.h> Structure for verify flash region integrity.

Match vector length is fixed and depends on size from hash algorithm used to verify flash integrity. The current available algorithm is SHA-256.

Public Members

size_t clen

Match vector data

4.17.5 Flash Circular Buffer (FCB)

Flash circular buffer provides an abstraction through which you can treat flash like a FIFO. You append entries to the end, and read data from the beginning.

**Note:** As of Zephyr release 2.1 the NVS storage API is recommended over FCB for use as a back-end for the settings API.

Description

Entries in the flash contain the length of the entry, the data within the entry, and checksum over the entry contents.

Storage of entries in flash is done in a FIFO fashion. When you request space for the next entry, space is located at the end of the used area. When you start reading, the first entry served is the oldest entry in flash.

Entries can be appended to the end of the area until storage space is exhausted. You have control over what happens next; either erase oldest block of data, thereby freeing up some space, or stop writing new data until existing data has been collected. FCB treats underlying storage as an array of flash sectors; when it erases old data, it does this a sector at a time.

Entries in the flash are checksummed. That is how FCB detects whether writing entry to flash completed ok. It will skip over entries which don't have a valid checksum.

Usage

To add an entry to circular buffer:

- Call `fcb_append()` to get the location where data can be written. If this fails due to lack of space, you can call `fcb_rotate()` to erase the oldest sector which will make the space. And then call `fcb_append()` again.
- Use `flash_area_write()` to write entry contents.
- Call `fcb_append_finish()` when done. This completes the writing of the entry by calculating the checksum.

To read contents of the circular buffer:

- Call `fcb_walk()` with a pointer to your callback function.
- Within callback function copy in data from the entry using `flash_area_read()`. You can tell when all data from within a sector has been read by monitoring the returned entry’s area pointer. Then you can call `fcb_rotate()`, if you're done with that data.
Alternatively:

- Call `fcb_getnext()` with 0 in entry offset to get the pointer to the oldest entry.
- Use `flash_area_read()` to read entry contents.
- Call `fcb_getnext()` with pointer to current entry to get the next one. And so on.

**API Reference**

The FCB subsystem APIs are provided by `fcb.h`:

**Data structures**

`group fcb_data_structures`

**Defines**

- `FCB_MAX_LEN`  
  Max length of element

- `FCB_ENTRY_FA_DATA_OFF(entry)`  
  Helper macro for calculating the data offset related to the fcb `flash_area` start offset.

  **Parameters**

  - entry – fcb entry structure

- `struct fcb_entry`  
  
  #include `<fcb.h>` FCB entry info structure. This data structure describes the element location in the flash.

  You would use it to figure out what parameters to pass to `flash_area_read()` to read element contents. Or to `flash_area_write()` when adding a new element. Entry location is pointer to area (within fcb->`f_sectors`), and offset within that area.

- `struct flash_sector *fe_sector`  
  Pointer to info about sector where data are placed

- `uint32_t fe_elem_off`  
  Offset from the start of the sector to beginning of element.

- `uint32_t fe_data_off`  
  Offset from the start of the sector to the start of element.

- `uint16_t fe_data_len`  
  Size of data area in fcb entry

- `struct fcb_entry_ctx`  
  
  #include `<fcb.h>` Structure for transferring complete information about FCB entry location within flash memory.
Public Members

struct fcb_entry loc
   FCB entry info

const struct flash_area *fap
   Flash area where the entry is placed

struct fcb
   #include <fcb.h> FCB instance structure.
   The following data structure describes the FCB itself. First part should be filled in by the user before calling fcb_init. The second part is used by FCB for its internal bookkeeping.

Public Members

uint32_t f_magic
   Magic value, should not be 0xFFFFFFFF. It is xored with inversion of f_erase_value and placed in the beginning of FCB flash sector. FCB uses this when determining whether sector contains valid data or not. Giving it value of 0xFFFFFFFF means leaving bytes of the file in “erased” state.

uint8_t f_version
   Current version number of the data

uint8_t f_sector_cnt
   Number of elements in sector array

uint8_t f_scratch_cnt
   Number of sectors to keep empty. This can be used if you need to have scratch space for garbage collecting when FCB fills up.

struct flash_sector *f_sectors
   Array of sectors, must be contiguous

struct k_mutex f_mtx
   Locking for accessing the FCB data, internal state

struct flash_sector *f_oldest
   Pointer to flash sector containing the oldest data, internal state

struct fcb_entry f_active
   internal state

uint16_t f_active_id
   Flash location where the newest data is, internal state

uint8_t f_align
   writes to flash have to aligned to this, internal state
const struct flash_area *fap

Flash area used by the fcb instance, internal state. This can be transfer to FCB user

uint8_t f_erase_value

The value flash takes when it is erased. This is read from flash parameters and initialized upon call to fcb_init.

API functions

group fcb_api

Flash Circular Buffer APIs.

Typedefs

typedef int (*fcb_walk_cb)(struct fcb_entry_ctx *loc_ctx, void *arg)

FCB Walk callback function type.

Type of function which is expected to be called while walking over fcb entries thanks to a fcb_walk call.

Entry data can be read using flash_area_read(), using loc_ctx fields as arguments. If cb wants to stop the walk, it should return non-zero value.

Param loc_ctx [in]
entry location information (full context)

Param arg [inout] callback context, transferred from fcb_walk.

Return
0 continue walking, non-zero stop walking.

Functions

int fcb_init(int f_area_id, struct fcb *fcb)

Initialize FCB instance.

Parameters

• f_area_id – [in] ID of flash area where fcb storage resides.
• fcb – [inout] FCB instance structure.

Returns
0 on success, non-zero on failure.

int fcb_append(struct fcb *fcb, uint16_t len, struct fcb_entry *loc)

Appends an entry to circular buffer.

When writing the contents for the entry, use loc->fe_sector and loc->fe_data_off with flash_area_write() to fcb flash_area. When you're finished, call fcb_append_finish() with loc as argument.

Parameters

• fcb – [in] FCB instance structure.
• len – [in] Length of data which are expected to be written as the entry payload.
• loc – [out] entry location information
Returns
0 on success, non-zero on failure.

int fcb_append_finish(struct fcb *fcb, struct fcb_entry *append_loc)
Finishes entry append operation.

Parameters
• fcb – [in] FCB instance structure.
• append_loc – [in] entry location information

Returns
0 on success, non-zero on failure.

int fcb_walk(struct fcb *fcb, struct flash_sector *sector, fcb_walk_cb cb, void *cb_arg)
Walk over all entries in the FCB sector

Parameters
• sector – [in] fcb sector to be walked. If null, traverse entire storage.
• fcb – [in] FCB instance structure.
• cb – [in] pointer to the function which gets called for every entry. If cb wants to stop the walk, it should return non-zero value.
• cb_arg – [inout] callback context, transferred to the callback implementation.

Returns
0 on success, negative on failure (or transferred form callback return-value), positive transferred form callback return-value

int fcb_getnext(struct fcb *fcb, struct fcb_entry *loc)
Get next fcb entry location.

Function to obtain fcb entry location in relation to entry pointed by loc. If loc->fe_sector is set and loc->fe_elem_off is not 0 function fetches next fcb entry location. If loc->fe_sector is NULL function fetches the oldest entry location within FCB storage. loc->fe_sector is set and loc->fe_elem_off is 0 function fetches the first entry location in the fcb sector.

Parameters
• fcb – [in] FCB instance structure.
• loc – [inout] entry location information

Returns
0 on success, non-zero on failure.

int fcb_rotate(struct fcb *fcb)
Rotate fcb sectors

Function erases the data from oldest sector. Upon that the next sector becomes the oldest. Active sector is also switched if needed.

Parameters
• fcb – [in] FCB instance structure.

int fcb_append_to_scratch(struct fcb *fcb)
Start using the scratch block.

Take one of the scratch blocks into use. So a scratch sector becomes active sector to which entries can be appended.

Parameters
• `fcb` – [in] FCB instance structure.

Returns
0 on success, non-zero on failure.

```c
int fcb_free_sector_cnt(struct fcb *fcb)
```
Get free sector count.

Parameters
• `fcb` – [in] FCB instance structure.

Returns
Number of free sectors.

```c
int fcb_is_empty(struct fcb *fcb)
```
Check whether FCB has any data.

Parameters
• `fcb` – [in] FCB instance structure.

Returns
Positive value if fcb is empty, otherwise 0.

```c
int fcb_offset_last_n(struct fcb *fcb, uint8_t entries, struct fcb_entry *last_n_entry)
```
Finds the fcb entry that gives back up to n entries at the end.

Parameters
• `fcb` – [in] FCB instance structure.
• `entries` – [in] number of fcb entries the user wants to get
• `last_n_entry` – [out] last_n_entry the `fcb_entry` to be returned

Returns
0 on there are any fcbs available; -ENOENT otherwise

```c
int fcb_clear(struct fcb *fcb)
```
Clear fcb instance storage.

Parameters
• `fcb` – [in] FCB instance structure.

Returns
0 on success; non-zero on failure

4.17.6 Stream Flash

The Stream Flash module takes contiguous fragments of a stream of data (e.g. from radio packets), aggregates them into a user-provided buffer, then when the buffer fills (or stream ends) writes it to a raw flash partition. It supports providing the read-back buffer to the client to use in validating the persisted stream content.

One typical use of a stream write operation is when receiving a new firmware image to be used in a DFU operation.

There are several reasons why one might want to use buffered writes instead of writing the data directly as it is made available. Some devices have hardware limitations which does not allow flash writes to be performed in parallel with other operations, such as radio RX and TX. Also, fewer write operations result in faster response times seen from the application.
Persistent stream write progress

Some stream write operations, such as DFU operations, may run for a long time. When performing such long running operations it can be useful to be able to save the stream write progress to persistent storage so that the operation can resume at the same point after an unexpected interruption.

The Stream Flash module offers an API for loading, saving and clearing stream write progress to persistent storage using the Settings module. The API can be enabled using CONFIG_STREAM_FLASH_PROGRESS.

API Reference

**group stream_flash**

Abstraction over stream writes to flash.

**Typedefs**

typedef int (*stream_flash_callback_t)(uint8_t *buf, size_t len, size_t offset)

Signature for callback invoked after flash write completes.

Functions of this type are invoked with a buffer containing data read back from the flash after a flash write has completed. This enables verifying that the data has been correctly stored (for instance by using a SHA function). The write buffer ‘buf’ provided in stream_flash_init is used as a read buffer for this purpose.

**Param buf**

Pointer to the data read.

**Param len**

The length of the data read.

**Param offset**

The offset the data was read from.

**Functions**

```c
int stream_flash_init(struct stream_flash_ctx *ctx, const struct device *fdev, uint8_t *buf, size_t buf_len, size_t offset, size_t size, stream_flash_callback_t cb)
```

Initialize context needed for stream writes to flash.

**Parameters**

- **ctx** – context to be initialized
- **fdev** – Flash device to operate on
- **buf** – Write buffer
- **buf_len** – Length of write buffer. Can not be larger than the page size. Must be multiple of the flash device write-block-size.
- **offset** – Offset within flash device to start writing to
- **size** – Number of bytes available for performing buffered write. If this is ‘0’, the size will be set to the total size of the flash device minus the offset.
- **cb** – Callback to be invoked on completed flash write operations.

**Returns**

non-negative on success, negative errno code on fail
size_t stream_flash_bytes_written(struct stream_flash_ctx *ctx)
    Read number of bytes written to the flash.

Note: api-tags: pre-kernel-ok isr-ok

Parameters
• ctx – context

Returns
Number of payload bytes written to flash.

int stream_flash_buffered_write(struct stream_flash_ctx *ctx, const uint8_t *data, size_t len, bool flush)
    Process input buffers to be written to flash device in single blocks. Will store remainder
    between calls.
    A final call to this function with flush set to true will write out the remaining block buffer to
    flash.

Parameters
• ctx – context
• data – data to write
• len – Number of bytes to write
• flush – when true this forces any buffered data to be written to flash A flush
    write should be the last write operation in a sequence of write operations for
    given context (although this is not mandatory if the total data size is a multiple
    of the buffer size).

Returns
non-negative on success, negative errno code on fail

int stream_flash_erase_page(struct stream_flash_ctx *ctx, off_t off)
    Erase the flash page to which a given offset belongs.
    This function erases a flash page to which an offset belongs if this page is not the page previ-
    ously erased by the provided ctx (ctx->last_erased_page_start_offset).

Parameters
• ctx – context
• off – offset from the base address of the flash device

Returns
non-negative on success, negative errno code on fail

int stream_flash_progress_load(struct stream_flash_ctx *ctx, const char *settings_key)
    Load persistent stream write progress stored with key settings_key.
    This function should be called directly after stream_flash_init to load previous stream write
    progress before writing any data. If the loaded progress has fewer bytes written than ctx then
    it will be ignored.

Parameters
• ctx – context
• settings_key – key to use with the settings module for loading the stream
    write progress
Returns
non-negative on success, negative errno code on fail

int stream_flash_progress_save(struct stream_flash_ctx *ctx, const char *settings_key)
Save persistent stream write progress using key settings_key.

Parameters
- ctx – context
- settings_key – key to use with the settings module for storing the stream write progress

Returns
non-negative on success, negative errno code on fail

int stream_flash_progress_clear(struct stream_flash_ctx *ctx, const char *settings_key)
Clear persistent stream write progress stored with key settings_key.

Parameters
- ctx – context
- settings_key – key previously used for storing the stream write progress

Returns
non-negative on success, negative errno code on fail

struct stream_flash_ctx
#include <stream_flash.h> Structure for stream flash context.

Users should treat these structures as opaque values and only interact with them through the below API.

4.18 Task Watchdog

4.18.1 Overview

Many microcontrollers feature a hardware watchdog timer peripheral. Its purpose is to trigger an action (usually a system reset) in case of severe software malfunctions. Once initialized, the watchdog timer has to be restarted (“fed”) in regular intervals to prevent it from timing out. If the software got stuck and does not manage to feed the watchdog anymore, the corrective action is triggered to bring the system back to normal operation.

In real-time operating systems with multiple tasks running in parallel, a single watchdog instance may not be sufficient anymore, as it can be used for only one task. This software watchdog based on kernel timers provides a method to supervise multiple threads or tasks (called watchdog channels).

An existing hardware watchdog can be used as an optional fallback if the task watchdog itself or the scheduler has a malfunction.

The task watchdog uses a kernel timer as its backend. If configured properly, the timer ISR is never actually called during normal operation, as the timer is continuously updated in the feed calls.

It's currently not possible to have multiple instances of task watchdogs. Instead, the task watchdog API can be accessed globally to add or delete new channels without passing around a context or device pointer in the firmware.

The maximum number of channels is predefined via Kconfig and should be adjusted to match exactly the number of channels required by the application.
4.18.2 Configuration Options

Related configuration options can be found under `subsys/task_wdt/Kconfig`.

- `CONFIG_TASK_WDT`
- `CONFIG_TASK_WDT_CHANNELS`
- `CONFIG_TASK_WDT_HW_FALLBACK`
- `CONFIG_TASK_WDT_MIN_TIMEOUT`
- `CONFIG_TASK_WDT_HW_FALLBACK_DELAY`

4.18.3 API Reference

`group task_wdt_api`

Task Watchdog APIs.

**Typedefs**

typedef void (*task_wdt_callback_t)(int channel_id, void *user_data)

Task watchdog callback.

**Functions**

```c
int task_wdt_init(const struct device *hw_wdt)
```

Initialize task watchdog.

This function sets up necessary kernel timers and the hardware watchdog (if desired as fallback). It has to be called before `task_wdt_add()` and `task_wdt_feed()`.

**Parameters**

- `hw_wdt` – Pointer to the hardware watchdog device used as fallback. Pass NULL if no hardware watchdog fallback is desired.

**Return values**

- `0` – If successful.
- `-ENOTSUP` – If assigning a hardware watchdog is not supported.
- `-Errno` – Negative errno if the fallback hw_wdt is used and the install timeout API fails. See `wdt_install_timeout()` API for possible return values.

```c
int task_wdt_add(uint32_t reload_period, task_wdt_callback_t callback, void *user_data)
```

Install new timeout.

Adds a new timeout to the list of task watchdog channels.

**Parameters**

- `reload_period` – Period in milliseconds used to reset the timeout
- `callback` – Function to be called when watchdog timer expired. Pass NULL to use system reset handler.
- `user_data` – User data to associate with the watchdog channel.

**Return values**
• channel_id – If successful, a non-negative value indicating the index of the channel to which the timeout was assigned. This ID is supposed to be used as the parameter in calls to task_wdt_feed().

• -EINVAL – If the reload_period is invalid.

• -ENOMEM – If no more timeouts can be installed.

```c
int task_wdt_delete(int channel_id)
```
Delete task watchdog channel.

Deletes the specified channel from the list of task watchdog channels. The channel is now available again for other tasks via task_wdt_add() function.

**Parameters**

- channel_id – Index of the channel as returned by task_wdt_add().

**Return values**

- 0 – If successful.

- EINVAL – If there is no installed timeout for supplied channel.

```c
int task_wdt_feed(int channel_id)
```
Feed specified watchdog channel.

This function loops through all installed task watchdogs and updates the internal kernel timer used as for the software watchdog with the next due timeout.

**Parameters**

- channel_id – Index of the fed channel as returned by task_wdt_add().

**Return values**

- 0 – If successful.

- EINVAL – If there is no installed timeout for supplied channel.

### 4.19 Trusted Firmware-M

#### 4.19.1 Trusted Firmware-M Overview

**Trusted Firmware-M (TF-M)** is a reference implementation of the Platform Security Architecture (PSA) IoT Security Framework. It defines and implements an architecture and a set of software components that aim to address some of the main security concerns in IoT products.

Zephyr RTOS has been PSA Certified since Zephyr 2.0.0 with TF-M 1.0, and is currently integrated with TF-M 1.4.1.

**What Does TF-M Offer?**

Through a set of secure services and by design, TF-M provides:

- Isolation of secure and non-secure resources
- Embedded-appropriate crypto
- Management of device secrets (keys, etc.)
- Firmware verification (and encryption)
- Protected off-chip data storage and retrieval
- Proof of device identity (device attestation)
Audit logging

Build System Integration

When using TF-M with a supported platform, TF-M will be automatically built and link in the background as part of the standard Zephyr build process. This build process makes a number of assumptions about how TF-M is being used, and has certain implications about what the Zephyr application image can and cannot do:

- The secure processing environment (secure boot and TF-M) starts first
- Resource allocation for Zephyr relies on choices made in the secure image.

Architecture Overview

A TF-M application will, generally, have the following three parts, from most to least trusted, left-to-right, with code execution happening in the same order (secure boot > secure image > ns image).

While the secure bootloader is optional, it is enabled by default, and secure boot is an important part of providing a secure solution:

<table>
<thead>
<tr>
<th>Secure Processing Environment (SPE)</th>
<th>NSPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>bl2.bin</td>
<td>zephyr.bin</td>
</tr>
<tr>
<td>Secure Boot</td>
<td>Trusted Firmware-M APIs</td>
</tr>
<tr>
<td>(Secure Image)</td>
<td>Zephyr</td>
</tr>
<tr>
<td></td>
<td>(NS Image)</td>
</tr>
</tbody>
</table>

Communication between the (Zephyr) Non-Secure Processing Environment (NSPE) and the (TF-M) Secure Processing Environment image happens based on a set of PSA APIs, and normally makes use of an IPC mechanism that is included as part of the TF-M build, and implemented in Zephyr (see modules/trusted-firmware-m/interface).

Root of Trust (RoT) Architecture

TF-M is based upon a Root of Trust (RoT) architecture. This allows for hierarchies of trust from most, to less, to least trusted, providing a sound foundation upon which to build or access trusted services and resources.

The benefit of this approach is that less trusted components are prevented from accessing or compromising more critical parts of the system, and error conditions in less trusted environments won’t corrupt more trusted, isolated resources.

The following RoT hierarchy is defined for TF-M, from most to least trusted:

- PSA Root of Trust (PRoT), which consists of:
  - PSA Immutable Root of Trust: secure boot
  - PSA Updateable Root of Trust: most trusted secure services
- Application Root of Trust (ARoT): isolated secure services

The PSA Immutable Root of Trust is the most trusted piece of code in the system, to which subsequent Roots of Trust are anchored. In TF-M, this is the secure boot image, which verifies that the secure and non-secure images are valid, have not been tampered with, and come from a reliable source. The secure bootloader also verifies new images during the firmware update process, thanks to the public signing key(s) built into it. As the name implies, this image is immutable.
The **PSA Updateable Root of Trust** implements the most trusted secure services and components in TF-M, such as the Secure Partition Manager (SPM), and shared secure services like PSA Crypto, Internal Trusted Storage (ITS), etc. Services in the PSA Updateable Root of Trust have access to other resources in the same Root of Trust.

The **Application Root of Trust** is a reduced-privilege area in the secure processing environment which, depending on the isolation level chosen when building TF-M, has limited access to the PRoT, or even other ARoT services at the highest isolation levels. Some standard services exist in the ARoT, such as Protected Storage (PS), and generally custom secure services that you implement should be placed in the ARoT, unless a compelling reason is present to place them in the PRoT.

These divisions are distinct from the **untrusted code**, which runs in the non-secure environment, and has the least privilege in the system. This is the Zephyr application image in this case.

### Isolation Levels

At present, there are three distinct isolation levels defined in TF-M, with increasingly rigid boundaries between regions. The isolation level used will depend on your security requirements, and the system resources available to you.

- **Isolation Level 1** is the lowest isolation level, and the only major boundary is between the secure and non-secure processing environment, usually by means of Arm TrustZone on Armv8-M processors. There is no distinction here between the PSA Updateable Root of Trust (PRoT) and the Application Root of Trust (ARoT). They execute at the same privilege level. This isolation level will lead to the smallest combined application images.

- **Isolation Level 2** builds upon level one by introducing a distinction between the PSA Updateable Root of Trust and the Application Root of Trust, where ARoT services have limited access to PRoT services, and can only communicate with them through public APIs exposed by the PRoT services. ARoT services, however, are not strictly isolated from one another.

- **Isolation Level 3** is the highest isolation level, and builds upon level 2 by isolating ARoT services from each other, so that each ARoT is essentially silo’ed from other services. This provides the highest level of isolation, but also comes at the cost of additional overhead and code duplication between services.

The current isolation level can be checked via `CONFIG_TFM_ISOLATION_LEVEL`.

### Secure Boot

The default secure bootloader in TF-M is based on MCUBoot, and is referred to as BL2 in TF-M (for the second-stage bootloader, potentially after a HW-based bootloader on the secure MCU, etc.).

All images in TF-M are hashed and signed, with the hash and signature verified by MCUBoot during the firmware update process.

Some key features of MCUBoot as used in TF-M are:

- Public signing key(s) are baked into the bootloader
- S and NS images can be signed using different keys
- Firmware images can optionally be encrypted
- Client software is responsible for writing a new image to the secondary slot
- By default, uses static flash layout of two identically-sized memory regions
- Optional security counter for rollback protection

When dealing with (optionally) encrypted images:

- Only the payload is encrypted (header, TLVs are plain text)
- Hashing and signing are applied over the un-encrypted data
- Uses AES-CTR-128 or AES-CTR-256 for encryption
- Encryption key randomized every encryption cycle (via `imgtool`)
• The \texttt{AES-CTR} key is included in the image and can be encrypted using:
  
  – \texttt{RSA-OAEP}
  – \texttt{AES-KW} (128 or 256 bits depending on the \texttt{AES-CTR} key length)
  – \texttt{ECIES-P256}
  – \texttt{ECIES-X25519}

Key config properties to control secure boot in Zephyr are:

• \texttt{CONFIG_TFM_BL2} toggles the bootloader (default = \texttt{y}).
• \texttt{CONFIG_TFM_KEY_FILE_S} overrides the secure signing key.
• \texttt{CONFIG_TFM_KEY_FILE_NS} overrides the non-secure signing key.

\textbf{Secure Processing Environment}  Once the secure bootloader has finished executing, a TF-M based secure image will begin execution in the \textit{secure processing environment}. This is where our device will be initially configured, and any secure services will be initialised.

Note that the starting state of our device is controlled by the secure firmware, meaning that when the non-secure Zephyr application starts, peripherals may not be in the HW-default reset state. In case of doubts, be sure to consult the board support packages in TF-M, available in the \texttt{platform/ext/target/} folder of the TF-M module (which is in \texttt{modules/tee/tf-m/trusted-firmware-m/} within a default Zephyr west workspace.)

\textbf{Secure Services}  As of TF-M 1.4.1, the following secure services are generally available (although vendor support may vary):

• Audit Logging (Audit)
• Crypto (Crypto)
• Firmware Update (FWU)
• Initial Attestation (IAS)
• Platform (Platform)
• Secure Storage, which has two parts:
  – Internal Trusted Storage (ITS)
  – Protected Storage (PS)

A template also exists for creating your own custom services.

For full details on these services, and their exposed APIs, please consult the \texttt{TF-M Documentation}.

\textbf{Key Management and Derivation}  Key and secret management is a critical part of any secure device. You need to ensure that key material is available to regions that require it, but not to anything else, and that it is stored securely in a way that makes it difficult to tamper with or maliciously access.

The \texttt{Internal Trusted Storage} service in TF-M is used by the \texttt{PSA Crypto} service (which itself makes use of mbedtls) to store keys, and ensure that private keys are only ever accessible to the secure processing environment. Crypto operations that make use of key material, such as when signing payloads or when decrypting sensitive data, all take place via key handles. At no point should the key material ever be exposed to the NS environment.

One exception is that private keys can be provisioned into the secure processing environment as a one-way operation, such as during a factory provisioning process, but even this should be avoided where possible, and a request should be made to the SPE (via the PSA Crypto service) to generate a new private key itself, and the public key for that can be requested during provisioning and logged in the factory. This ensures the private key material is never exposed, or even known during the provisioning phase.
TF-M also makes extensive use of the **Hardware Unique Key (HUK)**, which every TF-M device must provide. This device-unique key is used by the **Protected Storage** service, for example, to encrypt information stored in external memory. For example, this ensures that the contents of flash memory can’t be decrypted if they are removed and placed on a new device, since each device has its own unique HUK used while encrypting the memory contents the first time.

HUKs provide an additional advantage for developers, in that they can be used to derive new keys, and the **derived keys** don’t need to be stored since they can be regenerated from the HUK at startup, using an additional salt/seed value (depending on the key derivation algorithm used). This removes the storage issue and a frequent attack vector. The HUK itself is usually highly protected in secure devices, and inaccessible directly by users.

**TFM_CRYPTO_ALG_HUK_DERIVATION** identifies the default key derivation algorithm used if a software implementation is used. The current default algorithm is **HKDF (RFC 5869)** with a SHA-256 hash. Other hardware implementations may be available on some platforms.

### Non-Secure Processing Environment

Zephyr is used for the NSPE, using a board that is supported by TF-M where the `CONFIG_BUILD_WITH_TFM` flag has been enabled.

Generally, you simply need to select the `*_ns` variant of a valid target (for example `mps2_an521_ns`), which will configure your Zephyr application to run in the NSPE, correctly build and link it with the TF-M secure images, sign the secure and non-secure images, and merge the three binaries into a single `tfm_merged.hex` file. The `west flash` command will flash `tfm_merged.hex` by default in this configuration.

At present, Zephyr can not be configured to be used as the secure processing environment.

### 4.19.2 TF-M Requirements

The following are some of the boards that can be used with TF-M:

<table>
<thead>
<tr>
<th>Board</th>
<th>NSPE board name</th>
</tr>
</thead>
<tbody>
<tr>
<td>mps2_an521_board</td>
<td>mps2_an521_ns (qemu supported)</td>
</tr>
<tr>
<td>mps3_an547_board</td>
<td>mps3_an547_ns (qemu supported)</td>
</tr>
<tr>
<td>bl5340_dvk</td>
<td>bl5340_dvk_cpuapp_ns</td>
</tr>
<tr>
<td>lpcxpresso55s69</td>
<td>lpcxpresso55s69_ns</td>
</tr>
<tr>
<td>nrf9160dk_nrf9160</td>
<td>nrf9160dk_nrf9160_ns</td>
</tr>
<tr>
<td>nrf5340dk_nrf5340</td>
<td>nrf5340dk_nrf5340_cpuapp_ns</td>
</tr>
<tr>
<td>b_u585i_iot02a_board</td>
<td>b_u585i_iot02a_ns</td>
</tr>
<tr>
<td>nucleo_l552ze_q_board</td>
<td>nucleo_l552ze_q_ns</td>
</tr>
<tr>
<td>stm32l562e_dk_board</td>
<td>stm32l562e_dk_ns</td>
</tr>
<tr>
<td>v2m_musca_b1_board</td>
<td>v2m_musca_b1_ns</td>
</tr>
<tr>
<td>v2m_musca_s1_board</td>
<td>v2m_musca_s1_ns</td>
</tr>
</tbody>
</table>

You can run `west boards -n _ns$` to search for non-secure variants of different board targets. To make sure TF-M is supported for a board in its output, check that `CONFIG_TRUSTED_EXECUTION_NONSECURE` is set to `y` in that board's default configuration.

### Software Requirements

The following Python modules are required when building TF-M binaries:

- cryptography
- pyasn1
- pyyaml
• cbor>=1.0.0
• imgtool>=1.9.0
• jinja2
• click

You can install them via:

```bash
$ pip3 install --user cryptography pyasn1 pycrypto cbor>=1.0.0 imgtool>=1.9.0
   jinja2 click
```

They are used by TF-M's signing utility to prepare firmware images for validation by the bootloader.

Part of the process of generating binaries for QEMU and merging signed secure and non-secure binaries on certain platforms also requires the use of the `srec_cat` utility.

This can be installed on Linux via:

```bash
$ sudo apt-get install srec
```

And on OS X via:

```bash
$ brew install srec
```

For Windows-based systems, please make sure you have a copy of the utility available on your system path. See, for example: SRecord for Windows

### 4.19.3 TF-M Build System

When building a valid `_ns` board target, TF-M will be built in the background, and linked with the Zephyr non-secure application. No knowledge of TF-M's build system is required in most cases, and the following will build a TF-M and Zephyr image pair, and run it in qemu with no additional steps required:

```bash
$ west build -p auto -t mps2_an521_ns samples/tfm_integration/psa_crypto/ -
   \t run
```

The outputs and certain key steps in this build process are described here, however, since you will need to understand and interact with the outputs, and deal with signing the secure and non-secure images before deploying them.

### Images Created by the TF-M Build

The TF-M build system creates the following executable files:

- `tfm_s` - TF-M secure firmware
- `tfm_ns` - TF-M non-secure app (only used by regression tests).
- `bl2` - TF-M MCUboot, if enabled

For each of these, it creates `.bin`, `.hex`, `.elf`, and `.axf` files.

The TF-M build system also creates signed variants of `tfm_s` and `tfm_ns`, and a file which combines them:

- `tfm_s_signed`
- `tfm_ns_signed`
- `tfm_s_ns_signed`
For each of these, only .bin files are created.

The TF-M non-secure app is discarded in favor of Zephyr non-secure app except when running the TF-M regression test suite.

The Zephyr build system usually signs both tfm_s and the Zephyr non-secure app itself. See below for details.

The 'tfm' target contains properties for all these paths. For example, the following will resolve to <path>/tfm_s.hex:

```
$<TARGET_PROPERTY:tfm,TFM_S_HEX_FILE>
```

See the top level CMakeLists.txt file in the tfm module for an overview of all the properties.

**Signing Images**

When CONFIG_TFM_BL2 is set to y, TF-M uses a secure bootloader (BL2) and firmware images must be signed with a private key. The firmware image is validated by the bootloader during updates using the corresponding public key, which is stored inside the secure bootloader firmware image.

By default, <tfm-dir>/b12/ext/mcuboot/root-rsa-3072.pem is used to sign secure images, and <tfm-dir>/b12/ext/mcuboot/root-rsa-3072_1.pem is used to sign non-secure images. These default .pem keys can (and should) be overridden using the CONFIG_TFM_KEY_FILE_S and CONFIG_TFM_KEY_FILE_NS config flags.

To satisfy PSA Certified Level 1 requirements, **You MUST replace the default .pem file with a new key pair!**

To generate a new public/private key pair, run the following commands:

```
$ imgtool keygen -k root-rsa-3072_s.pem -t rsa-3072
$ imgtool keygen -k root-rsa-3072_ns.pem -t rsa-3072
```

You can then place the new .pem files in an alternate location, such as your Zephyr application folder, and reference them in the prj.conf file via the CONFIG_TFM_KEY_FILE_S and CONFIG_TFM_KEY_FILE_NS config flags.

**Warning:** Be sure to keep your private key file in a safe, reliable location! If you lose this key file, you will be unable to sign any future firmware images, and it will no longer be possible to update your devices in the field!

After the built-in signing script has run, it creates a tfm_merged.hex file that contains all three binaries: bl2, tfm_s, and the zephyr app. This hex file can then be flashed to your development board or run in QEMU.

**Custom CMake arguments** When building a Zephyr application with TF-M it might be necessary to control the CMake arguments passed to the TF-M build.

Zephyr TF-M build offers several Kconfig options for controlling the build, but doesn't cover every CMake argument supported by the TF-M build system.

The TFM_CMAKE_OPTIONS property on the zephyr_property_target can be used to pass custom CMake arguments to the TF-M build system.

To pass the CMake argument -DFOO=bar to the TF-M build system, place the following CMake snippet in your CMakeLists.txt file.
```cpp
set_property(TARGET zephyr_property_target
    APPEND PROPERTY TFM_CMAKE_OPTIONS
    -DFOO=bar)
```

**Note:** The `TFM_CMAKE_OPTIONS` is a list so it is possible to append multiple options. Also CMake generator expressions are supported, such as `$<1:-DFOO=bar>`

---

**Footprint and Memory Usage**

The build system offers targets to view and analyse RAM and ROM usage in generated images. The tools run on the final images and give information about size of symbols and code being used in both RAM and ROM. For more information on these tools look here: Footprint and Memory Usage

Use the `tfm_ram_report` to get the RAM report for TF-M secure firmware (tfm_s).

**Using west:**

```
west build -b mps2_an521_ns samples/hello_world
west build -t tfm_ram_report
```

**Using CMake and ninja:**

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2_an521_ns samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild tfm_ram_report
```

Use the `tfm_rom_report` to get the ROM report for TF-M secure firmware (tfm_s).

**Using west:**

```
west build -b mps2_an521_ns samples/hello_world
west build -t tfm_rom_report
```

**Using CMake and ninja:**

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2_an521_ns samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild tfm_rom_report
```

Use the `bl2_ram_report` to get the RAM report for TF-M MCUboot, if enabled.

**Using west:**

```
west build -b mps2_an521_ns samples/hello_world
west build -t bl2_ram_report
```

**Using CMake and ninja:**

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2_an521_ns samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild bl2_ram_report
```
Use the `bl2_rom_report` to get the ROM report for TF-M MCUboot, if enabled.

Using west:

```bash
west build -b mps2_an521_ns samples/hello_world
west build -t bl2_rom_report
```

Using CMake and ninja:

```bash
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2_an521_ns samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild bl2_rom_report
```

### 4.19.4 Trusted Firmware-M Integration

The Trusted Firmware-M (TF-M) section contains information about the integration between TF-M and Zephyr RTOS. Use this information to help understand how to integrate TF-M with Zephyr for Cortex-M platforms and make use of its secure run-time services in Zephyr applications.

#### Board Definitions

TF-M will be built for the secure processing environment along with Zephyr if the `CONFIG_BUILD_WITH_TFM` flag is set to `y`.

Generally, this value should never be set at the application level, however, and all config flags required for TF-M should be set in a board variant with the `_ns` suffix.

This board variant must define an appropriate flash, SRAM and peripheral configuration that takes into account the initialisation process in the secure processing environment. `CONFIG_TFM_BOARD` must also be set via `modules/trusted-firmware-m/Kconfig.tfm` to the board name that TF-M expects for this target, so that it knows which target to build for the secure processing environment.

**Example**: `mps2_an521_ns` The `mps2_an521` target is a dual-core Arm Cortex-M33 evaluation board that, when using the default board variant, would generate a secure Zephyr binary.

The optional `mps2_an521_ns` target, however, sets these additional kconfig flags that indicate that Zephyr should be built as a non-secure image, linked with TF-M as an external project, and optionally the secure bootloader:

- `CONFIG_TRUSTED_EXECUTION_NONSECURE y`
- `CONFIG_ARM_TRUSTZONE_M y`

Comparing the `mps2_an521.dts` and `mps2_an521_ns.dts` files, we can see that the `_ns` version defines offsets in flash and SRAM memory, which leave the required space for TF-M and the secure bootloader:

```plaintext
reserved-memory {
    #address-cells = <1>;
    #size-cells = <1>;
    ranges;

    /* The memory regions defined below must match what the TF-M
    * project has defined for that board - a single image boot is
    * assumed. Please see the memory layout in:
    * https://git.trustedfirmware.org/TF-M/trusted-firmware-m.git/tree/
    * platform/ext/target/mps2/an521/partition/flash_layout.h
    */
}
```

(continues on next page)
This reserves 1 MB of code memory and 1 MB of RAM for secure boot and TF-M, such that our non-secure Zephyr application code will start at 0x10000, with RAM at 0x28100000. 512 KB code memory is available for the NS zephyr image, along with 1 MB of RAM. This matches the flash memory layout we see in flash_layout.h in TF-M:

- 0x0000_0000 BL2 – MCUBoot (0.5 MB)
- 0x0008_0000 Secure image primary slot (0.5 MB)
- 0x0010_0000 Non-secure image primary slot (0.5 MB)
- 0x0018_0000 Secure image secondary slot (0.5 MB)
- 0x0020_0000 Non-secure image secondary slot (0.5 MB)
- 0x0020_0000 Scratch area (0.5 MB)
- 0x0030_0000 Protected Storage Area (20 KB)
- 0x0030_5000 Internal Trusted Storage Area (16 KB)
- 0x0030_9000 NV counters area (4 KB)
- 0x0030_A000 Unused (984 KB)

mps2/an521 will be passed in to Tf-M as the board target, specified via CONFIG_TFM_BOARD.

### 4.19.5 Test Suites

TF-M includes two sets of test suites:

- tf-m-tests - Standard TF-M specific regression tests
- psa-arch-tests - Test suites for specific PSA APIs (secure storage, etc.)

These test suites can be run from Zephyr via an appropriate sample application in the samples/tfm_integration folder.

#### TF-M Regression Tests

The regression test suite can be run via the tfm_regression_test sample. This sample tests various services and communication mechanisms across the NS/S boundary via the PSA APIs. They provide a useful sanity check for proper integration between the NS RTOS (Zephyr in this case) and the secure application (TF-M).

#### PSA Arch Tests

The PSA Arch Test suite, available via tfm_psa_test, contains a number of test suites that can be used to validate that PSA API specifications are being followed by the secure application, TF-M being an implementation of the Platform Security Architecture (PSA).

Only one of these suites can be run at a time, with the available test suites described via CONFIG_TFM_PSA_TEST_* KConfig flags:
Purpose

The output of these test suites is required to obtain PSA Certification for your specific board, RTOS (Zephyr here), and PSA implementation (TF-M in this case).

They also provide a useful test case to validate any PRs that make meaningful changes to TF-M, such as enabling a new TF-M board target, or making changes to the core TF-M module(s). They should generally be run as a coherence check before publishing a new PR for new board support, etc.

4.20 USB device support

4.20.1 USB device controller driver

The USB Device Controller Driver Layer implements the low level control routines to deal directly with the hardware. All device controller drivers should implement the APIs described in include/zephyr/drivers/usb/usb_dc.h. This allows the integration of new USB device controllers to be done without changing the upper layers. With this API it is not possible to support more than one controller instance at runtime.

API reference

`group _usb_device_controller_api`

USB Device Controller API.

**Typedefs**

typedef void (*`usb_dc_ep_callback`)(uint8_t ep, enum `usb_dc_ep_cb_status_code` cb_status)

Callback function signature for the USB Endpoint status

typedef void (*`usb_dc_status_callback`)(enum `usb_dc_status_code` cb_status, const uint8_t *param)

Callback function signature for the device

**Enums**

enum `usb_dc_status_code`

USB Driver Status Codes.

Status codes reported by the registered device status callback.

*Values:*

- `USB_DC_ERROR` USB error reported by the controller
- `USB_DC_RESET` USB reset
enumerator USB_DC_CONNECTED
    USB connection established, hardware enumeration is completed

enumerator USB_DC_CONFIGURED
    USB configuration done

enumerator USB_DC_DISCONNECTED
    USB connection lost

enumerator USB_DC_SUSPEND
    USB connection suspended by the HOST

enumerator USB_DC_RESUME
    USB connection resumed by the HOST

enumerator USB_DC_INTERFACE
    USB interface selected

enumerator USB_DC_SET_HALT
    Set Feature ENDPOINT_HALT received

enumerator USB_DC_CLEAR_HALT
    Clear Feature ENDPOINT_HALT received

enumerator USB_DC_SOF
    Start of Frame received

enumerator USB_DC_UNKNOWN
    Initial USB connection status

enum usb_dc_ep_cb_status_code
    USB Endpoint Callback Status Codes.
    Status Codes reported by the registered endpoint callback.
    Values:

enumerator USB_DC_EP_SETUP
    SETUP received

enumerator USB_DC_EP_DATA_OUT
    Out transaction on this EP, data is available for read

enumerator USB_DC_EP_DATA_IN
    In transaction done on this EP

enum usb_dc_ep_transfer_type
    USB Endpoint Transfer Type.
    Values:
enumerator USB_DC_EP_CONTROL = 0
    Control type endpoint

eenumerator USB_DC_EP_ISOCHRONOUS
    Isochronous type endpoint

eenumerator USB_DC_EP_BULK
    Bulk type endpoint

eenumerator USB_DC_EP_INTERRUPT
    Interrupt type endpoint

enum usb_dc_ep_synchronization_type
    USB Endpoint Synchronization Type.

    Note: Valid only for Isochronous Endpoints

    Values:

eenumerator USB_DC_EP_NO_SYNCHRONIZATION = (0U << 2U)
    No Synchronization

eenumerator USB_DC_EPASYNCHRONOUS = (1U << 2U)
    Asynchronous

eenumerator USB_DC_EP_ADAPTIVE = (2U << 2U)
    Adaptive

eenumerator USB_DC_EP_SYNCHRONOUS = (3U << 2U)
    Synchronous

Functions

int usb_dc_attach(void)
    Attach USB for device connection.
    Function to attach USB for device connection. Upon success, the USB PLL is enabled, and the
    USB device is now capable of transmitting and receiving on the USB bus and of generating
    interrupts.

    Returns
    0 on success, negative errno code on fail.

int usb_dc_detach(void)
    Detach the USB device.
    Function to detach the USB device. Upon success, the USB hardware PLL is powered down
    and USB communication is disabled.

    Returns
    0 on success, negative errno code on fail.
int usb_dc_reset(void)
    Reset the USB device.

This function returns the USB device and firmware back to its initial state. N.B. the USB PLL
is handled by the usb_detach function

Returns
    0 on success, negative errno code on fail.

int usb_dc_set_address(const uint8_t addr)
    Set USB device address.

Parameters
    • addr – [in] Device address

Returns
    0 on success, negative errno code on fail.

void usb_dc_set_status_callback(const usb_dc_status_callback cb)
    Set USB device controller status callback.

Function to set USB device controller status callback. The registered callback is used to re-
port changes in the status of the device controller. The status code are described by the
usb_dc_status_code enumeration.

Parameters
    • cb – [in] Callback function

int usb_dc_ep_check_cap(const struct usb_dc_ep_cfg_data *const cfg)
    check endpoint capabilities

Function to check capabilities of an endpoint. usb_dc_ep_cfg_data structure provides the end-
point configuration parameters: endpoint address, endpoint maximum packet size and end-
point type. The driver should check endpoint capabilities and return 0 if the endpoint config-
uration is possible.

Parameters
    • cfg – [in] Endpoint config

Returns
    0 on success, negative errno code on fail.

int usb_dc_ep_configure(const struct usb_dc_ep_cfg_data *const cfg)
    Configure endpoint.

Function to configure an endpoint. usb_dc_ep_cfg_data structure provides the endpoint con-
figuration parameters: endpoint address, endpoint maximum packet size and endpoint type.

Parameters
    • cfg – [in] Endpoint config

Returns
    0 on success, negative errno code on fail.

int usb_dc_ep_set_stall(const uint8_t ep)
    Set stall condition for the selected endpoint.

Parameters
    • ep – [in] Endpoint address corresponding to the one listed in the device con-
figuration table

Returns
    0 on success, negative errno code on fail.
int usb_dc_ep_clear_stall(const uint8_t ep)
    Clear stall condition for the selected endpoint.

Parameters
    • ep – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
    0 on success, negative errno code on fail.

int usb_dc_ep_is_stalled(const uint8_t ep, uint8_t *const stalled)
    Check if the selected endpoint is stalled.

Parameters
    • ep – [in] Endpoint address corresponding to the one listed in the device configuration table
    • stalled – [out] Endpoint stall status

Returns
    0 on success, negative errno code on fail.

int usb_dc_ep_halt(const uint8_t ep)
    Halt the selected endpoint.

Parameters
    • ep – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
    0 on success, negative errno code on fail.

int usb_dc_ep_enable(const uint8_t ep)
    Enable the selected endpoint. Upon success interrupts are enabled for the corresponding endpoint and the endpoint is ready for transmitting/receiving data.

Parameters
    • ep – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
    0 on success, negative errno code on fail.

int usb_dc_ep_disable(const uint8_t ep)
    Disable the selected endpoint. Upon success interrupts are disabled for the corresponding endpoint and the endpoint is no longer able for transmitting/receiving data.

Parameters
    • ep – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
    0 on success, negative errno code on fail.

int usb_dc_ep_flush(const uint8_t ep)
    Flush the selected endpoint.

This function flushes the FIFOs for the selected endpoint.

Parameters
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
0 on success, negative errno code on fail.

int usb_dc_ep_write(const uint8_t *ep, const uint8_t *data, const uint32_t data_len, uint32_t *ret_bytes)

Write data to the specified endpoint.

This function is called to write data to the specified endpoint. The supplied usb_ep_callback function will be called when data is transmitted out.

Parameters
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table
• data – [in] Pointer to data to write
• data_len – [in] Length of the data requested to write. This may be zero for a zero length status packet.
• ret_bytes – [out] Bytes scheduled for transmission. This value may be NULL if the application expects all bytes to be written

Returns
0 on success, negative errno code on fail.

int usb_dc_ep_read(const uint8_t *ep, uint8_t *data, const uint32_t max_data_len, uint32_t *read_bytes)

Read data from the specified endpoint.

This function is called by the endpoint handler function, after an OUT interrupt has been received for that EP. The application must only call this function through the supplied usb_ep_callback function. This function clears the ENDPOINT NAK, if all data in the endpoint FIFO has been read, so as to accept more data from host.

Parameters
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table
• data – [in] Pointer to data buffer to write to
• max_data_len – [in] Max length of data to read
• read_bytes – [out] Number of bytes read. If data is NULL and max_data_len is 0 the number of bytes available for read should be returned.

Returns
0 on success, negative errno code on fail.

int usb_dc_ep_set_callback(const uint8_t *ep, const usb_dc_ep_callback cb)

Set callback function for the specified endpoint.

Function to set callback function for notification of data received and available to application or transmit done on the selected endpoint, NULL if callback not required by application code. The callback status code is described by usb_dc_ep_cb_status_code.

Parameters
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table
• cb – [in] Callback function

Returns
0 on success, negative errno code on fail.
int usb_dc_ep_read_wait(uint8_t ep, uint8_t *data, uint32_t max_data_len, uint32_t *read_bytes)
Read data from the specified endpoint.
This is similar to usb_dc_ep_read, the difference being that, it doesn't clear the endpoint NAKs so that the consumer is not bogged down by further upcalls till he is done with the processing of the data. The caller should reactivate ep by invoking usb_dc_ep_read_continue() do so.

Parameters
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table
• data – [in] Pointer to data buffer to write to
• max_data_len – [in] Max length of data to read
• read_bytes – [out] Number of bytes read. If data is NULL and max_data_len is 0 the number of bytes available for read should be returned.

Returns
0 on success, negative errno code on fail.

int usb_dc_ep_read_continue(uint8_t ep)
Continue reading data from the endpoint.
Clear the endpoint NAK and enable the endpoint to accept more data from the host. Usually called after usb_dc_ep_read_wait() when the consumer is fine to accept more data. Thus these calls together act as a flow control mechanism.

Parameters
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
0 on success, negative errno code on fail.

int usb_dc_ep_mps(uint8_t ep)
Get endpoint max packet size.

Parameters
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
Endpoint max packet size (mps)

int usb_dc_wakeup_request(void)
Start the host wake up procedure.
Function to wake up the host if it’s currently in sleep mode.

Returns
0 on success, negative errno code on fail.

struct usb_dc_ep_cfg_data
#include <usb_dc.h> USB Endpoint Configuration.
Structure containing the USB endpoint configuration.

Public Members
4.20.2 USB device stack

The USB device stack is a hardware independent interface between USB device controller driver and USB device class drivers or customer applications. It is a port of the LPCUSB device stack and has been modified and expanded over time. It provides the following functionalities:

- Uses the APIs provided by the device controller drivers to interact with the USB device controller.
- Responds to standard device requests and returns standard descriptors, essentially handling 'Chapter 9' processing, specifically the standard device requests in table 9-3 from the universal serial bus specification revision 2.0.
- Provides a programming interface to be used by USB device classes or customer applications. The APIs is described in include/zephyr/usb/usb_device.h

The device stack has few limitations with which it is not possible to support more than one controller instance at runtime, and only one USB device configuration is supported.

Supported USB classes:

- USB Audio (experimental)
- USB CDC ACM
- USB CDC ECM
- USB CDC EEM
- RNDIS
- USB MSC
- USB DFU
- Bluetooth HCI over USB
- USB HID class

List of samples for different purposes. CDC ACM and HID samples have configuration overlays for composite configuration.

Implementing a non-standard USB class

The configuration of USB Device is done in the stack layer.

The following structures and callbacks need to be defined:

- Part of USB Descriptor table
- USB Endpoint configuration table
- USB Device configuration structure
- Endpoint callbacks
* Optionally class, vendor and custom handlers

For example, for the USB loopback application:

```c
struct usb_loopback_config {
    struct usb_if_descriptor if0;
    struct usb_ep_descriptor if0_out_ep;
    struct usb_ep_descriptor if0_in_ep;
} __packed;

USBD_CLASS_DESCR_DEFINE(primary, 0) struct usb_loopback_config loopback_cfg = {
    /* Interface descriptor 0 */
    .if0 = {
        .bLength = sizeof(struct usb_if_descriptor),
        .bDescriptorType = USB_DESC_INTERFACE,
        .bInterfaceNumber = 0,
        .bAlternateSetting = 0,
        .bNumEndpoints = 2,
        .bInterfaceClass = USB_BCC_VENDOR,
        .bInterfaceSubClass = 0,
        .bInterfaceProtocol = 0,
        .iInterface = 0,
    },

    /* Data Endpoint OUT */
    .if0_out_ep = {
        .bLength = sizeof(struct usb_ep_descriptor),
        .bDescriptorType = USB_DESC_ENDPOINT,
        .bEndpointAddress = LOOPBACK_OUT_EP_ADDR,
        .bmAttributes = USB_DC_EP_BULK,
        .wMaxPacketSize = sys_cpu_to_le16(CONFIG_LOOPBACK_BULK_EP_MPS),
        .bInterval = 0x00,
    },

    /* Data Endpoint IN */
    .if0_in_ep = {
        .bLength = sizeof(struct usb_ep_descriptor),
        .bDescriptorType = USB_DESC_ENDPOINT,
        .bEndpointAddress = LOOPBACK_IN_EP_ADDR,
        .bmAttributes = USB_DC_EP_BULK,
        .wMaxPacketSize = sys_cpu_to_le16(CONFIG_LOOPBACK_BULK_EP_MPS),
        .bInterval = 0x00,
    },
};
```

Endpoint configuration:

```c
static struct usb_ep_cfg_data ep_cfg[] = {
    { .ep_cb = loopback_out_cb, .ep_addr = LOOPBACK_OUT_EP_ADDR, },
    { .ep_cb = loopback_in_cb, .ep_addr = LOOPBACK_IN_EP_ADDR, }
};
```

USB Device configuration structure:
USBD_DEFINE_CFG_DATA(loopback_config) = {
    .usb_device_description = NULL,
    .interface_config = loopback_interface_config,
    .interface_descriptor = &loopback_cfg.if0,
    .cb_usb_status = loopback_status_cb,
    .interface = {
        .class_handler = NULL,
        .custom_handler = NULL,
        .vendor_handler = loopback_vendor_handler,
    },
    .num_endpoints = ARRAY_SIZE(ep_cfg),
    .endpoint = ep_cfg,
};

The vendor device requests are forwarded by the USB stack core driver to the class driver through the registered vendor handler.

For the loopback class driver, loopback_vendor_handler() processes the vendor requests:

```c
static int loopback_vendor_handler(struct usb_setup_packet *setup,
    int32_t *len, uint8_t **data)
{
    LOG_DBG("Class request: bRequest 0x%x bmRequestType 0x%x len %d",
        setup->bRequest, setup->bmRequestType, *len);

    if (setup->RequestType.recipient != USB_REQTYPE_RECIPIENT_DEVICE) {
        return -ENOTSUP;
    }

    if (usb_reqtype_is_to_device(setup) &&
        setup->bRequest == 0x5b) {
        LOG_DBG("Host-to-Device, data %p", *data);
        /*
         * Copy request data in loopback_buf buffer and reuse it later in control device-to-host transfer.
         * /
         * memcpy(loopback_buf, *data,
         * MIN(sizeof(loopback_buf), setup->wLength));
         * return 0;
     }

    if ((usb_reqtype_is_to_host(setup)) &&
        (setup->bRequest == 0x5c)) {
        LOG_DBG("Device-to-Host, wLength %d, data %p",
            setup->wLength, *data);
        *data = loopback_buf;
        *len = MIN(sizeof(loopback_buf), setup->wLength);
        return 0;
    }

    return -ENOTSUP;
}
```

The class driver waits for the USB_DC_CONFIGURED device status code before transmitting any data.
USB Vendor and Product identifiers

The USB Vendor ID for the Zephyr project is 0x2FE3. This USB Vendor ID must not be used when a vendor integrates Zephyr USB device support into its own product.

Each USB sample has its own unique Product ID. The USB maintainer, if one is assigned, or otherwise the Zephyr Technical Steering Committee, may allocate other USB Product IDs based on well-motivated and documented requests.

The following Product IDs are currently used:

<table>
<thead>
<tr>
<th>Sample</th>
<th>PID</th>
</tr>
</thead>
<tbody>
<tr>
<td>usb_cdc-acm</td>
<td>0x0001</td>
</tr>
<tr>
<td>usb_cdc-acm_composite</td>
<td>0x0002</td>
</tr>
<tr>
<td>usb_hid-cdc</td>
<td>0x0003</td>
</tr>
<tr>
<td>cdc-acm-console</td>
<td>0x0004</td>
</tr>
<tr>
<td>usb_dfu</td>
<td>0x0005</td>
</tr>
<tr>
<td>usb_hid</td>
<td>0x0006</td>

</tbody>
</table>

The USB device descriptor field bcdDevice (Device Release Number) represents the Zephyr kernel major and minor versions as a binary coded decimal value.

API reference

There are two ways to transmit data, using the ‘low’ level read/write API or the ‘high’ level transfer API.

Low level API

To transmit data to the host, the class driver should call usb_write(). Upon completion the registered endpoint callback will be called. Before sending another packet the class driver should wait for the completion of the previous write. When data is received, the registered endpoint callback is called. usb_read() should be used for retrieving the received data. For CDC ACM sample driver this happens via the OUT bulk endpoint handler (cdc_acm_bulk_out) mentioned in the endpoint array (cdc_acm_ep_data).

High level API

The usb_transfer method can be used to transfer data to/from the host. The transfer API will automatically split the data transmission into one or more USB transaction(s), depending endpoint max packet size. The class driver does not have to implement endpoint callback and should set this callback to the generic usb_transfer_ep_callback.

group _usb_device_core_api

USB Device Core Layer API.

Defines

USB_TRANS_READ

USB_TRANS_WRITE
typedef void (*usb_ep_callback)(uint8_t ep, enum usb_dc_ep_cb_status_code cb_status)
    Callback function signature for the USB Endpoint status.

typedef int (*usb_request_handler)(struct usb_setup_packet *setup, int32_t *transfer_len, uint8_t **payload_data)
    Callback function signature for class specific requests.

    Function which handles Class specific requests corresponding to an interface number specified in the device descriptor table. For host to device direction the 'len' and 'payload_data' contain the length of the received data and the pointer to the received data respectively. For device to host class requests, 'len' and 'payload_data' should be set by the callback function with the length and the address of the data to be transmitted buffer respectively.

typedef void (*usb_interface_config)(struct usb_desc_header *head, uint8_t bInterfaceNumber)
    Function for interface runtime configuration.

typedef void (*usb_transfer_callback)(uint8_t ep, int tsize, void *priv)
    Callback function signature for transfer completion.

Functions

int usb_set_config(const uint8_t *usb_descriptor)
Configure USB controller.

    Function to configure USB controller. Configuration parameters must be valid or an error is returned

    Parameters
    • usb_descriptor – [in] USB descriptor table

    Returns
    0 on success, negative errno code on fail

int usb_deconfig(void)
Deconfigure USB controller.

    This function returns the USB device to it's initial state

    Returns
    0 on success, negative errno code on fail

int usb_enable(usb_dc_status_callback status_cb)
Enable the USB subsystem and associated hardware.

    This function initializes the USB core subsystem and enables the corresponding hardware so that it can begin transmitting and receiving on the USB bus, as well as generating interrupts. Class-specific initialization and registration must be performed by the user before invoking this, so that any data or events on the bus are processed correctly by the associated class handling code.

    Parameters
• status_cb – [in] Callback registered by user to notify about USB device controller state.

**Returns**
0 on success, negative errno code on fail.

```c
int usb_disable(void)
```

Disable the USB device.

Function to disable the USB device. Upon success, the specified USB interface is clock gated in hardware, it is no longer capable of generating interrupts.

**Returns**
0 on success, negative errno code on fail

```c
int usb_write(uint8_t ep, const uint8_t *data, uint32_t data_len, uint32_t *bytes_ret)
```

Write data to the specified endpoint.

Function to write data to the specified endpoint. The supplied usb_ep_callback will be called when transmission is done.

**Parameters**
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table
• data – [in] Pointer to data to write
• data_len – [in] Length of data requested to write. This may be zero for a zero length status packet.
• bytes_ret – [out] Bytes written to the EP FIFO. This value may be NULL if the application expects all bytes to be written

**Returns**
0 on success, negative errno code on fail

```c
int usb_read(uint8_t ep, uint8_t *data, uint32_t max_data_len, uint32_t *ret_bytes)
```

Read data from the specified endpoint.

This function is called by the Endpoint handler function, after an OUT interrupt has been received for that EP. The application must only call this function through the supplied usb_ep_callback function.

**Parameters**
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table
• data – [in] Pointer to data buffer to write to
• max_data_len – [in] Max length of data to read
• ret_bytes – [out] Number of bytes read. If data is NULL and max_data_len is 0 the number of bytes available for read is returned.

**Returns**
0 on success, negative errno code on fail

```c
int usb_ep_set_stall(uint8_t ep)
```

Set STALL condition on the specified endpoint.

This function is called by USB device class handler code to set stall condition on endpoint.

**Parameters**
• ep – [in] Endpoint address corresponding to the one listed in the device configuration table
Returns
0 on success, negative errno code on fail

int usb_ep_clear_stall(uint8_t ep)
Clears STALL condition on the specified endpoint.
This function is called by USB device class handler code to clear stall condition on endpoint.

Parameters
* ep – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
0 on success, negative errno code on fail

int usb_ep_read_wait(uint8_t ep, uint8_t *data, uint32_t max_data_len, uint32_t *read_bytes)
Read data from the specified endpoint.
This is similar to usb_ep_read, the difference being that, it doesn’t clear the endpoint NAKs so that the consumer is not bogged down by further upcalls till he is done with the processing of the data. The caller should reactivate ep by invoking usb_ep_read_continue() do so.

Parameters
* ep – [in] Endpoint address corresponding to the one listed in the device configuration table
* data – [in] pointer to data buffer to write to
* max_data_len – [in] max length of data to read
* read_bytes – [out] Number of bytes read. If data is NULL and max_data_len is 0 the number of bytes available for read should be returned.

Returns
0 on success, negative errno code on fail.

int usb_ep_read_continue(uint8_t ep)
Continue reading data from the endpoint.
Clear the endpoint NAK and enable the endpoint to accept more data from the host. Usually called after usb_ep_read_wait() when the consumer is fine to accept more data. Thus these calls together acts as flow control mechanism.

Parameters
* ep – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
0 on success, negative errno code on fail.

void usb_transfer_ep_callback(uint8_t ep, enum usb_dc_ep_cb_status_code)
Transfer management endpoint callback.
If a USB class driver wants to use high-level transfer functions, driver needs to register this callback as usb endpoint callback.

int usb_transfer(uint8_t ep, uint8_t *data, size_t dlen, unsigned int flags, usb_transfer_callback cb, void *priv)
Start a transfer.
Start a usb transfer to/from the data buffer. This function is asynchronous and can be executed in IRQ context. The provided callback will be called on transfer completion (or error) in thread context.

Parameters
• **ep** – [in] Endpoint address corresponding to the one listed in the device configuration table
• **data** – [in] Pointer to data buffer to write-to/read-from
• **dlen** – [in] Size of data buffer
• **flags** – [in] Transfer flags (USB_TRANS_READ, USB_TRANS_WRITE…)
• **cb** – [in] Function called on transfer completion/failure
• **priv** – [in] Data passed back to the transfer completion callback

Returns
0 on success, negative errno code on fail.

```c
int usb_transfer_sync(uint8_t ep, uint8_t *data, size_t dlen, unsigned int flags)
```

Start a transfer and block-wait for completion.

Synchronous version of `usb_transfer`, wait for transfer completion before returning.

Parameters
• **ep** – [in] Endpoint address corresponding to the one listed in the device configuration table
• **data** – [in] Pointer to data buffer to write-to/read-from
• **dlen** – [in] Size of data buffer
• **flags** – [in] Transfer flags

Returns
number of bytes transferred on success, negative errno code on fail.

```c
void usb_cancel_transfer(uint8_t ep)
```

Cancel any ongoing transfer on the specified endpoint.

Parameters
• **ep** – [in] Endpoint address corresponding to the one listed in the device configuration table

```c
void usb_cancel_transfers(void)
```

Cancel all ongoing transfers.

```c
bool usb_transfer_is_busy(uint8_t ep)
```

Check that transfer is ongoing for the endpoint.

Parameters
• **ep** – [in] Endpoint address corresponding to the one listed in the device configuration table

Returns
ture if transfer is ongoing, false otherwise.

```c
int usb_wakeup_request(void)
```

Start the USB remote wakeup procedure.

Function to request a remote wakeup. This feature must be enabled in configuration, otherwise it will always return -ENOTSUP error.

Returns
0 on success, negative errno code on fail, i.e. when the bus is already active.

```c
bool usb_get_remote_wakeup_status(void)
```

Get status of the USB remote wakeup feature.
Returns
true if remote wakeup has been enabled by the host, false otherwise.

struct usb_ep_cfg_data
#include <usb_device.h> USB Endpoint Configuration.
This structure contains configuration for the endpoint.

Public Members

*usb_ep_callback ep_cb
Callback function for notification of data received and available to application or transmit done, NULL if callback not required by application code

uint8_t ep_addr
The number associated with the EP in the device configuration structure
IN EP = 0x80 | <endpoint number>
OUT EP = 0x00 | <endpoint number>

struct usb_interface_cfg_data
#include <usb_device.h> USB Interface Configuration.
This structure contains USB interface configuration.

Public Members

*usb_request_handler class_handler
Handler for USB Class specific Control (EP 0) communications

*usb_request_handler vendor_handler
Handler for USB Vendor specific commands

*usb_request_handler custom_handler
The custom request handler gets a first chance at handling the request before it is handed over to the 'chapter 9' request handler. return 0 on success, -EINVAL if the request has not been handled by the custom handler and instead needs to be handled by the core USB stack. Any other error code to denote failure within the custom handler.

struct usb_cfg_data
#include <usb_device.h> USB device configuration.
The Application instantiates this with given parameters added using the “usb_set_config” function. Once this function is called changes to this structure will result in undefined behavior. This structure may only be updated after calls to usb_deconfig.

Public Members

const uint8_t *usb_device_description
USB device description, see http://www.beyondlogic.org/usbnutshell/usb5.shtml#DeviceDescriptors
void *interface_descriptor

  Pointer to interface descriptor

usb_interface_config interface_config

  Function for interface runtime configuration

void (*cb_usb_status)(struct usb_cfg_data *cfg, enum usb_dc_status_code cb_status, const uint8_t *param)

  Callback to be notified on USB connection status change

struct usb_interface_cfg_data interface

  USB interface (Class) handler and storage space

uint8_t num_endpoints

  Number of individual endpoints in the device configuration

struct usb_ep_cfg_data *endpoint

  Pointer to an array of endpoint structs of length equal to the number of EP associated with the device description, not including control endpoints

### 4.20.3 Testing USB device support

**Testing over USPIP in native_posix**

A virtual USB controller implemented through USBIP might be used to test the USB Device stack. Follow the general build procedure to build the USB sample for the native_posix configuration.

Run built sample with:

```bash
west build -t run
```

In a terminal window, run the following command to list USB devices:

```bash
$ usbip list -r localhost
Exportable USB devices
========================
- 127.0.0.1
  1-1: unknown vendor : unknown product (2fe3:0100)
    : /sys/devices/pci0000:00/0000:00:01.2/usb1/1-1
    : (Defined at Interface level) (00/00/00)
    : 0 - Vendor Specific Class / unknown subclass / unknown protocol (ff/00/
-00)
```

In a terminal window, run the following command to attach the USB device:

```bash
$ sudo usbip attach -r localhost -b 1-1
```

The USB device should be connected to your Linux host, and verified with the following commands:

```bash
$ sudo usbip port
Imported USB devices
=====================
Port 00: <Port in Use> at Full Speed(12Mbps)
  unknown vendor : unknown product (2fe3:0100)
```

(continues on next page)
4.20.4 USB Human Interface Devices (HID) support

Since the USB HID specification is not only used by the USB subsystem, the USB HID API is split into two header files include/zephyr/usb/class/hid.h and include/zephyr/usb/class/usb_hid.h. The second includes a specific part for HID support in the USB device stack.

HID Item helpers

HID item helper macros can be used to compose a HID Report Descriptor. The names correspond to those used in the USB HID Specification.

Example of a HID Report Descriptor:

```c
static const uint8_t hid_report_desc[] = {
    HID_USAGE_PAGE(HID_USAGE_GEN_DESKTOP),
    HID_USAGE(HID_USAGE_GEN_DESKTOP_UNDEFINED),
    HID_COLLECTION(HID_COLLECTION_APPLICATION),
    HID_LOGICAL_MIN8(0),
    /* logical maximum 255 */
    HID_LOGICAL_MAX16(0xFF, 0x00),
    HID_REPORT_ID(1),
    HID_REPORT_SIZE(8),
    HID_REPORT_COUNT(1),
    HID_USAGE(HID_USAGE_GEN_DESKTOP_UNDEFINED),
    /* HID_INPUT (Data, Variable, Absolute) */
    HID_INPUT(0x02),
    HID_END_COLLECTION,
};
```

HID items reference

```c
group usb_hid_items

Defines

HID_ITEM(bTag, bType, bSize)
Define HID short item.

Parameters

- bTag – Item tag
- bType – Item type
- bSize – Item data size

Returns

HID Input item
```
HID_INPUT(a)
Define HID Input item with the data length of one byte.
For usage examples, see \texttt{HID\_MOUSE\_REPORT\_DESC()}, \texttt{HID\_KEYBOARD\_REPORT\_DESC()}

\textbf{Parameters}
- \texttt{a} – Input item data

\textbf{Returns}
- HID Input item

HID_OUTPUT(a)
Define HID Output item with the data length of one byte.
For usage examples, see \texttt{HID\_KEYBOARD\_REPORT\_DESC()}

\textbf{Parameters}
- \texttt{a} – Output item data

\textbf{Returns}
- HID Output item

HID_FEATURE(a)
Define HID Feature item with the data length of one byte.

\textbf{Parameters}
- \texttt{a} – Feature item data

\textbf{Returns}
- HID Feature item

HID_COLLECTION(a)
Define HID Collection item with the data length of one byte.
For usage examples, see \texttt{HID\_MOUSE\_REPORT\_DESC()}, \texttt{HID\_KEYBOARD\_REPORT\_DESC()}

\textbf{Parameters}
- \texttt{a} – Collection item data

\textbf{Returns}
- HID Collection item

HID\_END\_COLLECTION
Define HID End Collection (non-data) item.
For usage examples, see \texttt{HID\_MOUSE\_REPORT\_DESC()}, \texttt{HID\_KEYBOARD\_REPORT\_DESC()}

\textbf{Returns}
- HID End Collection item

HID\_USAGE\_PAGE(page)
Define HID Usage Page item.
For usage examples, see \texttt{HID\_MOUSE\_REPORT\_DESC()}, \texttt{HID\_KEYBOARD\_REPORT\_DESC()}

\textbf{Parameters}
- \texttt{page} – Usage Page

\textbf{Returns}
- HID Usage Page item
HID_LOGICAL_MIN8(a)
Define HID Logical Minimum item with the data length of one byte.
For usage examples, see HID_MOUSE_REPORT_DESC(), HID_KEYBOARD_REPORT_DESC()

Parameters
• a – Minimum value in logical units

Returns
HID Logical Minimum item

HID_LOGICAL_MAX8(a)
Define HID Logical Maximum item with the data length of one byte.
For usage examples, see HID_MOUSE_REPORT_DESC(), HID_KEYBOARD_REPORT_DESC()

Parameters
• a – Maximum value in logical units

Returns
HID Logical Maximum item

HID_LOGICAL_MIN16(a, b)
Define HID Logical Minimum item with the data length of two bytes.

Parameters
• a – Minimum value lower byte
• b – Minimum value higher byte

Returns
HID Logical Minimum item

HID_LOGICAL_MAX16(a, b)
Define HID Logical Maximum item with the data length of two bytes.

Parameters
• a – Minimum value lower byte
• b – Minimum value higher byte

Returns
HID Logical Maximum item

HID_LOGICAL_MIN32(a, b, c, d)
Define HID Logical Minimum item with the data length of four bytes.

Parameters
• a – Minimum value lower byte
• b – Minimum value low middle byte
• c – Minimum value high middle byte
• d – Minimum value higher byte

Returns
HID Logical Minimum item

HID_LOGICAL_MAX32(a, b, c, d)
Define HID Logical Maximum item with the data length of four bytes.

Parameters
• a – Minimum value lower byte
• b – Minimum value low middle byte
• c – Minimum value high middle byte
• d – Minimum value higher byte

**Returns**
HID Logical Maximum item

**HID_REPORT_SIZE(size)**
Define HID Report Size item with the data length of one byte.
For usage examples, see `HID_MOUSE_REPORT_DESC()`, `HID_KEYBOARD_REPORT_DESC()`

**Parameters**
• size – Report field size in bits

**Returns**
HID Report Size item

**HID_REPORT_ID(id)**
Define HID Report ID item with the data length of one byte.

**Parameters**
• id – Report ID

**Returns**
HID Report ID item

**HID_REPORT_COUNT(count)**
Define HID Report Count item with the data length of one byte.
For usage examples, see `HID_MOUSE_REPORT_DESC()`, `HID_KEYBOARD_REPORT_DESC()`

**Parameters**
• count – Number of data fields included in the report

**Returns**
HID Report Count item

**HID_USAGE(idx)**
Define HID Usage Index item with the data length of one byte.
For usage examples, see `HID_MOUSE_REPORT_DESC()`, `HID_KEYBOARD_REPORT_DESC()`

**Parameters**
• idx – Number of data fields included in the report

**Returns**
HID Usage Index item

**HID_USAGE_MIN8(a)**
Define HID Usage Minimum item with the data length of one byte.
For usage examples, see `HID_MOUSE_REPORT_DESC()`, `HID_KEYBOARD_REPORT_DESC()`

**Parameters**
• a – Starting Usage

**Returns**
HID Usage Minimum item

**HID_USAGE_MAX8(a)**
Define HID Usage Maximum item with the data length of one byte.
For usage examples, see `HID_MOUSE_REPORT_DESC()`, `HID_KEYBOARD_REPORT_DESC()`

**Parameters**
• a – Ending Usage

Returns
HID Usage Maximum item

HID_USAGE_MIN16(a, b)
Define HID Usage Minimum item with the data length of two bytes.
For usage examples, see \textit{HID_MOUSE_REPORT_DESC()}, \textit{HID_KEYBOARD_REPORT_DESC()}

Parameters
• a – Starting Usage lower byte
• b – Starting Usage higher byte

Returns
HID Usage Minimum item

HID_USAGE_MAX16(a, b)
Define HID Usage Maximum item with the data length of two bytes.
For usage examples, see \textit{HID_MOUSE_REPORT_DESC()}, \textit{HID_KEYBOARD_REPORT_DESC()}

Parameters
• a – Ending Usage lower byte
• b – Ending Usage higher byte

Returns
HID Usage Maximum item

\textbf{HID types reference}

group \texttt{usb_hid_types}

**HID Mouse and Keyboard report descriptors**

The pre-defined Mouse and Keyboard report descriptors can be used by a HID device implementation or simply as examples.

```c
#define HID_MOUSE_REPORT_DESC(bcnt)

Simple HID mouse report descriptor for n button mouse.

**Parameters**
- bcnt – Button count. Allowed values from 1 to 8.

```c
#define HID_KEYBOARD_REPORT_DESC()

Simple HID keyboard report descriptor.

**Enums**

```c
enum hid_kbd_code

HID keyboard button codes.

**Values:**
- enumerator HID_KEY_A = 4
- enumerator HID_KEY_B = 5
- enumerator HID_KEY_C = 6
- enumerator HID_KEY_D = 7
- enumerator HID_KEY_E = 8
- enumerator HID_KEY_F = 9
- enumerator HID_KEY_G = 10
- enumerator HID_KEY_H = 11

**HID Class Device API reference**

USB HID devices like mouse, keyboard, or any other specific device use this API.

group usb_hid_device_api

**Typedefs**

typedef int (*hid_cb_t)(const struct device *dev, struct usb_setup_packet *setup, int32_t *len, uint8_t **data)

typedef void (*hid_int_ready_callback)(const struct device *dev)

typedef void (*hid_protocol_cb_t)(const struct device *dev, uint8_t protocol)

typedef void (*hid_idle_cb_t)(const struct device *dev, uint16_t report_id)
Functions

void usb_hid_register_device(const struct device *dev, const uint8_t *desc, size_t size, const struct hid_ops *op)

Register HID device.

Parameters

• dev – [in] Pointer to USB HID device
• desc – [in] Pointer to HID report descriptor
• size – [in] Size of HID report descriptor
• op – [in] Pointer to USB HID device interrupt struct

int hid_int_ep_write(const struct device *dev, const uint8_t *data, uint32_t data_len, uint32_t *bytes_ret)

Write to USB HID interrupt endpoint buffer.

Parameters

• dev – [in] Pointer to USB HID device
• data – [in] Pointer to data buffer
• data_len – [in] Length of data to copy

Returns

0 on success, negative errno code on fail.

int hid_int_ep_read(const struct device *dev, uint8_t *data, uint32_t max_data_len, uint32_t *ret_bytes)

Read from USB HID interrupt endpoint buffer.

Parameters

• dev – [in] Pointer to USB HID device
• data – [in] Pointer to data buffer
• max_data_len – [in] Max length of data to copy
• ret_bytes – [out] Number of bytes to copy. If data is NULL and max_data_len is 0 the number of bytes available in the buffer will be returned.

Returns

0 on success, negative errno code on fail.

int usb_hid_set_proto_code(const struct device *dev, uint8_t proto_code)

Set USB HID class Protocol Code.

Should be called before usb_hid_init().

Parameters

• dev – [in] Pointer to USB HID device
• proto_code – [in] Protocol Code to be used for bInterfaceProtocol

Returns

0 on success, negative errno code on fail.

int usb_hid_init(const struct device *dev)

Initialize USB HID class support.

Parameters

• dev – [in] Pointer to USB HID device
Returns
0 on success, negative errno code on fail.

struct hid_ops
#include <usb_hid.h> USB HID device interface.

4.20.5 USB device stack CDC ACM support

The CDC ACM class is used as backend for different subsystems in Zephyr. However, its configuration
may not be easy for the inexperienced user. Below is a description of the different use cases and some
pitfalls.

The interface for CDC ACM user is UART driver API. But there are two important differences in behavior
to a real UART controller:

• Data transfer is only possible after the USB device stack has been initialized and started, until then
  any data is discarded
• If device is connected to the host, it still needs an application on the host side which requests the
data

The devicetree compatible property for CDC ACM UART is zephyr,cdc-acm-uart. CDC ACM support
is automatically selected when USB device support is enabled and a compatible node in the devicetree
sources is present. If necessary, CDC ACM support can be explicitly disabled by CONFIG_USB_CDC_ACM.
About four CDC ACM UART instances can be defined and used, limited by the maximum number of
supported endpoints on the controller.

CDC ACM UART node is supposed to be child of a USB device controller node. Since the designation of
the controller nodes varies from vendor to vendor, and our samples and application should be as generic
as possible, the default USB device controller is usually assigned an zephyr_udc0 node label. Often, CDC
ACM UART is described in a devicetree overlay file and looks like this:

&zephyr_udc0 {
  cdc_acm_uart0: cdc_acm_uart0 {
    compatible = "zephyr,cdc-acm-uart";
    label = "CDC_ACM_0";
  };
};

Samples usb_cdc-acm and usb_hid-cdc have similar overlay files. And since no special properties are
present, it may seem overkill to use devicetree to describe CDC ACM UART. The motivation behind using
devicetree is the easy interchangeability of a real UART controller and CDC ACM UART in applications.

Console over CDC ACM UART

With the CDC ACM UART node from above and zephyr,console property of the chosen node, we can
describe that CDC ACM UART is to be used with the console. A similar overlay file is used by cdc-acm-console.

/ {
  chosen {
    zephyr,console = &cdc_acm_uart0;
  };
};

&zephyr_udc0 {
  cdc_acm_uart0: cdc_acm_uart0 {
    compatible = "zephyr,cdc-acm-uart";
  };
};

(continues on next page)
Before the application uses the console, it is recommended to wait for the DTR signal:

```c
const struct device *const dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_console));
uint32_t dtr = 0;
if (usb_enable(NULL)) {
    return;
}
while (!dtr) {
    uart_line_ctrl_get(dev, UART_LINE_CTRL_DTR, &dtr);
    k_sleep(K_MSEC(100));
}
printk("nuqneH\\n");
```

**CDC ACM UART as backend**

As for the console sample, it is possible to configure CDC ACM UART as backend for other subsystems by setting `Chosen nodes` properties.

List of few Zephyr specific chosen properties which can be used to select CDC ACM UART as backend for a subsystem or application:

- `zephyr,bt-c2h-uart` used in Bluetooth, for example see `bluetooth-hci-uart-sample`
- `zephyr,ot-uart` used in OpenThread, for example see `coprocessor-sample`
- `zephyr,shell-uart` used by shell for serial backend, for example see `samples/subsys/shell/shell_module`
- `zephyr,uart-mcumgr` used by `smp_svr_sample`

### 4.21 Virtualization

**4.21.1 Inter-VM Shared Memory**

**Overview**

As Zephyr is enabled to run as a guest OS on Qemu and ACRN it might be necessary to make VMs aware of each other, or aware of the host. This is made possible by exposing a shared memory among parties via a feature called ivshmem, which stands for inter-VM Shared Memory.
The two types are supported: a plain shared memory (ivshmem-plain) or a shared memory with the ability for a VM to generate an interruption on another, and thus to be interrupted as well itself (ivshmem-doorbell).

Please refer to the official Qemu ivshmem documentation for more information.

Support

Zephyr supports both version: plain and doorbell. Ivshmem driver can be built by enabling CONFIG_IVSHMEM. By default, this will expose the plain version. CONFIG_IVSHMEM_DOORBELL needs to be enabled to get the doorbell version.

Because the doorbell version uses MSI-X vectors to support notification vectors, the CONFIG_IVSHMEM_MSI_X_VECTORS has to be tweaked to the amount of vectors that will be needed.

Note that a tiny shell module can be exposed to test the ivshmem feature by enabling CONFIG_IVSHMEM_SHELL.

API Reference

group ivshmem

ivshmem reference API

Typedef

typedef size_t (*ivshmem_get_mem_f)(const struct device *dev, uintptr_t *memmap)

typedef uint32_t (*ivshmem_get_id_f)(const struct device *dev)

typedef uint16_t (*ivshmem_get_vectors_f)(const struct device *dev)

typedef int (*ivshmem_int_peer_f)(const struct device *dev, uint32_t peer_id, uint16_t vector)

typedef int (*ivshmem_register_handler_f)(const struct device *dev, struct k_poll_signal *signal, uint16_t vector)

Functions

size_t ivshmem_get_mem(const struct device *dev, uintptr_t *memmap)

Get the inter-VM shared memory.

Parameters

- dev – Pointer to the device structure for the driver instance
- memmap – A pointer to fill in with the memory address

Returns

the size of the memory mapped, or 0
uint32_t ivshmem_get_id(const struct device *dev)
Get our VM ID.

**Parameters**
- dev – Pointer to the device structure for the driver instance

**Returns**
our VM ID or 0 if we are not running on doorbell version

uint16_t ivshmem_get_vectors(const struct device *dev)
Get the number of interrupt vectors we can use.

**Parameters**
- dev – Pointer to the device structure for the driver instance

**Returns**
the number of available interrupt vectors

int ivshmem_int_peer(const struct device *dev, uint32_t peer_id, uint16_t vector)
Interrupt another VM.

**Parameters**
- dev – Pointer to the device structure for the driver instance
- peer_id – The VM ID to interrupt
- vector – The interrupt vector to use

**Returns**
0 on success, a negative errno otherwise

int ivshmem_register_handler(const struct device *dev, struct k_poll_signal *signal, uint16_t vector)
Register a vector notification (interrupt) handler.

Note: The returned status, if positive, to a raised signal is the vector that generated the signal. This lets the possibility to the user to have one signal for all vectors, or one per-vector.

**Parameters**
- dev – Pointer to the device structure for the driver instance
- signal – A pointer to a valid and ready to be signaled struct k_poll_signal. Or NULL to unregister any handler registered for the given vector.
- vector – The interrupt vector to get notification from

**Returns**
0 on success, a negative errno otherwise

struct ivshmem_driver_api
#include <ivshmem.h>

### 4.22 Real Time I/O (RTIO)

- **Problem**
- **Inspiration, introducing io_uring**
RTIO provides a framework for doing asynchronous operation chains with event driven I/O. This section covers the RTIO API, queues, executor, iodev, and common usage patterns with peripheral devices.

RTIO takes a lot of inspiration from Linux's io_uring in its operations and API as that API matches up well with hardware DMA transfer queues and descriptions.

A quick sales pitch on why RTIO works well in many scenarios:

1. API is DMA and interrupt friendly
2. No buffer copying
3. No callbacks
4. Blocking or non-blocking operation

### 4.22.1 Problem

An application wishing to do complex DMA or interrupt driven operations today in Zephyr requires direct knowledge of the hardware and how it works. There is no understanding in the DMA API of other Zephyr devices and how they relate.

This means doing complex audio, video, or sensor streaming requires direct hardware knowledge or leaky abstractions over DMA controllers. Neither is ideal.

To enable asynchronous operations, especially with DMA, a description of what to do rather than direct operations through C and callbacks is needed. Enabling DMA features such as channels with priority, and sequences of transfers requires more than a simple list of descriptions.

Using DMA and/or interrupt driven I/O shouldn’t dictate whether or not the call is blocking or not.

### 4.22.2 Inspiration, introducing io_uring

It’s better not to reinvent the wheel (or ring in this case) and io_uring as an API from the Linux kernel provides a winning model. In io_uring there are two lock-free ring buffers acting as queues shared between the kernel and a userland application. One queue for submission entries which may be chained and flushed to create concurrent sequential requests. A second queue for completion queue events. Only a single syscall is actually required to execute many operations, the io_uring_submit call. This call may block the caller when a number of operations to wait on is given.

This model maps well to DMA and interrupt driven transfers. A request to do a sequence of operations in an asynchronous way directly relates to the way hardware typically works with interrupt driven state machines potentially involving multiple peripheral IPs like bus and DMA controllers.

### 4.22.3 Submission Queue and Chaining

The submission queue (sq), is the description of the operations to perform in concurrent chains.

For example imagine a typical SPI transfer where you wish to write a register address to then read from. So the sequence of operations might be...

1. Chip Select
2. Clock Enable
3. Write register address into SPI transmit register
4. Read from the SPI receive register into a buffer
5. Disable clock
6. Disable Chip Select

If anything in this chain of operations fails give up. Some of those operations can be embodied in a device abstraction that understands a read or write implicitly means setup the clock and chip select. The transactional nature of the request also needs to be embodied in some manner. Of the operations above perhaps the read could be done using DMA as its large enough make sense. That requires an understanding of how to setup the device’s particular DMA to do so.

The above sequence of operations is embodied in RTIO as chain of submission queue entries (sqe). Chaining is done by setting a bitflag in an sqe to signify the next sqe must wait on the current one.

Because the chip select and clocking is common to a particular SPI controller and device on the bus it is embodied in what RTIO calls an iodev.
Multiple operations against the same iodev are done in the order provided as soon as possible. If two operation chains have varying points using the same device its possible one chain will have to wait for another to complete.

4.22.4 Completion Queue

In order to know when a sqe has completed there is a completion queue (cq) with completion queue events (cqe). A sqe once completed results in a cqe being pushed into the cq. The ordering of cqe may not be the same order of sqe. A chain of sqe will however ensure ordering and failure cascading.

Other potential schemes are possible but a completion queue is a well trod idea with io_uring and other similar operating system APIs.

4.22.5 Executor and IODev

Turning submission queue entries (sqe) into completion queue events (cqe) is the job of objects implementing the executor and iodev APIs. These APIs enable coordination between themselves to enable things like DMA transfers.

The end result of these APIs should be a method to resolve the request by deciding some of the following questions with heuristic/constraint based decision making.

- Polling, Interrupt, or DMA transfer?
- If DMA, are the requirements met (peripheral supported by DMAC, etc).

The executor is meant to provide policy for when to use each transfer type, and provide the common code for walking through submission queue chains by providing calls the iodev may use to signal completion, error, or a need to suspend and wait.

4.22.6 Outstanding Questions

RTIO is not a complete API and solution, and is currently evolving to best fit the nature of an RTOS. The general ideas behind a pair of queues to describe requests and completions seems sound and has been proven out in other contexts. Questions remain though.

Timeouts and Deadlines

Timeouts and deadlines are key to being Real-Time. Real-Time in Zephyr means being able to do things when an application wants them done. That could mean different things from a deadline with best effort attempts or a timeout and failure.

These features would surely be useful in many cases, but would likely add some significant complexities. It's something to decide upon, and even if enabled would likely be a compile time optional feature leading to complex testing.

Cancellation

Canceling an already queued operation could be possible with a small API addition to perhaps take both the RTIO context and a pointer to the submission queue entry. However, cancellation as an API induces many potential complexities that might not be appropriate. It's something to be decided upon.
Userspace Support

RTIO with userspace is certainly plausible but would require the equivalent of a memory map call to map the shared ringbuffers and also potentially dma buffers.

Additionally a DMA buffer interface would likely need to be provided for coherence and MMU usage.

IODev and Executor API

Lastly the API between an executor and iodev is incomplete.

There are certain interactions that should be supported. Perhaps things like expanding a submission queue entry into multiple submission queue entries in order to split up work that can be done by a device and work that can be done by a DMA controller.

In some SoCs only specific DMA channels may be used with specific devices. In others there are requirements around needing a DMA handshake or specific triggering setups to tell the DMA when to start its operation.

None of that, from the outward facing API, is an issue.

It is however an unresolved task and issue from an internal API between the executor and iodev. This requires some SoC specifics and enabling those generically isn’t likely possible. That’s ok, an iodev and dma executor should be vendor specific, but an API needs to be there between them that is not!

Special Hardware: Intel HDA

In some cases there’s a need to always do things in a specific order with a specific buffer allocation strategy. Consider a DMA that requires the usage of a circular buffer segmented into blocks that may only be transferred one after another. This is the case of the Intel HDA stream for audio.

In this scenario the above API can still work, but would require an additional buffer allocator to work with fixed sized segments.

4.22.7 When to Use

It’s important to understand when DMA like transfers are useful and when they are not. It’s a poor idea to assume that something made for high throughput will work for you. There is a computational, memory, and latency cost to setup the description of transfers.

Polling at 1Hz an air sensor will almost certainly result in a net negative result compared to ad-hoc sensor (i2c/spi) requests to get the sample.

Continuous transfers, driven by timer or interrupt, of data from a peripheral’s on board FIFO over I2C, I3C, SPI, MIPI, I2S, etc. . . maybe, but not always!

4.22.8 Examples

Examples speak loudly about the intended uses and goals of an API. So several key examples are presented below. Some are entirely plausible today without a big leap. Others (the sensor example) would require additional work in other APIs outside of RTIO as a sub system and are theoretical.

Chained Blocking Requests

A common scenario is needing to write the register address to then read from. This can be accomplished by chaining a write into a read operation.

The transaction on i2c is implicit for each operation chain.
int do_some_io(void)
{
    struct rtio_sqe *write_sqe = rtio_spsc_acquire(ez_io.sq);
    struct rtio_sqe *read_sqe = rtio_spsc_acquire(ez_io.sq);

    rtio_sqe_prep_write(write_sqe, i2c_dev, RTIO_PRIO_LOW, &reg_addr, 2);
    write_sqe->flags = RTIO_SQE_CHAINED; /* the next item in the queue will wait on this one */

    rtio_sqe_prep_read(read_sqe, i2c_dev, RTIO_PRIO_LOW, buf, 32);
    rtio_submit(rtio_inplace_executor, &ez_io, 2);

    struct rtio_cqe *read_cqe = rtio_spsc_consume(ez_io.cq);
    struct rtio_cqe *write_cqe = rtio_spsc_consume(ez_io.cq);

    if(read_cqe->result < 0) {
        LOG_ERR("read failed!");
    }

    if(write_cqe->result < 0) {
        LOG_ERR("write failed!");
    }

    rtio_spsc_release(ez_io.cq);
    rtio_spsc_release(ez_io.cq);
}

Non blocking device to device

Imagine wishing to read from one device on an I2C bus and then write the same buffer to a device on a SPI bus without blocking the thread or setting up callbacks or other IPC notification mechanisms.

Perhaps an I2C temperature sensor and a SPI lowrawan module. The following is a simplified version of that potential operation chain.
/* subsequent ops fail */
struct rtio_sqe *write_sqe = rtio_spsc_acquire(ez_io.sq);
rtio_sqe_prep_write(write_sqe, spi_dev, RTIO_PRIO_LOW, buf, 32);

/* call will return immediately without blocking if possible */
rtio_submit(rtio_inplace_executor, &ez_io, 0);

/* These calls might return NULL if the operations have not yet completed! */
for (int i = 0; i < 2; i++) {
    struct rtio_cqe *cqe = rtio_spsc_consume(ez_io.cq);
    while(cqe == NULL) {
        cqe = rtio_spsc_consume(ez_io.cq);
        k_yield();
    }
    if(cqe->userdata == &read && cqe->result < 0) {
        LOG_ERR("read from i2c failed!");
    }
    if(cqe->userdata == &write && cqe->result < 0) {
        LOG_ERR("write to spi failed!");
    }
    /* Must release the completion queue event after consume */
    rtio_spsc_release(ez_io.cq);
}

Nested iodevs for Devices on Buses (Sensors), Theoretical

Consider a device like a sensor or audio codec sitting on a bus.

It's useful to consider that the sensor driver can use RTIO to do I/O on the SPI bus, while also being an
RTIO device itself. The sensor iodev can set aside a small portion of the buffer in front or in back to
store some metadata describing the format of the data. This metadata could then be used in creating a
sensor readings iterator which lazily lets you map over each reading, doing calculations such as FIR/IIR
filtering, or perhaps translating the readings into other numerical formats with useful measurement units
such as SI. RTIO is a common movement API and allows for such uses while not deciding the mechanism.

This same sort of setup could be done for other data streams such as audio or video.

/* Note that the sensor device itself can use RTIO to get data over I2C/SPI
   * potentially with DMA, but we don't need to worry about that here
   * All we need to know is the device tree node_id and that it can be an iodev
   */
RTIO_SENSOR_IODEV(sensor_dev, DEVICE_DT_GET(DT_NODE(super6axis));

RTIO_DEFINE(ez_io, 4, 4);

/* The sensor driver decides the minimum buffer size for us, we decide how
   * many bufs. This could be a typical multiple of a fifo packet the sensor
   * produces, ICM42688 for example produces a FIFO packet of 20 bytes in
   * 20bit mode at 32KHz so perhaps we'd like to get 4 bufs of 4ms of data
   * each in this setup to process on. and its already been defined here for us.
   */
#include <sensors/icm42688_p.h>
static uint8_t bufs[4][ICM42688_RTIO_BUF_SIZE];

(continues on next page)
int do_some_sensors(void) {
    /* Obtain a dmac executor from the DMA device */
    struct device *dma = DEVICE_DT_GET(DT_NODE(dma0));
    const struct rtio_executor *rtio_dma_exec =
        dma_rtio_executor(dma);

    /*
     * Set the executor for our queue context
     */
    rtio_set_executor(ez_io, rtio_dma_exec);

    /* Mostly we want to feed the sensor driver enough buffers to fill while
     * we wait and process! Small enough to process quickly with low latency,
     * big enough to not spend all the time setting transfers up.
     * It's assumed here that the sensor has been configured already
     * and each FIFO watermark interrupt that occurs it attempts
     * to pull from the queue, fill the buffer with a small metadata
     * offset using its own rtio request to the SPI bus using DMA.
     */
    for(int i = 0; i < 4; i++) {
        struct rtio_sqe *read_sqe = rtio_spsc_acquire(ez_io.sq);

        rtio_sqe_prep_read(read_sqe, sensor_dev, RTIO_PRIO_HIGH, bufs[i],
                        ICM42688_RTIO_BUF_SIZE);
    }
    struct device *sensor = DEVICE_DT_GET(DT_NODE(super6axis));
    struct sensor_reader reader;
    struct sensor_channels channels[4] = {
        SENSOR_TIMESTAMP_CHANNEL,
        SENSOR_CHANNEL(int32_t, SENSOR_ACC_X, 0, SENSOR_RAW),
        SENSOR_CHANNEL(int32_t SENSOR_ACC_Y, 0, SENSOR_RAW),
        SENSOR_CHANNEL(int32_t, SENSOR_ACC_Z, 0, SENSOR_RAW),
    };

    while (true) {
        /* call will wait for one completion event */
        rtio_submit(ez_io, 1);
        struct rtio_cqe *cqe = rtio_spsc_consume(ez_io.cq);
        if(cqe->result < 0) {
            LOG_ERR("read failed!");
            goto next;
        }

        /* Bytes read into the buffer */
        int32_t bytes_read = cqe->result;

        /* Retrieve soon to be reusable buffer pointer from completion */
        uint8_t *buf = cqe->userdata;

        /* Get an iterator (reader) that obtains sensor readings in integer
         * form, 16 bit signed values in the native sensor reading format */
        res = sensor_reader(sensor, buf, cqe->result, &reader, channels,
                            sizeof(channels));
        __ASSERT(res == 0);
    }
}

(continues on previous page)
```c
while(sensor_reader_next(&reader)) {
    printf("time(raw): %d, acc (x,y,z): (%d, %d, %d)\n",
           channels[0].value.u32, channels[1].value.i32,
           channels[2].value.i32, channels[3].value.i32);
}

next:
    /* Release completion queue event */
    rtio_spsc_release(ez_io.cq);

    /* resubmit a read request with the newly freed buffer to the sensor
        */
    struct rtio_sqe *read_sqe = rtio_spsc_acquire(ez_io.sq);
    rtio_sqe_prep_read(read_sqe, sensor_dev, RTIO_PRIO_HIGH, buf,\
                        ICM20649_RTIO_BUF_SIZE);
    rtio_sqe_submit(read_sqe);
}
```

### 4.22.9 API Reference

**RTIO API**

**group rtio_api**

RTIO API.

**Defines**

- **RTIO_OP_NOP**
  An operation that does nothing and will complete immediately

- **RTIO_OP_RX**
  An operation that receives (reads)

- **RTIO_OP_TX**
  An operation that transmits (writes)

- **RTIO_SQ_DEFINE(name, len)**
  Statically define and initialize a fixed length submission queue.

  **Parameters**
  
  - `name` – Name of the submission queue.
  - `len` – Queue length, power of 2 required (2, 4, 8).

- **RTIO_CQ_DEFINE(name, len)**
  Statically define and initialize a fixed length completion queue.

  **Parameters**
  
  - `name` – Name of the completion queue.
  - `len` – Queue length, power of 2 required (2, 4, 8).
RTIO_IODEV_SQ_DEFINE(name, len)
Statically define and initialize a fixed length iodev submission queue.

Parameters
• name – Name of the queue.
• len – Queue length, power of 2 required

RTIO_IODEV_DEFINE(name, iodev_api, qsize, iodev_data)
Statically define and initialize an RTIO IODev.

Parameters
• name – Name of the iodev
• iodev_api – Pointer to struct rtio_iodev_api
• qsize – Size of the submission queue, must be power of 2
• iodev_data – Data pointer

RTIO_DEFINE(name, exec, sq_sz, cq_sz)
Statically define and initialize an RTIO context.

Parameters
• name – Name of the RTIO
• exec – Symbol for rtio_executor (pointer)
• sq_sz – Size of the submission queue, must be power of 2
• cq_sz – Size of the completion queue, must be power of 2

Functions

static inline void rtio_sqe_prep_nop(struct rtio_sqe *sqe, const struct rtio_iodev *iodev, void *userdata)
Prepare a nop (no op) submission.

static inline void rtio_sqe_prep_read(struct rtio_sqe *sqe, const struct rtio_iodev *iodev, int8_t prio, uint8_t *buf, uint32_t len, void *userdata)
Prepare a read op submission.

static inline void rtio_sqe_prep_write(struct rtio_sqe *sqe, const struct rtio_iodev *iodev, int8_t prio, uint8_t *buf, uint32_t len, void *userdata)
Prepare a write op submission.

static inline void rtio_set_executor(struct rtio *r, struct rtio_executor *exc)
Set the executor of the rtio context.

static inline void rtio_iodev_submit(const struct rtio_sqe *sqe, struct rtio *r)
Perform a submitted operation with an iodev.

Parameters
• sqe – Submission to work on
• r – RTIO context

static inline uint32_t rtio_sqe_acquirable(struct rtio *r)
Count of acquirable submission queue events.

Parameters
• r – RTIO context
Returns
Count of acquirable submission queue events

static inline struct rtio_sqe *rtio_sqe_acquire(struct rtio *r)
Acquire a single submission queue event if available.

Parameters
• r – RTIO context

Return values
• sqe – A valid submission queue event acquired from the submission queue
• NULL – No submission queue event available

static inline void rtio_sqe_produce_all(struct rtio *r)
Produce all previously acquired sqe.

Parameters
• r – RTIO context

static inline void rtio_sqe_drop_all(struct rtio *r)
Drop all previously acquired sqe.

Parameters
• r – RTIO context

static inline struct rtio_cqe *rtio_cqe_consume(struct rtio *r)
Consume a single completion queue event if available.

If a completion queue event is returned rtio_cq_release(r) must be called at some point to release the cqe spot for the cqe producer.

Parameters
• r – RTIO context

Return values
• cqe – A valid completion queue event consumed from the completion queue
• NULL – No completion queue event available

static inline struct rtio_cqe *rtio_cqe_consume_block(struct rtio *r)
Wait for and consume a single completion queue event.

If a completion queue event is returned rtio_cq_release(r) must be called at some point to release the cqe spot for the cqe producer.

Parameters
• r – RTIO context

Return values
cqe – A valid completion queue event consumed from the completion queue

static inline void rtio_cqe_release_all(struct rtio *r)
Release all consumed completion queue events.

Parameters
• r – RTIO context

static inline void rtio_sqe_ok(struct rtio *r, const struct rtio_sqe *sqe, int result)
Inform the executor of a submission completion with success.

This may start the next asynchronous request if one is available.
Parameters

- \texttt{r} – RTIO context
- \texttt{sqe} – Submission that has succeeded
- \texttt{result} – Result of the request

static inline void \texttt{rtio\_sqe\_err(struct rtio *r, const struct rtio\_sqe *sqe, int result)}

Inform the executor of a submission completion with error.

This \textsc{shall} fail the remaining submissions in the chain.

Parameters

- \texttt{r} – RTIO context
- \texttt{sqe} – Submission that has failed
- \texttt{result} – Result of the request

static inline void \texttt{rtio\_cqe\_submit(struct rtio *r, int result, void *userdata)}

Submit a completion queue event with a given result and userdata.

Called by the executor to produce a completion queue event, no inherent locking is performed and this is not safe to do from multiple callers.

Parameters

- \texttt{r} – RTIO context
- \texttt{result} – Integer result code (could be -errno)
- \texttt{userdata} – Userdata to pass along to completion

static inline void \texttt{rtio\_access\_grant(struct rtio *r, struct k\_thread *t)}

Grant access to an RTIO context to a user thread.

\textbf{Return values}

- \texttt{0} – success
- \texttt{-ENOMEM} – not enough room in the queue

int \texttt{rtio\_sqe\_copy\_in(struct rtio *r, const struct rtio\_sqe *sqes, size\_t sqe\_count)}

Copy an array of SQEs into the queue.

Useful if a batch of submissions is stored in ROM or RTIO is used from user mode where a copy must be made.

Partial copying is not done as chained SQEs need to be submitted as a whole set.

Parameters

- \texttt{r} – RTIO context
- \texttt{sqes} – Pointer to an array of SQEs
- \texttt{sqe\_count} – Count of sqes in array

\textbf{Return values}

- \texttt{0} – success
- \texttt{-ENOMEM} – not enough room in the queue

int \texttt{rtio\_cqe\_copy\_out(struct rtio *r, struct rtio\_cqe *cqes, size\_t cqe\_count, k\_timeout\_t timeout)}

Copy an array of CQEs from the queue.

Copies from the RTIO context and its queue completion queue events, waiting for the given time period to gather the number of completions requested.

Parameters

- \texttt{r} – RTIO context
- \texttt{cqes} – Pointer to an array of SQEs
cqe_count – Count of sqes in array

timeout – Timeout to wait for each completion event. Total wait time is potentially timeout*cqe_count at maximum.

**Return values**
copy_count – Count of copied CQEs (0 to cqe_count)

```c
int rtio_submit(struct rtio *r, uint32_t wait_count)
```
Submit I/O requests to the underlying executor.

Submits the queue of submission queue events to the executor. The executor will do the work of managing tasks representing each submission chain, freeing submission queue events when done, and producing completion queue events as submissions are completed.

**Parameters**

- **r** – RTIO context
- **wait_count** – Number of submissions to wait for completion of.

**Return values**

0 – On success

```c
struct rtio_sqe
```
A submission queue event.

**Public Members**

- **op** – Op code
- **prio** – Op priority
- **flags** – Op Flags
- **iodev** – Device to operation on
- **userdata** – User provided pointer to data which is returned upon operation completion
  
  If unique identification of completions is desired this should be unique as well.
- **buf_len** – Length of buffer
- **buf** – Buffer to use

```c
struct rtio_sq
```
Submission queue.

This is used for typifying the members of an RTIO queue pair but nothing more.
struct rtio_cqe
#include <rtio.h> A completion queue event.

Public Members

int32_t result
Result from operation

void *userdata
Associated userdata with operation

struct rtio_cq
#include <rtio.h> Completion queue.
This is used for typifying the members of an RTIO queue pair but nothing more.

struct rtio_executor_api
#include <rtio.h>

Public Members

int (*submit)(struct rtio *, r)
Submit the request queue to executor.
The executor is responsible for interpreting the submission queue and creating concurrent execution chains.
Concurrency is optional and implementation dependent.

void (*ok)(struct rtio *, const struct rtio_sqe *, int result)
SQE completes successfully.

void (*err)(struct rtio *, const struct rtio_sqe *, int result)
SQE fails to complete.

struct rtio_executor
#include <rtio.h> An executor does the work of executing the submissions.
This could be a DMA controller backed executor, thread backed, or simple in place executor.
A DMA executor might schedule all transfers with priorities and use hardware arbitration.
A threaded executor might use a thread pool where each transfer chain is executed across the thread pool and the priority of the transfer is used as the thread priority.
A simple in place executor might simply loop over and execute each transfer in the calling threads context. Priority is entirely derived from the calling thread then.
An implementation of the executor must place this struct as its first member such that pointer aliasing works.
struct rtio

\#include <rtio.h> An RTIO queue pair that both the kernel and application work with.

The kernel is the consumer of the submission queue, and producer of the completion queue.
The application is the consumer of the completion queue and producer of the submission queue.
Nothing is done until a call is performed to do the work (rtio_execute).

struct rtio_iodev_api

\#include <rtio.h> API that an RTIO IO device should implement.

Public Members

void (*submit)(const struct rtio_sqe *sque, struct rtio *r)

Submission function for a request to the iodev.
The iodev is responsible for doing the operation described as a submission queue entry and reporting results using using rtio_sqe_ok or rtio_sqe_err once done.

struct rtio_iodev_sqe

\#include <rtio.h>

struct rtio_iodev_sq

\#include <rtio.h> IO device submission queue.

This is used for reifying the member of the rtio_iodev struct

struct rtio_iodev

\#include <rtio.h> An IO device with a function table for submitting requests.

RTIO SPSC API

\texttt{group rtio_spsc}

RTIO Single Producer Single Consumer (SPSC) Queue API.

Defines

RTIO_SPSC_INITIALIZER(name, type, sz)

Statically initialize an rtio_spsc.

Parameters

\begin{itemize}
  \item name – Name of the spsc symbol to be provided
  \item type – Type stored in the spsc
  \item sz – Size of the spsc, must be power of 2 (ex: 2, 4, 8)
\end{itemize}

RTIO_SPSC_DECLARE(name, type, sz)

Declare an anonymous struct type for an rtio_spsc.

Parameters

\begin{itemize}
  \item name – Name of the spsc symbol to be provided
\end{itemize}
• type – Type stored in the spsc
• sz – Size of the spsc, must be power of 2 (ex: 2, 4, 8)

RTIO_SPSC_DEFINE(name, type, sz)
Define an rtio_spsc with a fixed size.

Parameters
• name – Name of the spsc symbol to be provided
• type – Type stored in the spsc
• sz – Size of the spsc, must be power of 2 (ex: 2, 4, 8)

rtio_spsc_size(spsc)
Size of the SPSC queue.

Parameters
• spsc – SPSC reference

rtio_spsc_reset(spsc)
Initialize/reset a spsc such that its empty.
Note that this is not safe to do while being used in a producer/consumer situation with multiple calling contexts (isrs/threads).

Parameters
• spsc – SPSC to initialize/reset

rtio_spsc_acquire(spsc)
Acquire an element to produce from the SPSC.

Parameters
• spsc – SPSC to acquire an element from for producing

Returns
A pointer to the acquired element or null if the spsc is full

rtio_spsc_produce(spsc)
Produce one previously acquired element to the SPSC.
This makes one element available to the consumer immediately

Parameters
• spsc – SPSC to produce the previously acquired element or do nothing

rtio_spsc_produce_all(spsc)
Produce all previously acquired elements to the SPSC.
This makes all previous acquired elements available to the consumer immediately

Parameters
• spsc – SPSC to produce all previously acquired elements or do nothing

rtio_spsc_drop_all(spsc)
Drop all previously acquired elements.
This makes all previous acquired elements available to be acquired again

Parameters
• spsc – SPSC to drop all previously acquired elements or do nothing
rtio_spsc_consume(spsc)
Consume an element from the spsc.

Parameters
• spsc – Spsc to consume from

Returns
Pointer to element or null if no consumable elements left

rtio_spsc_release(spsc)
Release a consumed element.

Parameters
• spsc – SPSC to release consumed element or do nothing

rtio_spsc_release_all(spsc)
Release all consumed elements.

Parameters
• spsc – SPSC to release consumed elements or do nothing

rtio_spsc_acquirable(spsc)
Count of acquirable in spsc.

Parameters
• spsc – SPSC to get item count for

rtio_spsc_consumable(spsc)
Count of consumables in spsc.

Parameters
• spsc – SPSC to get item count for

rtio_spsc_peek(spsc)
Peek at the first available item in queue.

Parameters
• spsc – Spsc to peek into

Returns
Pointer to element or null if no consumable elements left

rtio_spsc_next(spsc, item)
Peek at the next item in the queue from a given one.

Parameters
• spsc – SPSC to peek at
  • item – Pointer to an item in the queue

Returns
Pointer to element or null if none left

rtio_spsc_prev(spsc, item)
Get the previous item in the queue from a given one.

Parameters
• spsc – SPSC to peek at
  • item – Pointer to an item in the queue

Returns
Pointer to element or null if none left
struct rtio_spsc

Common SPSC attributes.

**Warning:** Not to be manipulated without the macros!

### 4.23 Zephyr message bus (zbus)

The *Zephyr message bus* - *Zbus* is a lightweight and flexible message bus enabling a simple way for threads to talk to one another.

---

**4.23.1 Concepts**

Threads can broadcast messages to all interested observers using zbus. Many-to-many communication is possible. The bus implements message-passing and publish/subscribe communication paradigms that enable threads to communicate synchronously or asynchronously through shared memory. The communication through zbus is channel-based, where threads publish and read to and from using messages. Additionally, threads can observe channels and receive notifications from the bus when the channels are modified. Fig. 4.12 shows an example of a typical application using zbus in which the application logic (hardware independent) talks to other threads via message bus. Note that the threads are decoupled from each other because they only use zbus' channels and do not need to know each other to talk.

**Fig. 4.13** illustrates zbus' anatomy. The bus comprises:

- Set of channels that consists of a unique identifier, its control metadata information, and the message itself;
- **Virtual distributed event dispatcher** (VDED), the bus logic responsible for sending notifications to the observers. The VDED logic runs inside the publishing action in the same thread context, giving the bus an idea of a distributed execution. When a thread publishes to a channel, it also propagates the notifications to the observers;
- Threads (subscribers) and callbacks (listeners) publishing, reading, and receiving notifications from the bus.
Fig. 4.12: A typical zbus application architecture.

Fig. 4.13: Zbus internals details.
The bus makes the publish, read, and subscribe actions available over channels. Publishing and reading are available in all RTOS contexts except inside an Interrupt Service Routine (ISR). The publish and read operations were designed to be simple and fast; the procedure is a mutex locking followed by a memory copy to and from a shared memory region. Zbus observers' registration can be:

- Static, defined in compile time. It is not possible to remove at runtime, but it is possible to suppress it by calling the `zbus_obs_set_enable();`
- Dynamic, it can be added and removed to and from a channel at runtime.

For illustration purposes, suppose a usual sensor-based solution in Fig. 4.14. When the timer is triggered, it pushes an action to a workqueue that publishes to the `Start trigger` channel. As the sensor thread subscribed to the `Start trigger` channel, it starts to fetch the sensor data. Notice the event dispatcher executes the blink callback because it also listens to the `Start trigger` channel. When the sensor data is ready, the sensor thread publishes it to the `Sensor data` channel. The core thread as a `Sensor data` channel subscriber process the sensor data and stores it in an internal sample buffer. It repeats until the sample buffer is full; when it happens, the core thread aggregates the sample buffer information, prepares a package, and publishes that to the `Payload` channel. The Lora thread receives that because it is a `Payload` channel subscriber and sends the payload to the cloud. When the transmission is completed, the Lora thread publishes to the `Transmission done` channel. The blink callback will be executed again since it listens to the `Transmission done` channel.

For illustration purposes, suppose a usual sensor-based solution in Fig. 4.14. When the timer is triggered, it pushes an action to a workqueue that publishes to the `Start trigger` channel. As the sensor thread subscribed to the `Start trigger` channel, it starts to fetch the sensor data. Notice the event dispatcher executes the blink callback because it also listens to the `Start trigger` channel. When the sensor data is ready, the sensor thread publishes it to the `Sensor data` channel. The core thread as a `Sensor data` channel subscriber process the sensor data and stores it in an internal sample buffer. It repeats until the sample buffer is full; when it happens, the core thread aggregates the sample buffer information, prepares a package, and publishes that to the `Payload` channel. The Lora thread receives that because it is a `Payload` channel subscriber and sends the payload to the cloud. When the transmission is completed, the Lora thread publishes to the `Transmission done` channel. The blink callback will be executed again since it listens to the `Transmission done` channel.

Fig. 4.14: Zbus sensor-based application.

This way of implementing the solution gives us certain flexibility enabling us to change things independently. For example, suppose we would like to change the trigger from a timer to a button press. We can do that, and the change does not affect other parts of the system. Suppose, again, we would like to change the communication interface from LoRa to Bluetooth; for that, we only need to change the LoRa thread. No other change is needed to make that work. Thus, the developer would do that for every block of the image. Based on that, there is a sign zbus promotes decoupling in the system architecture.

Another important aspect of using zbus is the reuse of system modules. If a module, code portion with a set of well-defined behaviors, only uses zbus channels and not hardware interfaces, it can easily be reused in other solutions. For that, the new solution must implement the interfaces (set of channels) the module needs to work. That indicates zbus could improve the module reuse.

The last important note is the zbus solution reach. We can count on many different ways of using zbus to enable the developer to be as free as possible to create what they need with it. Messages can be dynamic or static allocated, notifications can be synchronous or asynchronous, the developer can control the channel in so many different ways claiming the channel, developers can add their metadata information to a channel by using the user-data field, the discretionary use of a validator enables the systems to be accurate over message format, and so on. Those characteristics increase the solutions that can be done with zbus and make it a good fit as an open-source community tool.
Limitations

Based on the fact that developers can use zbus to solve many different problems, some challenges arise. Zbus will not solve every problem, so it is necessary to analyze the situation to be sure zbus is applicable. For instance, based on the zbus benchmark, it would not be well suited to a high-speed stream of bytes between threads. The Pipe kernel object solves this kind of need.

Delivery guarantees Zbus always delivers the messages to the listeners. However, there are no message delivery guarantees for subscribers because zbus only sends the notification, but the message reading depends on the subscriber’s implementation. It is possible to increase the delivery rate by following design tips:

- Keep the listeners quick-as-possible (deal with them as ISRs). If some processing is needed, consider submitting a work to a work-queue;
- Try to give producers a high priority to avoid losses;
- Leave spare CPU for observers to consume data produced;
- Consider using message queues or pipes for intensive byte transfers.

Message delivery sequence The listeners (synchronous observers) will follow the channel definition sequence as the notification and message consumption sequence. However, the subscribers, as they have an asynchronous nature, all will receive the notification as the channel definition sequence but only will consume the data when they execute again, so the delivery respects the order, but the priority assigned to the subscribers will define the reaction sequence. All the listeners (static or dynamic) will receive the message before subscribers receive the notification. The sequence of delivery is: (i) static listeners; (ii) runtime listeners; (iii) static subscribers; at last (iv) runtime subscribers.

4.23.2 Implementation

Zbus operation depends on channels and observers. Therefore, it is necessary to determine its message and observers list during the channel definition. A message is a regular C struct; the observer can be a subscriber (asynchronous) or a listener (synchronous). Channels can have a validator function that enables a channel to accept only valid messages.

The following code defines and initializes a regular channel and its dependencies. This channel exchanges accelerometer data, for example.

```c
struct acc_msg {
    int x;
    int y;
    int z;
};

ZBUS_CHAN_DEFINE(acc_chan, /* Name */
    struct acc_msg, /* Message type */
    NULL, /* Validator */
    NULL, /* User Data */
    ZBUS_OBSERVERS(my_listener, my_subscriber), /* observers */
    ZBUS_MSG_INIT(.x = 0, .y = 0, .z = 0) /* Initial value {0} */
);

void listener_callback_example(const struct zbus_channel *chan)
{
    const struct acc_msg *acc;

    (continues on next page)
```
if (&acc_chan == chan) {
    acc = zbus_chan_const_msg(chan); // Direct message access
    LOG_DBG("From listener -> Acc x=%d, y=%d, z=%d", acc->x, acc->y, acc->z);
} }

ZBUS_LISTENER_DEFINE(my_listener, listener_callback_example);
ZBUS_SUBSCRIBER_DEFINE(my_subscriber, 4);
void subscriber_task(void)
{
    const struct zbus_channel *chan;
    while (!zbus_sub_wait(&my_subscriber, &chan, K_FOREVER)) {
        struct acc_msg acc = {0};
        if (&acc_chan == chan) {
            // Indirect message access
            zbus_chan_read(&acc_chan, &acc, K_NO_WAIT);
            LOG_DBG("From subscriber -> Acc x=%d, y=%d, z=%d", acc.x, acc.
˓
→y, acc.z);
        }
    }
}
K_THREAD_DEFINE(subscriber_task_id, 512, subscriber_task, NULL, NULL, NULL, 3, 0, 0);

Note: It is unnecessary to claim/lock a channel before accessing the message inside the listener since the event dispatcher calls listeners with the notifying channel already locked. Subscribers, however, must claim/lock that or use regular read operations to access the message after being notified.

The following code defines and initializes a hard channel and its dependencies. Only valid messages can be published to a hard channel. It is possible because a Validator function passed to the channel's definition. In this example, only messages with move equal to 0, -1, and 1 are valid. Publish function will discard all other values to move.

struct control_msg {
    int move;
};

bool control_validator(const void* msg, size_t msg_size) {
    const struct control_msg* cm = msg;
    bool is_valid = (cm->move == -1) || (cm->move == 0) || (cm->move == 1);
    return is_valid;
}

static int message_count = 0;

ZBUS_CHAN_DEFINE(control_chan, /* Name */
    struct control_msg, /* Message type */
    control_validator, /* Validator */
    &message_count, /* User data */
    ZBUS_OBSERVERS_EMPTY, /* observers */
    ZBUS_MSG_INIT(.move = 0) /* Initial value .move=0 */)
The following sections describe in detail how to use zbus features.

**Publishing to a channel**

Messages are published to a channel in zbus by calling `zbus_chan_pub()`. For example, the following code builds on the examples above and publishes to channel `acc_chan`. The code is trying to publish the message `acc1` to channel `acc_chan`, and it will wait up to one second for the message to be published. Otherwise, the operation fails.

```c
struct acc_msg acc1 = {.x = 1, .y = 1, .z = 1};
zbus_chan_pub(&acc_chan, &acc1, K_SECONDS(1));
```

**Warning:** Do not use this function inside an ISR.

**Reading from a channel**

Messages are read from a channel in zbus by calling `zbus_chan_read()`. So, for example, the following code tries to read the channel `acc_chan`, which will wait up to 500 milliseconds to read the message. Otherwise, the operation fails.

```c
struct acc_msg acc = {0};
zbus_chan_read(&acc_chan, &acc, K_MSEC(500));
```

**Warning:** Do not use this function inside an ISR.

**Forcing channel notification**

It is possible to force zbus to notify a channel's observers by calling `zbus_chan_notify()`. For example, the following code builds on the examples above and forces a notification for the channel `acc_chan`. Note this can send events with no message, which does not require any data exchange.

```c
zbus_chan_notify(&acc_chan, K_NO_WAIT);
```

**Warning:** Do not use this function inside an ISR.

**Declaring channels and observers**

For accessing channels or observers from files other than its defining files, it is necessary to declare them by calling `ZBUS_CHAN_DECLARE` and `ZBUS_OBS_DECLARE`. It is possible to declare more than one channel or observer at the same call. The following code builds on the examples above and displays the defined channels and observers.

```c
ZBUS_OBS_DECLARE(my_listener, my_subscriber);
ZBUS_CHAN_DECLARE(acc_chan, version_chan);
```
Iterating over channels and observers

There is an iterator mechanism in zbus that enables the developer to execute some procedure per channel and observer. The sequence executed is sorted by channel or observer name.

```c
int count;

bool print_channel_data_iterator(const struct zbus_channel *chan) {
    LOG_DBG("%d - Channel %s:", count, zbus_chan_name(chan));
    LOG_DBG(" Message size: %d", zbus_chan_msg_size(chan));
    ++count;
    LOG_DBG(" Observers:");
    for (struct zbus_observer **obs = chan->observers; *obs != NULL; ++obs) {
        LOG_DBG(" - %s", zbus_obs_name(*obs));
    }
    return true;
}

bool print_observer_data_iterator(const struct zbus_observer *obs) {
    LOG_DBG("%d - %s %s", count, ((obs->queue != NULL) ? "Subscriber" : "Listener"), zbus_obs_name(obs));
    ++count;
    return true;
}

void main(void) {
    LOG_DBG("Channel list:");
    count = 0;
    zbus_iterate_over_channels(print_channel_data_iterator);

    LOG_DBG("Observers list:");
    count = 0;
    zbus_iterate_over_observers(print_observer_data_iterator);
}
```

The code will log the following output:

```
D: Channel list:
D: 0 - Channel acc_chan:
D:   Message size: 12
D:   Observers:
D:     - my_listener
D:     - my_subscriber
D: 1 - Channel version_chan:
D:   Message size: 4
D:   Observers:
D:   Observers list:
D: 0 - Listener my_listener
D: 1 - Subscriber my_subscriber
```

Advanced channel control

Zbus was designed to be as flexible and extensible as possible. Thus there are some features designed to provide some control and extensibility to the bus.
Listeners message access  

For performance purposes, listeners can access the receiving channel message directly since they already have the mutex lock for it. To access the channel's message, the listener should use the `zbus_chan_const_msg` because the channel passed as an argument to the listener function is a constant pointer to the channel. The const pointer ensures that the message will be kept unchanged during the notification process.

```c
void listener_callback_example(const struct zbus_channel *chan)
{
    const struct acc_msg *acc;
    if (&acc_chan == chan) {
        acc = zbus_chan_const_msg(chan); // Use this
        // instead of zbus_chan_read(chan, &acc, K_MSEC(200))
        // or zbus_chan_msg(chan)
        LOG_DBG("From listener -> Acc x=%d, y=%d, z=%d", acc->x, acc->y, acc->z);
    }
}
```

User Data  

There is a possibility of injecting data into the channel's metadata by passing the `user_data` pointer to the channel's definition macro. The `user_data` field enables others to access the data. Note that it needs to be set individually for each channel.

Claim and finish a channel  

To take more control over channels, two function were added `zbus_chan_claim()` and `zbus_chan_finish()`. With these functions, it is possible to access the channel's metadata safely. When a channel is claimed, no actions are available to that channel. After finishing the channel, all the actions are available again.

**Warning:** Never change the fields of the channel struct directly. It may cause zbus behavior inconsistencies and concurrency issues.

The following code builds on the examples above and claims the `acc_chan` to set the `user_data` to the channel. Suppose we would like to count how many times the channels exchange messages. We defined the `user_data` to have the 32 bits integer. This code could be added to the listener code described above.

```c
if (!zbus_chan_claim(&acc_chan, K_MSEC(200))) {
    int *message_counting = (int *) zbus_chan_user_data(acc_chan);
    *message_counting += 1;
    zbus_chan_finish(&acc_chan);
}
```

**Warning:** Do not use these functions inside an ISR.

Runtime observer registration  

It is possible to add observers to channels in runtime. This feature uses the object pool pattern technique in which the dynamic nodes are pre-allocated and can be used and recycled. Therefore, it is necessary to set the pool size by changing the feature `CONFIG_ZBUS_RUNTIME_OBSERVERS_POOL_SIZE` to enable this feature. Furthermore, it uses memory slabs. When necessary, turn on the `CONFIG_MEM_SLAB_TRACE_MAX_UTILIZATION` configuration to track the maximum usage of the pool. The following example illustrates the runtime registration usage.

```c
ZBUS_LISTENER_DEFINE(my_listener, callback);
// ...
```
void thread_entry(void) {
    // ...
    /* Adding the observer to channel chan1 */
    zbus_chan_add_obs(&chan1, &my_listener);
    /* Removing the observer from channel chan1 */
    zbus_chan_rm_obs(&chan1, &my_listener);
}

Zbus can only use a limited number of dynamic observers. The configuration option CONFIG_ZBUS_RUNTIME_OBSERVERS_POOL_SIZE represents the size of the runtime observers pool (memory slab). Change that to fit the solution needs. Use the k_mem_slab_num_used_get() to verify how many runtime observers slots are available. The function k_mem_slab_max_used_get() will provide information regarding the maximum number of used slots count reached during the execution. Use that to set the appropriate pool size avoiding waste. The following code illustrates how to use that.

extern struct k_mem_slab _zbus_runtime_obs_pool;
uint32_t slots_available = k_mem_slab_num_free_get(&_zbus_runtime_obs_pool);
uint32_t max_usage = k_mem_slab_max_used_get(&_zbus_runtime_obs_pool);

Warning: Do not use _zbus_runtime_obs_pool memory slab directly. It may lead to inconsistencies.

4.23.3 Samples

For a complete overview of zbus usage, take a look at the samples. There are the following samples available:

- zbus-hello-world-sample illustrates the code used above in action;
- zbus-work-queue-sample shows how to define and use different kinds of observers. Note there is an example of using a work queue instead of executing the listener as an execution option;
- zbus-dyn-channel-sample demonstrates how to use dynamically allocated exchanging data in zbus;
- zbus-uart-bridge-sample shows an example of sending the operation of the channel to a host via serial;
- zbus-remote-mock-sample illustrates how to implement an external mock (on the host) to send and receive messages to and from the bus.
- zbus-runtime-obs-registration-sample illustrates a way of using the runtime observer registration feature;
- zbus-benchmark-sample implements a benchmark with different combinations of inputs.

4.23.4 Suggested Uses

Use zbus to transfer data (messages) between threads in one-to-one, one-to-many, and many-to-many synchronously or asynchronously.

Note: Zbus can be used to transfer streams from the producer to the consumer. However, this can increase zbus' communication latency. So maybe consider a Pipe a good alternative for this communication topology.
4.23.5 Configuration Options

For enabling zbus, it is necessary to enable the CONFIG_ZBUS option.

Related configuration options:
- CONFIG_ZBUS_CHANNEL_NAME
- CONFIG_ZBUS_OBSERVER_NAME
- CONFIG_ZBUS_STRUCTS_ITERABLE_ACCESS
- CONFIG_ZBUS_RUNTIME_OBSERVERS_POOL_SIZE

4.23.6 API Reference

```group zbus_apis
Zbus API.

Defines

ZBUS_OBS_DECLARE(....)
This macro list the observers to be used in a file. Internally, it declares the observers with the extern statement. Note it is only necessary when the observers are declared outside the file.

ZBUS_CHAN_DECLARE(....)
This macro list the channels to be used in a file. Internally, it declares the channels with the extern statement. Note it is only necessary when the channels are declared outside the file.

ZBUS_OBSERVERS_EMPTY
This macro indicates the channel has no observers.

ZBUS_OBSERVERS(....)
This macro indicates the channel has listed observers. Note the sequence of observer notification will follow the same as listed.

ZBUS_CHAN_DEFINE(_name, _type, _validator, _user_data, _observers, _init_val)
Zbus channel definition.
This macro defines a channel.

See also:

struct zbus_channel

Parameters

- _name – The channel's name.
- _type – The Message type. It must be a struct or union.
- _validator – The validator function.
- _user_data – A pointer to the user data.
- _observers – The observers list. The sequence indicates the priority of the observer. The first the highest priority.
- _init_val – The message initialization.
ZBUS_MSG_INIT(_val, ...)  
Initialize a message.  
This macro initializes a message by passing the values to initialize the message struct or union.  

Parameters  
• _val – [in] Variadic with the initial values. ZBUS_INIT(0) means {0}, as ZBUS_INIT(a=10, b=30) means {a=10, b=30}.  

ZBUS_SUBSCRIBER_DEFINE(_name, _queue_size)  
Define and initialize a subscriber.  
This macro defines an observer of subscriber type. It defines a message queue where the subscriber will receive the notification asynchronously, and initialize the struct zbus_observer defining the subscriber.  

Parameters  
• _name – [in] The subscriber’s name.  
• _queue_size – [in] The notification queue’s size.  

ZBUS_LISTENER_DEFINE(_name, _cb)  
Define and initialize a listener.  
This macro defines an observer of listener type. This macro establishes the callback where the listener will be notified synchronously, and initialize the struct zbus_observer defining the listener.  

Parameters  
• _name – [in] The listener's name.  

Functions  

int zbus_chan_pub(const struct zbus_channel *chan, const void *msg, k_timeout_t timeout)  
Publish to a channel.  
This routine publishes a message to a channel.  

Parameters  
• chan – The channel’s reference.  
• msg – Reference to the message where the publish function copies the channel’s message data from.  
• timeout – Waiting period to publish the channel, or one of the special values K_NO_WAIT and K_FOREVER.  

Return values  
• 0 – Channel published.  
• -ENOMEMSG – The message is invalid based on the validator function or some of the observers could not receive the notification.  
• -EBUSY – The channel is busy.  
• -EAGAIN – Waiting period timed out.  
• -EFAULT – A parameter is incorrect, the notification could not be sent to one or more observer, or the function context is invalid (inside an ISR). The function only returns this value when the CONFIG_ZBUS_ASSERT_MOCK is enabled.
int zbus_chan_read(const struct zbus_channel *chan, void *msg, k_timeout_t timeout)

Read a channel.

This routine reads a message from a channel.

**Parameters**

- **msg** – [out] Reference to the message where the read function copies the channel's message data to.
- **timeout** – [in] Waiting period to read the channel, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**

- **0** – Channel read.
- **-EBUSY** – The channel is busy.
- **-EAGAIN** – Waiting period timed out.
- **-EFAULT** – A parameter is incorrect, or the function context is invalid (inside an ISR). The function only returns this value when the CONFIG_ZBUS_ASSERT_MOCK is enabled.

int zbus_chan_claim(const struct zbus_channel *chan, k_timeout_t timeout)

Claim a channel.

This routine claims a channel. During the claiming period the channel is blocked for publishing, reading, notifying or claiming again. Finishing is the only available action.

**Warning:** After calling this routine, the channel cannot be used by other thread until the zbus_chan_finish routine is performed.

**Warning:** This routine should only be called once before a zbus_chan_finish.

**Parameters**

- **timeout** – [in] Waiting period to claim the channel, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**

- **0** – Channel claimed.
- **-EBUSY** – The channel is busy.
- **-EAGAIN** – Waiting period timed out.
- **-EFAULT** – A parameter is incorrect, or the function context is invalid (inside an ISR). The function only returns this value when the CONFIG_ZBUS_ASSERT_MOCK is enabled.

int zbus_chan_finish(const struct zbus_channel *chan)

Finish a channel claim.

This routine finishes a channel claim. After calling this routine with success, the channel will be able to be used by other thread.
Warning: This routine must only be used after a zbus_chan_claim.

Parameters
- chan – The channel's reference.

Return values
- 0 – Channel finished.
- -EPERM – The channel was claimed by other thread.
- -EINVAL – The channel's mutex is not locked.
- -EFAULT – A parameter is incorrect, or the function context is invalid (inside an ISR). The function only returns this value when the CONFIG_ZBUS_ASSERT_MOCK is enabled.

int zbus_chan_notify(const struct zbus_channel *chan, k_timeout_t timeout)

Force a channel notification.

This routine forces the event dispatcher to notify the channel's observers even if the message has no changes. Note this function could be useful after claiming/finishing actions.

Parameters
- chan – The channel's reference.
- timeout – Waiting period to notify the channel, or one of the special values K_NO_WAIT and K_FOREVER.

Return values
- 0 – Channel notified.
- -EPERM – The current thread does not own the channel.
- -EBUSY – The channel's mutex returned without waiting.
- -EAGAIN – Timeout to acquiring the channel's mutex.
- -EFAULT – A parameter is incorrect, the notification could not be sent to one or more observer, or the function context is invalid (inside an ISR). The function only returns this value when the CONFIG_ZBUS_ASSERT_MOCK is enabled.

static inline const char *zbus_chan_name(const struct zbus_channel *chan)

Get the channel's name.

This routine returns the channel's name reference.

Parameters
- chan – The channel's reference.

Returns
Channel's name reference.

static inline void *zbus_chan_msg(const struct zbus_channel *chan)

Get the reference for a channel message directly.

This routine returns the reference of a channel message.

Warning: This function must only be used directly for acquired (locked by mutex) channels. This can be done inside a listener for the receiving channel or after claim a channel.

Parameters
static inline const void *zbus_chan_const_msg(const struct zbus_channel *chan)

Get a constant reference for a channel message directly.

This routine returns a constant reference of a channel message. This should be used inside
listeners to access the message directly. In this way zbus prevents the listener of changing the
notifying channel's message during the notification process.

**Warning:** This function must only be used directly for acquired (locked by mutex) chan-
nels. This can be done inside a listener for the receiving channel or after claim a channel.

Parameters

- chan – The channel's constant reference.

Returns

A constant channel's message reference.

static inline uint16_t zbus_chan_msg_size(const struct zbus_channel *chan)

Get the channel's message size.

This routine returns the channel's message size.

Parameters

- chan – The channel's reference.

Returns

Channel's message size.

static inline void *zbus_chan_user_data(const struct zbus_channel *chan)

Get the channel's user data.

This routine returns the channel's user data.

Parameters

- chan – The channel's reference.

Returns

Channel's user data.

int zbus_chan_add_obs(const struct zbus_channel *chan, const struct zbus_observer *obs,
                       k_timeout_t timeout)

Add an observer to a channel.

This routine adds an observer to the channel.

Parameters

- chan – The channel's reference.
- obs – The observer's reference to be added.
- timeout – Waiting period to add an observer, or one of the special values
  K_NO_WAIT and K_FOREVER.

Return values

- 0 – Observer added to the channel.
- -EALREADY – The observer is already present in the channel's runtime observers list.
• -ENOMEM – Returned without waiting.
• -EAGAIN – Waiting period timed out.
• -EINVAL – Some parameter is invalid.

int zbus_chan_rm_obs(const struct zbus_channel *chan, const struct zbus_observer *obs,
                      k_timeout_t timeout)

Remove an observer from a channel.

This routine removes an observer to the channel.

Parameters

• chan – The channel’s reference.
• obs – The observer’s reference to be removed.
• timeout – Waiting period to remove an observer, or one of the special values
  K_NO_WAIT and K_FOREVER.

Return values

• 0 – Observer removed to the channel.
• -EINVAL – Invalid data supplied.
• -EBUSY – Returned without waiting.
• -EAGAIN – Waiting period timed out.
• -ENODATA – no observer found in channel’s runtime observer list.
• -ENOMEM – Returned without waiting.

struct k_mem_slab *zbus_runtime_obs_pool(void)

Get zbus runtime observers pool.

This routine returns a reference of the runtime observers pool.

Returns

Reference of runtime observers pool.

static inline int zbus_obs_set_enable(struct zbus_observer *obs, bool enabled)

Change the observer state.

This routine changes the observer state. A channel when disabled will not receive notifications
from the event dispatcher.

Parameters

• enabled – [in] State to be. When false the observer stops to receive notifica-
  tions.

Return values

• 0 – Observer set enable.
• -EFAULT – A parameter is incorrect, or the function context is invalid
  (inside an ISR). The function only returns this value when the CONFIG_ZBUS_ASSERT_MOCK is enabled.

static inline const char *zbus_obs_name(const struct zbus_observer *obs)

Get the observer’s name.

This routine returns the observer’s name reference.

Parameters

• obs – The observer’s reference.
**Returns**
The observer's name reference.

```c
int zbus_sub_wait(const struct zbus_observer *sub, const struct zbus_channel **chan, k_timeout_t timeout)
```
Wait for a channel notification.

This routine makes the subscriber to wait a notification. The notification comes as a channel reference.

**Parameters**
- **chan** – [out] The notification channel's reference.
- **timeout** – [in] Waiting period for a notification arrival, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**
- **0** – Notification received.
- **-ENOMSG** – Returned without waiting.
- **-EAGAIN** – Waiting period timed out.
- **-EINVAL** – The observer is not a subscriber.
- **-EFAULT** – A parameter is incorrect, or the function context is invalid (inside an ISR). The function only returns this value when the CONFIG_ZBUS_ASSERT_MOCK is enabled.

```c
bool zbus_iterate_over_channels(bool (*iterator_func)(const struct zbus_channel *chan))
```
Iterate over channels.

Enables the developer to iterate over the channels giving to this function an iterator_func which is called for each channel. If the iterator_func returns false all the iteration stops.

**Return values**
- **true** – Iterator executed for all channels.
- **false** – Iterator could not be executed. Some iterate returned false.

```c
bool zbus_iterate_over_observers(bool (*iterator_func)(const struct zbus_observer *obs))
```
Iterate over observers.

Enables the developer to iterate over the observers giving to this function an iterator_func which is called for each observer. If the iterator_func returns false all the iteration stops.

**Return values**
- **true** – Iterator executed for all channels.
- **false** – Iterator could not be executed. Some iterate returned false.

```c
struct zbus_channel
```

```
#include <zbus.h>
```

Type used to represent a channel.

Every channel has a `zbus_channel` structure associated used to control the channel access and usage.

**Public Members**
const char *const name
    Channel name.

const uint16_t message_size
    Message size. Represents the channel's message size.

void *const user_data
    User data available to extend zbus features. The channel must be claimed before using
    this field.

void *const message
    Message reference. Represents the message's reference that points to the actual shared
    memory region.

bool (*const validator)(const void *msg, size_t msg_size)
    Message validator. Stores the reference to the function to check the message validity
    before actually performing the publishing. No invalid messages can be published. Every
    message is valid when this field is empty.

struct k_mutex *mutex
    Access control mutex. Points to the mutex used to avoid race conditions for accessing the
    channel.

sys_slist_t *runtime_observers
    Dynamic channel observer list. Represents the channel's observers list, it can be empty or
    have listeners and subscribers mixed in any sequence. It can be changed in runtime.

const struct zbus_observer *const *observers
    Channel observer list. Represents the channel's observers list, it can be empty or have
    listeners and subscribers mixed in any sequence.

struct zbus_observer
    
    #include <zbus.h> Type used to represent an observer.

    Every observer has an representation structure containing the relevant information. An ob-
    server is a code portion interested in some channel. The observer can be notified syn-
    chronously or asynchronously and it is called listener and subscriber respectively. The ob-
    server can be enabled or disabled during runtime by change the enabled boolean field of the
    structure. The listeners have a callback function that is executed by the bus with the index
    of the changed channel as argument when the notification is sent. The subscribers have a
    message queue where the bus enqueues the index of the changed channel when a notification
    is sent.

    See also:
    
    zbus_obs_set_enable function to properly change the observer's enabled field.

Public Members

const char *const name
    Observer name.
```c
bool enabled
   Enabled flag. Indicates if observer is receiving notification.

struct k_msgq *const queue
   Observer message queue. It turns the observer into a subscriber.

void (*const callback)(const struct zbus_channel *chan)
   Observer callback function. It turns the observer into a listener.
```

## 4.24 Miscellaneous

### 4.24.1 Checksum APIs

**CRC**

```c

group crc

Enums

enum crc_type
   CRC algorithm enumeration.
   These values should be used with the CRC dispatch function.
   Values:

enumerator CRC7_BE
   Use `crc7_be`

enumerator CRC8
   Use `crc8`

enumerator CRC8_CCITT
   Use `crc8_ccitt`

enumerator CRC16
   Use `crc16`

enumerator CRC16_ANSI
   Use `crc16_ansi`

enumerator CRC16_CCITT
   Use `crc16_ccitt`

enumerator CRC16_ITU_T
   Use `crc16_itu_t`
```
enumerator CRC32_C
   Use \texttt{crc32_c}

enumerator CRC32_IEEE
   Use \texttt{crc32_ieee}

Functions

\begin{verbatim}
uint16_t crc16(uint16_t poly, uint16_t seed, const uint8_t *src, size_t len)
\end{verbatim}
Generic function for computing a CRC-16 without input or output reflection.
Compute CRC-16 by passing in the address of the input, the input length and polynomial used in addition to the initial value. This is $O(n \cdot 8)$ where $n$ is the length of the buffer provided. No reflection is performed.

\textbf{Note:} If you are planning to use a CRC based on poly \texttt{0x1012} the functions \texttt{crc16_itu_t()} is faster and thus recommended over this one.

\begin{itemize}
\item \texttt{poly} – The polynomial to use omitting the leading $x^{16}$ coefficient
\item \texttt{seed} – Initial value for the CRC computation
\item \texttt{src} – Input bytes for the computation
\item \texttt{len} – Length of the input in bytes
\end{itemize}

Returns
The computed CRC16 value (without any XOR applied to it)

\begin{verbatim}
uint16_t crc16_reflect(uint16_t poly, uint16_t seed, const uint8_t *src, size_t len)
\end{verbatim}
Generic function for computing a CRC-16 with input and output reflection.
Compute CRC-16 by passing in the address of the input, the input length and polynomial used in addition to the initial value. This is $O(n \cdot 8)$ where $n$ is the length of the buffer provided. Both input and output are reflected.

The following checksums can, among others, be calculated by this function, depending on the value provided for the initial seed and the value the final calculated CRC is XORed with:

\begin{itemize}
\item CRC-16/ANSI, CRC-16/MODBUS, CRC-16/USB, CRC-16/IBM \url{https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-modbus} \texttt{poly: 0x8005 (0xA001)}
   \texttt{initial seed: 0xffff, xor output: 0x0000}
\end{itemize}

\textbf{Note:} If you are planning to use a CRC based on poly \texttt{0x1012} the function \texttt{crc16_ccitt()} is faster and thus recommended over this one.

\begin{itemize}
\item \texttt{poly} – The polynomial to use omitting the leading $x^{16}$ coefficient. Important: please reflect the poly. For example, use \texttt{0xA001} instead of \texttt{0x8005} for CRC-16-MODBUS.
\item \texttt{seed} – Initial value for the CRC computation
\end{itemize}
• src – Input bytes for the computation
• len – Length of the input in bytes

Returns
The computed CRC16 value (without any XOR applied to it)

uint8_t crc8(const uint8_t *src, size_t len, uint8_t polynomial, uint8_t initial_value, bool reversed)

Generic function for computing CRC 8.
Compute CRC 8 by passing in the address of the input, the input length and polynomial used in addition to the initial value.

Parameters
• src – Input bytes for the computation
• len – Length of the input in bytes
• polynomial – The polynomial to use omitting the leading x^8 coefficient
• initial_value – Initial value for the CRC computation
• reversed – Should we use reflected/reversed values or not

Returns
The computed CRC8 value

uint16_t crc16_ccitt(uint16_t seed, const uint8_t *src, size_t len)

Compute the checksum of a buffer with polynomial 0x1021, reflecting input and output.
This function is able to calculate any CRC that uses 0x1021 as its polynomial and requires reflecting both the input and the output. It is a fast variant that runs in O(n) time, where n is the length of the input buffer.

The following checksums can, among others, be calculated by this function, depending on the value provided for the initial seed and the value the final calculated CRC is XORed with:

• CRC-16/CCITT, CRC-16/CCITT-TRUE, CRC-16/KERMIT https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-kermit initial seed: 0x0000, xor output: 0x0000

Note: To calculate the CRC across non-contiguous blocks use the return value from block N-1 as the seed for block N.
uint16_t crc16_itu_t(uint16_t seed, const uint8_t *src, size_t len)

Compute the checksum of a buffer with polynomial 0x1021, no reflection of input or output.

This function is able to calculate any CRC that uses 0x1021 as its polynomial and requires no reflection on both the input and the output. It is a fast variant that runs in \( O(n) \) time, where \( n \) is the length of the input buffer.

The following checksums can, among others, be calculated by this function, depending on the value provided for the initial seed and the value the final calculated CRC is XORed with:

- CRC-16/XMODEM, CRC-16/ACORN, CRC-16/LTE https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-xmodem initial seed: 0x0000, xor output: 0x0000
- CRC16/CCITT-FALSE, CRC-16/IBM-3740, CRC-16/AUTOSAR https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-ibm-3740 initial seed: 0xffff, xor output: 0x0000
- CRC-16/GSM https://reveng.sourceforge.io/crc-catalogue/16.htm#crc.cat.crc-16-gsm initial seed: 0x0000, xor output: 0xffff

Note: To calculate the CRC across non-contiguous blocks use the return value from block N-1 as the seed for block N.

Parameters
- seed – Value to seed the CRC with
- src – Input bytes for the computation
- len – Length of the input in bytes

Returns
The computed CRC16 value (without any XOR applied to it)

static inline uint16_t crc16_ansi(const uint8_t *src, size_t len)

Compute the ANSI (or Modbus) variant of CRC-16.

The ANSI variant of CRC-16 uses 0x8005 (0xA001 reflected) as its polynomial with the initial * value set to 0xffff.

Parameters
- src – Input bytes for the computation
- len – Length of the input in bytes

Returns
The computed CRC16 value

uint32_t crc32_ieee(const uint8_t *data, size_t len)

Generate IEEE conform CRC32 checksum.

Parameters
- *data – Pointer to data on which the CRC should be calculated.
- len – Data length.

Returns
CRC32 value.

```c
uint32_t crc32_ieee_update(uint32_t crc, const uint8_t *data, size_t len)
Update an IEEE conforming CRC32 checksum.

Parameters
• crc – CRC32 checksum that needs to be updated.
• *data – Pointer to data on which the CRC should be calculated.
• len – Data length.

Returns
CRC32 value.
```

```c
uint32_t crc32_c(uint32_t crc, const uint8_t *data, size_t len, bool first_pkt, bool last_pkt)
Calculate CRC32C (Castagnoli) checksum.

Parameters
• crc – CRC32C checksum that needs to be updated.
• *data – Pointer to data on which the CRC should be calculated.
• len – Data length.
• first_pkt – Whether this is the first packet in the stream.
• last_pkt – Whether this is the last packet in the stream.

Returns
CRC32 value.
```

```c
uint8_t crc8_ccitt(uint8_t initial_value, const void *buf, size_t len)
Compute CCITT variant of CRC 8.
Normal CCITT variant of CRC 8 is using 0x07.

Parameters
• initial_value – Initial value for the CRC computation
• buf – Input bytes for the computation
• len – Length of the input in bytes

Returns
The computed CRC8 value
```

```c
uint8_t crc7_be(uint8_t seed, const uint8_t *src, size_t len)
Compute the CRC-7 checksum of a buffer.
See JESD84-A441. Used by the MMC protocol. Uses 0x09 as the polynomial with no reflection. The CRC is left justified, so bit 7 of the result is bit 6 of the CRC.

Parameters
• seed – Value to seed the CRC with
• src – Input bytes for the computation
• len – Length of the input in bytes

Returns
The computed CRC7 value
```

```c
static inline uint32_t crc_by_type(enum crc_type type, const uint8_t *src, size_t len, uint32_t seed, uint32_t poly, bool reflect, bool first, bool last)
Compute a CRC checksum, in a generic way.
This is a dispatch function that calls the individual CRC routine determined by type.
```
For 7, 8, and 16-bit CRCs, the relevant seed and poly values should be passed in via the least-significant byte(s).

Similarly, for 7, 8, and 16-bit CRCs, the relevant result is stored in the least-significant byte(s) of the returned value.

**Parameters**

- **type** – CRC algorithm to use.
- **src** – Input bytes for the computation
- **len** – Length of the input in bytes
- **seed** – Value to seed the CRC with
- **poly** – The polynomial to use omitting the leading coefficient
- **reflect** – Should we use reflected/reversed values or not
- **first** – Whether this is the first packet in the stream.
- **last** – Whether this is the last packet in the stream.

**Returns**

`uint32_t` the computed CRC value

### 4.24.2 Structured Data APIs

**JSON**

**group** `json`

**Defines**

```c
JSON_OBJ_DESCR_PRIM(struct_, field_name_, type_)
```

Helper macro to declare a descriptor for supported primitive values.

Here's an example of use:

```c
struct foo {
    int some_int;
};

struct json_obj_descr foo[] = {
    JSON_OBJ_DESCR_PRIM(struct foo, some_int, JSON_TOK_NUMBER),
};
```

**Parameters**

- **struct_** – Struct packing the values
- **field_name_** – Field name in the struct
- **type_** – Token type for JSON value corresponding to a primitive type. Must be one of: `JSON_TOK_STRING` for strings, `JSON_TOK_NUMBER` for numbers, `JSON_TOK_TRUE` (or `JSON_TOK_FALSE`) for booleans.
**JSON_OBJ_DESCR_OBJECT**

```c
JSON_OBJ_DESCR_OBJECT(struct_, field_name_, sub_descr_)
```

Helper macro to declare a descriptor for an object value.

Here's an example of use:

```c
struct nested {
    int foo;
    struct {
        int baz;
    } bar;
};
```

```c
struct json_obj_descr nested_bar[] = {
    { ... declare bar.baz descriptor ... },
};
```

```c
struct json_obj_descr nested[] = {
    { ... declare foo descriptor ... },
    JSON_OBJ_DESCR_OBJECT(struct nested, bar, nested_bar),
};
```

**Parameters**

- `struct_` – Struct packing the values
- `field_name_` – Field name in the struct
- `sub_descr_` – Array of `json_obj_descr` describing the subobject

**JSON_OBJ_DESCR_ARRAY**

```c
JSON_OBJ_DESCR_ARRAY(struct_, field_name_, max_len_, len_field_, elem_type_)
```

Helper macro to declare a descriptor for an array of primitives.

Here's an example of use:

```c
struct example {
    int foo[10];
    size_t foo_len;
};
```

```c
struct json_obj_descr array[] = {
    JSON_OBJ_DESCR_ARRAY(struct example, foo, 10, foo_len,
                          JSON_TOK_NUMBER)
};
```

**Parameters**

- `struct_` – Struct packing the values
- `field_name_` – Field name in the struct
- `max_len_` – Maximum number of elements in array
- `len_field_` – Field name in the struct for the number of elements in the array
- `elem_type_` – Element type, must be a primitive type

**JSON_OBJ_DESCR_OBJ_ARRAY**

```c
JSON_OBJ_DESCR_OBJ_ARRAY(struct_, field_name_, max_len_, len_field_, elem_descr_,
                          elem_descr_len_)
```

Helper macro to declare a descriptor for an array of objects.
Here's an example of use:

```c
struct person_height {
    const char *name;
    int height;
};

struct people_heights {
    struct person_height heights[10];
    size_t heights_len;
};

struct json_obj_descr person_height_descr[] = {
    JSON_OBJ_DESCR_PRIM(struct person_height, name, JSON_TOK_STRING),
    JSON_OBJ_DESCR_PRIM(struct person_height, height, JSON_TOK_NUMBER),
};

struct json_obj_descr array[] = {
    JSON_OBJ_DESCR_OBJ_ARRAY(struct people_heights, heights, 10,
                              heights_len, person_height_descr,
                              ARRAY_SIZE(person_height_descr)),
};
```

Parameters

- `struct_` – Struct packing the values
- `field_name_` – Field name in the struct containing the array
- `max_len_` – Maximum number of elements in the array
- `len_field_` – Field name in the struct for the number of elements in the array
- `elem_descr_` – Element descriptor, pointer to a descriptor array
- `elem descr_len_` – Number of elements in elem descr_

`JSON_OBJ_DESCR_ARRAY_ARRAY(struct_, field_name_, max_len_, len_field_, elem descr_,
                             elem descr_len_)`

Helper macro to declare a descriptor for an array of array.

Here's an example of use:

```c
struct person_height {
    const char *name;
    int height;
};

struct person_heights_array {
    struct person_height heights;
}

struct people_heights {
    struct person_heights_array heights[10];
    size_t heights_len;
};
```

(continues on next page)
struct json_obj_descr person_height_descr[] = {
    JSON_OBJ_DESCR_PRIM(struct person_height, name, JSON_TOK_STRING),
    JSON_OBJ_DESCR_PRIM(struct person_height, height, JSON_TOK_NUMBER),
};

struct json_obj_descr person_height_array_descr[] = {
    JSON_OBJ_DESCR_OBJECT(struct person_heights_array,
                            heights, person_height_descr),
};

struct json_obj_descr array_array[] = {
    JSON_OBJ_DESCR_ARRAY_ARRAY(struct people_heights, heights, 10,
                                heights_len, person_height_array_descr,
                                ARRAY_SIZE(person_height_array_descr)),
};

**Parameters**

- struct - Struct packing the values
- field_name - Field name in the struct containing the array
- max_len - Maximum number of elements in the array
- len_field - Field name in the struct for the number of elements in the array
- elem_descr - Element descriptor, pointer to a descriptor array
- elem_descr_len - Number of elements in elem_descr

`JSON_OBJ_DESCR_PRIM_NAMED(struct_, json_field_name_, struct_field_name_, type_)`

Variant of `JSON_OBJ_DESCR_PRIM` that can be used when the structure and JSON field names differ.

This is useful when the JSON field is not a valid C identifier.

**See also:**

`JSON_OBJ_DESCR_PRIM`

**Parameters**

- struct - Struct packing the values.
- json_field_name - String, field name in JSON strings
- struct_field_name - Field name in the struct
- type - Token type for JSON value corresponding to a primitive type.

`JSON_OBJ_DESCR_OBJECT_NAMED(struct_, json_field_name_, struct_field_name_, sub_descr_)`

Variant of `JSON_OBJ_DESCR_OBJECT` that can be used when the structure and JSON field names differ.

This is useful when the JSON field is not a valid C identifier.

**See also:**

`JSON_OBJ_DESCR_OBJECT`
• **struct_** – Struct packing the values
• **json_field_name_** – String, field name in JSON strings
• **struct_field_name_** – Field name in the struct
• **sub_descr_** – Array of `json_obj_descr` describing the subobject

```c
JSON_OBJ_DESCR_ARRAY_NAMED(struct_, json_field_name_, struct_field_name_, max_len_,
     len_field_, elem_type_)
```

Variant of `JSON_OBJ_DESCR_ARRAY` that can be used when the structure and JSON field names differ.

This is useful when the JSON field is not a valid C identifier.

**See also:**

`JSON_OBJ_DESCR_ARRAY`

**Parameters**

• **struct_** – Struct packing the values
• **json_field_name_** – String, field name in JSON strings
• **struct_field_name_** – Field name in the struct
• **max_len_** – Maximum number of elements in array
• **len_field_** – Field name in the struct for the number of elements in the array
• **elem_type_** – Element type, must be a primitive type

```c
JSON_OBJ_DESCR_OBJ_ARRAY_NAMED(struct_, json_field_name_, struct_field_name_, max_len_,
     len_field_, elem_descr_, elem_descr_len_)
```

Variant of `JSON_OBJ_DESCR_OBJ_ARRAY` that can be used when the structure and JSON field names differ.

This is useful when the JSON field is not a valid C identifier.

Here's an example of use:

```c
struct person_height {
    const char *name;
    int height;
};

struct people_heights {
    struct person_height heights[10];
    size_t heights_len;
};

struct json_obj_descr person_height_descr[] = {
    JSON_OBJ_DESCR_PRIM(struct person_height, name, JSON_TOK_STRING),
    JSON_OBJ_DESCR_PRIM(struct person_height, height, JSON_TOK_NUMBER),
};

struct json_obj_descr array[] = {
    JSON_OBJ_DESCR_OBJ_ARRAY_NAMED(struct people_heights, 
        "people-heights", heights, 10, heights_len,
    )
};
```

(continues on next page)
Parameters

- `struct_` – Struct packing the values
- `json_field_name_` – String, field name of the array in JSON strings
- `struct_field_name_` – Field name in the struct containing the array
- `max_len_` – Maximum number of elements in the array
- `len_field_` – Field name in the struct for the number of elements in the array
- `elem_descr_` – Element descriptor, pointer to a descriptor array
- `elem_descr_len_` – Number of elements in `elem descr_`

Typedefs

typedef int (*json_append_bytes_t)(const char *bytes, size_t len, void *data)
Function pointer type to append bytes to a buffer while encoding JSON data.

**Param bytes**
Contents to write to the output

**Param len**
Number of bytes to append to output

**Param data**
User-provided pointer

**Return**
This callback function should return a negative number on error (which will be propagated to the return value of `json_objEncode()`), or 0 on success.

Enums

enum json_tokens

**Values:**

- enumerator `JSON_TOK_NONE` = '\''
- enumerator `JSON_TOK_OBJECT_START` = '{'
- enumerator `JSON_TOK_OBJECT_END` = '}'
- enumerator `JSON_TOK_LIST_START` = '['
- enumerator `JSON_TOK_ARRAY_START` = '['
- enumerator `JSON_TOK_LIST_END` = ']'

(continued from previous page)
Functions

```c
int json_obj_parse(char *json, size_t len, const struct json_obj_descr *descr, size_t descr_len, void *val)
```

Parses the JSON-encoded object pointed to by `json`, with size `len`, according to the descriptor pointed to by `descr`. Values are stored in a struct pointed to by `val`. Set up the descriptor like this:

```c
struct s { int foo; char *bar; } struct json_obj_descr descr[] = { JSON_OBJ_DESCR_PRIM(struct s, foo, JSON_TOK_NUMBER), JSON_OBJ_DESCR_PRIM(struct s, bar, JSON_TOK_STRING), };
```

Since this parser is designed for machine-to-machine communications, some liberties were taken to simplify the design: (1) strings are not unescaped (but only valid escape sequences are accepted); (2) no UTF-8 validation is performed; and (3) only integer numbers are supported (no `strtod()` in the minimal libc).

**Parameters**

- `json` – Pointer to JSON-encoded value to be parsed
- `len` – Length of JSON-encoded value
- `descr` – Pointer to the descriptor array
- `descr_len` – Number of elements in the descriptor array. Must be less than 31 due to implementation detail reasons (if more fields are necessary, use two descriptors)
• **val** – Pointer to the struct to hold the decoded values

**Returns**

< 0 if error, bitmap of decoded fields on success (bit 0 is set if first field in the descriptor has been properly decoded, etc).

```c
int json_arr_parse(char *json, size_t len, const struct json_obj_descr *descr, void *val)
```
Parses the JSON-encoded array pointed to by `json`, with size `len`, according to the descriptor pointed to by `descr`. Values are stored in a struct pointed to by `val`. Set up the descriptor like this:

```c
struct s { int foo; char *bar; } struct json_obj_descr descr[] = {
  JSON_OBJ_DESCR_PRIM(struct s, foo, JSON_TOK_NUMBER),
  JSON_OBJ_DESCR_PRIM(struct s, bar, JSON_TOK_STRING),
};
```

Since this parser is designed for machine-to-machine communications, some liberties were taken to simplify the design: (1) strings are not unescaped (but only valid escape sequences are accepted); (2) no UTF-8 validation is performed; and (3) only integer numbers are supported (no `strtod()` in the minimal libc).

**Parameters**

• `json` – Pointer to JSON-encoded array to be parsed
• `len` – Length of JSON-encoded array
• `descr` – Pointer to the descriptor array
• `val` – Pointer to the struct to hold the decoded values

**Returns**

0 if array has been successfully parsed. A negative value indicates an error (as defined on `errno.h`).

```c
int json_arr_separate_object_parse_init(struct json_obj *json, char *payload, size_t len)
```
Initialize single-object array parsing.

JSON-encoded array data is going to be parsed one object at a time. Data is provided by `payload` with the size of `len` bytes.

Function validate that Json Array start is detected and initialize `json` object for Json object parsing separately.

**Parameters**

• `json` – Provide storage for parser states. To be used when parsing the array.
• `payload` – Pointer to JSON-encoded array to be parsed
• `len` – Length of JSON-encoded array

**Returns**

0 if array start is detected and initialization is successful or negative error code in case of failure.

```c
int json_arr_separate_parse_object(struct json_obj *json, const struct json_obj_descr *descr, size_t descr_len, void *val)
```
Parse a single object from array.

Parses the JSON-encoded object pointed to by `json` object array, with size `len`, according to the descriptor pointed to by `descr`.

**Parameters**

• `json` – Pointer to JSON-object message state
• `descr` – Pointer to the descriptor array
• descr_len – Number of elements in the descriptor array. Must be less than 31.
• val – Pointer to the struct to hold the decoded values

Returns
< 0 if error, 0 for end of message, bitmap of decoded fields on success (bit 0 is set if first field in the descriptor has been properly decoded, etc).

ssize_t json_escape(char *str, size_t *len, size_t buf_size)
Escapes the string so it can be used to encode JSON objects.

Parameters
• str – The string to escape; the escape string is stored the buffer pointed to by this parameter
• len – Points to a size_t containing the size before and after the escaping process
• buf_size – The size of buffer str points to

Returns
0 if string has been escaped properly, or -ENOMEM if there was not enough space to escape the buffer

size_t json_calc_escaped_len(const char *str, size_t len)
Calculates the JSON-escaped string length.

Parameters
• str – The string to analyze
• len – String size

Returns
The length str would have if it were escaped

ssize_t json_calc_encoded_len(const struct json_obj_descr *descr, size_t descr_len, const void *val)
Calculates the string length to fully encode an object.

Parameters
• descr – Pointer to the descriptor array
• descr_len – Number of elements in the descriptor array
• val – Struct holding the values

Returns
Number of bytes necessary to encode the values if >0, an error code is returned.

int json_obj_encode_buf(const struct json_obj_descr *descr, size_t descr_len, const void *val, char *buffer, size_t buf_size)
Encodes an object in a contiguous memory location.

Parameters
• descr – Pointer to the descriptor array
• descr_len – Number of elements in the descriptor array
• val – Struct holding the values
• buffer – Buffer to store the JSON data
• buf_size – Size of buffer, in bytes, with space for the terminating NUL character

Returns
0 if object has been successfully encoded. A negative value indicates an error (as defined on errno.h).
int json_arr_encode_buf(const struct json_obj_descr *descr, const void *val, char *buffer, size_t buf_size)

Encodes an array in a contiguous memory location.

**Parameters**

- **descr** – Pointer to the descriptor array
- **val** – Struct holding the values
- **buffer** – Buffer to store the JSON data
- **buf_size** – Size of buffer, in bytes, with space for the terminating NUL character

**Returns**

0 if object has been successfully encoded. A negative value indicates an error (as defined on errno.h).

int json_obj_encode(const struct json_obj_descr *descr, size_t descr_len, const void *val, json_append_bytes_t append_bytes, void *data)

Encodes an object using an arbitrary writer function.

**Parameters**

- **descr** – Pointer to the descriptor array
- **descr_len** – Number of elements in the descriptor array
- **val** – Struct holding the values
- **append_bytes** – Function to append bytes to the output
- **data** – Data pointer to be passed to the append_bytes callback function.

**Returns**

0 if object has been successfully encoded. A negative value indicates an error.

int json_arr_encode(const struct json_obj_descr *descr, const void *val, json_append_bytes_t append_bytes, void *data)

Encodes an array using an arbitrary writer function.

**Parameters**

- **descr** – Pointer to the descriptor array
- **val** – Struct holding the values
- **append_bytes** – Function to append bytes to the output
- **data** – Data pointer to be passed to the append_bytes callback function.

**Returns**

0 if object has been successfully encoded. A negative value indicates an error.

struct json_token

#include <json.h>

struct json_lexer

#include <json.h>

struct json_obj

#include <json.h>
JSON Web Tokens (JWT) are an open, industry standard [RFC 7519](https://tools.ietf.org/html/rfc7519) method for representing claims securely between two parties. Although JWT is fairly flexible, this API is limited to creating the simplistic tokens needed to authenticate with the Google Core IoT infrastructure.

**group jwt**

JSON Web Token (JWT)

**Functions**

```c
int jwt_init_builder(struct jwt_builder *builder, char *buffer, size_t buffer_size)
```

Initialize the JWT builder.

Initialize the given JWT builder for the creation of a fresh token. The buffer size should at least be as long as JWT_BUILDER_MAX_SIZE returns.

**Parameters**

- `builder` – The builder to initialize.
- `buffer` – The buffer to write the token to.
- `buffer_size` – The size of this buffer. The token will be NULL terminated, which needs to be allowed for in this size.

**Return values**

- `0` – Success
- `-ENOSPC` – Buffer is insufficient to initialize

```c
int jwt_add_payload(struct jwt_builder *builder, int32_t exp, int32_t iat, const char *aud)
```

add JWT primary payload.

```c
int jwt_sign(struct jwt_builder *builder, const char *der_key, size_t der_key_len)
```

Sign the JWT token.

```c
static inline size_t jwt_payload_len(struct jwt_builder *builder)
```

**struct jwt_builder**

#include `<jwt.h>` JWT data tracking.

JSON Web Tokens contain several sections, each encoded in base-64. This structure tracks the token as it is being built, including limits on the amount of available space. It should be initialized with `jwt_init()`.
Public Members

char *base
   The base of the buffer we are writing to.

char *buf
   The place in this buffer where we are currently writing.

size_t len
   The length remaining to write.

bool overflowed
   Flag that is set if we try to write past the end of the buffer. If set, the token is not valid.
Chapter 5

Build and Configuration Systems

5.1 Build System (CMake)

CMake is used to build your application together with the Zephyr kernel. A CMake build is done in two stages. The first stage is called configuration. During configuration, the CMakeLists.txt build scripts are executed. After configuration is finished, CMake has an internal model of the Zephyr build, and can generate build scripts that are native to the host platform.

CMake supports generating scripts for several build systems, but only Ninja and Make are tested and supported by Zephyr. After configuration, you begin the build stage by executing the generated build scripts. These build scripts can recompile the application without involving CMake following most code changes. However, after certain changes, the configuration step must be executed again before building. The build scripts can detect some of these situations and reconfigure automatically, but there are cases when this must be done manually.

Zephyr uses CMake's concept of a 'target' to organize the build. A target can be an executable, a library, or a generated file. For application developers, the library target is the most important to understand. All source code that goes into a Zephyr build does so by being included in a library target, even application code.

Library targets have source code, that is added through CMakeLists.txt build scripts like this:

```
target_sources(app PRIVATE src/main.c)
```

In the above CMakeLists.txt, an existing library target named app is configured to include the source file src/main.c. The PRIVATE keyword indicates that we are modifying the internals of how the library is being built. Using the keyword PUBLIC would modify how other libraries that link with app are built. In this case, using PUBLIC would cause libraries that link with app to also include the source file src/main.c, behavior that we surely do not want. The PUBLIC keyword could however be useful when modifying the include paths of a target library.

5.1.1 Build and Configuration Phases

The Zephyr build process can be divided into two main phases: a configuration phase (driven by CMake) and a build phase (driven by Make or Ninja).

Configuration Phase

The configuration phase begins when the user invokes CMake to generate a build system, specifying a source application directory and a board target.
Configuration overview...

*.dts/*.dtsi files

C preprocessor

Preprocessed devicetree...

Bindings (YAML files)

Scripts in scripts/d...

Final devicetree, zephyr.dts

dtc: optional, for warning...

Kconfig files

Scripts in scripts/kconfig...

devicetree_generated.h...

Outputs

autocnf.h

.config

devicetree.h...

Makefile or Ninja file (...

Viewer does not support full SVG 1.1
CMake begins by processing the \texttt{CMakeLists.txt} file in the application directory, which refers to the \texttt{CMakeLists.txt} file in the Zephyr top-level directory, which in turn refers to \texttt{CMakeLists.txt} files throughout the build tree (directly and indirectly). Its primary output is a set of Makefiles or Ninja files to drive the build process, but the CMake scripts also do some processing of their own, which is explained here.

Note that paths beginning with \texttt{build/} below refer to the build directory you create when running CMake.

**Devicetree**

\texttt{*.dts} (\textit{devicetree source}) and \texttt{*.dtsi} (\textit{devicetree source include}) files are collected from the target's architecture, SoC, board, and application directories.

\texttt{*.dtsi} files are included by \texttt{*.dts} files via the C preprocessor (often abbreviated \texttt{cpp}, which should not be confused with C++). The C preprocessor is also used to merge in any devicetree \texttt{*.overlay} files, and to expand macros in \texttt{*.dts}, \texttt{*.dtsi}, and \texttt{*.overlay} files. The preprocessor output is placed in \texttt{build/zephyr/zephyr.dts.pre}.

The preprocessed devicetree sources are parsed by \texttt{gen\_defines.py} to generate a \texttt{build/zephyr/include/generated/devicetree\_generated.h} header with preprocessor macros.

Source code should access preprocessor macros generated from devicetree by including the \texttt{devicetree.h} header, which includes \texttt{devicetree\_generated.h}.

\texttt{gen\_defines.py} also writes the final devicetree to \texttt{build/zephyr/zephyr.dts} in the build directory. This file's contents may be useful for debugging.

If the devicetree compiler \texttt{dtc} is installed, it is run on \texttt{build/zephyr/zephyr.dts} to catch any extra warnings and errors generated by this tool. The output from \texttt{dtc} is unused otherwise, and this step is skipped if \texttt{dtc} is not installed.

The above is just a brief overview. For more information on devicetree, see \textit{Devicetree Guide}.

**Kconfig**

Kconfig files define available configuration options for for the target architecture, SoC, board, and application, as well as dependencies between options.

Kconfig configurations are stored in \textit{configuration files}. The initial configuration is generated by merging configuration fragments from the board and application (e.g. \texttt{prj.conf}).

The output from Kconfig is an \texttt{autoconf.h} header with preprocessor assignments, and a \texttt{.config} file that acts both as a saved configuration and as configuration output (used by CMake). The definitions in \texttt{autoconf.h} are automatically exposed at compile time, so there is no need to include this header.

Information from devicetree is available to Kconfig, through the functions defined in \texttt{kconfigfunctions.py}.

See \textit{the Kconfig section of the manual} for more information.

**Build Phase**

The build phase begins when the user invokes \texttt{make} or \texttt{ninja}. Its ultimate output is a complete Zephyr application in a format suitable for loading/flashign on the desired target board (\texttt{zephyr.elf}, \texttt{zephyr.hex}, etc.) The build phase can be broken down, conceptually, into four stages: the pre-build, first-pass binary, final binary, and post-processing.

**Pre-build**

Pre-build occurs before any source files are compiled, because during this phase header files used by the source files are generated.

**Offset generation**

Access to high-level data structures and members is sometimes required when the definitions of
those structures is not immediately accessible (e.g., assembly language). The generation of `offsets.h` (by `gen_offset_header.py`) facilitates this.

**System call boilerplate**

The `gen_syscall.py` and `parse_syscalls.py` scripts work together to bind potential system call functions with their implementations.

**Intermediate binaries**

Compilation proper begins with the first intermediate binary. Source files (C and assembly) are collected from various subsystems (which ones is decided during the configuration phase), and compiled into archives (with reference to header files in the tree, as well as those generated during the configuration phase and the pre-build stage(s)).

The exact number of intermediate binaries is decided during the configuration phase.

If memory protection is enabled, then:
Partition grouping

The `gen_app_partitions.py` script scans all the generated archives and outputs linker scripts to ensure that application partitions are properly grouped and aligned for the target's memory protection hardware.

Then `cpp` is used to combine linker script fragments from the target's architecture/SoC, the kernel tree, optionally the partition output if memory protection is enabled, and any other fragments selected during the configuration process, into a `linker.cmd` file. The compiled archives are then linked with `ld` as specified in the `linker.cmd`.

Unfixed size binary

The unfixed size intermediate binary is produced when `User Mode` is enabled or `Devicetree` is in use. It produces a binary where sizes are not fixed and thus it may be used by post-process steps that will impact the size of the final binary.

Fixed size binary

The fixed size intermediate binary is produced when `User Mode` is enabled or when generated IRQ tables are used, `CONFIG_GEN_ISR_TABLES` It produces a binary where sizes are fixed and thus the size must not change between the intermediate binary and the final binary.

Intermediate binaries post-processing  The binaries from the previous stage are incomplete, with empty and/or placeholder sections that must be filled in by, essentially, reflection.

To complete the build procedure the following scripts are executed on the intermediate binaries to produce the missing pieces needed for the final binary.

When `User Mode` is enabled:

Partition alignment

The `gen_app_partitions.py` script scans the unfixed size binary and generates an app shared memory aligned linker script snippet where the partitions are sorted in descending order.

When `Devicetree` is used:
Device dependencies
The `gen_handles.py` script scans the unfixed size binary to determine relationships between devices that were recorded from devicetree data, and replaces the encoded relationships with values that are optimized to locate the devices actually present in the application.

When `CONFIG_GEN_ISR_TABLES` is enabled:
The `gen_isr_tables.py` script scant the fixed size binary and creates an `isr_tables.c` source file with a hardware vector table and/or software IRQ table.

When `User Mode` is enabled:
Kernel object hashing
The `gen_kobject_list.py` scans the `ELF DWARF` debug data to find the address of the all kernel objects. This list is passed to `gperf`, which generates a perfect hash function and table of those addresses, then that output is optimized by `process_gperf.py`, using known properties of our special case.

When no intermediate binary post-processing is required then the first intermediate binary will be directly used as the final binary.

Final binary   The binary from the previous stage is incomplete, with empty and/or placeholder sections that must be filled in by, essentially, reflection.
The link from the previous stage is repeated, this time with the missing pieces populated.

Post processing   Finally, if necessary, the completed kernel is converted from `ELF` to the format expected by the loader and/or flash tool required by the target. This is accomplished in a straightforward manner with `objdump`.

964 Chapter 5. Build and Configuration Systems
5.1.2 Supporting Scripts and Tools

The following is a detailed description of the scripts used during the build process.

scripts/build/gen_syscalls.py

Script to generate system call invocation macros

This script parses the system call metadata JSON file emitted by parse_syscalls.py to create several files:

- A file containing weak aliases of any potentially unimplemented system calls, as well as the system call dispatch table, which maps system call type IDs to their handler functions.
- A header file defining the system call type IDs, as well as function prototypes for all system call handler functions.
- A directory containing header files. Each header corresponds to a header that was identified as containing system call declarations. These generated headers contain the inline invocation functions for each system call in that header.

scripts/build/gen_handles.py

Translate generic handles into ones optimized for the application.

Immutable device data includes information about dependencies, e.g. that a particular sensor is controlled through a specific I2C bus and that it signals event on a pin on a specific GPIO controller. This information is encoded in the first-pass binary using identifiers derived from the devicetree. This script extracts those identifiers and replaces them with ones optimized for use with the devices actually present.
For example the sensor might have a first-pass handle defined by its devicetree ordinal 52, with the I2C driver having ordinal 24 and the GPIO controller ordinal 14. The runtime ordinal is the index of the corresponding device in the static devicetree array, which might be 6, 5, and 3, respectively.

The output is a C source file that provides alternative definitions for the array contents referenced from the immutable device objects. In the final link these definitions supersede the ones in the driver-specific object file.

scripts/build/gen_kobject_list.py

Script to generate gperf tables of kernel object metadata

User mode threads making system calls reference kernel objects by memory address, as the kernel/driver APIs in Zephyr are the same for both user and supervisor contexts. It is necessary for the kernel to be able to validate accesses to kernel objects to make the following assertions:

• That the memory address points to a kernel object
• The kernel object is of the expected type for the API being invoked
• The kernel object is of the expected initialization state
• The calling thread has sufficient permissions on the object

For more details see the Kernel Objects section in the documentation.

The zephyr build generates an intermediate ELF binary, zephyr_prebuilt.elf, which this script scans looking for kernel objects by examining the DWARF debug information to look for instances of data structures that are considered kernel objects. For device drivers, the API struct pointer populated at build time is also examined to disambiguate between various device driver instances since they are all ‘struct device’.

This script can generate five different output files:

• A gperf script to generate the hash table mapping kernel object memory addresses to kernel object metadata, used to track permissions, object type, initialization state, and any object-specific data.

• A header file containing generated macros for validating driver instances inside the system call handlers for the driver subsystem APIs.

• A code fragment included by kernel.h with one enum constant for each kernel object type and each driver instance.

• The inner cases of a switch/case C statement, included by kernel/userspace.c, mapping the kernel object types and driver instances to their human-readable representation in the otype_to_str() function.

• The inner cases of a switch/case C statement, included by kernel/userspace.c, mapping kernel object types to their sizes. This is used for allocating instances of them at runtime (CONFIG_DYNAMIC_OBJECTS) in the obj_size_get() function.

scripts/build/gen_offset_header.py

This script scans a specified object file and generates a header file that defined macros for the offsets of various found struct type members (particularly symbols ending with _OFFSET or _SIZEOF), primarily intended for use in assembly code.

scripts/build/parse_syscalls.py

Script to scan Zephyr include directories and emit system call and subsystem metadata

System calls require a great deal of boilerplate code in order to implement completely. This script is the first step in the build system's process of auto-generating this code by doing a text scan of directories
containing C or header files, and building up a database of system calls and their function call prototypes. This information is emitted to a generated JSON file for further processing.

This script also scans for struct definitions such as __subsystem and __net_socket, emitting a JSON dictionary mapping tags to all the struct declarations found that were tagged with them.

If the output JSON file already exists, its contents are checked against what information this script would have outputted; if the result is that the file would be unchanged, it is not modified to prevent unnecessary incremental builds.

**arch/x86/gen_idt.py**

Generate Interrupt Descriptor Table for x86 CPUs.

This script generates the interrupt descriptor table (IDT) for x86. Please consult the IA Architecture SW Developer Manual, volume 3, for more details on this data structure.

This script accepts as input the zephyr_prebuilt.elf binary, which is a link of the Zephyr kernel without various build-time generated data structures (such as the IDT) inserted into it. This kernel image has been properly padded such that inserting these data structures will not disturb the memory addresses of other symbols. From the kernel binary we read a special section “intList” which contains the desired interrupt routing configuration for the kernel, populated by instances of the IRQ_CONNECT() macro.

This script outputs three binary tables:

1. The interrupt descriptor table itself.
2. A bitfield indicating which vectors in the IDT are free for installation of dynamic interrupts at runtime.
3. An array which maps configured IRQ lines to their associated vector entries in the IDT, used to program the APIC at runtime.

**arch/x86/gen_gdt.py**

Generate a Global Descriptor Table (GDT) for x86 CPUs.

For additional detail on GDT and x86 memory management, please consult the IA Architecture SW Developer Manual, vol. 3.

This script accepts as input the zephyr_prebuilt.elf binary, which is a link of the Zephyr kernel without various build-time generated data structures (such as the GDT) inserted into it. This kernel image has been properly padded such that inserting these data structures will not disturb the memory addresses of other symbols.

The input kernel ELF binary is used to obtain the following information:

- Memory addresses of the Main and Double Fault TSS structures so GDT descriptors can be created for them
- Memory addresses of where the GDT lives in memory, so that this address can be populated in the GDT pseudo descriptor
- whether userspace or HW stack protection are enabled in Kconfig

The output is a GDT whose contents depend on the kernel configuration. With no memory protection features enabled, we generate flat 32-bit code and data segments. If hardware-based stack overflow protection or userspace is enabled, we additionally create descriptors for the main and double-fault IA tasks, needed for userspace privilege elevation and double-fault handling. If userspace is enabled, we also create flat code/data segments for ring 3 execution.
scripts/build/gen_relocate_app.py

This script will relocate .text, .rodata, .data and .bss sections from required files and places it in the required memory region. This memory region and file are given to this python script in the form of a string.

Example of such a string would be:

```
SRAM2:COPY:/home/xyz/zephyr/samples/hello_world/src/main.c,
SRAM1:COPY:/home/xyz/zephyr/samples/hello_world/src/main2.c, 
FLASH2:NOCOPY:/home/xyz/zephyr/samples/hello_world/src/main3.c
```

One can also specify the program header for a given memory region:

```
SRAM2:\.phdr0:COPY:/home/xyz/zephyr/samples/hello_world/src/main.c
```

To invoke this script:

```
python3 gen_relocate_app.py -i input_string -o generated_linker -c generated_code
```

Configuration that needs to be sent to the python script.

- If the memory is like SRAM1/SRAM2/CCD/AON then place full object in the sections
- If the memory type is appended with _DATA / _TEXT/ _RODATA/ _BSS only the selected memory is placed in the required memory region. Others are ignored.
- COPY/NOCOPY defines whether the script should generate the relocation code in code_relocation.c or not

Multiple regions can be appended together like SRAM2_DATA_BSS this will place data and bss inside SRAM2.

scripts/build/process_gperf.py

gperf C file post-processor

We use gperf to build up a perfect hashtable of pointer values. The way gperf does this is to create a table ‘wordlist’ indexed by a string representation of a pointer address, and then doing memcmp() on a string passed in for comparison

We are exclusively working with 4-byte pointer values. This script adjusts the generated code so that we work with pointers directly and not strings. This saves a considerable amount of space.

scripts/build/gen_app_partitions.py

Script to generate a linker script organizing application memory partitions

Applications may declare build-time memory domain partitions with K_APPMEM_PARTITION_DEFINE, and assign globals to them using K_APP_DMEM or K_APP_BMEM macros. For each of these partitions, we need to route all their data into appropriately-sized memory areas which meet the size/alignment constraints of the memory protection hardware.

This linker script is created very early in the build process, before the build attempts to link the kernel binary, as the linker script this tool generates is a necessary pre-condition for kernel linking. We extract the set of memory partitions to generate by looking for variables which have been assigned to input sections that follow a defined naming convention. We also allow entire libraries to be pulled in to assign their globals to a particular memory partition via command line directives.

This script takes as inputs:

- The base directory to look for compiled objects
- key/value pairs mapping static library files to what partitions their globals should end up in.
The output is a linker script fragment containing the definition of the app shared memory section, which is further divided, for each partition found, into data and BSS for each partition.

5.2 Devicetree

A devicetree is a hierarchical data structure primarily used to describe hardware. Zephyr uses devicetree in two main ways:

- to describe hardware to the Device Driver Model
- to provide that hardware's initial configuration

This page links to a high level guide on devicetree as well as reference material.

5.2.1 Devicetree Guide

The pages in this section are a high-level guide to using devicetree for Zephyr development.

Introduction to devicetree

Tip: This is a conceptual overview of devicetree and how Zephyr uses it. For step-by-step guides and examples, see Devicetree HOWTOs.

A devicetree is a hierarchical data structure that describes hardware. The Devicetree specification defines its source and binary representations. Zephyr uses devicetree to describe the hardware available on its boards, as well as that hardware's initial configuration.

There are two types of devicetree input files: devicetree sources and devicetree bindings. The sources contain the devicetree itself. The bindings describe its contents, including data types. The build system uses devicetree sources and bindings to produce a generated C header. The generated header's contents are abstracted by the devicetree.h API, which you can use to get information from your devicetree.

Here is a simplified view of the process:

Fig. 5.1: Devicetree build flow

All Zephyr and application source code files can include and use devicetree.h. This includes device drivers, applications, tests, the kernel, etc.

The API itself is based on C macros. The macro names all start with DT_. In general, if you see a macro that starts with DT_ in a Zephyr source file, it's probably a devicetree.h macro. The generated C header contains macros that start with DT_ as well; you might see those in compiler error messages. You always can tell a generated- from a non-generated macro: generated macros have some lowercased letters, while the devicetree.h macro names have all capital letters.
Some information defined in devicetree is available via CONFIG_ macros generated from Kconfig. This is often done for backwards compatibility, since Zephyr has used Kconfig for longer than devicetree, and is still in the process of converting some information from Kconfig to devicetree. It is also done to allow Kconfig overrides of default values taken from devicetree. Devicetree information is referenced from Kconfig via Kconfig functions. See Devicetree versus Kconfig for some additional comparisons with Kconfig.

Syntax and structure  As the name indicates, a devicetree is a tree. The human-readable text format for this tree is called DTS (for devicetree source), and is defined in the Devicetree specification. Here is an example DTS file:

```
/dts-v1/
/
  a-node {
    subnode_nodelabel: a-sub-node {
      foo = <3>;
    };
  }

```
The /dts-v1/; line means the file's contents are in version 1 of the DTS syntax, which has replaced a now-obsolete “version 0”.

The tree has three nodes:

1. A root node: /
2. A node named a-node, which is a child of the root node
3. A node named a-sub-node, which is a child of a-node

Nodes can be assigned node labels, which are unique shorthands that can be used to refer to the labeled node elsewhere in the devicetree. Above, a-sub-node has the node label subnode_nodelabel, which can be accessed via DT_NODELABEL(subnode_nodelabel). A node can have zero, one, or multiple node labels.

Devicetree nodes have paths identifying their locations in the tree. Like Unix file system paths, devicetree paths are strings separated by slashes (/), and the root node's path is a single slash: /. Otherwise, each node's path is formed by concatenating the node's ancestors' names with the node's own name, separated by slashes. For example, the full path to a-sub-node is /a-node/a-sub-node.

Devicetree nodes can also have properties. Properties are name/value pairs. Property values can be any sequence of bytes. In some cases, the values are an array of what are called cells. A cell is just a 32-bit unsigned integer.

Node a-sub-node has a property named foo, whose value is a cell with value 3. The size and type of foo's value are implied by the enclosing angle brackets (< and >) in the DTS.

See Writing property values below for more example property values.

In practice, devicetree nodes usually correspond to some hardware, and the node hierarchy reflects the hardware's physical layout. For example, let's consider a board with three I2C peripherals connected to an I2C bus controller on an SoC, like this:

Nodes corresponding to the I2C bus controller and each I2C peripheral would be present in the devicetree. Reflecting the hardware layout, the I2C peripheral nodes would be children of the bus controller node. Similar conventions exist for representing other types of hardware.

The DTS would look something like this:
Properties are used in practice to describe or configure the hardware the node represents. For example, an I2C peripheral's node has a property whose value is the peripheral's address on the bus.

Here's a tree representing the same example, but with real-world node names and properties you might see when working with I2C devices.

This is the corresponding DTS:

```
/dts-v1/
/
{
  soc {
    i2c@40003000 {
      i2c-peripheral-1 {
      }
      i2c-peripheral-2 {
      }
      i2c-peripheral-3 {
      }
    }
  }
};

apds9960@39 {
  compatible = "avago,apds9960";
  reg = <0x39>;
};
ti_hdc@43 {
  compatible = "ti,hdc", "ti,hdc1010";
  reg = <0x43>;
}
```
In addition to showing more realistic names and properties, the above example introduces a new devicetree concept: unit addresses. Unit addresses are the parts of node names after an "at" sign (@), like 40003000 in i2c@40003000, or 39 in apds9960@39. Unit addresses are optional: the soc node does not have one.

Some more details about unit addresses and important properties follow.

**Unit address examples**  In devicetree, unit addresses give a node’s address in the address space of its parent node. Here are some example unit addresses for different types of hardware.

**Memory-mapped peripherals**

The peripheral’s register map base address. For example, the node named i2c@40003000 represents an I2C controller whose register map base address is 0x40003000.

**I2C peripherals**

The peripheral’s address on the I2C bus. For example, the child node apds9960@39 of the I2C controller in the previous section has I2C address 0x39.

**SPI peripherals**

An index representing the peripheral’s chip select line number. (If there is no chip select line, 0 is
Memory
The physical start address. For example, a node named `memory@2000000` represents RAM starting at physical address 0x2000000.

Memory-mapped flash
Like RAM, the physical start address. For example, a node named `flash@8000000` represents a flash device whose physical start address is 0x8000000.

Fixed flash partitions
This applies when the devicetree is used to store a flash partition table. The unit address is the partition’s start offset within the flash memory. For example, take this flash device and its partitions:

```c
flash@8000000 {
    /* ... */
    partitions {
        partition@0 { /* ... */ };
        partition@20000 { /* ... */ };
        /* ... */
    };
}
```

The node named `partition@0` has offset 0 from the start of its flash device, so its base address is 0x8000000. Similarly, the base address of the node named `partition@20000` is 0x8020000.

Important properties
Some important properties are:

compatible
The name of the hardware device the node represents.

The recommended format is "vendor,device", like "avago,apds9960", or a sequence of these, like "ti,hdc", "ti,hdc1010". The vendor part is an abbreviated name of the vendor. The file `dts/bindings/vendor-prefixes.txt` contains a list of commonly accepted vendor names. The device part is usually taken from the datasheet.

It is also sometimes a value like `gpio-keys`, `mmio-sram`, or `fixed-clock` when the hardware’s behavior is generic.

The build system uses the compatible property to find the right bindings for the node. Device drivers use `devicetree.h` to find nodes with relevant compatibles, in order to determine the available hardware to manage.

The compatible property can have multiple values. Additional values are useful when the device is a specific instance of a more general family, to allow the system to match from most- to least-specific device drivers.

Within Zephyr’s bindings syntax, this property has type `string-array`.

reg
Information used to address the device. The value is specific to the device (i.e. is different depending on the compatible property).

The reg property is a sequence of `(address, length)` pairs. Each pair is called a “register block”. Here are some common patterns:

- Devices accessed via memory-mapped I/O registers (like `i2c@40003000`): `address` is usually the base address of the I/O register space, and `length` is the number of bytes occupied by the registers.
- I2C devices (like `apds9960@39` and its siblings): `address` is a slave address on the I2C bus. There is no `length` value.
- SPI devices: `address` is a chip select line number; there is no `length`.

5.2. Devicetree
You may notice some similarities between the `reg` property and common unit addresses described above. This is not a coincidence. The `reg` property can be seen as a more detailed view of the addressable resources within a device than its unit address.

**status**

A string which describes whether the node is enabled.

The devicetree specification allows this property to have values "okay", "disabled", "reserved", "fail", and "fail-sss". Only the values "okay" and "disabled" are currently relevant to Zephyr; use of other values currently results in undefined behavior.

A node is considered enabled if its status property is either "okay" or not defined (i.e. does not exist in the devicetree source). Nodes with status "disabled" are explicitly disabled. (For backwards compatibility, the value "ok" is treated the same as "okay", but this usage is deprecated.) Device-tree nodes which correspond to physical devices must be enabled for the corresponding `struct device` in the Zephyr driver model to be allocated and initialized.

**interrupts**

Information about interrupts generated by the device, encoded as an array of one or more `interrupt specifiers`. Each interrupt specifier has some number of cells. See section 2.4, `Interrupts and Interrupt Mapping`, in the Devicetree Specification release v0.3 for more details.

Zephyr's devicetree bindings language lets you give a name to each cell in an interrupt specifier.

---

**Note:** Earlier versions of Zephyr made frequent use of the `label` property, which is distinct from the standard `node label`. Use of the label `property` in new devicetree bindings, as well as use of the `DT_LABEL` macro in new code, are actively discouraged. Label properties continue to persist for historical reasons in some existing bindings and overlays, but should not be used in new bindings or device implementations.

---

**Writing property values**

This section describes how to write property values in DTS format. The property types in the table below are described in detail in `Devicetree bindings`.

Some specifics are skipped in the interest of keeping things simple; if you're curious about details, see the devicetree specification.

<table>
<thead>
<tr>
<th>Property type</th>
<th>How to write</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>Double quoted</td>
<td><code>a-string = &quot;hello, world!&quot;;</code></td>
</tr>
<tr>
<td>int</td>
<td>Between angle brackets (<code>&lt;</code> and <code>&gt;</code>)</td>
<td><code>an-int = &lt;1&gt;;</code></td>
</tr>
<tr>
<td>boolean</td>
<td>For <code>true</code>, with no value (for <code>false</code>, use <code>/delete-property/</code>)</td>
<td><code>my-true-boolean;</code></td>
</tr>
<tr>
<td>array</td>
<td>Between angle brackets (<code>&lt;</code> and <code>&gt;</code>) separated by spaces</td>
<td><code>foo = &lt;0xdeadbeef 1234 0&gt;;</code></td>
</tr>
<tr>
<td>uint8-array</td>
<td>In hexadecimal without leading 0x, between square brackets ([ and ]).</td>
<td><code>a-byte-array = [00 01 ab];</code></td>
</tr>
<tr>
<td>string-array</td>
<td>Separated by commas</td>
<td><code>a-string-array = &quot;string one&quot;, &quot;string two&quot;, &quot;string three&quot;;</code></td>
</tr>
<tr>
<td>phandle</td>
<td>Between angle brackets (<code>&lt;</code> and <code>&gt;</code>)</td>
<td><code>a-phandle = &lt;&amp;mynode&gt;;</code></td>
</tr>
<tr>
<td>handles</td>
<td>Between angle brackets (<code>&lt;</code> and <code>&gt;</code>) separated by spaces</td>
<td><code>some-handles = &lt;&amp;mynode0 &amp;mynode1 &amp;mynode2&gt;;</code></td>
</tr>
<tr>
<td>handle-array</td>
<td>Between angle brackets (<code>&lt;</code> and <code>&gt;</code>) separated by spaces</td>
<td><code>a-handle-array = &lt;&amp;mynode0 1 2 &amp;mynode1 3 4&gt;;</code></td>
</tr>
</tbody>
</table>

Additional notes on the above:

- Boolean properties are true if present. They should not have a value. A boolean property is only false if it is completely missing in the DTS.
• The `foo` property value above has three cells with values `0xdeadbeef`, `1234`, and `0`, in that order. Note that hexadecimal and decimal numbers are allowed and can be intermixed. Since Zephyr transforms DTS to C sources, it is not necessary to specify the endianness of an individual cell here.

• 64-bit integers are written as two 32-bit cells in big-endian order. The value `0xaaaa0000babb1111` would be written `<0xaaaa0000 0xbabb1111>`.

• The `a-byte-array` property value is the three bytes `0x00`, `0x01`, and `0xab`, in that order.

• Parentheses, arithmetic operators, and bitwise operators are allowed. The `bar` property contains a single cell with value 64:

```
bar = <(2 * (1 << 5))>;  
```

Note that the entire expression must be parenthesized.

• Property values refer to other nodes in the devicetree by their phandles. You can write a phandle using `&foo`, where `foo` is a node label. Here is an example devicetree fragment:

```
foo: device@0 { };  
device@1 {  
    sibling = <&foo 1 2>;  
};  
```

The `sibling` property of node `device@1` contains three cells, in this order:

1. The `device@0` node's phandle, which is written here as `&foo` since the `device@0` node has a node label `foo`
2. The value 1
3. The value 2

In the devicetree, a phandle value is a cell – which again is just a 32-bit unsigned int. However, the Zephyr devicetree API generally exposes these values as node identifiers. Node identifiers are covered in more detail in Devicetree access from C/C++.

• Array and similar type property values can be split into several `<>` blocks, like this:

```
foo = <1 2>, <3 4>;  // Okay for 'type: array'
foo = <&label1 &label2>, <&label3 &label4>;  // Okay for 'type: phandles'
foo = <&label1 1 2>, <&label2 3 4>;  // Okay for 'type: phandle-array'
```

This is recommended for readability when possible if the value can be logically grouped into blocks of sub-values.

Aliases and chosen nodes  There are two additional ways beyond node labels to refer to a particular node without specifying its entire path: by alias, or by chosen node.

Here is an example devicetree which uses both:

```
/dts-v1/;  
/ {  
    chosen {  
        zephyr,console = &uart0;  
    };  
    aliases {  
        my-uart = &uart0;  
    };  
    soc {  
```

(continues on next page)
The /aliases and /chosen nodes do not refer to an actual hardware device. Their purpose is to specify other nodes in the devicetree.

Above, my-uart is an alias for the node with path /soc/serial@12340000. Using its node label uart0, the same node is set as the value of the chosen zephyr,console node.

Zephyr sample applications sometimes use aliases to allow overriding the particular hardware device used by the application in a generic way. For example, blinky-sample uses this to abstract the LED to blink via the led0 alias.

The /chosen node’s properties are used to configure system- or subsystem-wide values. See Chosen nodes for more information.

**Input and output files** This section describes the input and output files shown in the figure at the top of this introduction in more detail.

![Devicetree input (green) and output (yellow) files](image)

**Input files** There are four types of devicetree input files:
The devicetree files inside the `zephyr` directory look like this:

```
boards/<ARCH>/<BOARD>/<BOARD>.dts
dts/common/skeleton.dtsi
dts/<ARCH>/*/*<SOC>.dtsi
dts/bindings/*/*/binding.yaml
```

Generally speaking, every supported board has a `BOARD.dts` file describing its hardware. For example, the `reel_board` has `boards/arm/reel_board/reel_board.dts`.

`BOARD.dts` includes one or more `.dtsi` files. These `.dtsi` files describe the CPU or system-on-chip Zephyr runs on, perhaps by including other `.dtsi` files. They can also describe other common hardware features shared by multiple boards. In addition to these includes, `BOARD.dts` also describes the board’s specific hardware.

The `dts/common` directory contains `skeleton.dtsi`, a minimal include file for defining a complete devicetree. Architecture-specific subdirectories (`dts/<ARCH>`) contain `.dtsi` files for CPUs or SoCs which extend `skeleton.dtsi`.

The C preprocessor is run on all devicetree files to expand macro references, and includes are generally done with `#include <filename>` directives, even though DTS has a `/include/ "<filename>"` syntax.

`BOARD.dts` can be extended or modified using `overlays`. Overlays are also DTS files; the `.overlay` extension is just a convention which makes their purpose clear. Overlays adapt the base devicetree for different purposes:

- Zephyr applications can use overlays to enable a peripheral that is disabled by default, select a sensor on the board for an application specific purpose, etc. Along with `Configuration System (Kconfig)`, this makes it possible to reconfigure the kernel and device drivers without modifying source code.

- Overlays are also used when defining `Shields`.

The build system automatically picks up `.overlay` files stored in certain locations. It is also possible to explicitly list the overlays to include, via the `DTC_OVERLAY_FILE` CMake variable. See `Set devicetree overlays` for details.

The build system combines `BOARD.dts` and any `.overlay` files by concatenating them, with the overlays put last. This relies on DTS syntax which allows merging overlapping definitions of nodes in the devicetree. See `Example: FRDM-K64F and Hexiwear K64` for an example of how this works (in the context of `.dtsi` files, but the principle is the same for overlays). Putting the contents of the `.overlay` files last allows them to override `BOARD.dts`.

`Devicetree bindings` (which are YAML files) are essentially glue. They describe the contents of devicetree sources, includes, and overlays in a way that allows the build system to generate C macros usable by device drivers and applications. The `dts/bindings` directory contains bindings.

**Scripts and tools** The following libraries and scripts, located in `scripts/dts/`, create output files from input files. Their sources have extensive documentation.

- `dtlib.py` A low-level DTS parsing library.
- `edtlib.py` A library layered on top of dtlib that uses bindings to interpret properties and give a higher-level view of the devicetree. Uses dtlib to do the DTS parsing.
gen_defines.py
A script that uses edtlib to generate C preprocessor macros from the devicetree and bindings.

In addition to these, the standard dtc (devicetree compiler) tool is run on the final devicetree if it is installed on your system. This is just to catch errors or warnings. The output is unused. Boards may need to pass dtc additional flags, e.g. for warning suppression. Board directories can contain a file named pre_dt_board.cmake which configures these extra flags, like this:

```bash
list(APPEND EXTRA_DTC_FLAGS "-Wno-simple_bus_reg")
```

Output files These are created in your application’s build directory.

**Warning:** Don’t include the header files directly. *Devicetree access from C/C++ explains what to do instead.*

<build>/zephyr/zephyr.dts.pre
The preprocessed DTS source. This is an intermediate output file, which is input to gen_defines.py and used to create zephyr.dts and devicetree_generated.h.

<build>/zephyr/include/generated/devicetree_generated.h
The generated macros and additional comments describing the devicetree. Included by devicetree.h.

<build>/zephyr/zephyr.dts
The final merged devicetree. This file is output by gen_defines.py. It is useful for debugging any issues. If the devicetree compiler dtc is installed, it is also run on this file, to catch any additional warnings or errors.

Design goals

Zephyr’s use of devicetree has evolved significantly over time, and further changes are expected. The following are the general design goals, along with specific examples about how they impact Zephyr’s source code, and areas where more work remains to be done.

**Single source for all hardware information** Zephyr shall obtain its hardware descriptions exclusively from devicetree.

**Examples**

- New device drivers shall use devicetree APIs to determine which devices to create if possible.
- In-tree sample applications shall use aliases to determine which of multiple possible generic devices of a given type will be used in the current build. For example, the blinky-sample uses this to determine the LED to blink.
- Boot-time pin muxing and pin control can be accomplished via devicetree.

**Example remaining work**

- Zephyr’s Test Runner (Twister) currently use board.yaml files to determine the hardware supported by a board. This should be obtained from devicetree instead.
- Various device drivers currently use Kconfig to determine which instances of a particular compatible are enabled. This can and should be done with devicetree overlays instead.
- Board-level documentation still contains tables of hardware support which are generated and maintained by hand. This can and should be obtained from the board level devicetree instead.
• Runtime determination of \texttt{struct device} relationships should be done using information obtained from devicetree, e.g. for device power management.

**Source compatibility with other operating systems**  Zephyr’s devicetree tooling is based on a generic layer which is interoperable with other devicetree users, such as the Linux kernel. Zephyr’s binding language \textit{semantics} can support Zephyr-specific attributes, but shall not express Zephyr-specific relationships.

**Examples**

• Zephyr’s devicetree source parser, \texttt{dtlib.py}, is source-compatible with other tools like \texttt{dtc} in both directions: \texttt{dtlib.py} can parse \texttt{dtc} output, and \texttt{dtc} can parse \texttt{dtlib.py} output.

• Zephyr’s “extended dtlib” library, \texttt{edtlib.py}, shall not include Zephyr-specific features. Its purpose is to provide a higher-level view of the devicetree for common elements like interrupts and buses. Only the high-level \texttt{gen_defines.py} script, which is built on top of \texttt{edtlib.py}, contains Zephyr-specific knowledge and features.

**Example remaining work**

• Zephyr has a custom \textit{Devicetree bindings} language \textit{syntax}. While Linux’s \texttt{dtschema} does not yet meet Zephyr’s needs, we should try to follow what it is capable of representing in Zephyr’s own bindings.

• Due to inflexibility in the bindings language, Zephyr cannot support the full set of bindings supported by Linux.

• Devicetree source sharing between Zephyr and Linux is not done.

**Devicetree bindings**

A devicetree on its own is only half the story for describing hardware, as it is a relatively unstructured format. \textit{Devicetree bindings} provide the other half.

A devicetree binding declares requirements on the contents of nodes, and provides semantic information about the contents of valid nodes. Zephyr devicetree bindings are YAML files in a custom format (Zephyr does not use the dt-schema tools used by the Linux kernel).

This page introduces bindings, describes what they do, notes where they are found, and explains their data format.

\textbf{Note:}  See the \textit{Bindings index} for reference information on bindings built in to Zephyr.

Inferred bindings

Introduction

Devicetree nodes are matched to bindings using their compatible properties.

During the Configuration Phase, the build system tries to match each node in the devicetree to a binding file. When this succeeds, the build system uses the information in the binding file both when validating the node's contents and when generating macros for the node.

A simple example

Here is an example devicetree node:

```c
/* Node in a DTS file */
bar-device {
    compatible = "foo-company,bar-device";
    num-foos = <3>;
};
```

Here is a minimal binding file which matches the node:

```
# A YAML binding matching the node

compatible: "foo-company,bar-device"

properties:
    num-foos:
        type: int
        required: true
```

The build system matches the bar-device node to its YAML binding because the node's compatible property matches the binding's compatible: line.

What the build system does with bindings

The build system uses bindings both to validate devicetree nodes and to convert the devicetree's contents into the generated devicetree_generated.h header file.

For example, the build system would use the above binding to check that the required num-foos property is present in the bar-device node, and that its value, <3>, has the correct type.

The build system will then generate a macro for the bar-device node's num-foos property, which will expand to the integer literal 3. This macro lets you get the value of the property in C code using the API which is discussed later in this guide in Devicetree access from C/C++.
For another example, the following node would cause a build error, because it has no `num-foos` property, and this property is marked required in the binding:

```yaml
bad-node {
    compatible = "foo-company,bar-device";
};
```

**Other ways nodes are matched to bindings** If a node has more than one string in its `compatible` property, the build system looks for compatible bindings in the listed order and uses the first match. Take this node as an example:

```yaml
baz-device {
    compatible = "foo-company,baz-device", "generic-baz-device";
};
```

The `baz-device` node would get matched to a binding with a `compatible: "generic-baz-device"` line if the build system can't find a binding with a `compatible: "foo-company,baz-device"` line.

Nodes without compatible properties can be matched to bindings associated with their parent nodes. These are called "child bindings". If a node describes hardware on a bus, like I2C or SPI, then the bus type is also taken into account when matching nodes to bindings. (The Bindings file syntax section below describes how to write child bindings and bus-specific bindings.)

Some special nodes without compatible properties are matched to **Inferred bindings**. For these nodes, the build system generates macros based on the properties in the final devicetree.

**Where bindings are located** Binding file names usually match their `compatible:` lines. For example, the above example binding would be named `foo-company,bar-device.yaml` by convention.

The build system looks for bindings in `dts/bindings` subdirectories of the following places:

- the zephyr repository
- your application source directory
- your board directory
- any directories in the `DTS_ROOT` CMake variable
- any module that defines a `dts_root` in its `Build settings`

The build system will consider any YAML file in any of these, including in any subdirectories, when matching nodes to bindings. A file is considered YAML if its name ends with `.yaml` or `.yml`.

**Warning:** The binding files must be located somewhere inside the `dts/bindings` subdirectory of the above places.

For example, if `my-app` is your application directory, then you must place application-specific bindings inside `my-app/dts/bindings`. So `my-app/dts/bindings/serial/my-company,my-serial-port.yaml` would be found, but `my-app/my-company,my-serial-port.yaml` would be ignored.

**Bindings file syntax** Zephyr bindings files are YAML files. The top-level value in the file is a mapping. A simple example is given above.

The top-level keys in the mapping look like this:

```yaml
# A high level description of the device the binding applies to:
description: |
    This is the Vendomatic company's foo-device.
```

(continues on next page)
Descriptions which span multiple lines (like this) are OK, and are encouraged for complex bindings.

See https://yaml-multiline.info/ for formatting help.

# You can include definitions from other bindings using this syntax:
include: other.yaml

# Used to match nodes to this binding as discussed above:
compatible: "manufacturer,foo-device"

properties:
  # Requirements for and descriptions of the properties that this
  # binding's nodes need to satisfy go here.

child-binding:
  # You can constrain the children of the nodes matching this binding
  # using this key.

  # If the node describes bus hardware, like an SPI bus controller
  # on an SoC, use 'bus:' to say which one, like this:
  bus: spi

  # If the node instead appears as a device on a bus, like an external
  # SPI memory chip, use 'on-bus:' to say what type of bus, like this.
  # Like 'compatible', this key also influences the way nodes match
  # bindings.
  on-bus: spi

foo-cells:
  # "Specifier" cell names for the 'foo' domain go here; example 'foo'
  # values are 'gpio', 'pwm', and 'dma'. See below for more information.

The following sections describe these keys in more detail:

- Description
- Compatible
- Properties
- Child-binding
- Bus
- On-bus
- Specifier cell names (*-cells)
- Include

The `include:` key usually appears early in the binding file, but it is documented last here because you need to know how the other keys work before understanding `include:`.

**Description** A free-form description of node hardware goes here. You can put links to datasheets or example nodes or properties as well.

**Compatible** This key is used to match nodes to this binding as described above. It should look like this in a binding file:
# Note the comma-separated vendor prefix and device name
compatible: "manufacturer,device"

This devicetree node would match the above binding:

device {
    compatible = "manufacturer,device";
};

Assuming no binding has compatible: "manufacturer,device-v2", it would also match this node:

device-2 {
    compatible = "manufacturer,device-v2", "manufacturer,device";
};

Each node's compatible property is tried in order. The first matching binding is used. The on-bus: key can be used to refine the search.

If more than one binding for a compatible is found, an error is raised.

The manufacturer prefix identifies the device vendor. See dts/bindings/vendor-prefixes.txt for a list of accepted vendor prefixes. The device part is usually from the datasheet.

Some bindings apply to a generic class of devices which do not have a specific vendor. In these cases, there is no vendor prefix. One example is the gpio-leds compatible which is commonly used to describe board LEDs connected to GPIOs.

If more than one binding for a compatible is found, an error is raised.

**Properties**

The properties: key describes the properties that nodes which match the binding can contain.

For example, a binding for a UART peripheral might look something like this:

compatible: "manufacturer,serial"

properties:
    reg:
        type: array
description: UART peripheral MMIO register space
required: true
current-speed:
    type: int
description: current baud rate
required: true

The properties in the following node would be validated by the above binding:

my-serial@deadbeef {
    compatible = "manufacturer,serial";
    reg = <0xdeadbeef 0x1000>;
    current-speed = <115200>;
};

This is used to check that required properties appear, and to control the format of output generated for them.

Except for some special properties, like reg, whose meaning is defined by the devicetree specification itself, only properties listed in the properties: key will have generated macros.

5.2. Devicetree
Example property definitions  Here are some more examples.

properties:
  # Describes a property like 'current-speed = <115200>;'. We pretend that
  # it's obligatory for the example node and set 'required: true'.
  current-speed:
    type: int
    required: true
    description: Initial baud rate for bar-device

  # Describes an optional property like 'keys = "foo", "bar";'
  keys:
    type: string-array
    description: Keys for bar-device

  # Describes an optional property like 'maximum-speed = "full-speed";
  # the enum specifies known values that the string property may take
  maximum-speed:
    type: string
    description: Configures USB controllers to work up to a specific speed.
    enum:
      - "low-speed"
      - "full-speed"
      - "high-speed"
      - "super-speed"

  # Describes an optional property like 'resolution = <16>;'
  # the enum specifies known values that the int property may take
  resolution:
    type: int
    enum:
      - 8
      - 16
      - 24
      - 32

  # Describes a required property '#address-cells = <1>'; the const
  # specifies that the value for the property is expected to be the value 1
  "#address-cells":
    type: int
    required: true
    const: 1

  int-with-default:
    type: int
    default: 123
    description: Value for int register, default is power-up configuration.

  array-with-default:
    type: array
    default: [1, 2, 3]
    description: Same as 'array-with-default = <1 2 3>,'

  string-with-default:
    type: string
    default: "foo"

  string-array-with-default:
    type: string-array
Property entry syntax  As shown by the above examples, each property entry in a binding looks like this:

```
<property name>:
  required: <true | false>
  type: <string | int | boolean | array | uint8-array | string-array | phandle | phandles | phandle-array | path | compound>
  deprecated: <true | false>
  default: <default>
  description: <description of the property>
  enum:
    - <item1>
    - <item2>
    ...
    - <itemN>
  const: <string | int | array | uint8-array | string-array
```

Required properties  If a node matches a binding but is missing any property which the binding defines with `required: true`, the build fails.

Note: A property is implicitly optional unless `required: true` is specified. Using `required: false` is therefore redundant and strongly discouraged.

Property types  The type of a property constrains its values. The following types are available. See Writing property values for more details about writing values of each type in a DTS file.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Example in DTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>exactly one string</td>
<td>status = &quot;disabled&quot;;</td>
</tr>
<tr>
<td>int</td>
<td>exactly one 32-bit value (cell)</td>
<td>current-speed = &lt;115200&gt;;</td>
</tr>
<tr>
<td>boolean</td>
<td>flags that don't take a value when true, and are absent if false</td>
<td>hw-flow-control;</td>
</tr>
<tr>
<td>array</td>
<td>zero or more 32-bit values (cells)</td>
<td>offsets = &lt;0x100 0x200 0x300&gt;;</td>

<tr>
<td>string-array</td>
<td>zero or more strings</td>
<td>dma-names = &quot;tx&quot;, &quot;rx&quot;;</td>
</tr>
<tr>
<td>phandle</td>
<td>exactly one phandle</td>
<td>interrupt-parent = &amp;gic;</td>
</tr>
<tr>
<td>phandles</td>
<td>zero or more phandles</td>
<td>pinctrl-0 = &amp;usart2_tx_pd5 &amp;usart2_rx_pd6;</td>
</tr>
<tr>
<td>phandle-array</td>
<td>a list of phandles and 32-bit cells (usually specifiers)</td>
<td>dmas = &amp;dma0 2, &amp;dma0 3;</td>
</tr>
<tr>
<td>path</td>
<td>a path to a node as a phandle path reference or path string</td>
<td>zephyr,bt-c2h-uart = &amp;uart0; or foo = &quot;/path/to/some/node&quot;;</td>
</tr>
<tr>
<td>compound</td>
<td>a catch-all for more complex types (no macros will be generated)</td>
<td>foo = &amp;label, [01 02];</td>
</tr>
</tbody>
</table>
**Deprecated properties**  A property with `deprecated: true` indicates to both the user and the tooling that the property is meant to be phased out.

The tooling will report a warning if the devicetree includes the property that is flagged as deprecated. (This warning is upgraded to an error in the Test Runner (Twister) for upstream pull requests.)

**Default values for properties**  The optional `default:` setting gives a value that will be used if the property is missing from the devicetree node.

For example, with this binding fragment:
