    2.2.2 Advanced Platform Setup ............................ 15  
    2.2.3 Install a Toolchain ................................. 20  
    2.2.4 Updating the Zephyr SDK toolchain ............... 20  
    2.2.5 Cloning the Zephyr Repositories ................... 20  
    2.2.6 Export Zephyr CMake package ..................... 21  
    2.2.7 Board Aliases ....................................... 21  
    2.2.8 Build and Run an Application ..................... 21  
  2.3 Environment Variables .................................. 23  
    2.3.1 Setting Variables .................................... 23  
    2.3.2 Zephyr Environment Scripts ......................... 25  
    2.3.3 Important Environment Variables ................... 25  
  2.4 Application Development ............................... 26  
    2.4.1 Overview ............................................ 26  
    2.4.2 Application types .................................... 27  
    2.4.3 Creating an Application ............................. 29  
    2.4.4 Important Build System Variables ................. 31  
    2.4.5 Application CMakeLists.txt ......................... 32  
    2.4.6 CMakeCache.txt ..................................... 34  
    2.4.7 Application Configuration ........................... 34  
    2.4.8 Application-Specific Code .......................... 35  
    2.4.9 Building an Application ............................ 35  
    2.4.10 Run an Application ................................ 39  
    2.4.11 Custom Board, Devicetree and SOC Definitions ... 40  
  2.5 Debugging ................................................ 43  
    2.5.1 Application Debugging ............................... 43  
    2.5.2 Debug with Eclipse ................................. 45
2.5.3 Debugging I2C communication .......................................................... 47
2.6 API Status and Guidelines ................................................................. 48
  2.6.1 API Overview ................................................................. 48
  2.6.2 API Lifecycle ................................................................. 50
  2.6.3 API Design Guidelines ..................................................... 54
  2.6.4 API Terminology ............................................................. 55
2.7 Language Support ........................................................................... 58
  2.7.1 C Language Support .......................................................... 58
  2.7.2 C++ Language Support ....................................................... 68
2.8 Optimizations ................................................................................. 70
  2.8.1 Optimizing for Footprint ....................................................... 70
  2.8.2 Optimization Tools ............................................................. 71
2.9 Flashing and Hardware Debugging .................................................. 76
  2.9.1 Flash & Debug Host Tools ................................................. 76
  2.9.2 Debug Probes ..................................................................... 81
2.10 Modules (External projects) ............................................................. 86
  2.10.1 Modules vs west projects ....................................................... 87
  2.10.2 Module Repositories ........................................................... 87
  2.10.3 Contributing to Zephyr modules .......................................... 88
  2.10.4 Licensing requirements and policies .................................... 90
  2.10.5 Documentation requirements .............................................. 90
  2.10.6 Testing requirements .......................................................... 91
  2.10.7 Deprecating and removing modules .................................... 91
  2.10.8 Integrate modules in Zephyr build system .......................... 92
  2.10.9 Module yaml file description .............................................. 92
  2.10.10 Submitting changes to modules ........................................ 100
2.11 West (Zephyr’s meta-tool) ............................................................... 101
  2.11.1 Installing west .................................................................. 101
  2.11.2 West Release Notes .......................................................... 102
  2.11.3 Troubleshooting West ......................................................... 113
  2.11.4 Basics .............................................................................. 116
  2.11.5 Built-in commands ............................................................. 119
  2.11.6 Workspaces ..................................................................... 122
  2.11.7 West Manifests ................................................................. 126
  2.11.8 Configuration ................................................................... 156
  2.11.9 Extensions ....................................................................... 159
  2.11.10 Building, Flashing and Debugging .................................... 162
  2.11.11 Signing Binaries ............................................................... 176
  2.11.12 Additional Zephyr extension commands ......................... 179
  2.11.13 History and Motivation .................................................... 181
  2.11.14 Moving to West .............................................................. 183
  2.11.15 Using Zephyr without west ............................................... 184
2.12 Testing .......................................................................................... 185
  2.12.1 Test Framework ............................................................... 185
  2.12.2 Test Runner (Twister) ......................................................... 207

2.13 Static Code Analysis (SCA) .............................................................. 237
  2.13.1 SCA Tool infrastructure ..................................................... 237
  2.13.2 Native SCA Tool support ................................................... 238
2.14 Toolchains .................................................................................... 239
  2.14.1 Zephyr SDK .................................................................... 239
  2.14.2 Arm Compiler 6 ............................................................... 242
  2.14.3 Cadence Tensilica Xtensa C/C++ Compiler (XCC) ............. 243
  2.14.4 DesignWare ARC MetaWare Development Toolkit (MWDT) 244
  2.14.5 GNU Arm Embedded ....................................................... 244
5 Build and Configuration Systems

5.1 Build System (CMake) ........................................ 1121
  5.1.1 Build and Configuration Phases .................. 1121
  5.1.2 Supporting Scripts and Tools .................. 1127

5.2 Devicetree .................................................. 1131
  5.2.1 Devicetree Guide .................................. 1131
  5.2.2 Devicetree Reference ............................. 1191

5.3 Configuration System (Kconfig) .................. 1368
  5.3.1 Interactive Kconfig interfaces ............... 1368
  5.3.2 Setting Kconfig configuration values ...... 1373
  5.3.3 Kconfig - Tips and Best Practices .......... 1377
  5.3.4 Custom Kconfig Preprocessor Functions 1391
  5.3.5 Kconfig extensions ............................ 1393

5.4 Snippets .................................................. 1394
  5.4.1 Using Snippets .................................. 1394
  5.4.2 Built-in snippets ............................... 1395
  5.4.3 Writing Snippets ............................... 1396
  5.4.4 Snippets Design ................................ 1399

5.5 Zephyr CMake Package ................................. 1400
  5.5.1 Zephyr CMake package export (west) .......... 1400
  5.5.2 Zephyr CMake package export (without west) 1400
  5.5.3 Zephyr Base Environment Setting ............ 1400
  5.5.4 Zephyr CMake Package Search Order .......... 1401
  5.5.5 Zephyr CMake Package Version ............... 1402
  5.5.6 Multiple Zephyr Installations (Zephyr workspace) 1403
  5.5.7 Zephyr Build Configuration CMake packages .... 1404
  5.5.8 Zephyr CMake package source code .......... 1405

5.6 Sysbuild (System build) ............................. 1406
  5.6.1 Definitions .................................... 1406
  5.6.2 Architectural Overview ....................... 1406
  5.6.3 Building with sysbuild ....................... 1407
  5.6.4 Configuration namespaceing .................. 1408
  5.6.5 Sysbuild flashing using west flash .......... 1409
  5.6.6 Sysbuild debugging using west debug ......... 1410
  5.6.7 Building a sample with MCUboot ............... 1410
  5.6.8 Sysbuild Kconfig file ....................... 1410
  5.6.9 Sysbuild targets ................................ 1411
  5.6.10 Dedicated image build targets .............. 1411
  5.6.11 Adding Zephyr applications to sysbuild .... 1412
  5.6.12 Adding non-Zephyr applications to sysbuild 1415
  5.6.13 Extending sysbuild ........................... 1415

5.7 Application version management ..................... 1415
6 Connectivity

6.1 Bluetooth

6.1.1 Overview

6.1.2 Bluetooth Stack Architecture

6.1.3 Bluetooth Low Energy Controller

6.1.4 Bluetooth Audio Architecture

6.1.5 Bluetooth Qualification

6.1.6 Bluetooth tools

6.1.7 Developing Bluetooth Applications

6.1.8 AutoPTS on Windows 10 with nRF52 board

6.1.9 AutoPTS on Linux

6.1.10 Bluetooth APIs

6.1.11 Bluetooth Shell

6.2 Networking

6.2.1 Overview

6.2.2 Network Stack Architecture

6.2.3 Network Connectivity API

6.2.4 Networking with the host system

6.2.5 Monitor Network Traffic

6.2.6 Networking APIs

6.2.7 Connection Manager

6.3 LoRa and LoRaWAN

6.3.1 Overview

6.3.2 Configuration Options

6.3.3 API Reference

6.4 USB

6.4.1 USB device support

6.4.2 USB device support APIs

6.4.3 New experimental USB device support

6.4.4 New USB device support APIs

6.4.5 USB host support APIs

6.4.6 USB-C device stack

6.4.7 Human Interface Devices (HID)

7 Hardware Support

7.1 Architecture-related Guides

7.1.1 Zephyr support status on ARC processors

7.1.2 Arm Cortex-M Developer Guide

7.1.3 Zephyr support status on RISC-V processors

7.1.4 Semihosting Guide

7.1.5 Additional Functionality

7.1.6 x86 Developer Guide

7.2 Barriers API

7.3 Cache Interface

7.3.1 Cache API

7.4 Peripheral and Hardware Emulators

7.4.1 Overview

7.4.2 Concept

7.4.3 Creating a Device Driver Emulator

7.4.4 Available Emulators

7.4.5 Samples

7.5 Peripherals
### 7.5 Devices

Chapter 1

Introduction

The Zephyr OS is based on a small-footprint kernel designed for use on resource-constrained and embedded systems: from simple embedded environmental sensors and LED wearables to sophisticated embedded controllers, smart watches, and IoT wireless applications.

The Zephyr kernel supports multiple architectures, including:

- ARCv2 (EM and HS) and ARCv3 (HS6X)
- ARMv6-M, ARMv7-M, and ARMv8-M (Cortex-M)
- ARMv7-A and ARMv8-A (Cortex-A, 32- and 64-bit)
- ARMv7-R, ARMv8-R (Cortex-R, 32- and 64-bit)
- Intel x86 (32- and 64-bit)
- MIPS (MIPS32 Release 1 specification)
- NIOS II Gen 2
- RISC-V (32- and 64-bit)
- SPARC V8
- Tensilica Xtensa

The full list of supported boards based on these architectures can be found here.

1.1 Licensing

Zephyr is permissively licensed using the Apache 2.0 license (as found in the LICENSE file in the project’s GitHub repo). There are some imported or reused components of the Zephyr project that use other licensing, as described in Licensing of Zephyr Project components.

1.2 Distinguishing Features

Zephyr offers a large and ever growing number of features including:

Extensive suite of Kernel services

Zephyr offers a number of familiar services for development:

- Multi-threading Services for cooperative, priority-based, non-preemptive, and preemptive threads with optional round robin time-slicing. Includes POSIX pthreads compatible API support.
- Interrupt Services for compile-time registration of interrupt handlers.
• **Memory Allocation Services** for dynamic allocation and freeing of fixed-size or variable-size memory blocks.

• **Inter-thread Synchronization Services** for binary semaphores, counting semaphores, and mutex semaphores.

• **Inter-thread Data Passing Services** for basic message queues, enhanced message queues, and byte streams.

• **Power Management Services** such as overarching, application or policy-defined, System Power Management and fine-grained, driver-defined, Device Power Management.

**Multiple Scheduling Algorithms**

Zephyr provides a comprehensive set of thread scheduling choices:

• Cooperative and Preemptive Scheduling

• Earliest Deadline First (EDF)

• Meta IRQ scheduling implementing “interrupt bottom half” or “tasklet” behavior

• Timeslicing: Enables time slicing between preemptible threads of equal priority

• Multiple queuing strategies:
  – Simple linked-list ready queue
  – Red/black tree ready queue
  – Traditional multi-queue ready queue

**Highly configurable / Modular for flexibility**

Allows an application to incorporate only the capabilities it needs as it needs them, and to specify their quantity and size.

**Cross Architecture**

Supports a wide variety of supported boards with different CPU architectures and developer tools. Contributions have added support for an increasing number of SoCs, platforms, and drivers.

**Memory Protection**

Implements configurable architecture-specific stack-overflow protection, kernel object and device driver permission tracking, and thread isolation with thread-level memory protection on x86, ARC, and ARM architectures, userspace, and memory domains.

For platforms without MMU/MPU and memory constrained devices, supports combining application-specific code with a custom kernel to create a monolithic image that gets loaded and executed on a system's hardware. Both the application code and kernel code execute in a single shared address space.

**Compile-time resource definition**

Allows system resources to be defined at compile-time, which reduces code size and increases performance for resource-limited systems.

**Optimized Device Driver Model**

Provides a consistent device model for configuring the drivers that are part of the platform/system and a consistent model for initializing all the drivers configured into the system and allows the reuse of drivers across platforms that have common devices/IP blocks.

**Devicetree Support**

Use of `devicetree` to describe hardware. Information from devicetree is used to create the application image.

**Native Networking Stack supporting multiple protocols**

Networking support is fully featured and optimized, including LwM2M and BSD sockets compatible support. OpenThread support (on Nordic chipsets) is also provided - a mesh network designed to securely and reliably connect hundreds of products around the home.
Bluetooth Low Energy 5.0 support
Bluetooth 5.0 compliant (ESR10) and Bluetooth Low Energy Controller support (LE Link Layer). Includes Bluetooth mesh and a Bluetooth qualification-ready Bluetooth controller.

- Generic Access Profile (GAP) with all possible LE roles
- Generic Attribute Profile (GATT)
- Pairing support, including the Secure Connections feature from Bluetooth 4.2
- Clean HCI driver abstraction
- Raw HCI interface to run Zephyr as a Controller instead of a full Host stack
- Verified with multiple popular controllers
- Highly configurable

Mesh Support:
- Relay, Friend Node, Low-Power Node (LPN) and GATT Proxy features
- Both Provisioning bearers supported (PB-ADV & PB-GATT)
- Highly configurable, fitting in devices with at least 16k RAM

Native Linux, macOS, and Windows Development
A command-line CMake build environment runs on popular developer OS systems. A native POSIX port lets you build and run Zephyr as a native application on Linux and other OSes, aiding development and testing.

Virtual File System Interface with LittleFS and FATFS Support
LittleFS and FATFS Support, FCB (Flash Circular Buffer) for memory constrained applications, and file system enhancements for logging and configuration.

Powerful multi-backend logging Framework
Support for log filtering, object dumping, panic mode, multiple backends (memory, networking, filesystem, console, . . . ) and integration with the shell subsystem.

User friendly and full-featured Shell interface
A multi-instance shell subsystem with user-friendly features such as autocompletion, wildcards, coloring, metakeys (arrows, backspace, ctrl+u, etc.) and history. Support for static commands and dynamic sub-commands.

Settings on non-volatile storage
The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. Settings items are stored as key-value pair strings.

Non-volatile storage (NVS)
NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Native POSIX port
Supports running Zephyr as a Linux application with support for various subsystems and networking.

1.3 Community Support
Community support is provided via mailing lists and Discord; see the Resources below for details.

Chapter 2

Developing with Zephyr

2.1 Getting Started Guide

Follow this guide to:

- Set up a command-line Zephyr development environment on Ubuntu, macOS, or Windows (instructions for other Linux distributions are discussed in Install Linux Host Dependencies)
- Get the source code
- Build, flash, and run a sample application

2.1.1 Select and Update OS

Click the operating system you are using.

Ubuntu

This guide covers Ubuntu version 18.04 LTS and later.

```
sudo apt update
dsudo apt upgrade
```

macOS

On macOS Mojave or later, select System Preferences > Software Update. Click Update Now if necessary. On other versions, see this Apple support topic.

Windows

Select Start > Settings > Update & Security > Windows Update. Click Check for updates and install any that are available.

2.1.2 Install dependencies

Next, you’ll install some host dependencies using your package manager.

The current minimum required version for the main dependencies are:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Min. Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMake</td>
<td>3.20.5</td>
</tr>
<tr>
<td>Python</td>
<td>3.8</td>
</tr>
<tr>
<td>Devicetree compiler</td>
<td>1.4.6</td>
</tr>
</tbody>
</table>
Ubuntu

1. If using an Ubuntu version older than 22.04, it is necessary to add extra repositories to meet the minimum required versions for the main dependencies listed above. In that case, download, inspect and execute the Kitware archive script to add the Kitware APT repository to your sources list. A detailed explanation of kitware-archive.sh can be found here kitware third-party apt repository:

   ```
   wget https://apt.kitware.com/kitware-archive.sh
   sudo bash kitware-archive.sh
   ```

2. Use apt to install the required dependencies:

   ```
   sudo apt install --no-install-recommends git cmake ninja-build gperf \
   ccache dfu-util device-tree-compiler wget \
   python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils \
   --file \ 
   make gcc gcc-multilib g++-multilib libSDL2-2.0 libmagic1
   ```

3. Verify the versions of the main dependencies installed on your system by entering:

   ```
   cmake --version
   python3 --version
   dtc --version
   ```

   Check those against the versions in the table in the beginning of this section. Refer to the Install Linux Host Dependencies page for additional information on updating the dependencies manually.

macOS

1. Install Homebrew:

   ```
   /bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/HEAD/install.sh)"
   ```

2. Use brew to install the required dependencies:

   ```
   brew install cmake ninja gperf python3 ccache qemu dtc wget libmagic
   ```

Windows

**Note:** Due to issues finding executables, the Zephyr Project doesn’t currently support application flashing using the Windows Subsystem for Linux (WSL) (WSL). Therefore, we don’t recommend using WSL when getting started.

These instructions must be run in a `cmd.exe` command prompt. The required commands differ on PowerShell.

These instructions rely on Chocolatey. If Chocolatey isn’t an option, you can install dependencies from their respective websites and ensure the command line tools are on your `PATH environment variable`.

1. Install chocolatey.

2. Open a `cmd.exe` window as Administrator. To do so, press the Windows key, type “cmd.exe”, right-click the result, and choose Run as Administrator.

3. Disable global confirmation to avoid having to confirm the installation of individual programs:

   ```
   choco feature enable -n allowGlobalConfirmation
   ```

4. Use choco to install the required dependencies:
choco install cmake --installargs 'ADD_CMAKE_TO_PATH=System'
choco install ninja gperf python git dtc-msys2 wget 7zip

5. Close the window and open a new cmd.exe window as a regular user to continue.

2.1.3 Get Zephyr and install Python dependencies

Next, clone Zephyr and its modules into a new west workspace named zephyrproject. You'll also install Zephyr's additional Python dependencies.

**Note:** It is easy to run into Python package incompatibilities when installing dependencies at a system or user level. This situation can happen, for example, if working on multiple Zephyr versions or other projects using Python on the same machine. For this reason it is suggested to use Python virtual environments.

Ubuntu

Install within virtual environment

1. Use apt to install Python venv package:
   ```
sudo apt install python3-venv
   ```

2. Create a new virtual environment:
   ```
   python3 -m venv ~/zephyrproject/.venv
   ```

3. Activate the virtual environment:
   ```
   source ~/zephyrproject/.venv/bin/activate
   ```
   
   Once activated your shell will be prefixed with (.venv). The virtual environment can be deactivated at any time by running deactivate.

   **Note:** Remember to activate the virtual environment every time you start working.

4. Install west:
   ```
   pip install west
   ```

5. Get the Zephyr source code:
   ```
   west init ~/zephyrproject
cd ~/zephyrproject
west update
   ```

6. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.
   ```
west zephyr-export
   ```

7. Zephyr's scripts/requirements.txt file declares additional Python dependencies. Install them with pip.
   ```
   pip install -r ~/zephyrproject/zephyr/scripts/requirements.txt
   ```

Install globally
1. Install west, and make sure ~/.local/bin is on your PATH environment variable:

```bash
pip3 install --user -U west
echo 'export PATH=~/.local/bin:"$PATH"' >> ~/.bashrc
source ~/.bashrc
```

2. Get the Zephyr source code:

```bash
west init ~/zephyrproject
cd ~/zephyrproject
west update
```

3. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```bash
west zephyr-export
```

4. Zephyr’s scripts/requirements.txt file declares additional Python dependencies. Install them with pip3.

```bash
pip3 install --user -r ~/zephyrproject/zephyr/scripts/requirements.txt
```

macOS

Install within virtual environment

1. Create a new virtual environment:

```bash
python3 -m venv ~/zephyrproject/.venv
```

2. Activate the virtual environment:

```bash
source ~/zephyrproject/.venv/bin/activate
```

Once activated your shell will be prefixed with (.venv). The virtual environment can be deactivated at any time by running deactivate.

**Note:** Remember to activate the virtual environment every time you start working.

3. Install west:

```bash
pip install west
```

4. Get the Zephyr source code:

```bash
west init ~/zephyrproject
cd ~/zephyrproject
west update
```

5. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

```bash
west zephyr-export
```

6. Zephyr’s scripts/requirements.txt file declares additional Python dependencies. Install them with pip.

```bash
pip install -r ~/zephyrproject/zephyr/scripts/requirements.txt
```

Install globally
1. Install west:
   
   ```bash
   pip3 install -U west
   ```

2. Get the Zephyr source code:
   
   ```bash
   west init ~/zephyrproject
cd ~/zephyrproject
west update
   ```

3. Export a **Zephyr CMake package**. This allows CMake to automatically load boilerplate code required for building Zephyr applications.
   
   ```bash
   west zephyr-export
   ```

4. Zephyr's `scripts/requirements.txt` file declares additional Python dependencies. Install them with `pip3`.
   
   ```bash
   pip3 install -r ~/zephyrproject/zephyr/scripts/requirements.txt
   ```

**Windows**

Install within virtual environment

1. Create a new virtual environment:
   
   ```bash
   cd %HOMEPATH%
   python -m venv zephyrproject\.venv
   ```

2. Activate the virtual environment:
   
   ```bash
   :: cmd.exe
   zephyrproject\.venv\Scripts\activate.bat
   :: PowerShell
   zephyrproject\.venv\Scripts\Activate.ps1
   ```

   Once activated your shell will be prefixed with `.venv`. The virtual environment can be deactivated at any time by running `deactivate`.

   **Note:** Remember to activate the virtual environment every time you start working.

3. Install west:
   
   ```bash
   pip install west
   ```

4. Get the Zephyr source code:
   
   ```bash
   west init zephyrproject
cd zephyrproject
west update
   ```

5. Export a **Zephyr CMake package**. This allows CMake to automatically load boilerplate code required for building Zephyr applications.
   
   ```bash
   west zephyr-export
   ```

6. Zephyr's `scripts/requirements.txt` file declares additional Python dependencies. Install them with `pip`.
   
   ```bash
   pip install -r %HOMEPATH%\zephyrproject\zephyr\scripts\requirements.txt
   ```

---

**2.1. Getting Started Guide**
Install globally

1. Install west:

   ```
   pip3 install -U west
   ```

2. Get the Zephyr source code:

   ```
   cd %HOMEPATH%
   west init zephyrproject
   cd zephyrproject
   west update
   ```

3. Export a Zephyr CMake package. This allows CMake to automatically load boilerplate code required for building Zephyr applications.

   ```
   west zephyr-export
   ```

4. Zephyr's `scripts\requirements.txt` file declares additional Python dependencies. Install them with pip3.

   ```
   pip3 install -r %HOMEPATH%\zephyrproject\zephyr\scripts\requirements.txt
   ```

### 2.1.4 Install Zephyr SDK

The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr's supported architectures, which include a compiler, assembler, linker and other programs required to build Zephyr applications.

It also contains additional host tools, such as custom QEMU and OpenOCD builds that are used to emulate, flash and debug Zephyr applications.

**Ubuntu**

1. Download and verify the Zephyr SDK bundle:

   ```
   cd ~
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/zephyr-sdk-0.16.3_linux-x86_64.tar.xz
   wget -0 --https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/zephyr-sdk-0.16.3_linux-x86_64.tar.xz | shasum --check --ignore-missing
   ```

   If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace `x86_64` with `aarch64` in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

   ```
   tar xvf zephyr-sdk-0.16.3_linux-x86_64.tar.xz
   ```

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following locations:

- `$HOME`
- `$HOME/.local`
- `$HOME/.local/opt`
- `$HOME/bin`
- `/opt`
- `/usr/local`
The Zephyr SDK bundle archive contains the `zephyr-sdk-0.16.3` directory and, when extracted under $HOME, the resulting installation path will be $HOME/zephyr-sdk-0.16.3.

3. Run the Zephyr SDK bundle setup script:
   ```bash
cd zephyr-sdk-0.16.3
./setup.sh
```

**Note:** You only need to run the setup script once after extracting the Zephyr SDK bundle.

You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

4. Install udev rules, which allow you to flash most Zephyr boards as a regular user:
   ```bash
   sudo cp ~/zephyr-sdk-0.16.3/sysroots/x86_64-pokysdk-linux/usr/share/openocd/
   "contrib/60-openocd.rules" /etc/udev/rules.d
   sudo udevadm control --reload
   ```

**macOS**

1. Download and verify the Zephyr SDK bundle:
   ```bash
cd ~
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/
"zephyr-sdk-0.16.3_macos-x86_64.tar.xz"
wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/
"sha256.sum" | shasum --check --ignore-missing
   ```

If your host architecture is 64-bit ARM (Apple Silicon, also known as M1), replace `x86_64` with `aarch64` in order to download the 64-bit ARM macOS SDK.

2. Extract the Zephyr SDK bundle archive:
   ```bash
tar xvf zephyr-sdk-0.16.3_macos-x86_64.tar.xz
   ```

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following locations:

- $HOME
- $HOME/.local
- $HOME/.local/opt
- $HOME/bin
- /opt
- /usr/local

The Zephyr SDK bundle archive contains the `zephyr-sdk-0.16.3` directory and, when extracted under $HOME, the resulting installation path will be $HOME/zephyr-sdk-0.16.3.

3. Run the Zephyr SDK bundle setup script:
   ```bash
cd zephyr-sdk-0.16.3
./setup.sh
```

**Note:** You only need to run the setup script once after extracting the Zephyr SDK bundle.
You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

**Windows**

1. Open a `cmd.exe` window by pressing the Windows key typing “cmd.exe”.
2. Download the Zephyr SDK bundle:

   ```
   cd %HOMEPATH%
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/zephyr-sdk-0.16.3_windows-x86_64.7z
   ```
3. Extract the Zephyr SDK bundle archive:

   ```
   7z x zephyr-sdk-0.16.3_windows-x86_64.7z
   ```

   **Note:** It is recommended to extract the Zephyr SDK bundle at one of the following locations:

   - `%HOMEPATH%`
   - `%PROGRAMFILES%`

   The Zephyr SDK bundle archive contains the `zephyr-sdk-0.16.3` directory and, when extracted under `%HOMEPATH%`, the resulting installation path will be `%HOMEPATH%\zephyr-sdk-0.16.3`.

4. Run the Zephyr SDK bundle setup script:

   ```
   cd zephyr-sdk-0.16.3
   setup.cmd
   ```

   **Note:** You only need to run the setup script once after extracting the Zephyr SDK bundle.

   You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

---

**2.1.5 Build the Blinky Sample**

**Note:** `blinky` is compatible with most, but not all, boards. If your board does not meet Blinky’s `blinky-sample-requirements`, then `hello_world` is a good alternative.

If you are unsure what name `west` uses for your board, `west boards` can be used to obtain a list of all boards Zephyr supports.

Build the `blinky` with `west build`, changing `<your-board-name>` appropriately for your board:

**Ubuntu**

```

cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

**macOS**

```

cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

**Windows**
The `-p always` option forces a pristine build, and is recommended for new users. Users may also use the `-p auto` option, which will use heuristics to determine if a pristine build is required, such as when building another sample.

### 2.1.6 Flash the Sample

Connect your board, usually via USB, and turn it on if there's a power switch. If in doubt about what to do, check your board’s page in boards.

Then flash the sample using `west flash`:

```bash
west flash
```

You may need to install additional `host tools` required by your board. The `west flash` command will print an error if any required dependencies are missing.

If you're using blinky, the LED will start to blink as shown in this figure:

![Fig. 1: Phytec reel_board running blinky](image)

### 2.1.7 Next Steps

Here are some next steps for exploring Zephyr:

- Try other samples-and-demos
- Learn about `Application Development` and the `west` tool
- Find out about west's `flashing and debugging` features, or more about `Flashing and Hardware Debugging` in general
- Check out `Beyond the Getting Started Guide` for additional setup alternatives and ideas
- Discover `Resources` for getting help from the Zephyr community
2.1.8 Troubleshooting Installation

Here are some tips for fixing some issues related to the installation process.

Double Check the Zephyr SDK Variables When Updating

When updating Zephyr SDK, check whether the `ZEPHYR_TOOLCHAIN_VARIANT` or `ZEPHYR_SDK_INSTALL_DIR` environment variables are already set. See Updating the Zephyr SDK toolchain for more information.

For more information about these environment variables in Zephyr, see Important Environment Variables.

2.1.9 Asking for Help

You can ask for help on a mailing list or on Discord. Please send bug reports and feature requests to GitHub.

- **Mailing Lists**: [users@lists.zephyrproject.org](mailto:users@lists.zephyrproject.org) is usually the right list to ask for help. Search archives and sign up here.
- **Discord**: You can join with this Discord invite.
- **GitHub**: Use GitHub issues for bugs and feature requests.

How to Ask

**Important**: Please search this documentation and the mailing list archives first. Your question may have an answer there.

Don’t just say “this isn’t working” or ask “is this working?”. Include as much detail as you can about:

1. What you want to do
2. What you tried (commands you typed, etc.)
3. What happened (output of each command, etc.)

Use Copy/Paste

Please copy/paste text instead of taking a picture or a screenshot of it. Text includes source code, terminal commands, and their output.

Doing this makes it easier for people to help you, and also helps other users search the archives. Unnecessary screenshots exclude vision impaired developers; some are major Zephyr contributors. Accessibility has been recognized as a basic human right by the United Nations.

When copy/pasting more than 5 lines of computer text into Discord or Github, create a snippet using three backticks to delimit the snippet.

2.2 Beyond the Getting Started Guide

The Getting Started Guide gives a straight-forward path to set up your Linux, macOS, or Windows environment for Zephyr development. In this document, we delve deeper into Zephyr development setup issues and alternatives.
2.2.1 Python and pip

Python 3 and its package manager, pip\(^1\), are used extensively by Zephyr to install and run scripts required to compile and run Zephyr applications, set up and maintain the Zephyr development environment, and build project documentation.

Depending on your operating system, you may need to provide the --user flag to the pip3 command when installing new packages. This is documented throughout the instructions. See Installing Packages in the Python Packaging User Guide for more information about pip\(^1\), including information on --user.

- On Linux, make sure ~/.local/bin is at the front of your PATH environment variable, or programs installed with --user won't be found. Installing with --user avoids conflicts between pip and the system package manager, and is the default on Debian-based distributions.
- On macOS, Homebrew disables --user.
- On Windows, see the Installing Packages information on --user if you require using this option.

On all operating systems, pip's -U flag installs or updates the package if the package is already installed locally but a more recent version is available. It is good practice to use this flag if the latest version of a package is required. (Check the scripts/requirements.txt file to see if a specific Python package version is expected.)

2.2.2 Advanced Platform Setup

Here are some alternative instructions for more advanced platform setup configurations for supported development platforms:

**Install Linux Host Dependencies**

Documentation is available for these Linux distributions:

- Ubuntu
- Fedora
- Clear Linux
- Arch Linux

For distributions that are not based on rolling releases, some of the requirements and dependencies may not be met by your package manager. In that case please follow the additional instructions that are provided to find software from sources other than the package manager.

**Note:** If you're working behind a corporate firewall, you'll likely need to configure a proxy for accessing the internet, if you haven't done so already. While some tools use the environment variables http_proxy and https_proxy to get their proxy settings, some use their own configuration files, most notably apt and git.

**Update Your Operating System** Ensure your host system is up to date.

Ubuntu

\(^1\) pip is Python's package installer. Its install command first tries to re-use packages and package dependencies already installed on your computer. If that is not possible, pip install downloads them from the Python Package Index (PyPI) on the Internet.

\(^2\) The package versions requested by Zephyr's requirements.txt may conflict with other requirements on your system, in which case you may want to set up a virtualenv for Zephyr development.
Install Requirements and Dependencies  

Note that both Ninja and Make are installed with these instructions; you only need one.

Ubuntu

```bash
sudo apt-get install --no-install-recommends git cmake ninja-build gperf \
  ccache dfu-util device-tree-compiler wget \
  python3-dev python3-pip python3-setuptools python3-tk python3-wheel xx-utils file \
  --libpython3.8-dev \
  make gcc gcc-multilib g++-multilib libstdc++-dev libmagic1
```

Fedora

```bash
sudo dnf install git cmake ninja-build gperf \
  ccache dfu-util device-tree-compiler wget \
  python3-pip python3-tkinter xx file glibc-devel.i686 libstdc++-devel.i686 python38 \
  SDL2-devel
```

Clear Linux

```bash
sudo swupd bundle-add c-basic dev-utils dfu-util dtc \
  os-core-dev python-basic python3-basic python3-tcl
```

The Clear Linux focus is on *native* performance and security and not cross-compilation. For that reason it uniquely exports by default to the *environment* of all users a list of compiler and linker flags. Zephyr's CMake build system will either warn or fail because of these. To clear the C/C++ flags among these and fix the Zephyr build, run the following command as root then log out and back in:

```bash
echo 'unset CFLAGS CXXFLAGS' >> /etc/profile.d/unset_cflags.sh
```

Note this command unsets the C/C++ flags for *all users on the system*. Each Linux distribution has a unique, relatively complex and potentially evolving sequence of bash initialization files sourcing each other and Clear Linux is no exception. If you need a more flexible solution, start by looking at the logic in `/usr/share/defaults/etc/profile`.

Arch Linux

```bash
sudo pacman -S git cmake ninja gperf ccache dfu-util dtc wget \
  python-pip python-setuptools python-wheel tk xx file make
```

CMake  

A *recent CMake version* is required. Check what version you have by using `cmake --version`. If you have an older version, there are several ways of obtaining a more recent one:
• On Ubuntu, you can follow the instructions for adding the kitware third-party apt repository to get an updated version of cmake using apt.

• Download and install a packaged cmake from the CMake project site. (Note this won’t uninstall the previous version of cmake.)

```bash
cd ~
wget https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-\--Linux-x86_64.sh
chmod +x cmake-3.21.1-Linux-x86_64.sh
sudo ./cmake-3.21.1-Linux-x86_64.sh --skip-license --prefix=/usr/local
hash -r
```

The `hash -r` command may be necessary if the installation script put cmake into a new location on your PATH.

• Download and install from the pre-built binaries provided by the CMake project itself in the CMake Downloads page. For example, to install version 3.21.1 in `~/bin/cmake`:

```bash
mkdir $HOME/bin/cmake && cd $HOME/bin/cmake
wget https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-\--Linux-x86_64.sh
yes | sh cmake-3.21.1-Linux-x86_64.sh | cat
echo "export PATH=$PWD/cmake-3.21.1-Linux-x86_64/bin:PATH" >> $HOME/.zephyrrc
```

• Use pip3:

```bash
pip3 install --user cmake
```

Note this won’t uninstall the previous version of cmake and will install the new cmake into your `~/.local/bin` folder so you’ll need to add `~/.local/bin` to your PATH. (See Python and pip for details.)

• Check your distribution’s beta or unstable release package library for an update.

• On Ubuntu you can also use snap to get the latest version available:

```bash
sudo snap install cmake
```

After updating cmake, verify that the newly installed cmake is found using `cmake --version`. You might also want to uninstall the CMake provided by your package manager to avoid conflicts. (Use `which cmake` to find other installed versions.)

**DTC (Device Tree Compiler)**  A recent DTC version is required. Check what version you have by using `dtc --version`. If you have an older version, either install a more recent one by building from source, or use the one that is bundled in the Zephyr SDK by installing it.

**Python**  A modern Python 3 version is required. Check what version you have by using `python3 --version`.

If you have an older version, you will need to install a more recent Python 3. You can build from source, or use a backport from your distribution’s package manager channels if one is available. Isolating this Python in a virtual environment is recommended to avoid interfering with your system Python.

**Install the Zephyr Software Development Kit (SDK)**  The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr’s supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).
The Zephyr SDK supports the following target architectures:

- ARC (32-bit and 64-bit; ARCv1, ARCv2, ARCv3)
- ARM (32-bit and 64-bit; ARMv6, ARMv7, ARMv8; A/R/M Profiles)
- MIPS (32-bit and 64-bit)
- Nios II
- RISC-V (32-bit and 64-bit; RV32I, RV32E, RV64I)
- x86 (32-bit and 64-bit)
- Xtensa

Follow these steps to install the Zephyr SDK:

1. **Download and verify the Zephyr SDK bundle:**
   ```
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/
   --zephyr-sdk-0.16.3_linux-x86_64.tar.xz
   wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/
   --sha256.sum | shasum --check --ignore-missing
   ```
   You can change 0.16.3 to another version if needed; the Zephyr SDK Releases page contains all available SDK releases.

   If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace x86_64 with aarch64 in order to download the 64-bit ARM Linux SDK.

2. **Extract the Zephyr SDK bundle archive:**
   ```
   cd <sdk download directory>
   tar xvf zephyr-sdk-0.16.3_linux-x86_64.tar.xz
   ```

3. **Run the Zephyr SDK bundle setup script:**
   ```
   cd zephyr-sdk-0.16.3
   ./setup.sh
   ```
   If this fails, make sure Zephyr’s dependencies were installed as described in Install Requirements and Dependencies.

If you want to uninstall the SDK, remove the directory where you installed it. If you relocate the SDK directory, you need to re-run the setup script.

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following locations:

- `$HOME`
- `$HOME/.local`
- `$HOME/.local/opt`
- `$HOME/bin`
- `/opt`
- `/usr/local`

The Zephyr SDK bundle archive contains the zephyr-sdk-0.16.3 directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-0.16.3`.

If you install the Zephyr SDK outside any of these locations, you must register the Zephyr SDK in the CMake package registry by running the setup script, or set ZEPHYR_SDK_INSTALL_DIR to point to the Zephyr SDK installation directory.
You can also use `ZEPHYR_SDK_INSTALL_DIR` for pointing to a directory containing multiple Zephyr SDKs, allowing for automatic toolchain selection. For example, `ZEPHYR_SDK_INSTALL_DIR=/company/tools`, where the `company/tools` folder contains the following subfolders:

- `/company/tools/zephyr-sdk-0.13.2`
- `/company/tools/zephyr-sdk-a.b.c`
- `/company/tools/zephyr-sdk-x.y.z`

This allows the Zephyr build system to choose the correct version of the SDK, while allowing multiple Zephyr SDKs to be grouped together at a specific path.

Building on Linux without the Zephyr SDK  The Zephyr SDK is provided for convenience and ease of use. It provides toolchains for all Zephyr target architectures, and does not require any extra flags when building applications or running tests. In addition to cross-compilers, the Zephyr SDK also provides pre-built host tools. It is, however, possible to build without the SDK's toolchain by using another toolchain as described in the Toolchains section.

As already noted above, the SDK also includes prebuilt host tools. To use the SDK's prebuilt host tools with a toolchain from another source, you must set the `ZEPHYR_SDK_INSTALL_DIR` environment variable to the Zephyr SDK installation directory. To build without the Zephyr SDK's prebuilt host tools, the `ZEPHYR_SDK_INSTALL_DIR` environment variable must be unset.

To make sure this variable is unset, run:

```
unset ZEPHYR_SDK_INSTALL_DIR
```

macOS alternative setup instructions

**Important note about Gatekeeper**  Starting with macOS 10.15 Catalina, applications launched from the macOS Terminal application (or any other terminal emulator) are subject to the same system security policies that are applied to applications launched from the Dock. This means that if you download executable binaries using a web browser, macOS will not let you execute those from the Terminal by default. In order to get around this issue you can take two different approaches:

- Run `xattr -r -d com.apple.quarantine /path/to/folder` where `/path/to/folder` is the path to the enclosing folder where the executables you want to run are located.
- Open “System Preferences” -> “Security and Privacy” -> “Privacy” and then scroll down to “Developer Tools”. Then unlock the lock to be able to make changes and check the checkbox corresponding to your terminal emulator of choice. This will apply to any executable being launched from such terminal program.

Note that this section does not apply to executables installed with Homebrew, since those are automatically un-quarantined by `brew` itself. This is however relevant for most Toolchains.

**Additional notes for MacPorts users**  While MacPorts is not officially supported in this guide, it is possible to use MacPorts instead of Homebrew to get all the required dependencies on macOS. Note also that you may need to install `rust` and `cargo` for the Python dependencies to install correctly.

Windows alternative setup instructions

**Windows 10 WSL (Windows Subsystem for Linux)**  If you are running a recent version of Windows 10 you can make use of the built-in functionality to natively run Ubuntu binaries directly on a standard command-prompt. This allows you to use software such as the Zephyr SDK without setting up a virtual machine.

2.2. Beyond the Getting Started Guide
1. **Install the Windows Subsystem for Linux (WSL).**

   **Note:** For the Zephyr SDK to function properly you will need Windows 10 build 15002 or greater. You can check which Windows 10 build you are running in the “About your PC” section of the System Settings. If you are running an older Windows 10 build you might need to install the Creator’s Update.

2. Follow the Ubuntu instructions in the [Install Linux Host Dependencies](#) document.

### 2.2.3 Install a Toolchain

Zephyr binaries are compiled and linked by a toolchain comprised of a cross-compiler and related tools which are different from the compiler and tools used for developing software that runs natively on your host operating system.

You can install the Zephyr SDK to get toolchains for all supported architectures, or install an alternate toolchain recommended by the SoC vendor or a specific board (check your specific board-level documentation).

You can configure the Zephyr build system to use a specific toolchain by setting environment variables such as `ZEPHYR_TOOLCHAIN_VARIANT` to a supported value, along with additional variable(s) specific to the toolchain variant.

### 2.2.4 Updating the Zephyr SDK toolchain

When updating Zephyr SDK, check whether the `ZEPHYR_TOOLCHAIN_VARIANT` or `ZEPHYR_SDK_INSTALL_DIR` environment variables are already set.

- If the variables are not set, the latest compatible version of Zephyr SDK will be selected by default. Proceed to next step without making any changes.

- If `ZEPHYR_TOOLCHAIN_VARIANT` is set, the corresponding toolchain will be selected at build time. Zephyr SDK is identified by the value `zephyr`. If the `ZEPHYR_TOOLCHAIN_VARIANT` environment variable is not `zephyr`, then either unset it or change its value to `zephyr` to make sure Zephyr SDK is selected.

- If the `ZEPHYR_SDK_INSTALL_DIR` environment variable is set, it will override the default lookup location for Zephyr SDK. If you install Zephyr SDK to one of the recommended locations, you can unset this variable. Otherwise, set it to your chosen install location.

For more information about these environment variables in Zephyr, see [Important Environment Variables](#).

### 2.2.5 Cloning the Zephyr Repositories

The Zephyr project source is maintained in the GitHub zephyr repo. External modules used by Zephyr are found in the parent GitHub Zephyr project. Because of these dependencies, it's convenient to use the Zephyr-created `west` tool to fetch and manage the Zephyr and external module source code. See [Basics](#) for more details.

Once your development tools are installed, use `West (Zephyr’s meta-tool)` to create, initialize, and download sources from the zephyr and external module repos. We’ll use the name `zephyrproject`, but you can choose any name that does not contain a space anywhere in the path.
The `west update` command fetches and keeps Modules (External projects) in the `zephyrproject` folder in sync with the code in the local zephyr repo.

**Warning:** You must run `west update` any time the `zephyr/west.yml` changes, caused, for example, when you pull the zephyr repository, switch branches in it, or perform a git bisect inside of it.

**Keeping Zephyr updated**

To update the Zephyr project source code, you need to get the latest changes via git. Afterwards, run `west update` as mentioned in the previous paragraph.

```
# replace zephyrproject with the path you gave west init
cd zephyrproject/zephyr
git pull
west update
```

### 2.2.6 Export Zephyr CMake package

The Zephyr CMake Package can be exported to CMake's user package registry if it has not already been done as part of Getting Started Guide.

### 2.2.7 Board Aliases

Developers who work with multiple boards may find explicit board names cumbersome and want to use aliases for common targets. This is supported by a CMake file with content like this:

```
# Variable foo_BOARD_ALIAS=bar replaces BOARD=foo with BOARD=bar and
# sets BOARD_ALIAS=foo in the CMake cache.
set(pca10028_BOARD_ALIAS nrf51dk_nrf51422)
set(pca10056_BOARD_ALIAS nrf52840dk_nrf52840)
set(k64f_BOARD_ALIAS frdm_k64f)
set(sltb004a_BOARD_ALIAS efr32mg_sltb004a)
```

and specifying its location in `ZEPHYR_BOARD_ALIASES`. This enables use of aliases pca10028 in contexts like `cmake -DBOARD=pca10028` and `west -b pca10028`.

### 2.2.8 Build and Run an Application

You can build, flash, and run Zephyr applications on real hardware using a supported host system. Depending on your operating system, you can also run it in emulation with QEMU, or as a native POSIX application. Additional information about building applications can be found in the Building an Application section.

**Build Blinky**

Let's build the blinky sample application.
Zephyr applications are built to run on specific hardware, called a “board”\(^2\). We’ll use the Phytec reel_board here, but you can change the `reel_board` build target to another value if you have a different board. See boards or run west boards from anywhere inside the `zephyrproject` directory for a list of supported boards.

1. Go to the zephyr repository:
   ```
cd zephyrproject/zephyr
   ```

2. Build the blinky sample for the `reel_board`:
   ```
west build -b reel_board samples/basic/blinky
   ```

The main build products will be in `build/zephyr`; `build/zephyr/zephyr.elf` is the blinky application binary in ELF format. Other binary formats, disassembly, and map files may be present depending on your board.

The other sample applications in the `samples` folder are documented in `samples-and-demos`.

**Note:** If you want to re-use an existing build directory for another board or application, you need to add the parameter `-p=auto` to `west build` to clean out settings and artifacts from the previous build.

### Run the Application by Flashing to a Board

Most hardware boards supported by Zephyr can be flashed by running `west flash`. This may require board-specific tool installation and configuration to work properly.

See [Run an Application](#) and your specific board's documentation in boards for additional details.

### Setting udev rules

Flashing a board requires permission to directly access the board hardware, usually managed by installation of the flashing tools. On Linux systems, if the `west flash` command fails, you likely need to define udev rules to grant the needed access permission.

Udev is a device manager for the Linux kernel and the udev daemon handles all user space events raised when a hardware device is added (or removed) from the system. We can add a rules file to grant access permission by non-root users to certain USB-connected devices.

The OpenOCD (On-Chip Debugger) project conveniently provides a rules file that defined board-specific rules for most Zephyr-supported arm-based boards, so we recommend installing this rules file by downloading it from their sourceforge repo, or if you’ve installed the Zephyr SDK there is a copy of this rules file in the SDK folder:

- Either download the OpenOCD rules file and copy it to the right location:
  ```
  wget -O 60-openocd.rules https://sf.net/p/openocd/code/ci/master/tree/contrib/60-
  openocd.rules?format=raw
  sudo cp 60-openocd.rules /etc/udev/rules.d
  ```

- Or copy the rules file from the Zephyr SDK folder:
  ```
  sudo cp ${ZEPHYR_SDK_INSTALL_DIR}/sysroots/x86_64-pokysdk-linux/usr/share/
  openocd/contrib/60-openocd.rules /etc/udev/rules.d
  ```

---

\(^2\) This has become something of a misnomer over time. While the target can be, and often is, a microprocessor running on its own dedicated hardware board, Zephyr also supports using QEMU to run targets built for other architectures in emulation, targets which produce native host system binaries that implement Zephyr's driver interfaces with POSIX APIs, and even running different Zephyr-based binaries on CPU cores of differing architectures on the same physical chip. Each of these hardware configurations is called a “board,” even though that doesn’t always make perfect sense in context.
Then, in either case, ask the udev daemon to reload these rules:

```
sudo udevadm control --reload
```

Unplug and plug in the USB connection to your board, and you should have permission to access the board hardware for flashing. Check your board-specific documentation (boards) for further information if needed.

**Run the Application in QEMU**

On Linux and macOS, you can run Zephyr applications via emulation on your host system using QEMU when targeting either the x86 or ARM Cortex-M3 architectures. (QEMU is included with the Zephyr SDK installation.)

For example, you can build and run the hello_world sample using the x86 emulation board configuration (`qemu_x86`), with:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
west build -t run
```

To exit QEMU, type `Ctrl-a`, then `x`.

Use `qemu_cortex_m3` to target an emulated Arm Cortex-M3 sample.

**Run a Sample Application natively (POSIX OS)**

You can compile some samples to run as host processes on a POSIX OS. This is currently only tested on Linux hosts. See `native_posix` for more information. On 64-bit host operating systems, you need to install a 32-bit C library; see `native_posix_deps` for details.

First, build Hello World for `native_posix`.

```
# From the root of the zephyr repository
west build -b native_posix samples/hello_world
```

Next, run the application.

```
west build -t run
# or just run zephyr.exe directly:
./build/zephyr/zephyr.exe
```

Press `Ctrl-C` to exit.

You can run `./build/zephyr/zephyr.exe --help` to get a list of available options.

This executable can be instrumented using standard tools, such as `gdb` or `valgrind`.

### 2.3 Environment Variables

Various pages in this documentation refer to setting Zephyr-specific environment variables. This page describes how.

#### 2.3.1 Setting Variables
Option 1: Just Once

To set the environment variable `MY_VARIABLE` to `foo` for the lifetime of your current terminal window:

**Linux/macOS**

```bash
export MY_VARIABLE=foo
```

**Windows**

```cmd
set MY_VARIABLE=foo
```

**Warning:** This is best for experimentation. If you close your terminal window, use another terminal window or tab, restart your computer, etc., this setting will be lost forever.

Using options 2 or 3 is recommended if you want to keep using the setting.

Option 2: In all Terminals

**Linux/macOS**

Add the `export MY_VARIABLE=foo` line to your shell’s startup script in your home directory. For Bash, this is usually `~/.bashrc` on Linux or `~/.bash_profile` on macOS. Changes in these startup scripts don’t affect shell instances already started; try opening a new terminal window to get the new settings.

**Windows**

You can use the `setx` program in `cmd.exe` or the third-party RapidEE program.

To use `setx`, type this command, then close the terminal window. Any new `cmd.exe` windows will have `MY_VARIABLE` set to `foo`.

```cmd
setx MY_VARIABLE foo
```

To install RapidEE, a freeware graphical environment variable editor, using Chocolatey in an Administrator command prompt:

```cmd
choco install rapidee
```

You can then run `rapidee` from your terminal to launch the program and set environment variables. Make sure to use the “User” environment variables area – otherwise, you have to run RapidEE as administrator. Also make sure to save your changes by clicking the Save button at top left before exiting. Settings you make in RapidEE will be available whenever you open a new terminal window.

Option 3: Using `zephyrrc` files

Choose this option if you don’t want to make the variable’s setting available to all of your terminals, but still want to save the value for loading into your environment when you are using Zephyr.

**Linux/macOS**

Create a file named `~/.zephyrrc` if it doesn’t exist, then add this line to it:

```bash
export MY_VARIABLE=foo
```

To get this value back into your current terminal environment, **you must run** `source zephyr-env.sh` from the main `zephyr` repository. Among other things, this script sources `~/.zephyrrc`.

The value will be lost if you close the window, etc.; run `source zephyr-env.sh` again to get it back.

**Windows**

...
Add the line `set MY_VARIABLE=foo` to the file `%userprofile%\zephyrrc.cmd` using a text editor such as Notepad to save the value.

To get this value back into your current terminal environment, you must run `zephyr-env.cmd` in a `cmd.exe` window after changing directory to the main zephyr repository. Among other things, this script runs `%userprofile%\zephyrrc.cmd`.

The value will be lost if you close the window, etc.; run `zephyr-env.cmd` again to get it back.

These scripts:
- set `ZEPHYR_BASE` to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your `PATH` environment variable
- loads any settings from the `zephyrrc` files described above in Option 3: Using `zephyrrc` files.

You can thus use them any time you need any of these settings.

### 2.3.2 Zephyr Environment Scripts

You can use the zephyr repository scripts `zephyr-env.sh` (for macOS and Linux) and `zephyr-env.cmd` (for Windows) to load Zephyr-specific settings into your current terminal's environment. To do so, run this command from the zephyr repository:

**Linux/macOS**

```bash
source zephyr-env.sh
```

**Windows**

```
zephyr-env.cmd
```

These scripts:
- set `ZEPHYR_BASE` to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your `PATH` environment variable
- loads any settings from the `zephyrrc` files described above in Option 3: Using `zephyrrc` files.

You can thus use them any time you need any of these settings.

### 2.3.3 Important Environment Variables

Some Important Build System Variables can also be set in the environment. Here is a description of some of these important environment variables. This is not a comprehensive list.

**BOARD**

See Important Build System Variables.

**CONF_FILE**

See Important Build System Variables.

**SHIELD**

See Shields.

**ZEPHYR_BASE**

See Important Build System Variables.

2.3. Environment Variables
EXTRA_ZEPHYR_MODULES
See Important Build System Variables.

ZEPHYR_MODULES
See Important Build System Variables.

ZEPHYR_BOARD_ALIASES
See Board Aliases

The following additional environment variables are significant when configuring the toolchain used to build Zephyr applications.

ZEPHYR_SDK_INSTALL_DIR
Path where Zephyr SDK is installed.

ZEPHYR_TOOLCHAIN_VARIANT
The name of the toolchain to use.

{TOOLCHAIN}_TOOLCHAIN_PATH
Path to the toolchain specified by ZEPHYR_TOOLCHAIN_VARIANT. For example, if ZEPHYR_TOOLCHAIN_VARIANT=llvm, use LLVM_TOOLCHAIN_PATH. (Note the capitalization when forming the environment variable name.)

You might need to update some of these variables when you update the Zephyr SDK toolchain.

Emulators and boards may also depend on additional programs. The build system will try to locate those programs automatically, but may rely on additional CMake or environment variables to do so. Please consult your emulator’s or board’s documentation for more information. The following environment variables may be useful in such situations:

PATH
PATH is an environment variable used on Unix-like or Microsoft Windows operating systems to specify a set of directories where executable programs are located.

### 2.4 Application Development

**Note:** In this document, we'll assume:

- your *application directory*, `<app>`, is something like `<home>/zephyrproject/app`
- its *build directory* is `<app>/build`

These terms are defined below. On Linux/macOS, `<home>` is equivalent to `.`. On Windows, it's `%userprofile%`.

Keeping your application inside the workspace (`<home>/zephyrproject`) makes it easier to use `west build` and other commands with it. (You can put your application anywhere as long as `ZEPHYR_BASE` is set appropriately, though.)

#### 2.4.1 Overview

Zephyr’s build system is based on CMake.

The build system is application-centric, and requires Zephyr-based applications to initiate building the Zephyr source code. The application build controls the configuration and build process of both the application and Zephyr itself, compiling them into a single binary.
The main zephyr repository contains Zephyr's source code, configuration files, and build system. You also likely have installed various Modules (External projects) alongside the zephyr repository, which provide third party source code integration.

The files in the application directory link Zephyr and any modules with the application. This directory contains all application-specific files, such as application-specific configuration files and source code.

Here are the files in a simple Zephyr application:

```markdown
<app>
  ├── CMakeLists.txt
  │   ├── app.overlay
  │   │   ├── prj.conf
  │   │   │   └── main.c
  │   └── VERSION
  └── src
```

These contents are:

- **CMakeLists.txt**: This file tells the build system where to find the other application files, and links the application directory with Zephyr's CMake build system. This link provides features supported by Zephyr's build system, such as board-specific configuration files, the ability to run and debug compiled binaries on real or emulated hardware, and more.

- **app.overlay**: This is a devicetree overlay file that specifies application-specific changes which should be applied to the base devicetree for any board you build for. The purpose of devicetree overlays is usually to configure something about the hardware used by the application.

The build system looks for `app.overlay` by default, but you can add more devicetree overlays, and other default files are also searched for.

See Devicetree for more information about devicetree.

- **prj.conf**: This is a Kconfig fragment that specifies application-specific values for one or more Kconfig options. These application settings are merged with other settings to produce the final configuration. The purpose of Kconfig fragments is usually to configure the software features used by the application.

The build system looks for `prj.conf` by default, but you can add more Kconfig fragments, and other default files are also searched for.

See Kconfig Configuration below for more information.

- **VERSION**: A text file that contains several version information fields. These fields let you manage the lifecycle of the application and automate providing the application version when signing application images.

See Application version management for more information about this file and how to use it.

- **main.c**: A source code file. Applications typically contain source files written in C, C++, or assembly language. The Zephyr convention is to place them in a subdirectory of `<app>` named `src`.

Once an application has been defined, you will use CMake to generate a build directory, which contains the files you need to build the application and Zephyr, then link them together into a final binary you can run on your board. The easiest way to do this is with west build, but you can use CMake directly also. Application build artifacts are always generated in a separate build directory: Zephyr does not support “in-tree” builds.

The following sections describe how to create, build, and run Zephyr applications, followed by more detailed reference material.

## 2.4.2 Application types

We distinguish three basic types of Zephyr application based on where `<app>` is located:
We’ll discuss these more below. To learn how the build system supports each type, see Zephyr CMake Package.

### Zephyr repository application

An application located within the zephyr source code repository in a Zephyr west workspace is referred to as a Zephyr repository application. In the following example, the hello_world sample is a Zephyr repository application:

```
zephyrproject/
  .west/
  config
  zephyr/
    arch/
    boards/
    cmake/
    samples/
      hello_world/
  ...
  tests/
  ...
```

### Zephyr workspace application

An application located within a workspace, but outside the zephyr repository itself, is referred to as a Zephyr workspace application. In the following example, app is a Zephyr workspace application:

```
zephyrproject/
  .west/
    config
    zephyr/
    bootloader/
    modules/
    tools/
    <vendor/private-repositories>/
    applications/
      app/
```

### Zephyr freestanding application

A Zephyr application located outside of a Zephyr workspace is referred to as a Zephyr freestanding application. In the following example, app is a Zephyr freestanding application:

```
<home>/
  zephyrproject/
    .west/
      config
      zephyr/
```

(continues on next page)
2.4.3 Creating an Application

In Zephyr, you can either use a reference workspace application or create your application by hand.

**Using a Reference Workspace Application**

The example-application Git repository contains a reference *workspace application*. It is recommended to use it as a reference when creating your own application as described in the following sections.

The example-application repository demonstrates how to use several commonly-used features, such as:

- Custom board ports
- Custom devicetree bindings
- Custom device drivers
- Continuous Integration (CI) setup, including using *twister*
- A custom west *extension command*

**Basic example-application Usage** The easiest way to get started with the example-application repository within an existing Zephyr workspace is to follow these steps:

```
    cd <home>/zephyrproject
    git clone https://github.com/zephyrproject-rtos/example-application my-app
```

The directory name *my-app* above is arbitrary: change it as needed. You can now go into this directory and adapt its contents to suit your needs. Since you are using an existing Zephyr workspace, you can use *west build* or any other west commands to build, flash, and debug.

**Advanced example-application Usage** You can also use the example-application repository as a starting point for building your own customized Zephyr-based software distribution. This lets you do things like:

- remove Zephyr modules you don't need
- add additional custom repositories of your own
- override repositories provided by Zephyr with your own versions
- share the results with others and collaborate further

The example-application repository contains a *west.yml* file and is therefore also a west *manifest repository*. Use this to create a new, customized workspace by following these steps:
cd <home>
mkdir my-workspace
cd my-workspace
git clone https://github.com/zephyrproject-rtos/example-application my-manifest-repo
west init -l my-manifest-repo

This will create a new workspace with the T2 topology, with my-manifest-repo as the manifest repository. The my-workspace and my-manifest-repo names are arbitrary: change them as needed.

Next, customize the manifest repository. The initial contents of this repository will match the example-application's contents when you clone it. You can then edit my-manifest-repo/west.yml to your liking, changing the set of repositories in it as you wish. See Manifest Imports for many examples of how to add or remove different repositories from your workspace as needed. Make any other changes you need to other files.

When you are satisfied, you can run:

west update

and your workspace will be ready for use.

If you push the resulting my-manifest-repo repository somewhere else, you can share your work with others. For example, let's say you push the repository to https://git.example.com/my-manifest-repo. Other people can then set up a matching workspace by running:

west init -m https://git.example.com/my-manifest-repo my-workspace
cd my-workspace
west update

From now on, you can collaborate on the shared software by pushing changes to the repositories you are using and updating my-manifest-repo/west.yml as needed to add and remove repositories, or change their contents.

Creating an Application by Hand

You can follow these steps to create a basic application directory from scratch. However, using the example-application repository or one of Zephyr's samples-and-demos as a starting point is likely to be easier.

1. Create an application directory.

For example, in a Unix shell or Windows cmd.exe prompt:

mkdir app

Warning: Building Zephyr or creating an application in a directory with spaces anywhere on the path is not supported. So the Windows path C:\Users\YourName\app will work, but C:\Users\Your Name\app will not.

2. Create your source code files.

It's recommended to place all application source code in a subdirectory named src. This makes it easier to distinguish between project files and sources.

Continuing the previous example, enter:

cd app
mkdir src
3. Place your application source code in the `src` sub-directory. For this example, we’ll assume you created a file named `src/main.c`.

4. Create a file named `CMakeLists.txt` in the `app` directory with the following contents:

```cmake
cmake_minimum_required(VERSION 3.20.0)
find_package(Zephyr)
project(my_zephyr_app)
target_sources(app PRIVATE src/main.c)
```

Notes:

- The `cmake_minimum_required()` call is required by CMake. It is also invoked by the Zephyr package on the next line. CMake will error out if its version is older than either the version in your CMakeLists.txt or the version number in the Zephyr package.
- `find_package(Zephyr)` pulls in the Zephyr build system, which creates a CMake target named `app` (see Zephyr CMake Package). Adding sources to this target is how you include them in the build. The Zephyr package will define `Zephyr-Kernel` as a CMake project and enable support for the C, CXX, ASM languages.
- `project(my_zephyr_app)` defines your application’s CMake project. This must be called after `find_package(Zephyr)` to avoid interference with Zephyr's project (Zephyr-Kernel).
- `target_sources(app PRIVATE src/main.c)` is to add your source file to the app target. This must come after `find_package(Zephyr)` which defines the target. You can add as many files as you want with `target_sources()`.

5. Create at least one Kconfig fragment for your application (usually named `prj.conf`) and set Kconfig option values needed by your application there. See Kconfig Configuration. If no Kconfig options need to be set, create an empty file.

6. Configure any devicetree overlays needed by your application, usually in a file named `app.overlay`. See Set devicetree overlays.

7. Set up any other files you may need, such as `twister` configuration files, continuous integration files, documentation, etc.

### 2.4.4 Important Build System Variables

You can control the Zephyr build system using many variables. This section describes the most important ones that every Zephyr developer should know about.

**Note:** The variables `BOARD`, `CONF_FILE`, and `DTC_OVERLAY_FILE` can be supplied to the build system in 3 ways (in order of precedence):

- As a parameter to the `west build` or `cmake` invocation via the `-D` command-line switch. If you have multiple overlay files, you should use quotations, "file1.overlay;file2.overlay"
- As Environment Variables.
- As a `set(<VARIABLE> <VALUE>)` statement in your CMakeLists.txt

- `ZEPHYR_BASE`: Zephyr base variable used by the build system. `find_package(Zephyr)` will automatically set this as a cached CMake variable. But `ZEPHYR_BASE` can also be set as an environment variable in order to force CMake to use a specific Zephyr installation.
- `BOARD`: Selects the board that the application’s build will use for the default configuration. See boards for built-in boards, and Board Porting Guide for information on adding board support.
• **CONF_FILE**: Indicates the name of one or more Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. Each file includes Kconfig configuration values that override the default configuration values.

  See *The Initial Configuration* for more information.

• **EXTRA_CONF_FILE**: Additional Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. This can be useful in order to leave **CONF_FILE** at its default value, but “mix in” some additional configuration options.

• **DTC_OVERLAY_FILE**: One or more devicetree overlay files to use. Multiple files can be separated with semicolons. See *Set devicetree overlays* for examples and *Introduction to devicetree* for information about devicetree and Zephyr.

• **SHIELD**: see *Shields*

• **ZEPHYR_MODULES**: A CMake list containing absolute paths of additional directories with source code, Kconfig, etc. that should be used in the application build. See *Modules (External projects)* for details. If you set this variable, it must be a complete list of all modules to use, as the build system will not automatically pick up any modules from west.

• **EXTRA_ZEPHYR_MODULES**: Like **ZEPHYR_MODULES**, except these will be added to the list of modules found via west, instead of replacing it.

**Note**: You can use a Zephyr Build Configuration CMake packages to share common settings for these variables.

### 2.4.5 Application CMakeLists.txt

Every application must have a `CMakeLists.txt` file. This file is the entry point, or top level, of the build system. The final `zephyr.elf` image contains both the application and the kernel libraries.

This section describes some of what you can do in your `CMakeLists.txt`. Make sure to follow these steps in order.

1. If you only want to build for one board, add the name of the board configuration for your application on a new line. For example:

   ```cmake
   set(BOARD qemu_x86)
   ```

   Refer to boards for more information on available boards.

   The Zephyr build system determines a value for **BOARD** by checking the following, in order (when a **BOARD** value is found, CMake stops looking further down the list):

   • Any previously used value as determined by the CMake cache takes highest precedence. This ensures you don't try to run a build with a different **BOARD** value than you set during the build configuration step.

   • Any value given on the CMake command line (directly or indirectly via `west build`) using `-DBOARD=YOUR_BOARD` will be checked for and used next.

   • If an environment variable **BOARD** is set, its value will then be used.

   • Finally, if you set **BOARD** in your application `CMakeLists.txt` as described in this step, this value will be used.

2. If your application uses a configuration file or files other than the usual `prj.conf` (or `prj_YOUR_BOARD.conf`, where **YOUR_BOARD** is a board name), add lines setting the **CONF_FILE** variable to these files appropriately. If multiple filenames are given, separate them by a single space or semicolon. CMake lists can be used to build up configuration fragment files in a modular way when you want to avoid setting **CONF_FILE** in a single place. For example:
set(CONF_FILE "fragment_file1.conf")
list(APPEND CONF_FILE "fragment_file2.conf")

See *The Initial Configuration* for more information.

3. If your application uses devicetree overlays, you may need to set `DTC_OVERLAY_FILE`. See *Set devicetree overlays*.

4. If your application has its own kernel configuration options, create a `Kconfig` file in the same directory as your application's `CMakeLists.txt`.

   See the `Kconfig` section of the manual for detailed `Kconfig` documentation.

   An (unlikely) advanced use case would be if your application has its own unique configuration options that are set differently depending on the build configuration.

   If you just want to set application specific values for existing Zephyr configuration options, refer to the `CONF_FILE` description above.

   Structure your `Kconfig` file like this:

   ```
   # SPDX-License-Identifier: Apache-2.0
   mainmenu "Your Application Name"
   # Your application configuration options go here
   # Sources `Kconfig.zephyr` in the Zephyr root directory.
   # Note: All 'source' statements work relative to the Zephyr root directory (due
   # to the $srctree environment variable being set to $ZEPHYR_BASE). If you want
   # to 'source' relative to the current Kconfig file instead, use 'rsource' (or a
   # path relative to the Zephyr root).
   source "Kconfig.zephyr"
   ```

   **Note:** Environment variables in `source` statements are expanded directly, so you do not need to define an option `env="ZEPHYR_BASE"` Kconfig “bounce” symbol. If you use such a symbol, it must have the same name as the environment variable.

   See *Kconfig extensions* for more information.

   The `Kconfig` file is automatically detected when placed in the application directory, but it is also possible for it to be found elsewhere if the CMake variable `KCONFIG_ROOT` is set with an absolute path.

5. Specify that the application requires Zephyr on a new line, after any lines added from the steps above:

   ```
   find_package(Zephyr)
   project(my_zephyr_app)
   ```

   **Note:** `find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})` can be used if enforcing a specific Zephyr installation by explicitly setting the `ZEPHYR_BASE` environment variable should be supported. All samples in Zephyr supports the `ZEPHYR_BASE` environment variable.

6. Now add any application source files to the ‘app’ target library, each on their own line, like so:

   ```
   target_sources(app PRIVATE src/main.c)
   ```
Below is a simple example CMakeList.txt:

```cmake
set(BOARD qemu_x86)
find_package(Zephyr)
project(my_zephyr_app)
target_sources(app PRIVATE src/main.c)
```

The Cmake property HEX_FILES_TO_MERGE leverages the application configuration provided by Kconfig and CMake to let you merge externally built hex files with the hex file generated when building the Zephyr application. For example:

```cmake
set_property(GLOBAL APPEND PROPERTY HEX_FILES_TO_MERGE
            ${app_bootloader_hex}
            ${PROJECT_BINARY_DIR}/${KERNEL_HEX_NAME}
            ${app_provision_hex})
```

### 2.4.6 CMakeCache.txt

CMake uses a CMakeCache.txt file as persistent key/value string storage used to cache values between runs, including compile and build options and paths to library dependencies. This cache file is created when CMake is run in an empty build folder.

For more details about the CMakeCache.txt file see the official CMake documentation [runningcmake](#).

### 2.4.7 Application Configuration

#### Application Configuration Directory

Zephyr will use configuration files from the application’s configuration directory except for files with an absolute path provided by the arguments described earlier, for example CONF_FILE, EXTRA_CONF_FILE, DTC_OVERLAY_FILE, and EXTRA_DTC_OVERLAY_FILE.

The application configuration directory is defined by the APPLICATION_CONFIG_DIR variable.

APPLICATION_CONFIG_DIR will be set by one of the sources below with the highest priority listed first.

1. If APPLICATION_CONFIG_DIR is specified by the user with -DAPPLICATION_CONFIG_DIR=<path> or in a CMake file before find_package(Zephyr) then this folder is used as the application’s configuration directory.

2. The application’s source directory.

#### Kconfig Configuration

Application configuration options are usually set in prj.conf in the application directory. For example, C++ support could be enabled with this assignment:

```cmake
CONFIG_CPP=y
```

Looking at existing samples is a good way to get started.

See [Setting Kconfig configuration values](#) for detailed documentation on setting Kconfig configuration values. The [Initial Configuration](#) section on the same page explains how the initial configuration is derived. See kconfig-search for a complete list of configuration options. See [Hardening Tool](#) for security information related with Kconfig options.
The other pages in the Kconfig section of the manual are also worth going through, especially if you planning to add new configuration options.

**Experimental features**  
Zephyr is a project under constant development and thus there are features that are still in early stages of their development cycle. Such features will be marked [EXPERIMENTAL] in their Kconfig title.

The `CONFIG_WARN_EXPERIMENTAL` setting can be used to enable warnings at CMake configure time if any experimental feature is enabled.

```
CONFIG_WARN_EXPERIMENTAL=y
```

For example, if option `CONFIG_FOO` is experimental, then enabling it and `CONFIG_WARN_EXPERIMENTAL` will print the following warning at CMake configure time when you build an application:

```
warning: Experimental symbol FOO is enabled.
```

**Devicetree Overlays**

See [Set devicetree overlays](#).

### 2.4.8 Application-Specific Code

Application-specific source code files are normally added to the application's `src` directory. If the application adds a large number of files the developer can group them into sub-directories under `src`, to whatever depth is needed.

Application-specific source code should not use symbol name prefixes that have been reserved by the kernel for its own use. For more information, see Naming Conventions.

**Third-party Library Code**

It is possible to build library code outside the application's `src` directory but it is important that both application and library code targets the same Application Binary Interface (ABI). On most architectures there are compiler flags that control the ABI targeted, making it important that both libraries and applications have certain compiler flags in common. It may also be useful for glue code to have access to Zephyr kernel header files.

To make it easier to integrate third-party components, the Zephyr build system has defined CMake functions that give application build scripts access to the zephyr compiler options. The functions are documented and defined in `cmake/extensions.cmake` and follow the naming convention `zephyr_get_<type>_<format>`.

The following variables will often need to be exported to the third-party build system.

- `CMAKE_C_COMPILER`, `CMAKE_AR`.
- `ARCH` and `BOARD`, together with several variables that identify the Zephyr kernel version.

`samples/application_development/external_lib` is a sample project that demonstrates some of these features.

### 2.4.9 Building an Application

The Zephyr build system compiles and links all components of an application into a single application image that can be run on simulated hardware or real hardware.
Like any other CMake-based system, the build process takes place in two stages. First, build files (also known as a build system) are generated using the `cmake` command-line tool while specifying a generator. This generator determines the native build tool the build system will use in the second stage. The second stage runs the native build tool to actually build the source files and generate an image. To learn more about these concepts refer to the CMake introduction in the official CMake documentation.

Although the default build tool in Zephyr is `west`, Zephyr's meta-tool, which invokes `cmake` and the underlying build tool (ninja or make) behind the scenes, you can also choose to invoke `cmake` directly if you prefer. On Linux and macOS you can choose between the `make` and `ninja` generators (i.e. build tools), whereas on Windows you need to use `ninja`, since `make` is not supported on this platform. For simplicity we will use `ninja` throughout this guide, and if you choose to use `west build` to build your application know that it will default to `ninja` under the hood.

As an example, let's build the Hello World sample for the reel_board:

Using west:

```bash
west build -b reel_board samples/hello_world
```

Using CMake and ninja:

```bash
# Use cmake to configure a Ninja-based build system:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild
```

On Linux and macOS, you can also build with `make` instead of `ninja`:

Using west:

- to use `make` just once, add `-- -G"Unix Makefiles"` to the west build command line; see the `west build` documentation for an example.
- to use `make` by default from now on, run `west config build.generator "Unix Makefiles"`.

Using CMake directly:

```bash
# Use cmake to configure a Make-based build system:
cmake -Bbuild -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
make -Cbuild
```

### Basics

1. Navigate to the application directory `<app>`.
2. Enter the following commands to build the application's `zephyr.elf` image for the board specified in the command-line parameters:

   Using west:

   ```bash
   west build -b <board>
   ```

   Using CMake and ninja:

   ```bash
   mkdir build && cd build
   # Use cmake to configure a Ninja-based build system:
cmake -GNinja -DBOARD=<board> ..
   ```
Now run ninja on the generated build system:

```bash
ninja
```

If desired, you can build the application using the configuration settings specified in an alternate `.conf` file using the `CONF_FILE` parameter. These settings will override the settings in the application’s `.config` file or its default `.conf` file. For example:

Using west:

```bash
west build -b <board> -- -DCONF_FILE=prj.alternate.conf
```

Using CMake and ninja:

```bash
mkdir build && cd build
cmake -GNinja -DBOARD=<board> -DCONF_FILE=prj.alternate.conf ..
ninja
```

As described in the previous section, you can instead choose to permanently set the board and configuration settings by either exporting `BOARD` and `CONF_FILE` environment variables or by setting their values in your `CMakeLists.txt` using `set()` statements. Additionally, west allows you to set a default board.

## Build Directory Contents

When using the Ninja generator a build directory looks like this:

```
<app>/build
  └── build.ninja
  └── CMakeCache.txt
  └── CMakeFiles
  └── cmake_install.cmake
  └── rules.ninja
  └── zephyr
```

The most notable files in the build directory are:

- `build.ninja`, which can be invoked to build the application.
- A `zephyr` directory, which is the working directory of the generated build system, and where most generated files are created and stored.

After running `ninja`, the following build output files will be written to the `zephyr` sub-directory of the build directory. (This is not the Zephyr base directory, which contains the Zephyr source code etc. and is described above.)

- `.config`, which contains the configuration settings used to build the application.

  **Note:** The previous version of `.config` is saved to `.config.old` whenever the configuration is updated. This is for convenience, as comparing the old and new versions can be handy.

- Various object files (.o files and .a files) containing compiled kernel and application code.
- `zephyr.elf`, which contains the final combined application and kernel binary. Other binary output formats, such as `.hex` and `.bin`, are also supported.
Rebuilding an Application

Application development is usually fastest when changes are continually tested. Frequently rebuilding your application makes debugging less painful as the application becomes more complex. It's usually a good idea to rebuild and test after any major changes to the application's source files, CMakeLists.txt files, or configuration settings.

**Important:** The Zephyr build system rebuilds only the parts of the application image potentially affected by the changes. Consequently, rebuilding an application is often significantly faster than building it the first time.

Sometimes the build system doesn't rebuild the application correctly because it fails to recompile one or more necessary files. You can force the build system to rebuild the entire application from scratch with the following procedure:

1. Open a terminal console on your host computer, and navigate to the build directory `<app>/build`.
2. Enter one of the following commands, depending on whether you want to use west or cmake directly to delete the application's generated files, except for the `.config` file that contains the application's current configuration information.

   ```
   west build -t clean
   
   or
   
   ninja clean
   ```

   Alternatively, enter one of the following commands to delete all generated files, including the `.config` files that contain the application's current configuration information for those board types.

   ```
   west build -t pristine
   
   or
   
   ninja pristine
   ```

   If you use west, you can take advantage of its capability to automatically make the build folder pristine whenever it is required.

3. Rebuild the application normally following the steps specified in *Building an Application* above.

**Building for a board revision**

The Zephyr build system has support for specifying multiple hardware revisions of a single board with small variations. Using revisions allows the board support files to make minor adjustments to a board configuration without duplicating all the files described in *Create your board directory* for each revision.

To build for a particular revision, use `<board>@<revision>` instead of plain `<board>`. For example:

Using west:

```
west build -b <board>@<revision>
```

Using CMake and ninja:

```
mkdir build && cd build
cmake -GNinja -DBOARD=<board>@<revision> ..
ninja
```
Check your board's documentation for details on whether it has multiple revisions, and what revisions are supported.
When targeting a board revision, the active revision will be printed at CMake configure time, like this:

```
-- Board: plank, Revision: 1.5.0
```

### 2.4.10 Run an Application

An application image can be run on a real board or emulated hardware.

**Running on a Board**

Most boards supported by Zephyr let you flash a compiled binary using the `flash` target to copy the binary to the board and run it. Follow these instructions to flash and run an application on real hardware:

1. Build your application, as described in *Building an Application*.
2. Make sure your board is attached to your host computer. Usually, you'll do this via USB.
3. Run one of these console commands from the build directory, `<app>/build`, to flash the compiled Zephyr image and run it on your board:

   ```bash
   west flash
   ```

   or

   ```bash
   ninja flash
   ```

The Zephyr build system integrates with the board support files to use hardware-specific tools to flash the Zephyr binary to your hardware, then run it.

Each time you run the flash command, your application is rebuilt and flashed again.

In cases where board support is incomplete, flashing via the Zephyr build system may not be supported. If you receive an error message about flash support being unavailable, consult your board's documentation for additional information on how to flash your board.

**Note:** When developing on Linux, it's common to need to install board-specific udev rules to enable USB device access to your board as a non-root user. If flashing fails, consult your board's documentation to see if this is necessary.

**Running in an Emulator**

The kernel has built-in emulator support for QEMU (on Linux/macOS only, this is not yet supported on Windows). It allows you to run and test an application virtually, before (or in lieu of) loading and running it on actual target hardware. Follow these instructions to run an application via QEMU:

1. Build your application for one of the QEMU boards, as described in *Building an Application*.

   For example, you could set `BOARD` to:
   - `qemu_x86` to emulate running on an x86-based board
   - `qemu_cortex_m3` to emulate running on an ARM Cortex M3-based board

2. Run one of these console commands from the build directory, `<app>/build`, to run the Zephyr binary in QEMU:
3. Press Ctrl A, X to stop the application from running in QEMU. The application stops running and the terminal console prompt redisplays. Each time you execute the run command, your application is rebuilt and run again.

**Note:** If the (Linux only) Zephyr SDK is installed, the run target will use the SDK’s QEMU binary by default. To use another version of QEMU, set the environment variable QEMU_BIN_PATH to the path of the QEMU binary you want to use instead.

**Note:** You can choose a specific emulator by appending _<emulator>_ to your target name, for example west build -t run_qemu or ninja run_qemu for QEMU.

### 2.4.11 Custom Board, Devicetree and SOC Definitions

In cases where the board or platform you are developing for is not yet supported by Zephyr, you can add board, Devicetree and SOC definitions to your application without having to add them to the Zephyr tree.

The structure needed to support out-of-tree board and SOC development is similar to how boards and SOCs are maintained in the Zephyr tree. By using this structure, it will be much easier to upstream your platform related work into the Zephyr tree after your initial development is done.

Add the custom board to your application or a dedicated repository using the following structure:

```bash
boards/
    soc/
    CMakeLists.txt
    prj.conf
    README.rst
    src/
```

where the boards directory hosts the board you are building for:

```
boards
    x86
        my_custom_board
            doc
            img
            support
    src
```

and the soc directory hosts any SOC code. You can also have boards that are supported by a SOC that is available in the Zephyr tree.

#### Boards

Use the proper architecture folder name (e.g., x86, arm, etc.) under boards for my_custom_board. (See boards for a list of board architectures.)
Documentation (under doc/) and support files (under support/) are optional, but will be needed when submitting to Zephyr.

The contents of my_custom_board should follow the same guidelines for any Zephyr board, and provide the following files:

- my_custom_board_defconfig
- my_custom_board.dts
- my_custom_board.yaml
- board.cmake
- board.h
- CMakeLists.txt
- doc/
  - Kconfig.board
  - Kconfig.defconfig
- pinmux.c
- support/

Once the board structure is in place, you can build your application targeting this board by specifying the location of your custom board information with the -DBOARD_ROOT parameter to the CMake build system:

Using west:

```bash
west build -b <board name> -- -DBOARD_ROOT=<path to boards>
```

Using CMake and ninja:

```bash
cmake -Bbuild -GNinja -DBOARD=<board name> -DBOARD_ROOT=<path to boards> .
ninja -Cbuild
```

This will use your custom board configuration and will generate the Zephyr binary into your application directory.

You can also define the BOARD_ROOT variable in the application CMakeLists.txt file. Make sure to do so before pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`. 

**Note:** When specifying BOARD_ROOT in a CMakeLists.txt, then an absolute path must be provided, for example list(APPEND BOARD_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-board-root>). When using -DBOARD_ROOT=<board-root> both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

**SOC Definitions**

Similar to board support, the structure is similar to how SOCs are maintained in the Zephyr tree, for example:

```
soc
  - arm
    - st_stm32
      - common
      - stm3210
```

The file soc/Kconfig will create the top-level SoC/CPU/Configuration Selection menu in Kconfig.

Out of tree SoC definitions can be added to this menu using the SOC_ROOT CMake variable. This variable contains a semicolon-separated list of directories which contain SoC support files.

Following the structure above, the following files can be added to load more SoCs into the menu.
The Kconfig files above may describe the SoC or load additional SoC Kconfig files. An example of loading stm3110 specific Kconfig files in this structure:

```plaintext
soc
    arm
        st_stm32
            Kconfig
            Kconfig.soc
            Kconfig.defconfig
```

can be done with the following content in st_stm32/Kconfig.soc:

```plaintext
rsource "*/Kconfig.series"
```

Once the SOC structure is in place, you can build your application targeting this platform by specifying the location of your custom platform information with the -DSOC_ROOT parameter to the CMake build system:

Using west:

```
west build -b <board name> -- -DSOC_ROOT=<path to soc> -DBOARD_ROOT=<path to boards>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DSOC_ROOT=<path to soc> -DBOARD_ROOT=...
    -<path to boards>

ninja -Cbuild
```

This will use your custom platform configurations and will generate the Zephyr binary into your application directory.

See Build settings for information on setting SOC_ROOT in a module's zephyr/module.yml file.

Or you can define the SOC_ROOT variable in the application CMakeLists.txt file. Make sure to do so before pulling in the Zephyr boilerplate with find_package(Zephyr ...).

**Note:** When specifying SOC_ROOT in a CMakeLists.txt, then an absolute path must be provided, for example list(APPEND SOC_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-soc-root>). When using -DSOC_ROOT=<soc-root> both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

### Devicetree Definitions

Devicetree directory trees are found in APPLICATION_SOURCE_DIR, BOARD_DIR, and ZEPHYR_BASE, but additional trees, or DTS_ROOTs, can be added by creating this directory tree:

```
include/
dts/common/
dts/arm/
```

(continues on next page)
dts/
dts/bindings/

Where 'arm' is changed to the appropriate architecture. Each directory is optional. The binding directory contains bindings and the other directories contain files that can be included from DT sources.

Once the directory structure is in place, you can use it by specifying its location through the DTS_ROOT CMake Cache variable:

Using west:

```bash
west build -b <board name> -- -DDTS_ROOT=<path to dts root>
```

Using CMake and ninja:

```bash
cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_ROOT=<path to dts root> .
ninja -Cbuild
```

You can also define the variable in the application CMakeLists.txt file. Make sure to do so before pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.  

**Note:** When specifying DTS_ROOT in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND DTS_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-dts-root>). When using -DDTS_ROOT=<dts-root> both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Devicetree source are passed through the C preprocessor, so you can include files that can be located in a DTS_ROOT directory. By convention devicetree include files have a .dtsi extension.

You can also use the preprocessor to control the content of a devicetree file, by specifying directives through the DTS_EXTRA_CPPFLAGS CMake Cache variable:

Using west:

```bash
west build -b <board name> -- -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_FEATURE
```

Using CMake and ninja:

```bash
cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_FEATURE
ninja -Cbuild
```

## 2.5 Debugging

### 2.5.1 Application Debugging

This section is a quick hands-on reference to start debugging your application with QEMU. Most content in this section is already covered in QEMU and GNU_Debugger reference manuals.

In this quick reference, you’ll find shortcuts, specific environmental variables, and parameters that can help you to quickly set up your debugging environment.

The simplest way to debug an application running in QEMU is using the GNU Debugger and setting a local GDB server in your development system through QEMU.

You will need an ELF (Executable and Linkable Format) binary image for debugging purposes. The build system generates the image in the build directory. By default, the kernel binary name is `zephyr.elf`. The name can be changed using `CONFIG_KERNEL_BIN_NAME`. 

2.5. Debugging
GDB server

We will use the standard 1234 TCP port to open a GDB (GNU Debugger) server instance. This port number can be changed for a port that best suits the development environment. There are multiple ways to do this. Each way starts a QEMU instance with the processor halted at startup and with a GDB server instance listening for a connection.

Running QEMU directly You can run QEMU to listen for a “gdb connection” before it starts executing any code to debug it.

```
qemu -s -S <image>
```

will setup Qemu to listen on port 1234 and wait for a GDB connection to it.

The options used above have the following meaning:

- `-S` Do not start CPU at startup; rather, you must type `c` in the monitor.
- `-s` Shorthand for `-gdb tcp::1234`: open a GDB server on TCP port 1234.

Running QEMU via `ninja` Run the following inside the build directory of an application:

```
ninja debugserver
```

QEMU will write the console output to the path specified in `${QEMU_PIPE}` via CMake, typically `qemu-fifo` within the build directory. You may monitor this file during the run with `tail -f qemu-fifo`.

Running QEMU via `west` Run the following from your project root:

```
w west build -t debugserver_qemu
```

QEMU will write the console output to the terminal from which you invoked `west`.

Configuring the `gdbserver` listening device The Kconfig option `CONFIG_QEMU_GDBSERVER_LISTEN_DEV` controls the listening device, which can be a TCP port number or a path to a character device. GDB releases 9.0 and newer also support Unix domain sockets.

If the option is unset, then the QEMU invocation will lack a `-s` or a `-gdb` parameter. You can then use the `QEMU_EXTRA_FLAGS` shell environment variable to pass in your own listen device configuration.

GDB client

Connect to the server by running `gdb` and giving these commands:

```
$ path/to/gdb path/to/zephyr.elf
(gdb) target remote localhost:1234
(gdb) dir ZEPHYR_BASE
```

Note: Substitute the correct `ZEPHYR_BASE` for your system.

You can use a local GDB configuration .gdbinit to initialize your GDB instance on every run. Your home directory is a typical location for .gdbinit, but you can configure GDB to load from other locations, including the directory from which you invoked gdb. This example file performs the same configuration as above:
target remote localhost:1234
dir ZEPHYR_BASE

**Alternate interfaces**  
GDB provides a curses-based interface that runs in the terminal. Pass the `--tui` option when invoking `gdb` or give the `tui enable` command within `gdb`.

**Note:** The GDB version on your development system might not support the `--tui` option. Please make sure you use the GDB binary from the SDK which corresponds to the toolchain that has been used to build the binary.

Finally, the command below connects to the GDB server using the DDD (Data Display Debugger), a graphical frontend for GDB. The following command loads the symbol table from the ELF binary file, in this instance, `zephyr.elf`.

```
ddd --gdb --debugger "gdb zephyr.elf"
```

Both commands execute `gdb`. The command name might change depending on the toolchain you are using and your cross-development tools.

`ddd` may not be installed in your development system by default. Follow your system instructions to install it. For example, use `sudo apt-get install ddd` on an Ubuntu system.

**Debugging**

As configured above, when you connect the GDB client, the application will be stopped at system startup. You may set breakpoints, step through code, etc. as when running the application directly within `gdb`.

**Note:** `gdb` will not print the system console output as the application runs, unlike when you run a native application in GDB directly. If you just continue after connecting the client, the application will run, but nothing will appear to happen. Check the console output as described above.

### 2.5.2 Debug with Eclipse

**Overview**

CMake supports generating a project description file that can be imported into the Eclipse Integrated Development Environment (IDE) and used for graphical debugging.

The **GNU MCU Eclipse plug-ins** provide a mechanism to debug ARM projects in Eclipse with pyOCD, Segger J-Link, and OpenOCD debugging tools.

The following tutorial demonstrates how to debug a Zephyr application in Eclipse with pyOCD in Windows. It assumes you have already installed the GCC ARM Embedded toolchain and pyOCD.

**Set Up the Eclipse Development Environment**

1. Download and install **Eclipse IDE for C/C++ Developers**.
2. In Eclipse, install the **GNU MCU Eclipse plug-ins** by opening the menu `Window->Eclipse Marketplace...`, searching for **GNU MCU Eclipse**, and clicking `Install` on the matching result.
3. Configure the path to the pyOCD GDB server by opening the menu `Window->Preferences`, navigating to `MCU`, and setting the `Global pyOCD Path`.
Generate and Import an Eclipse Project

1. Set up a GNU Arm Embedded toolchain as described in GNU Arm Embedded.

2. Navigate to a folder outside of the Zephyr tree to build your application.

   # On Windows
   cd %userprofile%

   **Note:** If the build directory is a subdirectory of the source directory, as is usually done in Zephyr, CMake will warn:
   “The build directory is a subdirectory of the source directory.
   This is not supported well by Eclipse. It is strongly recommended to use a build directory which is a sibling of the source directory.”

3. Configure your application with CMake and build it with ninja. Note the different CMake generator specified by the -G"Eclipse CDT 4 - Ninja" argument. This will generate an Eclipse project description file,.project, in addition to the usual ninja build files.

   Using west:
   ```
   west build -b frdm_k64f %ZEPHYR_BASE%\samples\synchronization -- -G"Eclipse CDT 4 - Ninja"
   ```

   Using CMake and ninja:
   ```
   cmake -B build -GNinja -DBOARD=frdm_k64f -G"Eclipse CDT 4 - Ninja" %ZEPHYR_BASE%\samples\synchronization
   ninja -C build
   ```

4. In Eclipse, import your generated project by opening the menu File->Import… and selecting the option Existing Projects into Workspace. Browse to your application build directory in the choice, Select root directory:. Check the box for your project in the list of projects found and click the Finish button.

Create a Debugger Configuration

1. Open the menu Run->Debug Configurations…

2. Select GDB PyOCD Debugging, click the New button, and configure the following options:
   - In the Main tab:
     - Project: my_zephyr_app@build
     - C/C++ Application: zephyr/zephyr.elf
   - In the Debugger tab:
     - pyOCD Setup
       * Executable path: $pyocd_path/$pyocd_executable
       * Uncheck “Allocate console for semihosting”
     - Board Setup
       * Bus speed: 8000000 Hz
       * Uncheck “Enable semihosting”
     - GDB Client Setup
* Executable path example (use your GNUARMEMB_TOOLCHAIN_PATH): C:\gcc-arm-none-eabi-6_2017-q2-update\bin\arm-none-eabi-gdb.exe

- In the SVD Path tab:
  - File path: <workspace top>\modules\hal\nxp\mcux\devices\MK64F12\MK64F12.xml

**Note:** This is optional. It provides the SoC's memory-mapped register addresses and bitfields to the debugger.

3. Click the Debug button to start debugging.

**RTOS Awareness**

Support for Zephyr RTOS awareness is implemented in pyOCD v0.11.0 and later. It is compatible with GDB PyOCD Debugging in Eclipse, but you must enable CONFIG_DEBUG_THREAD_INFO=y in your application.

### 2.5.3 Debugging I2C communication

There is a possibility to log all or some of the I2C transactions done by the application. This feature is enabled by the Kconfig option CONFIG_I2C_DUMP_MESSAGES, but it uses the LOG_DBG function to print the contents so the CONFIG_I2C_LOG_LEVEL_DBG option must also be enabled.

The sample output of the dump looks like this:

```plaintext
D: I2C msg: io_i2c_ctrl17_port0, addr=50
D:   W len=01: 00
D:   R Sr P len=08:
D:   contents:
D: 43 42 41 00 00 00 00 00 |CBA.....
```

The first line indicates the I2C controller and the target address of the transaction. In above example, the I2C controller is named io_i2c_ctrl17_port0 and the target device address is 0x50

**Note:** the address, length and contents values are in hexadecimal, but lack the 0x prefix

Next lines contain messages, both sent and received. The contents of write messages is always shown, while the content of read messages is controlled by a parameter to the function i2c_dump_msgs_rw. This function is available for use by user, but is also called internally by i2c_transfer API function with read content dump enabled. Before the length parameter, the header of the message is printed using abbreviations:

- W - write message
- R - read message
- Sr - restart bit
- P - stop bit

The above example shows one write message with byte 0x00 representing the address of register to read from the I2C target. After that the log shows the length of received message and following that, the bytes read from the target 43 42 41 00 00 00 00 00. The content dump consist of both the hex and ASCII representation.
Filtering the I2C communication dump

By default, all I2C communication is logged between all I2C controllers and I2C targets. It may litter the log with unrelated devices and make it difficult to effectively debug the communication with a device of interest.

Enable the Kconfig option CONFIG_I2C_DUMP_MESSAGES_ALLOWLIST to create an allowlist of I2C targets to log. The allowlist of devices is configured using the devicetree, for example:

```c
/ {
    i2c {
        display0: some-display@a {
            ...
        };
        sensor3: some-sensor@b {
            ...
        };
    };

    i2c-dump-allowlist {
        compatible = "zephyr,i2c-dump-allowlist";
        devices = < &display0 >, < &sensor3 >;
    };
};
```

The filters nodes are identified by the compatible string with zephyr,i2c-dump-allowlist value. The devices are selected using the devices property with phandles to the devices on the I2C bus.

In the above example, the communication with device display0 and sensor3 will be displayed in the log.

### 2.6 API Status and Guidelines

#### 2.6.1 API Overview

The table lists Zephyr’s APIs and information about them, including their current stability level. More details about API changes between major releases are available in the zephyr_release_notes.

<table>

2.6.2 API Lifecycle

Developers using Zephyr’s APIs need to know how long they can trust that a given API will not change in future releases. At the same time, developers maintaining and extending Zephyr’s APIs need to be able to introduce new APIs that aren’t yet fully proven, and to potentially retire old APIs when they’re no longer optimal or supported by the underlying platforms.

Fig. 2: API Life Cycle

An up-to-date table of all APIs and their maturity level can be found in the API Overview page.
Experimental

Experimental APIs denote that a feature was introduced recently, and may change or be removed in future versions. Try it out and provide feedback to the community via the Developer mailing list.

The following requirements apply to all new APIs:

- Documentation of the API (usage) explaining its design and assumptions, how it is to be used, current implementation limitations, and future potential, if appropriate.
- The API introduction should be accompanied by at least one implementation of said API (in the case of peripheral APIs, this corresponds to one driver)
- At least one sample using the new API (may only build on one single board)

Peripheral APIs (Hardware Related) When introducing an API (public header file with documentation) for a new peripheral or driver subsystem, review of the API is enforced and is driven by the Architecture working group consisting of representatives from different vendors.

The API shall be promoted to unstable when it has at least two implementations on different hardware platforms.

Unstable

The API is in the process of settling, but has not yet had sufficient real-world testing to be considered stable. The API is considered generic in nature and can be used on different hardware platforms.

Note: Changes will not be announced.

Peripheral APIs (Hardware Related) The API shall be promoted from experimental to unstable when it has at least two implementations on different hardware platforms.

Hardware Agnostic APIs For hardware agnostic APIs, multiple applications using it are required to promote an API from experimental to unstable.

Stable

The API has proven satisfactory, but cleanup in the underlying code may cause minor changes. Backwards-compatibility will be maintained if reasonable.

An API can be declared stable after fulfilling the following requirements:

- Test cases for the new API with 100% coverage
- Complete documentation in code. All public interfaces shall be documented and available in online documentation.
- The API has been in-use and was available in at least 2 development releases
- Stable APIs can get backward compatible updates, bug fixes and security fixes at any time.

In order to declare an API stable, the following steps need to be followed:

1. A Pull Request must be opened that changes the corresponding entry in the API Overview table
2. An email must be sent to the devel mailing list announcing the API upgrade request
3. The Pull Request must be submitted for discussion in the next Zephyr Architecture meeting where, barring any objections, the Pull Request will be merged
Introducing incompatible changes  A stable API, as described above strives to remain backwards-compatible through its life-cycle. There are however cases where fulfilling this objective prevents technical progress or is simply unfeasible without unreasonable burden on the maintenance of the API and its implementation(s).

An incompatible change is defined as one that forces users to modify their existing code in order to maintain the current behavior of their application. The need for recompilation of applications (without changing the application itself) is not considered an incompatible change.

In order to restrict and control the introduction of a change that breaks the promise of backwards compatibility the following steps must be followed whenever such a change is considered necessary in order to accept it in the project:

1. An RFC issue must be opened on GitHub with the following content:

<table>
<thead>
<tr>
<th>Title:</th>
<th>RFC: API Change: &lt;subsystem&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contents:</td>
<td>- Problem Description:</td>
</tr>
<tr>
<td></td>
<td>- Background information on why the change is required</td>
</tr>
<tr>
<td></td>
<td>- Proposed Change (detailed):</td>
</tr>
<tr>
<td></td>
<td>- Brief description of the API change</td>
</tr>
<tr>
<td></td>
<td>- Detailed RFC:</td>
</tr>
<tr>
<td></td>
<td>- Function call changes</td>
</tr>
<tr>
<td></td>
<td>- Device Tree changes (source and bindings)</td>
</tr>
<tr>
<td></td>
<td>- Kconfig option changes</td>
</tr>
<tr>
<td></td>
<td>- Dependencies:</td>
</tr>
<tr>
<td></td>
<td>- Impact to users of the API, including the steps required to adapt out-of-tree users of the API to the change</td>
</tr>
</tbody>
</table>

   Instead of a written description of the changes, the RFC issue may link to a Pull Request containing those changes in code form.

2. The RFC issue must be labeled with the GitHub Stable API Change label

3. The RFC issue must be submitted for discussion in the next Zephyr Architecture meeting

4. An email must be sent to the devel mailing list with a subject identical to the RFC issue title and that links to the RFC issue

The RFC will then receive feedback through issue comments and will also be discussed in the Zephyr Architecture meeting, where the stakeholders and the community at large will have a chance to discuss it in detail.

Finally, and if not done as part of the first step, a Pull Request must be opened on GitHub. It is left to the person proposing the change to decide whether to introduce both the RFC and the Pull Request at the same time or to wait until the RFC has gathered consensus enough so that the implementation can proceed with confidence that it will be accepted. The Pull Request must include the following:

- A title that matches the RFC issue
- A link to the RFC issue
- The actual changes to the API
  - Changes to the API header file
  - Changes to the API implementation(s)
  - Changes to the relevant API documentation
  - Changes to Device Tree source and bindings
- The changes required to adapt in-tree users of the API to the change. Depending on the scope of this task this might require additional help from the corresponding maintainers
- An entry in the “API Changes” section of the release notes for the next upcoming release
- The labels API, Stable API Change and Release Notes, as well as any others that are applicable
Once the steps above have been completed, the outcome of the proposal will depend on the approval of the actual Pull Request by the maintainer of the corresponding subsystem. As with any other Pull Request, the author can request for it to be discussed and ultimately even voted on in the Zephyr TSC meeting.

If the Pull Request is merged then an email must be sent to the dev and user mailing lists informing them of the change.

**Note:** Incompatible changes will be announced in the “API Changes” section of the release notes.

---

**Deprecated**

**Note:** Unstable APIs can be removed without deprecation at any time. Deprecation and removal of APIs will be announced in the “API Changes” section of the release notes.

The following are the requirements for deprecating an existing API:

- **Deprecation Time (stable APIs):** 2 Releases The API needs to be marked as deprecated in at least two full releases. For example, if an API was first deprecated in release 1.14, it will be ready to be removed in 1.16 at the earliest. There may be special circumstances, determined by the Architecture working group, where an API is deprecated sooner.

- **What is required when deprecating:**
  - Mark as deprecated. This can be done by using the compiler itself (**__deprecated** for function declarations and **__DEPRECATED_MACRO** for macro definitions), or by introducing a Kconfig option (typically one that contains the DEPRECATED word in it) that, when enabled, reverts the APIs back to their previous form
  - Document the deprecation
  - Include the deprecation in the “API Changes” of the release notes for the next upcoming release
  - Code using the deprecated API needs to be modified to remove usage of said API
  - The change needs to be atomic and bisectable
  - Create a GitHub issue to track the removal of the deprecated API, and add it to the roadmap targeting the appropriate release (in the example above, 1.16).

During the deprecation waiting period, the API will be in the **deprecated** state. The Zephyr maintainers will track usage of deprecated APIs on docs.zephyrproject.org and support developers migrating their code. Zephyr will continue to provide warnings:

- API documentation will inform users that the API is deprecated.
- Attempts to use a deprecated API at build time will log a warning to the console.

---

**Retired**

In this phase, the API is removed.

The target removal date is 2 releases after deprecation is announced. The Zephyr maintainers will decide when to actually remove the API: this will depend on how many developers have successfully migrated from the deprecated API, and on how urgently the API needs to be removed.

If it's OK to remove the API, it will be removed. The maintainers will remove the corresponding documentation, and communicate the removal in the usual ways: the release notes, mailing lists, Github issues and pull-requests.

---

2.6. API Status and Guidelines 53
If it’s not OK to remove the API, the maintainers will continue to support migration and update the roadmap with the aim to remove the API in the next release.

2.6.3  API Design Guidelines

Zephyr development and evolution is a group effort, and to simplify maintenance and enhancements there are some general policies that should be followed when developing a new capability or interface.

Using Callbacks

Many APIs involve passing a callback as a parameter or as a member of a configuration structure. The following policies should be followed when specifying the signature of a callback:

- The first parameter should be a pointer to the object most closely associated with the callback. In the case of device drivers this would be `const struct device *dev`. For library functions it may be a pointer to another object that was referenced when the callback was provided.
- The next parameter(s) should be additional information specific to the callback invocation, such as a channel identifier, new status value, and/or a message pointer followed by the message length.
- The final parameter should be a `void *user_data` pointer carrying context that allows a shared callback function to locate additional material necessary to process the callback.

An exception to providing `user_data` as the last parameter may be allowed when the callback itself was provided through a structure that will be embedded in another structure. An example of such a case is `gpio_callback`, normally defined within a data structure specific to the code that also defines the callback function. In those cases further context can accessed by the callback indirectly by `CONTAINER_OF`.

Examples

- The requirements of `k_timer_expiry_t` invoked when a system timer alarm fires are satisfied by:

  ```c
  void handle_timeout(struct k_timer *timer)
  { ... }
  ```

  The assumption here, as with `gpio_callback`, is that the timer is embedded in a structure reachable from `CONTAINER_OF` that can provide additional context to the callback.

- The requirements of `counter_alarm_callback_t` invoked when a counter device alarm fires are satisfied by:

  ```c
  void handle_alarm(const struct device *dev,
                   uint8_t chan_id,
                   uint32_t ticks,
                   void *user_data)
  { ... }
  ```

  This provides more complete useful information, including which counter channel timed-out and the counter value at which the timeout occurred, as well as user context which may or may not be the `counter_alarm_cfg` used to register the callback, depending on user needs.

Conditional Data and APIs

APIs and libraries may provide features that are expensive in RAM or code size but are optional in the sense that some applications can be implemented without them. Examples of such feature include capturing a timestamp or providing an alternative interface. The developer in coordination with the community must determine whether enabling the features is to be controllable through a Kconfig option.
In the case where a feature is determined to be optional the following practices should be followed.

- Any data that is accessed only when the feature is enabled should be conditionally included via 
  `#ifdef CONFIG_MYFEATURE` in the structure or union declaration. This reduces memory use for 
  applications that don’t need the capability.

- Function declarations that are available only when the option is enabled should be provided un-
  conditionally. Add a note in the description that the function is available only when the specified 
  feature is enabled, referencing the required Kconfig symbol by name. In the cases where the func-
  tion is used but not enabled the definition of the function shall be excluded from compilation, so 
  references to the unsupported API will result in a link-time error.

- Where code specific to the feature is isolated in a source file that has no other content that file 
  should be conditionally included in `CMakeLists.txt`:
  ```
  zephyr_sources_ifdef(CONFIG_MYFEATURE foo_funcs.c)
  ```

- Where code specific to the feature is part of a source file that has other content the feature-specific 
  code should be conditionally processed using `#ifdef CONFIG_MYFEATURE`.

The Kconfig flag used to enable the feature should be added to the `PREDEFINED` variable in `doc/zephyr. 
doxygen.in` to ensure the conditional API and functions appear in generated documentation.

**Return Codes**

Implementations of an API, for example an API for accessing a peripheral might implement only a subset 
of the functions that is required for minimal operation. A distinction is needed between APIs that are not 
supported and those that are not implemented or optional:

- APIs that are supported but not implemented shall return `-ENOSYS`.
- Optional APIs that are not supported by the hardware should be implemented and the return code 
in this case shall be `-ENOTSUP`.
- When an API is implemented, but the particular combination of options requested in the call cannot
  be satisfied by the implementation the call shall return `-ENOTSUP`. (For example, a request for a 
level-triggered GPIO interrupt on hardware that supports only edge-triggered interrupts)

**2.6.4 API Terminology**

The following terms may be used as shorthand API tags to indicate the allowed calling context (thread, 
ISR, pre-kernel), the effect of a call on the current thread state, and other behavioral characteristics.

- **reschedule**
  - if executing the function reaches a reschedule point

- **sleep**
  - if executing the function can cause the invoking thread to sleep

- **no-wait**
  - if a parameter to the function can prevent the invoking thread from trying to sleep

- **isr-ok**
  - if the function can be safely called and will have its specified effect whether invoked from interrupt 
or thread context

- **pre-kernel-ok**
  - if the function can be safely called before the kernel has been fully initialized and will have its 
specified effect when invoked from that context.

- **async**
  - if the function may return before the operation it initializes is complete (i.e. function return and 
operation completion are asynchronous)
supervisor

if the calling thread must have supervisor privileges to execute the function

Details on the behavioral impact of each attribute are in the following sections.

details

The reschedule attribute is used on a function that can reach a reschedule point within its execution.

Details The significance of this attribute is that when a rescheduling function is invoked by a thread it is possible for that thread to be suspended as a consequence of a higher-priority thread being made ready. Whether the suspension actually occurs depends on the operation associated with the reschedule point and the relative priorities of the invoking thread and the head of the ready queue.

Note that in the case of timeslicing, or reschedule points executed from interrupts, any thread may be suspended in any function.

Functions that are not reschedule may be invoked from either thread or interrupt context.

Functions that are reschedule may be invoked from thread context.

Functions that are reschedule but not sleep may be invoked from interrupt context.

sleep

The sleep attribute is used on a function that can cause the invoking thread to sleep.

Explanation This attribute is of relevance specifically when considering applications that use only non-preemptible threads, because the kernel will not replace a running cooperative-only thread at a reschedule point unless that thread has explicitly invoked an operation that caused it to sleep.

This attribute does not imply the function will sleep unconditionally, but that the operation may require an invoking thread that would have to suspend, wait, or invoke k_yield() before it can complete its operation. This behavior may be mediated by no-wait.

Functions that are sleep are implicitly reschedule.

Functions that are sleep may be invoked from thread context.

Functions that are sleep may be invoked from interrupt and pre-kernel contexts if and only if invoked in no-wait mode.

no-wait

The no-wait attribute is used on a function that is also sleep to indicate that a parameter to the function can force an execution path that will not cause the invoking thread to sleep.

Explanation The paradigmatic case of a no-wait function is a function that takes a timeout, to which K_NO_WAIT can be passed. The semantics of this special timeout value are to execute the function's operation as long as it can be completed immediately, and to return an error code rather than sleep if it cannot.

It is use of the no-wait feature that allows functions like k_sem_take() to be invoked from ISRs, since it is not permitted to sleep in interrupt context.

A function with a no-wait path does not imply that taking that path guarantees the function is synchronous.
Functions with this attribute may be invoked from interrupt and pre-kernel contexts only when the parameter selects the no-wait path.

**isr-ok**

The isr-ok attribute is used on a function to indicate that it works whether it is being invoked from interrupt or thread context.

**Explanation** Any function that is not **sleep** is inherently **isr-ok**. Functions that are **sleep** are **isr-ok** if the implementation ensures that the documented behavior is implemented even if called from an interrupt context. This may be achieved by having the implementation detect the calling context and transfer the operation that would sleep to a thread, or by documenting that when invoked from a non-thread context the function will return a specific error (generally **-EWOULDBLOCK**).

Note that a function that is **no-wait** is safe to call from interrupt context only when the no-wait path is selected. **isr-ok** functions need not provide a no-wait path.

**pre-kernel-ok**

The pre-kernel-ok attribute is used on a function to indicate that it works as documented even when invoked before the kernel main thread has been started.

**Explanation** This attribute is similar to **isr-ok** in function, but is intended for use by any API that is expected to be called in **DEVICE_DEFINE()** or **SYS_INIT()** calls that may be invoked with **PRE_KERNEL_1** or **PRE_KERNEL_2** initialization levels.

Generally a function that is **pre-kernel-ok** checks **k_is_pre_kernel()** when determining whether it can fulfill its required behavior. In many cases it would also check **k_is_in_isr()** so it can be **isr-ok** as well.

**async**

A function is **async** (i.e. asynchronous) if it may return before the operation it initiates has completed. An asynchronous function will generally provide a mechanism by which operation completion is reported, e.g. a callback or event.

A function that is not asynchronous is synchronous, i.e. the operation will always be complete when the function returns. As most functions are synchronous this behavior does not have a distinct attribute to identify it.

**Explanation** Be aware that **async** is orthogonal to context-switching. Some APIs may provide completion information through a callback, but may suspend while waiting for the resource necessary to initiate the operation; an example is **spi_transceive_async()**.

If a function is both **no-wait** and **async** then selecting the no-wait path only guarantees that the function will not sleep. It does not affect whether the operation will be completed before the function returns.

**supervisor**

The supervisor attribute is relevant only in user-mode applications, and indicates that the function cannot be invoked from user mode.
2.7 Language Support

2.7.1 C Language Support

C is a general-purpose low-level programming language that is widely used for writing code for embedded systems.

Zephyr is primarily written in C and natively supports applications written in the C language. All Zephyr API functions and macros are implemented in C and available as part of the C header files under the include directory, so writing Zephyr applications in C gives the developers access to the most features.

The main() function must have the return type of int as Zephyr applications run in a “hosted” environment as defined by the C standard. Applications must return zero (0) from main. All non-zero return values are reserved.

Language Standards

Zephyr does not target a specific version of the C standards; however, the Zephyr codebase makes extensive use of the features newly introduced in the 1999 release of the ISO C standard (ISO/IEC 9899:1999, hereinafter referred to as C99) such as those listed below, effectively requiring the use of a compiler toolchain that supports the C99 standard and above:

- inline functions
- standard boolean types (bool in <stdbool.h>)
- fixed-width integer types ([u]intN_t in <stdint.h>)
- designated initializers
- variadic macros
- restrict qualification

Some Zephyr components make use of the features newly introduced in the 2011 release of the ISO C standard (ISO/IEC 9899:2011, hereinafter referred to as C11) such as the type-generic expressions using the _Generic keyword. For example, the cbprintf() component, used as the default formatted output processor for Zephyr, makes use of the C11 type-generic expressions, and this effectively requires most Zephyr applications to be compiled using a compiler toolchain that supports the C11 standard and above.

In summary, it is recommended to use a compiler toolchain that supports at least the C11 standard for developing with Zephyr. It is, however, important to note that some optional Zephyr components and external modules may make use of the C language features that have been introduced in more recent versions of the standards, in which case it will be necessary to use a more up-to-date compiler toolchain that supports such standards.

Standard Library

The C Standard Library is an integral part of any C program, and Zephyr provides the support for a number of different C libraries for the applications to choose from, depending on the compiler toolchain being used to build the application.

Common C library code Zephyr provides some C library functions that are designed to be used in conjunction with multiple C libraries. These either provide functions not available in multiple C libraries or are designed to replace functionality in the C library with code better suited for use in the Zephyr environment.
Time function  This provides an implementation of the standard C function, `time()`, relying on the Zephyr function, `clock_gettime()`. This function can be enabled by selecting `COMMON_LIBC_TIME`.

Dynamic Memory Management  The common dynamic memory management implementation can be enabled by selecting the `CONFIG_COMMON_LIBC_MALLOC` in the application configuration file.

The common C library internally uses the kernel memory heap API to manage the memory heap used by the standard dynamic memory management interface functions such as `malloc()` and `free()`.

The internal memory heap is normally located in the `.bss` section. When userspace is enabled, however, it is placed in a dedicated memory partition called `z_malloc_partition`, which can be accessed from the user mode threads. The size of the internal memory heap is specified by the `CONFIG_COMMON_LIBC_MALLOC_ARENA_SIZE`.

The default heap size for applications using the common C library is zero (no heap). For other C library users, if there is an MMU present, then the default heap is 16kB. Otherwise, the heap uses all available memory.

There are also separate controls to select `calloc()` (`COMMON_LIBC_CALLOC`) and `reallocarray()` (`COMMON_LIBC_REALLOCARRAY`). Both of these are enabled by default as that doesn't impact memory usage in applications not using them.

The standard dynamic memory management interface functions implemented by the common C library are thread safe and may be simultaneously called by multiple threads. These functions are implemented in `lib/libc/common/source/stdlib/malloc.c`.

Minimal libc  The most basic C library, named “minimal libc”, is part of the Zephyr codebase and provides the minimal subset of the standard C library required to meet the needs of Zephyr and its subsystems, primarily in the areas of string manipulation and display.

It is very low footprint and is suitable for projects that do not rely on less frequently used portions of the ISO C standard library. It can also be used with a number of different toolchains.

The minimal libc implementation can be found in `lib/libc/minimal` in the main Zephyr tree.

Functions  The minimal libc implements the minimal subset of the ISO/IEC 9899:2011 standard C library functions required to meet the needs of the Zephyr kernel, as defined by the Coding Guidelines Rule A.4.

Formatted Output  The minimal libc does not implement its own formatted output processor; instead, it maps the C standard formatted output functions such as `printf` and `sprintf` to the `cbprintf()` function, which is Zephyr's own C99-compatible formatted output implementation.

For more details, refer to the Formatted Output OS service documentation.

Dynamic Memory Management  The minimal libc uses the malloc api family implementation provided by the common C library, which itself is built upon the kernel memory heap API.

Error numbers  Error numbers are used throughout Zephyr APIs to signal error conditions as return values from functions. They are typically returned as the negative value of the integer literals defined in this section, and are defined in the `errno.h` header file.

A subset of the error numbers defined in the POSIX `errno.h` specification and other de-facto standard sources have been added to the minimal libc.

A conscious effort is made in Zephyr to keep the values of the minimal libc error numbers consistent with the different implementations of the C standard libraries supported by Zephyr. The minimal libc `errno.h` is checked against that of the Newlib to ensure that the error numbers are kept aligned.
Below is a list of the error number definitions. For the actual numeric values please refer to `errno.h`.

```plaintext
#define errnum  

EPERM
    Not owner.

ENOENT
    No such file or directory.

ESRCH
    No such context.

EINTR
    Interrupted system call.

EIO
    I/O error.

ENXIO
    No such device or address.

E2BIG
    Arg list too long.

ENOEXEC
    Exec format error.

EBADF
    Bad file number.

ECHILD
    No children.

EAGAIN
    No more contexts.

ENOMEM
    Not enough core.

EACCES
    Permission denied.
```
EFAULT
Bad address.

ENOTBLK
Block device required.

EBUSY
Mount device busy.

EEXIST
File exists.

EXDEV
Cross-device link.

ENODEV
No such device.

ENOTDIR
Not a directory.

EISDIR
Is a directory.

EINVAL
Invalid argument.

ENFILE
File table overflow.

EMFILE
Too many open files.

ENOTTY
Not a typewriter.

ETXTBSY
Text file busy.

EFBIG
File too large.

ENOSPC
No space left on device.

ESPIPE
Illegal seek.
EROFS
   Read-only file system.

EMLINK
   Too many links.

EPipe
   Broken pipe.

EDOM
   Argument too large.

ERANGE
   Result too large.

ENOMSG
   Unexpected message type.

EDEADLK
   Resource deadlock avoided.

ENOLCK
   No locks available.

ENOSTR
   STREAMS device required.

ENODATA
   Missing expected message data.

ETIME
   STREAMS timeout occurred.

ENOSR
   Insufficient memory.

EPROTO
   Generic STREAMS error.

EBADMSG
   Invalid STREAMS message.

ENOSYS
   Function not implemented.

ENOTEMPTY
   Directory not empty.
ENAMETOOLONG
  File name too long.

ELOOP
  Too many levels of symbolic links.

EOPNOTSUPP
  Operation not supported on socket.

EPFNOSUPPORT
  Protocol family not supported.

ECONNRESET
  Connection reset by peer.

ENOBUFS
  No buffer space available.

EAFNOSUPPORT
  Addr family not supported.

EPROTOTYPE
  Protocol wrong type for socket.

ENOTSOCK
  Socket operation on non-socket.

ENOPROTOOPT
  Protocol not available.

ESHUTDOWN
  Can't send after socket shutdown.

ECONNREFUSED
  Connection refused.

EADDRINUSE
  Address already in use.

ECONNABORTED
  Software caused connection abort.

ENETUNREACH
  Network is unreachable.

ENETDOWN
  Network is down.

2.7. Language Support
ETIMEDOUT
   Connection timed out.
EHOSTDOWN
   Host is down.
EHOSTUNREACH
   No route to host.
EINPROGRESS
   Operation now in progress.
EALREADY
   Operation already in progress.
EDESTADDRREQ
   Destination address required.
EMSGSIZE
   Message size.
EPROTONOSUPPORT
   Protocol not supported.
ESOCKTNOSUPPORT
   Socket type not supported.
EADDRNOTAVAIL
   Can't assign requested address.
ENETRESET
   Network dropped connection on reset.
EISCONN
   Socket is already connected.
ENOTCONN
   Socket is not connected.
ETOOMANYREFS
   Too many references: can't splice.
ENOTSUP
   Unsupported value.
EILSEQ
   Illegal byte sequence.
EOVERFLOW
Value overflow.

ECANCELED
Operation canceled.

EWOULDBLOCK
Operation would block.

**Newlib**  
Newlib is a complete C library implementation written for the embedded systems. It is a separate open source project and is not included in source code form with Zephyr. Instead, the Zephyr SDK includes a precompiled library for each supported architecture (libc.a and libm.a).

**Note:** Other 3rd-party toolchains, such as GNU Arm Embedded, also bundle the Newlib as a precompiled library.

Zephyr implements the “API hook” functions that are invoked by the C standard library functions in the Newlib. These hook functions are implemented in lib/libc/newlib/libc-hooks.c and translate the library internal system calls to the equivalent Zephyr API calls.

**Types of Newlib**  
The Newlib included in the Zephyr SDK comes in two versions: ‘full’ and ‘nano’ variants.

**Full Newlib**  
The Newlib full variant (libc.a and libm.a) is the most capable variant of the Newlib available in the Zephyr SDK, and supports almost all standard C library features. It is optimized for performance (prefers performance over code size) and its footprint is significantly larger than the the nano variant.

This variant can be enabled by selecting the CONFIG_NEWLIB_LIBC and de-selecting the CONFIG_NEWLIB_LIBC_NANO in the application configuration file.

**Nano Newlib**  
The Newlib nano variant (libc_nan.a and libm_nan.a) is the size-optimized version of the Newlib, and supports all features that the full variant supports except the new format specifiers introduced in C99, such as the char, long long type format specifiers (i.e. %hhX and %llX).

This variant can be enabled by selecting the CONFIG_NEWLIB_LIBC and CONFIG_NEWLIB_LIBC_NANO in the application configuration file.

Note that the Newlib nano variant is not available for all architectures. The availability of the nano variant is specified by the CONFIG_HAS_NEWLIB_LIBC_NANO.

**Formatted Output**  
Newlib supports all standard C formatted input and output functions, including printf, fprintf, sprintf and sscanf.

The Newlib formatted input and output function implementation supports all format specifiers defined by the C standard with the following exceptions:

- Floating point format specifiers (e.g. %f) require CONFIG_NEWLIB_LIBC_FLOAT_PRINTF and CONFIG_NEWLIB_LIBC_FLOAT_SCANF to be enabled.

- C99 format specifiers are not supported in the Newlib nano variant (i.e. %hhX for char, %llX for long long, %jX for intmax_t, %zX for size_t, %tX for ptrdiff_t).
**Dynamic Memory Management**  Newlib implements an internal heap allocator to manage the memory blocks used by the standard dynamic memory management interface functions (for example, `malloc()` and `free()`).

The internal heap allocator implemented by the Newlib may vary across the different types of the Newlib used. For example, the heap allocator implemented in the Full Newlib (`libc.a` and `libm.a`) of the Zephyr SDK requests larger memory chunks to the operating system and has a significantly higher minimum memory requirement compared to that of the Nano Newlib (`libc_nano.a` and `libm_nano.a`).

The only interface between the Newlib dynamic memory management functions and the Zephyr-side libc hooks is the `sbrk()` function, which is used by the Newlib to manage the size of the memory pool reserved for its internal heap allocator.

The `_sbrk()` hook function, implemented in `libc-hooks.c`, handles the memory pool size change requests from the Newlib and ensures that the Newlib internal heap allocator memory pool size does not exceed the amount of available memory space by returning an error when the system is out of memory.

When userspace is enabled, the Newlib internal heap allocator memory pool is placed in a dedicated memory partition called `z_malloc_partition`, which can be accessed from the user mode threads.

The amount of memory space available for the Newlib heap depends on the system configurations:

- When MMU is enabled (`CONFIG_MMU` is selected), the amount of memory space reserved for the Newlib heap is set by the size of the free memory space returned by the `k_mem_free_get()` function or the `CONFIG_NEWLIB_LIBC_MAX_MAPPED_REGION_SIZE`, whichever is the smallest.
- When MPU is enabled and the MPU requires power-of-two partition size and address alignment (`CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE` is set to a non-zero value), the amount of memory space reserved for the Newlib heap is set by the `CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE`.
- Otherwise, the amount of memory space reserved for the Newlib heap is equal to the amount of free (unallocated) memory in the SRAM region.

The standard dynamic memory management interface functions implemented by the Newlib are thread safe and may be simultaneously called by multiple threads.

**Picolibc**  Picolibc is a complete C library implementation written for the embedded systems, targeting C17 (ISO/IEC 9899:2018) and POSIX 2018 (IEEE Std 1003.1-2017) standards. Picolibc is an external open source project which is provided for Zephyr as a module, and included as part of the Zephyr SDK in precompiled form for each supported architecture (`libc.a`).

**Note:** Picolibc is also available for other 3rd-party toolchains, such as GNU Arm Embedded.

Zephyr implements the “API hook” functions that are invoked by the C standard library functions in the Picolibc. These hook functions are implemented in `lib/libc/picolibc/libc-hooks.c` and translate the library internal system calls to the equivalent Zephyr API calls.

**Picolibc Module**  When built as a Zephyr module, there are several configuration knobs available to adjust the feature set in the library, balancing what the library supports versus the code size of the resulting functions. Because the standard C++ library must be compiled for the target C library, the Picolibc module cannot be used with applications which use the standard C++ library. Building the Picolibc module will increase the time it takes to compile the application.

The Picolibc module can be enabled by selecting `CONFIG_PICOLIBC_USE_MODULE` in the application configuration file.

When updating the Picolibc module to a newer version, the toolchain-bundled Picolibc in the Zephyr SDK must also be updated to the same version.
Toolchain Picolibc  Starting with version 0.16, the Zephyr SDK includes precompiled versions of Picolibc for every target architecture, along with precompiled versions of libstdc++.

The toolchain version of Picolibc can be enabled by de-selecting CONFIG_PICOLIBC_USE_MODULE in the application configuration file.

For every release of Zephyr, the toolchain-bundled Picolibc and the Picolibc module are guaranteed to be in sync when using the recommended version of Zephyr SDK.

Building Without Toolchain bundled Picolibc  For toolchain where there is no bundled Picolibc, it is still possible to use Picolibc by building it from source. Note that any restrictions mentioned in Picolibc Module still apply.

To build without toolchain bundled Picolibc, the toolchain must enable CONFIG_PICOLIBC_SUPPORTED. For example, this needs to be added to the toolchain Kconfig file:

```
config TOOLCHAIN_<name>_PICOLIBC_SUPPORTED
  def_bool y
  select PICOLIBC_SUPPORTED
```

By enabling CONFIG_PICOLIBC_SUPPORTED, the build system would automatically build Picolibc from source with its module when there is no toolchain bundled Picolibc.

Formatted Output  Picolibc supports all standard C formatted input and output functions, including printf(), fprintf(), sprintf() and sscanf().

Picolibc formatted input and output function implementation supports all format specifiers defined by the C17 and POSIX 2018 standards with the following exceptions:

- Floating point format specifiers (e.g. %f) require CONFIG_PICOLIBC_IO_FLOAT.
- Long long format specifiers (e.g. %lld) require CONFIG_PICOLIBC_IO_LONG_LONG. This option is automatically enabled with CONFIG_PICOLIBC_IO_FLOAT.

Printk, cbprintf and friends  When using Picolibc, Zephyr formatted output functions are implemented in terms of stdio calls. This includes:

- printk, snprintf and vsnprintf
- cbprintf and cbvprintf
- fprintfcb, vfprintfcb, printfcb, vprintfcb, snprintfcb and vsnprintfcb

When using tagged args (CONFIG_CBPRINTF_PACKAGE_SUPPORT_TAGGED_ARGUMENTS and CBPRINTF_PACKAGE_ARGS_ARE_TAGGED), calls to cbprintf will not use Picolibc, so formatting of output using those code will differ from Picolibc results as the cbprintf functions are not completely C/POSIX compliant.

Math Functions  Picolibc provides full C17/IEEE STD 754-2019 support for float, double and long double math operations, except for long double versions of the Bessel functions.

Thread Local Storage  Picolibc uses Thread Local Storage (TLS) (where supported) for data which is supposed to remain local to each thread, like errno. This means that TLS support is enabled when using Picolibc. As all TLS variables are allocated out of the thread stack area, this can affect stack size requirements by a few bytes.
C Library Local Variables   Picolibc uses a few internal variables for things like heap management. These are collected in a dedicated memory partition called *z_libc_partition*. Applications using *CONFIG_USERSPACE* and memory domains must ensure that this partition is included in any domain active during Picolibc calls.

Dynamic Memory Management   Picolibc uses the malloc api family implementation provided by the *common C library*, which itself is built upon the *kernel memory heap API*.

Formatted Output

C defines standard formatted output functions such as *printf* and *snprintf* and these functions are implemented by the C standard libraries.

Each C standard library has its own set of requirements and configurations for selecting the formatted output modes and capabilities. Refer to each C standard library documentation for more details.

Dynamic Memory Management

C defines a standard dynamic memory management interface (for example, *malloc()* and *free()* ) and these functions are implemented by the C standard libraries.

While the details of the dynamic memory management implementation varies across different C standard libraries, all supported libraries must conform to the following conventions. Every supported C standard library shall:

- manage its own memory heap either internally or by invoking the hook functions (for example, *sbrk()* ) implemented in *libc-hooks.c*.
- maintain the architecture- and memory region-specific alignment requirements for the memory blocks allocated by the standard dynamic memory allocation interface (for example, *malloc()*).
- allocate memory blocks inside the *z_malloc_partition* memory partition when userspace is enabled. See *Pre-defined Memory Partitions*.

For more details regarding the C standard library-specific memory management implementation, refer to each C standard library documentation.

Note:  Native Zephyr applications should use the *memory management API* supported by the Zephyr kernel such as *k_malloc()* in order to take advantage of the advanced features that they offer.

C standard dynamic memory management interface functions such as *malloc()* should be used only by the portable applications and libraries that target multiple operating systems.

2.7.2  C++ Language Support

C++ is a general-purpose object-oriented programming language that is based on the C language.

Enabling C++ Support

Zephyr supports applications written in both C and C++. However, to use C++ in an application you must configure Zephyr to include C++ support by selecting the *CONFIG_CPP* in the application configuration file.

To enable C++ support, the compiler toolchain must also include a C++ compiler and the included compiler must be supported by the Zephyr build system. The *Zephyr SDK*, which includes the GNU C++
Compiler (part of GCC), is supported by Zephyr, and the features and their availability documented here assume the use of the Zephyr SDK.

The default C++ standard level (i.e. the language enforced by the compiler flags passed) for Zephyr apps is C++11. Other standards are available via kconfig choice, for example CONFIG_STD_CPP98. The oldest standard supported and tested in Zephyr is C++98.

When compiling a source file, the build system selects the C++ compiler based on the suffix (extension) of the files. Files identified with either a `.cpp` or a `.cxx` suffix are compiled using the C++ compiler. For example, `myCplusplusApp.cpp` is compiled using C++.

The C++ standard requires the `main()` function to have the return type of `int`. Your `main()` must be defined as `int main(void)`. Zephyr ignores the return value from main, so applications should not return status information and should, instead, return zero.

**Note:** Do not use C++ for kernel, driver, or system initialization code.

### Language Features

Zephyr currently provides only a subset of C++ functionality. The following features are not supported:

- Static global object destruction
- OS-specific C++ standard library classes (e.g. `std::thread`, `std::mutex`)

While not an exhaustive list, support for the following functionality is included:

- Inheritance
- Virtual functions
- Virtual tables
- Static global object constructors
- Dynamic object management with the `new` and `delete` operators
- Exceptions
- RTTI (runtime type information)
- Standard Template Library (STL)

Static global object constructors are initialized after the drivers are initialized but before the application `main()` function. Therefore, use of C++ is restricted to application code.

In order to make use of the C++ exceptions, the `CONFIG_CPP_EXCEPTIONS` must be selected in the application configuration file.

### Zephyr Minimal C++ Library

Zephyr minimal C++ library (`lib/cpp/minimal`) provides a minimal subset of the C++ standard library and application binary interface (ABI) functions to enable basic C++ language support. This includes:

- `new` and `delete` operators
- virtual function stub and vtables
- static global initializers for global constructors

The scope of the minimal C++ library is strictly limited to providing the basic C++ language support, and it does not implement any Standard Template Library (STL) classes and functions. For this reason, it is only suitable for use in the applications that implement their own (non-standard) class library and do rely on the Standard Template Library (STL) components.
Any application that makes use of the Standard Template Library (STL) components, such as `std::string` and `std::vector`, must enable the C++ standard library support.

### C++ Standard Library

The C++ Standard Library is a collection of classes and functions that are part of the ISO C++ standard (`std` namespace).

Zephyr does not include any C++ standard library implementation in source code form. Instead, it allows configuring the build system to link against the pre-built C++ standard library included in the C++ compiler toolchain.

To enable C++ standard library, select an applicable toolchain-specific C++ standard library type from the `CONFIG_LIBCPP_IMPLEMENTATION` in the application configuration file.

For instance, when building with the Zephyr SDK, the build system can be configured to link against the GNU C++ Library (`libstdc++.a`), which is a fully featured C++ standard library that provides all features required by the ISO C++ standard including the Standard Template Library (STL), by selecting `CONFIG_GLIBCXX_LIBCPP` in the application configuration file.

The following C++ standard libraries are supported by Zephyr:

- GNU C++ Library (`CONFIG_GLIBCXX_LIBCPP`)
- ARC MetaWare C++ Library (`CONFIG_ARCMWDT_LIBCPP`)

A Zephyr subsystem that requires the features from the full C++ standard library can select, from its config, `CONFIG_REQUIRES_FULL_LIBCPP`, which automatically selects a compatible C++ standard library unless the Kconfig symbol for a specific C++ standard library is selected.

### 2.8 Optimizations

Guides on how to optimize Zephyr for performance, power and footprint.

#### 2.8.1 Optimizing for Footprint

**Stack Sizes**

Stack sizes of various system threads are specified generously to allow for usage in different scenarios on as many supported platforms as possible. You should start the optimization process by reviewing all stack sizes and adjusting them for your application:

- `CONFIG_ISR_STACK_SIZE`
  - Set to 2048 by default
- `CONFIG_MAIN_STACK_SIZE`
  - Set to 1024 by default
- `CONFIG_IDLE_STACK_SIZE`
  - Set to 320 by default
- `CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE`
  - Set to 1024 by default
- `CONFIG_PRIVILEGED_STACK_SIZE`
  - Set to 1024 by default, depends on userspace feature.
Unused Peripherals

Some peripherals are enabled by default. You can disable unused peripherals in your project configuration, for example:

```
CONFIG_GPIO=n
CONFIG_SPI=n
```

Various Debug/Informational Options

The following options are enabled by default to provide more information about the running application and to provide means for debugging and error handling:

```
CONFIG_BOOT_BANNER
```
This option can be disabled to save a few bytes.

```
CONFIG_DEBUG
```
This option can be disabled for production builds.

MPU/MMU Support

Depending on your application and platform needs, you can disable MPU/MMU support to gain some memory and improve performance. Consider the consequences of this configuration choice though, because you’ll lose advanced stack checking and support.

2.8.2 Optimization Tools

Footprint and Memory Usage

The build system offers 3 targets to view and analyse RAM, ROM and stack usage in generated images. The tools run on the final image and give information about size of symbols and code being used in both RAM and ROM. Additionally, with features available through the compiler, we can also generate worst-case stack usage analysis:

Tools that are available as build system targets:

**Build Target: ram_report**  List all compiled objects and their RAM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `ram_report` target with your board:

Using west:

```
west build -b reel_board samples/hello_world
west build -t ram_report
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based build system:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild ram_report
```

which will generate something similar to the output below:
<table>
<thead>
<tr>
<th>Path</th>
<th>Size</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SystemCoreClock</td>

</tbody>
</table>
Build Target: **rom_report**  List all compiled objects and their ROM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the **rom_report** to get the ROM report:

Using west:

```bash
west build -b reel_board samples/hello_world
west build -t rom_report
```

Using CMake and ninja:

```bash
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild rom_report
```

which will generate something similar to the output below:

```
<table>
<thead>
<tr>

</table>
```

(continues on next page)
Build Target: puncover  This target uses a third-party tool called puncover which can be found at https://github.com/HBehrens/puncover. When this target is built, it will launch a local web server which will allow you to open a web client and browse the files and view their ROM, RAM, and stack usage. Before you can use this target, you will have to install the puncover python module:

```
pip3 install git+https://github.com/HBehrens/puncover --user
```

**Warning:** This is a third-party tool that might or might not be working at any given time. Please check the GitHub issues, and report new problems to the project maintainer.

Then:

Using west:

```
w west build -b reel_board samples/hello_world
west build -t puncover
```
Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild puncover
```

To view worst-case stack usage analysis, build this with the `CONFIG_STACK_USAGE` enabled.

Using west:

```
w west build -b reel_board samples/hello_world -- -DCONFIG_STACK_USAGE=y
west build -t puncover
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board -DCONFIG_STACK_USAGE=y samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild puncover
```

Data Structures

**Build Target: pahole**  
Poke-a-hole (pahole) is an object-file analysis tool to find the size of the data structures, and the holes caused due to aligning the data elements to the word-size of the CPU by the compiler.

Poke-a-hole (pahole) must be installed prior to using this target. It can be obtained from [https://git.kernel.org/pub/scm/devel/pahole/pahole.git](https://git.kernel.org/pub/scm/devel/pahole/pahole.git) and is available in the dwarves package in both fedora and ubuntu:

```
sudo apt-get install dwarves
```

or in fedora:

```
sudo dnf install dwarves
```

Using west:

```
w west build -b reel_board samples/hello_world
west build -t pahole
```

Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run ninja on the generated build system:
ninja -Cbuild pahole
```

After running this target, pahole will output the results to the console:

```
/* Used at: zephyr/isr_tables.c */
/* <80> ../include/sw_isr_table.h:30 */
struct _isr_table_entry {
    void * arg; /* 0 4 */
    void (*isr)(void *); /* 4 4 */
}(continues on next page)
```
2.9 Flashing and Hardware Debugging

2.9.1 Flash & Debug Host Tools

This guide describes the software tools you can run on your host workstation to flash and debug Zephyr applications.

Zephyr's west tool has built-in support for all of these in its flash, debug, debugserver, and attach commands, provided your board hardware supports them and your Zephyr board directory's board.cmake file declares that support properly. See Building, Flashing and Debugging for more information on these commands.

SAM Boot Assistant (SAM-BA)

Atmel SAM Boot Assistant (Atmel SAM-BA) allows In-System Programming (ISP) from USB or UART host without any external programming interface. Zephyr allows users to develop and program boards with SAM-BA support using west. Zephyr supports devices with/without ROM bootloader and both extensions from Arduino and Adafruit. Full support was introduced in Zephyr SDK 0.12.0.

The typical command to flash the board is:

```
west flash [ -r bossac ] [ -p /dev/ttyX ]
```

Flash configuration for devices:

With ROM bootloader

These devices don't need any special configuration. After building your application, just run west flash to flash the board.

Without ROM bootloader
For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see Flash map for details.

2. Have board .defconfig file with the CONFIG_USE_DT_CODE_PARTITION Kconfig option set to y to instruct the build system to use these partitions for code relocation. This option can also be set in prj.conf or any other Kconfig fragment.

3. Build and flash the SAM-BA bootloader on the device.

With compatible SAM-BA bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see Flash map for details.

2. Have board .defconfig file with the CONFIG_BOOTLOADER_BOSSA Kconfig option set to y. This will automatically select the CONFIG_USE_DT_CODE_PARTITION Kconfig option which instruct the build system to use these partitions for code relocation. The board .defconfig file should have CONFIG_BOOTLOADER_BOSSA_ARDUINO, CONFIG_BOOTLOADER_BOSSA_ADAFRUIT_UF2 or the CONFIG_BOOTLOADER_BOSSA_LEGACY Kconfig option set to y to select the right compatible SAM-BA bootloader mode. These options can also be set in prj.conf or any other Kconfig fragment.

3. Build and flash the SAM-BA bootloader on the device.

**Note:** The CONFIG_BOOTLOADER_BOSSA_LEGACY Kconfig option should be used as last resource. Try configure first with Devices without ROM bootloader.

**Typical flash layout and configuration** For bootloaders that reside on flash, the devicetree partition layout is mandatory. For devices that have a ROM bootloader, they are mandatory when the application uses a storage or other non-application partition. In this special case, the boot partition should be omitted and code_partition should start from offset 0. It is necessary to define the partitions with sizes that avoid overlaps, always.

A typical flash layout for devices without a ROM bootloader is:

```
/ {
    chosen {
        zephyr,code-partition = &code_partition;
    }
};

@flash0 {
    partitions {
        compatible = "fixed-partitions";
        #address-cells = <1>;
        #size-cells = <1>;

        boot_partition: partition@0 {
            label = "sam-ba";
            reg = <0x00000000 0x2000>;
            read-only;
        };

        code_partition: partition@2000 {
            label = "code";
            reg = <0x2000 0x3a000>;
            read-only;
        }
    }
}
```

(continues on next page)
A typical flash layout for devices with a ROM bootloader and storage partition is:

```c
/ {
    chosen {
        zephyr,code-partition = &code_partition;
    }
};

&flash0 {
    partitions {
        compatible = "fixed-partitions";
        #address-cells = <1>;
        #size-cells = <1>;

        code_partition: partition@0 { 
            label = "code";
            reg = <0x0 0xF0000>;
            read-only;
        }

        /*
         * The final 16 KiB is reserved for the application.
         * Storage partition will be used by FCB/LittleFS/NVS
         * if enabled.
         */
        storage_partition: partition@3c000 { 
            label = "storage";
            reg = <0x0003c000 0x00004000>;
        }
    }
};
```

Enabling SAM-BA runner  In order to instruct Zephyr west tool to use the SAM-BA bootloader the board.cmake file must have `include(${ZEPHYR_BASE}/boards/common/bossac.board.cmake)` entry. Note that Zephyr tool accept more entries to define multiple runners. By default, the first one will be selected when using `west flash` command. The remaining options are available passing the runner option, for instance `west flash -r bossac`.

More implementation details can be found in the boards documentation. As a quick reference, see these three board documentation pages:

- sam4e_xpro (ROM bootloader)
• adafruit_feather_m0_basic_proto (Adafruit UF2 bootloader)
• arduinoNano_33_iot (Arduino bootloader)
• arduinoNano_33_ble (Arduino legacy bootloader)

**Enabling BOSSAC on Windows Native [Experimental]** Zephyr SDK’s bossac is currently supported on Linux and macOS only. Windows support can be achieved by using the bossac version from BOSSA official releases. After installing using default options, the `bossac.exe` must be added to Windows PATH. A specific bossac executable can be used by passing the `--bossac` option, as follows:

```
west flash -r bossac --bossac="C:\Program Files (x86)\BOSSA\bossac.exe" --bossac-port="COMx"
```

**Note:** WSL is not currently supported.

**LinkServer Debug Host Tools**

Linkserver is a utility for launching and managing GDB servers for NXP debug probes, which also provides a command-line target flash programming capabilities. Linkserver can be used with the NXP MCUXpresso for Visual Studio Code implementation, with custom debug configurations based on GNU tools or as part of a headless solution for continuous integration and test. LinkServer can be used with MCU-Link, LPC-Link2, LPC11U35-based and OpenSDA based standalone or on-board debug probes from NXP.

NXP recommends installing LinkServer by using NXP’s MCUXpresso Installer. This method will also install the tools supporting the debug probes below, including NXP’s MCU-Link and LPCScrypt tools.

LinkServer is compatible with the following debug probes:

- **LPC-LINK2 CMSIS DAP Onboard Debug Probe**
- **MCU-Link CMSIS-DAP Onboard Debug Probe**
- **OpenSDA DAPLink Onboard Debug Probe**

Supported west commands:

1. flash
2. debug
3. debugserver
4. attach

Notes:

1. Probes can be listed with LinkServer:

```
LinkServer probes
```

2. With multiple debug probes attached to the host, use the LinkServer west runner `--probe` option to pass the probe index.

```
west flash --runner=linkserver --probe=3
```

3. Device-specific settings can be overridden with the west runner for LinkServer with the option `--override`. May be used multiple times. The format is dictated by LinkServer, e.g.:

```
west flash --runner=linkserver --override /device/memory/5/flash-driver=MIMXRT500_SFDP_MXIC_SPI_S.cfx
```
J-Link Debug Host Tools

Segger provides a suite of debug host tools for Linux, macOS, and Windows operating systems:

- J-Link GDB Server: GDB remote debugging
- J-Link Commander: Command-line control and flash programming
- RTT Viewer: RTT terminal input and output
- SystemView: Real-time event visualization and recording

These debug host tools are compatible with the following debug probes:

- LPC-Link2 J-Link Onboard Debug Probe
- OpenSDA J-Link Onboard Debug Probe
- MCU-Link JLink Onboard Debug Probe
- J-Link External Debug Probe
- ST-LINK/V2-1 Onboard Debug Probe

Check if your SoC is listed in J-Link Supported Devices.

Download and install the J-Link Software and Documentation Pack to get the J-Link GDB Server and Commander, and to install the associated USB device drivers. RTT Viewer and SystemView can be downloaded separately, but are not required.

Note that the J-Link GDB server does not yet support Zephyr RTOS-awareness.

OpenOCD Debug Host Tools

OpenOCD is a community open source project that provides GDB remote debugging and flash programming support for a wide range of SoCs. A fork that adds Zephyr RTOS-awareness is included in the Zephyr SDK; otherwise see Getting OpenOCD for options to download OpenOCD from official repositories.

These debug host tools are compatible with the following debug probes:

- OpenSDA DAPLink Onboard Debug Probe
- J-Link External Debug Probe
- ST-LINK/V2-1 Onboard Debug Probe

Check if your SoC is listed in OpenOCD Supported Devices.

Note: On Linux, openocd is available though the Zephyr SDK. Windows users should use the following steps to install openocd:

- Download openocd for Windows from here: OpenOCD Windows
- Copy bin and share dirs to C:\Program Files\OpenOCD\bin
- Add C:\Program Files\OpenOCD\bin to ‘PATH’ environment variable

pyOCD Debug Host Tools

pyOCD is an open source project from Arm that provides GDB remote debugging and flash programming support for Arm Cortex-M SoCs. It is distributed on PyPi and installed when you complete the Get Zephyr and install Python dependencies step in the Getting Started Guide. pyOCD includes support for Zephyr RTOS-awareness.

These debug host tools are compatible with the following debug probes:
• OpenSDA DAPLink Onboard Debug Probe
• ST-LINK/V2-1 Onboard Debug Probe

Check if your SoC is listed in pyOCD Supported Devices.

**Lauterbach TRACE32 Debug Host Tools**

Lauterbach TRACE32 is a product line of microprocessor development tools, debuggers and real-time tracer with support for JTAG, SWD, NEXUS or ETM over multiple core architectures, including Arm Cortex-A/-R/-M, RISC-V, Xtensa, etc. Zephyr allows users to develop and program boards with Lauterbach TRACE32 support using `west`.

The runner consists of a wrapper around TRACE32 software, and allows a Zephyr board to execute a custom start-up script (Practice Script) for the different commands supported, including the ability to pass extra arguments from CMake. It is up to the board using this runner to define the actions performed on each command.

**Install Lauterbach TRACE32 Software**  Download Lauterbach TRACE32 software from the Lauterbach TRACE32 download website (registration required) and follow the installation steps described in Lauterbach TRACE32 Installation Guide.

**Flashing and Debugging**  Set the environment variable `T32_DIR` to the TRACE32 system directory. Then execute `west flash` or `west debug` commands to flash or debug the Zephyr application as detailed in Building, Flashing and Debugging. The debug command launches TRACE32 GUI to allow debug the Zephyr application, while the `flash` command hides the GUI and perform all operations in the background.

By default, the `t32` runner will launch TRACE32 using the default configuration file named `config.t32` located in the TRACE32 system directory. To use a different configuration file, supply the argument `--config CONFIG` to the runner, for example:

```
west flash --config myconfig.t32
```

For more options, run `west flash --context -r t32` to print the usage.

**Zephyr RTOS Awareness**  To enable Zephyr RTOS awareness follow the steps described in Lauterbach TRACE32 Zephyr OS Awareness Manual.

### 2.9.2 Debug Probes

A debug probe is special hardware which allows you to control execution of a Zephyr application running on a separate board. Debug probes usually allow reading and writing registers and memory, and support breakpoint debugging of the Zephyr application on your host workstation using tools like GDB. They may also support other debug software and more advanced features such as tracing program execution. For details on the related host software supported by Zephyr, see Flash & Debug Host Tools.

Debug probes are usually connected to your host workstation via USB; they are sometimes also accessible via an IP network or other means. They usually connect to the device running Zephyr using the JTAG or SWD protocols. Debug probes are either separate hardware devices or circuitry integrated into the same board which runs Zephyr.

Many supported boards in Zephyr include a second microcontroller that serves as an onboard debug probe, usb-to-serial adapter, and sometimes a drag-and-drop flash programmer. This eliminates the need to purchase an external debug probe and provides a variety of debug host tool options.

Several hardware vendors have their own branded onboard debug probe implementations: NXP LPC boards have LPC-Link2, NXP Kinetis (former Freescale) boards have OpenSDA, and ST boards have...
Each onboard debug probe microcontroller can support one or more types of firmware that communicate with their respective debug host tools. For example, an OpenSDA microcontroller can be programmed with DAPLink firmware to communicate with pyOCD or OpenOCD debug host tools, or with J-Link firmware to communicate with J-Link debug host tools.

### Debug Probes & Host Tools Compatibility Chart

</tbody>
</table>

Some supported boards in Zephyr do not include an onboard debug probe and therefore require an external debug probe. In addition, boards that do include an onboard debug probe often also have an SWD or JTAG header to enable the use of an external debug probe instead. One reason this may be useful is that the onboard debug probe may have limitations, such as lack of support for advanced debuggers or high-speed tracing. You may need to adjust jumpers to prevent the onboard debug probe from interfering with the external debug probe.

### MCU-Link CMSIS-DAP Onboard Debug Probe

The CMSIS-DAP debug probes allow debugging from any compatible toolchain, including IAR EWARM, Keil MDK, NXP’s MCUXpresso IDE and MCUXpresso extension for VS Code. In addition to debug probe functionality, the MCU-Link probes may also provide:

1. SWO trace end point: this virtual device is used by MCUXpresso to retrieve SWO trace data. See the MCUXpresso IDE documentation for more information.
2. Virtual COM (VCOM) port / UART bridge connected to the target processor
3. USB to UART, SPI and/or I2C interfaces (depending on MCU-Link type/implementation)
4. Energy measurements of the target MCU

This debug probe is compatible with the following debug host tools:

- **LinkServer Debug Host Tools**

This probe is realized by programming the MCU-Link microcontroller with the CMSIS-DAP MCU-Link firmware, which is already installed by default. NXP recommends using NXP’s MCUXpresso Installer, which installs both the MCU-Link host tools plus the LinkServer Debug Host Tools.

1. Put the MCU-Link microcontroller into DFU boot mode by attaching the DFU jumper, then powering up the board.
2. Run the `program_CMSIS` script, found in the installed MCU-Link scripts folder.
3. Remove the DFU jumper and power cycle the board.

### MCU-Link JLink Onboard Debug Probe

The MCU-Link J-Link is an onboard debug probe and usb-to-serial adapter supported on many NXP development boards.

This debug probe is compatible with the following debug host tools:
• **J-Link Debug Host Tools**

These probes do not have JLink firmware installed by default, and must be updated. NXP recommends using NXP’s MCUXpresso Installer, which installs both the *J-Link Debug Host Tools* plus the MCU-Link host tools.

1. Put the MCU-Link microcontroller into DFU boot mode by attaching the DFU jumper, then powering up the board.
2. Run the `program_JLINK` script, found in the installed MCU-Link scripts folder.
3. Remove the DFU jumper and power cycle the board.

**LPC-LINK2 CMSIS DAP Onboard Debug Probe**

The CMSIS-DAP debug probes allow debugging from any compatible toolchain, including IAR EWARM, Keil MDK, as well as NXP’s MCUXpresso IDE and MCUXpresso extension for VS Code. As well as providing debug probe functionality, the LPC-Link2 probes also provide:

1. SWO trace end point: this virtual device is used by MCUXpresso to retrieve SWO trace data. See the MCUXpresso IDE documentation for more information.
2. Virtual COM (VCOM) port / UART bridge connected to the target processor
3. LPCSIO bridge that provides communication to I2C and SPI slave devices

This probe is realized by programming the LPC-Link2 microcontroller with the CMSIS-DAP LPC-Link2 firmware. Download and install LPCScrypt to get the firmware and programming scripts.

**Note:** Verify the firmware supports your board by visiting [Firmware for LPCXpresso](#)

1. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then powering up the board.
2. Run the `program_CMSIS` script.
3. Remove the DFU jumper and power cycle the board.

**LPC-Link2 J-Link Onboard Debug Probe**

The LPC-Link2 J-Link is an onboard debug probe and usb-to-serial adapter supported on many NXP LPC and i.MX RT development boards.

This debug probe is compatible with the following debug host tools:

• **J-Link Debug Host Tools**

This probe is realized by programming the LPC-Link2 microcontroller with J-Link LPC-Link2 firmware. Download and install LPCScrypt to get the firmware and programming scripts.

**Note:** Verify the firmware supports your board by visiting [Firmware for LPCXpresso](#)

1. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then powering up the board.
2. Run the `program_JLINK` script.
3. Remove the DFU jumper and power cycle the board.
OpenSDA DAPLink Onboard Debug Probe

The OpenSDA DAPLink is an onboard debug probe and usb-to-serial adapter supported on many NXP Kinetis and i.MX RT development boards. It also includes drag-and-drop flash programming support.

This debug probe is compatible with the following debug host tools:

- pyOCD Debug Host Tools
- OpenOCD Debug Host Tools

This probe is realized by programming the OpenSDA microcontroller with DAPLink OpenSDA firmware. NXP provides OpenSDA DAPLink Board-Specific Firmwares.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you power on the board. Note that “bootloader mode” in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.

2. After you power on the board, release the reset button. A USB mass storage device called BOOTLOADER or MAINTENANCE will enumerate.

3. Copy the OpenSDA firmware binary to the USB mass storage device.

4. Power cycle the board, this time without holding the reset button. You should see three USB devices enumerate: a CDC device (serial port), a HID device (debug port), and a mass storage device (drag-and-drop flash programming).

OpenSDA J-Link Onboard Debug Probe

The OpenSDA J-Link is an onboard debug probe and usb-to-serial adapter supported on many NXP Kinetis and i.MX RT development boards.

This debug probe is compatible with the following debug host tools:

- J-Link Debug Host Tools

This probe is realized by programming the OpenSDA microcontroller with J-Link OpenSDA firmware. Segger provides OpenSDA J-Link Generic Firmwares and OpenSDA J-Link Board-Specific Firmwares, where the latter is generally recommended when available. Board-specific firmwares are required for i.MX RT boards to support their external flash memories, whereas generic firmwares are compatible with all Kinetis boards.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you power on the board. Note that “bootloader mode” in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.

2. After you power on the board, release the reset button. A USB mass storage device called BOOTLOADER or MAINTENANCE will enumerate.

3. Copy the OpenSDA firmware binary to the USB mass storage device.

4. Power cycle the board, this time without holding the reset button. You should see two USB devices enumerate: a CDC device (serial port) and a vendor-specific device (debug port).
J-Link External Debug Probe

Segger J-Link is a family of external debug probes, including J-Link EDU, J-Link PLUS, J-Link ULTRA+, and J-Link PRO, that support a large number of devices from different hardware architectures and vendors.

This debug probe is compatible with the following debug host tools:

- J-Link Debug Host Tools
- OpenOCD Debug Host Tools

Install the debug host tools before you program the firmware.

ST-LINK/V2-1 Onboard Debug Probe

ST-LINK/V2-1 is a serial and debug adapter built into all Nucleo and Discovery boards. It provides a bridge between your computer (or other USB host) and the embedded target processor, which can be used for debugging, flash programming, and serial communication, all over a simple USB cable.

It is compatible with the following host debug tools:

- OpenOCD Debug Host Tools
- J-Link Debug Host Tools

For some STM32 based boards, it is also compatible with:

- pyOCD Debug Host Tools

While it works out of the box with OpenOCD, it requires some flashing to work with J-Link. To do this, SEGGER offers a firmware upgrading the ST-LINK/V2-1 on board on the Nucleo and Discovery boards. This firmware makes the ST-LINK/V2-1 compatible with J-LinkOB, allowing users to take advantage of most J-Link features like the ultra fast flash download and debugging speed or the free-to-use GDBServer.

More information about upgrading ST-LINK/V2-1 to JLink or restore ST-Link/V2-1 firmware please visit: Segger over ST-Link

Flash and debug with ST-Link  Using OpenOCD

OpenOCD is available by default on ST-Link and configured as the default flash and debug tool. Flash and debug can be done as follows:

```bash
# From the root of the zephyr repository
west build -b None samples/hello_world
west flash
```

```bash
# From the root of the zephyr repository
west build -b None samples/hello_world
west debug
```

Using Segger J-Link

Once STLink is flashed with SEGGER FW and J-Link GDB server is installed on your host computer, you can flash and debug as follows:

Use CMake with `-DBOARD_FLASH_RUNNER=jlink` to change the default OpenOCD runner to J-Link. Alternatively, you might add the following line to your application CMakeList.txt file.

```cmake
set(BOARD_FLASH_RUNNER jlink)
```

If you use West (Zephyr's meta-tool) you can modify the default runner using the `--runner` (or `-r`) option.

2.9. Flashing and Hardware Debugging
To attach a debugger to your board and open up a debug console with jlink.

`west flash --runner jlink`

For more information about West and available options, see West (Zephyr's meta-tool).

If you configured your Zephyr application to use Segger RTT console instead, open telnet:

```
$ telnet localhost 19021
Trying ::1...
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
SEGGER J-Link V6.30f - Real time terminal output
J-Link STLink V21 compiled Jun 26 2017 10:35:16 V1.0, SN=773895351
Process: JLinkGDBServerCLExe
Zephyr Shell, Zephyr version: 1.12.99
Type 'help' for a list of available commands
```

If you get no RTT output you might need to disable other consoles which conflict with the RTT one if they are enabled by default in the particular sample or application you are running, such as disable UART_CONSOLE in menuconfig

Updating or restoring ST-Link firmware ST-Link firmware can be updated using STM32CubeProgrammer Tool. It is usually useful when facing flashing issues, for instance when using twister's device-testing option.

Once installed, you can update attached board ST-Link firmware with the following command

```
s java -jar ~/STMicroelectronics/STM32Cube/STM32CubeProgrammer/Drivers/FirmwareUpgrade/STLinkUpgrade.jar -sn <board_uid>
```

Where board_uid can be obtained using twister's generate-hardware-map option. For more information about twister and available options, see Test Runner (Twister).

### 2.10 Modules (External projects)

Zephyr relies on the source code of several externally maintained projects in order to avoid reinventing the wheel and to reuse as much well-established, mature code as possible when it makes sense. In the context of Zephyr's build system those are called modules. These modules must be integrated with the Zephyr build system, as described in more detail in other sections on this page.

To be classified as a candidate for being included in the default list of modules, an external project is required to have its own life-cycle outside the Zephyr Project, that is, reside in its own repository, and have its own contribution and maintenance workflow and release process. Zephyr modules should not contain code that is written exclusively for Zephyr. Instead, such code should be contributed to the main zephyr tree.

Modules to be included in the default manifest of the Zephyr project need to provide functionality or features endorsed and approved by the project Technical Steering Committee and should comply with the module licensing requirements and contribution guidelines. They should also have a Zephyr developer that is committed to maintain the module codebase.

Zephyr depends on several categories of modules, including but not limited to:

- Debugger integration
• Silicon vendor Hardware Abstraction Layers (HALs)
• Cryptography libraries
• File Systems
• Inter-Process Communication (IPC) libraries

Additionally, in some cases modules (particularly vendor HALs) can contain references to optional binary blobs.

This page summarizes a list of policies and best practices which aim at better organizing the workflow in Zephyr modules.

2.10.1 Modules vs west projects

Zephyr modules, described in this page, are not the same as west projects. In fact, modules do not require west at all. However, when using modules with west, then the build system uses west in order to find modules.

In summary:

Modules are repositories that contain a zephyr/module.yml file, so that the Zephyr build system can pull in the source code from the repository. West projects are entries in the projects: section in the west.yml manifest file. West projects are often also modules, but not always. There are west projects that are not included in the final firmware image (eg. tools) and thus do not need to be modules. Modules are found by the Zephyr build system either via west itself, or via the ZEPHYR_MODULES CMake variable.

The contents of this page only apply to modules, and not to west projects in general (unless they are a module themselves).

2.10.2 Module Repositories

• All modules included in the default manifest shall be hosted in repositories under the zephyrproject-rtos GitHub organization.
• The module repository codebase shall include a module.yml file in a zephyr/ folder at the root of the repository.
• Module repository names should follow the convention of using lowercase letters and dashes instead of underscores. This rule will apply to all new module repositories, except for repositories that are directly tracking external projects (hosted in Git repositories); such modules may be named as their external project counterparts.

Note: Existing module repositories that do not conform to the above convention do not need to be renamed to comply with the above convention.

• Module repositories names should be explicitly set in the zephyr/module.yml file.
• Modules should use “zephyr” as the default name for the repository main branch. Branches for specific purposes, for example, a module branch for an LTS Zephyr version, shall have names starting with the ‘zephyr_’ prefix.
• If the module has an external (upstream) project repository, the module repository should preserve the upstream repository folder structure.

Note: It is not required in module repositories to maintain a ‘master’ branch mirroring the master branch of the external repository. It is not recommended as this may generate confusion around the module’s main branch, which should be ‘zephyr’.
• Modules should expose all provided header files with an include pathname beginning with the module-name. (E.g., mcuboot should expose its bootutil/bootutil.h as “mcu-boot/bootutil/bootutil.h”.)

Synchronizing with upstream

It is preferred to synchronize a module repository with the latest stable release of the corresponding external project. It is permitted, however, to update a Zephyr module repository with the latest development branch tip, if this is required to get important updates in the module codebase. When synchronizing a module with upstream it is mandatory to document the rationale for performing the particular update.

Requirements for allowed practices

Changes to the main branch of a module repository, including synchronization with upstream code base, may only be applied via pull requests. These pull requests shall be verifiable by Zephyr CI and mergeable (e.g. with the Rebase and merge, or Create a merge commit option using Github UI). This ensures that the incoming changes are always reviewable, and the downstream module repository history is incremental (that is, existing commits, tags, etc. are always preserved). This policy also allows to run Zephyr CI, git lint, identity, and license checks directly on the set of changes that are to be brought into the module repository.

Note: Force-pushing to a module's main branch is not allowed.

Allowed practices

The following practices conform to the above requirements and should be followed in all modules repositories. It is up to the module code owner to select the preferred synchronization practice, however, it is required that the selected practice is consistently followed in the respective module repository.

Updating modules with a diff from upstream: Upstream changes brought as a single snapshot commit (manual diff) in a pull request against the module’s main branch, which may be merged using the Rebase & merge operation. This approach is simple and should be applicable to all modules with the downside of suppressing the upstream history in the module repository.

Note: The above practice is the only allowed practice in modules where the external project is not hosted in an upstream Git repository.

The commit message is expected to identify the upstream project URL, the version to which the module is updated (upstream version, tag, commit SHA, if applicable, etc.), and the reason for the doing the update.

Updating modules by merging the upstream branch: Upstream changes brought in by performing a Git merge of the intended upstream branch (e.g. main branch, latest release branch, etc.) submitting the result in pull request against the module main branch, and merging the pull request using the Create a merge commit operation. This approach is applicable to modules with an upstream project Git repository. The main advantages of this approach is that the upstream repository history (that is, the original commit SHAs) is preserved in the module repository. The downside of this approach is that two additional merge commits are generated in the downstream main branch.

2.10.3 Contributing to Zephyr modules

Individual Roles & Responsibilities

To facilitate management of Zephyr module repositories, the following individual roles are defined.

Administrator: Each Zephyr module shall have an administrator who is responsible for managing access to the module repository, for example, for adding individuals as Collaborators in the repository at the
request of the module owner. Module administrators are members of the Administrators team, that is a group of project members with admin rights to module GitHub repositories.

**Module owner:** Each module shall have a module code owner. Module owners will have the overall responsibility of the contents of a Zephyr module repository. In particular, a module owner will:

- coordinate code reviewing in the module repository
- be the default assignee in pull-requests against the repository’s main branch
- request additional collaborators to be added to the repository, as they see fit
- regularly synchronize the module repository with its upstream counterpart following the policies described in [Synchronizing with upstream](#)
- be aware of security vulnerability issues in the external project and update the module repository to include security fixes, as soon as the fixes are available in the upstream code base
- list any known security vulnerability issues, present in the module codebase, in Zephyr release notes.

**Note:** Module owners are not required to be Zephyr **Maintainers**.

**Merger:** The Zephyr Release Engineering team has the right and the responsibility to merge approved pull requests in the main branch of a module repository.

**Maintaining the module codebase**

Updates in the zephyr main tree, for example, in public Zephyr APIs, may require patching a module’s codebase. The responsibility for keeping the module codebase up to date is shared between the contributor of such updates in Zephyr and the module owner. In particular:

- the contributor of the original changes in Zephyr is required to submit the corresponding changes that are required in module repositories, to ensure that Zephyr CI on the pull request with the original changes, as well as the module integration testing are successful.
- the module owner has the overall responsibility for synchronizing and testing the module codebase with the zephyr main tree. This includes occasional advanced testing of the module's codebase in addition to the testing performed by Zephyr's CI. The module owner is required to fix issues in the module’s codebase that have not been caught by Zephyr pull request CI runs.

**Contributing changes to modules**

Submitting and merging changes directly to a module’s codebase, that is, before they have been merged in the corresponding external project repository, should be limited to:

- changes required due to updates in the zephyr main tree
- urgent changes that should not wait to be merged in the external project first, such as fixes to security vulnerabilities.

Non-trivial changes to a module's codebase, including changes in the module design or functionality should be discouraged, if the module has an upstream project repository. In that case, such changes shall be submitted to the upstream project, directly.

**Submitting changes to modules** describes in detail the process of contributing changes to module repositories.
**Contribution guidelines** Contributing to Zephyr modules shall follow the generic project Contribution guidelines.

**Pull Requests:** may be merged with minimum of 2 approvals, including an approval by the PR assignee. In addition to this, pull requests in module repositories may only be merged if the introduced changes are verified with Zephyr CI tools, as described in more detail in other sections on this page.

The merging of pull requests in the main branch of a module repository must be coupled with the corresponding manifest file update in the zephyr main tree.

**Issue Reporting:** GitHub issues are intentionally disabled in module repositories, in favor of a centralized policy for issue reporting. Tickets concerning, for example, bugs or enhancements in modules shall be opened in the main zephyr repository. Issues should be appropriately labeled using GitHub labels corresponding to each module, where applicable.

**Note:** It is allowed to file bug reports for zephyr modules to track the corresponding upstream project bugs in Zephyr. These bug reports shall not affect the Release Quality Criteria.

**2.10.4 Licensing requirements and policies**

All source files in a module's codebase shall include a license header, unless the module repository has main license file that covers source files that do not include license headers.

Main license files shall be added in the module's codebase by Zephyr developers, only if they exist as part of the external project, and they contain a permissive OSI-compliant license. Main license files should preferably contain the full license text instead of including an SPDX license identifier. If multiple main license files are present it shall be made clear which license applies to each source file in a module's codebase.

Individual license headers in module source files supersede the main license.

Any new content to be added in a module repository will require to have license coverage.

**Note:** Zephyr recommends conveying module licensing via individual license headers and main license files. This not a hard requirement; should an external project have its own practice of conveying how licensing applies in the module's codebase (for example, by having a single or multiple main license files), this practice may be accepted by and be referred to in the Zephyr module, as long as licensing requirements, for example OSI compliance, are satisfied.

**License policies**

When creating a module repository a developer shall:

- import the main license files, if they exist in the external project, and
- document (for example in the module README or .yml file) the default license that covers the module's codebase.

**License checks** License checks (via CI tools) shall be enabled on every pull request that adds new content in module repositories.

**2.10.5 Documentation requirements**

All Zephyr module repositories shall include an .rst file documenting:
• the scope and the purpose of the module
• how the module integrates with Zephyr
• the owner of the module repository
• synchronization information with the external project (commit, SHA, version etc.)
• licensing information as described in Licensing requirements and policies.

The file shall be required for the inclusion of the module and the contained information should be kept up to date.

2.10.6 Testing requirements

All Zephyr modules should provide some level of integration testing, ensuring that the integration with Zephyr works correctly. Integration tests:

• may be in the form of a minimal set of samples and tests that reside in the zephyr main tree
• should verify basic usage of the module (configuration, functional APIs, etc.) that is integrated with Zephyr.
• shall be built and executed (for example in QEMU) as part of twister runs in pull requests that introduce changes in module repositories.

Note: New modules, that are candidates for being included in the Zephyr default manifest, shall provide some level of integration testing.

Note: Vendor HALs are implicitly tested via Zephyr tests built or executed on target platforms, so they do not need to provide integration tests.

The purpose of integration testing is not to provide functional verification of the module; this should be part of the testing framework of the external project.

Certain external projects provide test suites that reside in the upstream testing infrastructure but are written explicitly for Zephyr. These tests may (but are not required to) be part of the Zephyr test framework.

2.10.7 Deprecating and removing modules

Modules may be deprecated for reasons including, but not limited to:

• Lack of maintainership in the module
• Licensing changes in the external project
• Codebase becoming obsolete

The module information shall indicate whether a module is deprecated and the build system shall issue a warning when trying to build Zephyr using a deprecated module.

Deprecated modules may be removed from the Zephyr default manifest after 2 Zephyr releases.

Note: Repositories of removed modules shall remain accessible via their original URL, as they are required by older Zephyr versions.
2.10.8 Integrate modules in Zephyr build system

The build system variable ZEPHYR_MODULES is a CMake list of absolute paths to the directories containing Zephyr modules. These modules contain CMakeLists.txt and Kconfig files describing how to build and configure them, respectively. Module CMakeLists.txt files are added to the build using CMake's add_subdirectory() command, and the Kconfig files are included in the build's Kconfig menu tree.

If you have west installed, you don't need to worry about how this variable is defined unless you are adding a new module. The build system knows how to use west to set ZEPHYR_MODULES. You can add additional modules to this list by setting the EXTRA_ZEPHYR_MODULES CMake variable or by adding an EXTRA_ZEPHYR_MODULES line to .zephyrc (See the section on Environment Variables for more details). This can be useful if you want to keep the list of modules found with west and also add your own.

Note: If the module FOO is provided by west but also given with -DEXTRA_ZEPHYR_MODULES=/<path>/foo then the module given by the command line variable EXTRA_ZEPHYR_MODULES will take precedence. This allows you to use a custom version of FOO when building and still use other Zephyr modules provided by west. This can for example be useful for special test purposes.

If you want to permanently add modules to the zephyr workspace and you are using zephyr as your manifest repository, you can also add a west manifest file into the submanifests directory. See submanifests/README.txt for more details.

See Basics for more on west workspaces.

Finally, you can also specify the list of modules yourself in various ways, or not use modules at all if your application doesn't need them.

2.10.9 Module yaml file description

A module can be described using a file named zephyr/module.yml. The format of zephyr/module.yml is described in the following:

Module name

Each Zephyr module is given a name by which it can be referred to in the build system.

The name should be specified in the zephyr/module.yml file. This will ensure the module name is not changeable through user-defined directory names or west manifest files:

    name: <name>

In CMake the location of the Zephyr module can then be referred to using the CMake variable ZEPHYR_<MODULE_NAME>_MODULE_DIR and the variable ZEPHYR_<MODULE_NAME>_CMAKE_DIR holds the location of the directory containing the module's CMakeLists.txt file.

Note: When used for CMake and Kconfig variables, all letters in module names are converted to uppercase and all non-alphanumeric characters are converted to underscores (_). As example, the module foo-bar must be referred to as ZEPHYR_FOO_BAR_MODULE_DIR in CMake and Kconfig.

Here is an example for the Zephyr module foo:

    name: foo
Note: If the name field is not specified then the Zephyr module name will be set to the name of the module folder. As example, the Zephyr module located in <workspace>/modules/bar will use bar as its module name if nothing is specified in zephyr/module.yml.

Module integration files (in-module)

Inclusion of build files, CMakeLists.txt and Kconfig, can be described as:

```yaml
build:
  cmake: <cmake-directory>
  kconfig: <directory>/Kconfig
```

The `cmake: <cmake-directory>` part specifies that `<cmake-directory>` contains the CMakeLists.txt to use. The `kconfig: <directory>/Kconfig` part specifies the Kconfig file to use. Neither is required: cmake defaults to zephyr, and kconfig defaults to zephyr/Kconfig.

Here is an example module.yml file referring to CMakeLists.txt and Kconfig files in the root directory of the module:

```yaml
build:
  cmake: .
  kconfig: Kconfig
```

Sysbuild integration

Sysbuild is the Zephyr build system that allows for building multiple images as part of a single application, the sysbuild build process can be extended externally with modules as needed, for example to add custom build steps or add additional targets to a build. Inclusion of sysbuild-specific build files, CMakeLists.txt and Kconfig, can be described as:

```yaml
build:
  sysbuild-cmake: <cmake-directory>
  sysbuild-kconfig: <directory>/Kconfig
```

The `sysbuild-cmake: <cmake-directory>` part specifies that `<cmake-directory>` contains the CMakeLists.txt to use. The `sysbuild-kconfig: <directory>/Kconfig` part specifies the Kconfig file to use.

Here is an example module.yml file referring to CMakeLists.txt and Kconfig files in the sysbuild directory of the module:

```yaml
build:
  sysbuild-cmake: sysbuild
  sysbuild-kconfig: sysbuild/Kconfig
```

The module description file zephyr/module.yml can also be used to specify that the build files, CMakeLists.txt and Kconfig, are located in a Module integration files (external).

Build files located in a MODULE_EXT_ROOT can be described as:

```yaml
build:
  sysbuild-cmake-ext: True
  sysbuild-kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.
Build system integration

When a module has a `module.yml` file, it will automatically be included into the Zephyr build system. The path to the module is then accessible through Kconfig and CMake variables.

**Zephyr modules**  In both Kconfig and CMake, the variable `ZEPHYR_<MODULE_NAME>_MODULE_DIR` contains the absolute path to the module.

In CMake, `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` contains the absolute path to the directory containing the `CMakeLists.txt` file that is included into CMake build system. This variable's value is empty if the module.yml file does not specify a `CMakeLists.txt`.

To read these variables for a Zephyr module named `foo`:

- In CMake: use `${ZEPHYR_FOO_MODULE_DIR}` for the module's top level directory, and `${ZEPHYR_FOO_CMAKE_DIR}` for the directory containing its `CMakeLists.txt`

- In Kconfig: use `$(ZEPHYR_FOO_MODULE_DIR)` for the module's top level directory

Notice how a lowercase module name `foo` is capitalized to `FOO` in both CMake and Kconfig.

These variables can also be used to test whether a given module exists. For example, to verify that `foo` is the name of a Zephyr module:

```cpp
if(ZEPHYR_FOO_MODULE_DIR)
    # Do something if FOO exists.
endif()
```

In Kconfig, the variable may be used to find additional files to include. For example, to include the file `some/Kconfig` in module `foo`:

```cpp
source "$(ZEPHYR_FOO_MODULE_DIR)/some/Kconfig"
```

During CMake processing of each Zephyr module, the following two variables are also available:

- the current module's top level directory: `${ZEPHYR_CURRENT_MODULE_DIR}`
- the current module's `CMakeLists.txt` directory: `${ZEPHYR_CURRENT_CMAKE_DIR}`

This removes the need for a Zephyr module to know its own name during CMake processing. The module can source additional CMake files using these `CURRENT` variables. For example:

```cpp
include(${ZEPHYR_CURRENT_MODULE_DIR}/cmake/code.cmake)
```

It is possible to append values to a Zephyr `CMake list` variable from the module's first `CMakeLists.txt` file. To do so, append the value to the list and then set the list in the `PARENT_SCOPE` of the `CMakeLists.txt` file. For example, to append `bar` to the `FOO_LIST` variable in the Zephyr `CMakeLists.txt` scope:

```cpp
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

An example of a Zephyr list where this is useful is when adding additional directories to the `SYSCALL_INCLUDE_DIRS` list.

**Sysbuild modules**  In both Kconfig and CMake, the variable `SYSBUILD_CURRENT_MODULE_DIR` contains the absolute path to the sysbuild module. In CMake, `SYSBUILD_CURRENT_CMAKE_DIR` contains the absolute path to the directory containing the `CMakeLists.txt` file that is included into CMake build system. This variable's value is empty if the module.yml file does not specify a `CMakeLists.txt`.

To read these variables for a sysbuild module:

- In CMake: use `${SYSBUILD_CURRENT_MODULE_DIR}` for the module's top level directory, and `${SYSBUILD_CURRENT_CMAKE_DIR}` for the directory containing its `CMakeLists.txt`
• In Kconfig: use \$\{SYSBUILD_CURRENT_MODULE_DIR\} for the module's top level directory

In Kconfig, the variable may be used to find additional files to include. For example, to include the file some/Kconfig:

```
source \"\$\{SYSBUILD_CURRENT_MODULE_DIR\}/some/Kconfig\"
```

The module can source additional CMake files using these variables. For example:

```
include(\$\{SYSBUILD_CURRENT_MODULE_DIR\}/cmake/code.cmake)
```

It is possible to append values to a Zephyr CMake list variable from the module's first CMakeLists.txt file. To do so, append the value to the list and then set the list in the PARENT_SCOPE of the CMakeLists.txt file. For example, to append bar to the FOO_LIST variable in the Zephyr CMakeLists.txt scope:

```
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

Sysbuild modules hooks  Sysbuild provides an infrastructure which allows a sysbuild module to define a function which will be invoked by sysbuild at a pre-defined point in the CMake flow.

Functions invoked by sysbuild:

• `<module-name>_pre_cmake(IMAGES <images>): This function is called for each sysbuild module before CMake configure is invoked for all images.

• `<module-name>_post_cmake(IMAGES <images>): This function is called for each sysbuild module after CMake configure has completed for all images.

• `<module-name>_pre_domains(IMAGES <images>): This function is called for each sysbuild module before domains yaml is created by sysbuild.

• `<module-name>_post_domains(IMAGES <images>): This function is called for each sysbuild module after domains yaml has been created by sysbuild.

arguments passed from sysbuild to the function defined by a module:

• `<images> is the list of Zephyr images that will be created by the build system.

If a module foo want to provide a post CMake configure function, then the module's sysbuild CMakeLists.txt file must define function foo_post_cmake() .

To facilitate naming of functions, the module name is provided by sysbuild CMake through the SYSBUILD_CURRENT_MODULE_NAME CMake variable when loading the module's sysbuild CMakeLists.txt file.

Example of how the foo sysbuild module can define foo_post_cmake():

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_post_cmake)
  cmake_parse_arguments(POST_CMAKE "" "" "" IMAGES" ${ARGN})
  message("Invoking ${CMAKE_CURRENT_FUNCTION}. Images: ${POST_CMAKE_IMAGES}"")
endfunction()
```

Zephyr module dependencies

A Zephyr module may be dependent on other Zephyr modules to be present in order to function correctly. Or it might be that a given Zephyr module must be processed after another Zephyr module, due to dependencies of certain CMake targets.

Such a dependency can be described using the depends field.
Here is an example for the Zephyr module foo that is dependent on the Zephyr module bar to be present in the build system:

```json
name: foo
build:
  depends:
    - bar
```

This example will ensure that bar is present when foo is included into the build system, and it will also ensure that bar is processed before foo.

**Module integration files (external)**

Module integration files can be located externally to the Zephyr module itself. The `MODULE_EXT_ROOT` variable holds a list of roots containing integration files located externally to Zephyr modules.

**Module integration files in Zephyr**  The Zephyr repository contains `CMakeLists.txt` and `Kconfig` build files for certain known Zephyr modules.

Those files are located under

```markdown
<ZEPHYR_BASE>
  modules
    <module_name>
      CMakeLists.txt
      Kconfig
```

**Module integration files in a custom location**  You can create a similar `MODULE_EXT_ROOT` for additional modules, and make those modules known to Zephyr build system.

Create a `MODULE_EXT_ROOT` with the following structure

```markdown
<MODULE_EXT_ROOT>
  modules
    modules.cmake
    <module_name>
      CMakeLists.txt
      Kconfig
```

and then build your application by specifying `-DMODULE_EXT_ROOT` parameter to the CMake build system. The `MODULE_EXT_ROOT` accepts a CMake list of roots as argument.

A Zephyr module can automatically be added to the `MODULE_EXT_ROOT` list using the module description file `zephyr/module.yml`, see **Build settings**.

**Note:**  `ZEPHYR_BASE` is always added as a `MODULE_EXT_ROOT` with the lowest priority. This allows you to overrule any integration files under `<ZEPHYR_BASE>/modules/<module_name>` with your own implementation of your own `MODULE_EXT_ROOT`.

The `modules.cmake` file must contain the logic that specifies the integration files for Zephyr modules via specifically named CMake variables.
To include a module's CMake file, set the variable `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` to the path containing the CMake file.

To include a module's Kconfig file, set the variable `ZEPHYR_<MODULE_NAME>_KCONFIG` to the path to the Kconfig file.

The following is an example on how to add support the the FOO module.

Create the following structure

```
<MODULE_EXT_ROOT>
  └── modules
      ├── modules.cmake
      │    └── CMakeLists.txt
      │    └── Kconfig
```

and inside the `modules.cmake` file, add the following content

```
set(ZEPHYR_FOO_CMAKE_DIR ${CMAKE_CURRENT_LIST_DIR}/foo)
set(ZEPHYR_FOO_KCONFIG ${CMAKE_CURRENT_LIST_DIR}/foo/Kconfig)
```

**Module integration files (zephyr/module.yml)** The module description file `zephyr/module.yml` can be used to specify that the build files, `CMakeLists.txt` and `Kconfig`, are located in a Module integration files (external).

Build files located in a `MODULE_EXT_ROOT` can be described as:

```
build:
  cmake-ext: True
  kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.

The Zephyr repository itself is always added as a Zephyr module ext root.

**Build settings**

It is possible to specify additional build settings that must be used when including the module into the build system.

All root settings are relative to the root of the module.

Build settings supported in the `module.yml` file are:

- `board_root`: Contains additional boards that are available to the build system. Additional boards must be located in a `<board_root>/boards` folder.
- `dts_root`: Contains additional dts files related to the architecture/soc families. Additional dts files must be located in a `<dts_root>/dts` folder.
- `snippet_root`: Contains additional snippets that are available for use. These snippets must be defined in `snippet.yml` files underneath the `<snippet_root>/snippets` folder. For example, if you have `snippet_root: foo`, then you should place your module's `snippet.yml` files in `<your-module>/foo/snippets` or any nested subdirectory.
- `soc_root`: Contains additional SoCs that are available to the build system. Additional SoCs must be located in a `<soc_root>/soc` folder.
- `arch_root`: Contains additional architectures that are available to the build system. Additional architectures must be located in a `<arch_root>/arch` folder.
• **module_ext_root**: Contains CMakeLists.txt and Kconfig files for Zephyr modules, see also *Module integration files (external)*.

• **sca_root**: Contains additional SCA tool implementations available to the build system. Each tool must be located in `<sca_root>/sca/<tool>` folder. The folder must contain a `sca.cmake`.

Example of a module.yaml file containing additional roots, and the corresponding file system layout.

```yaml
build:
  settings:
    board_root: .
    dts_root: .
    soc_root: .
    arch_root: .
    module_ext_root: .
```

requires the following folder structure:

```
<zephyr-module-root>
  ├── arch
  │   └── boards
  ├── dts
  └── modules
      └── soc
```

**Twister (Test Runner)**

To execute both tests and samples available in modules, the Zephyr test runner (twister) should be pointed to the directories containing those samples and tests. This can be done by specifying the path to both samples and tests in the `zephyr/module.yaml` file. Additionally, if a module defines out of tree boards, the module file can point twister to the path where those files are maintained in the module. For example:

```yaml
build:
  cmake: .
samples:
  - samples
tests:
  - tests
boards:
  - boards
```

**Binary Blobs**

Zephyr supports fetching and using *binary blobs*, and their metadata is contained entirely in `zephyr/module.yaml`. This is because a binary blob must always be associated with a Zephyr module, and thus the blob metadata belongs in the module's description itself.

Binary blobs are fetched using *west blobs*. If *west* is *not used*, they must be downloaded and verified manually.

The `blobs` section in `zephyr/module.yaml` consists of a sequence of maps, each of which has the following entries:

- **path**: The path to the binary blob, relative to the `zephyr/blobs/` folder in the module repository
- **sha256**: SHA-256 checksum of the binary blob file
- **type**: The *type of binary blob*. Currently limited to `img` or `lib`
Module Inclusion

Using West If west is installed and ZEPHYR_MODULES is not already set, the build system finds all the modules in your west installation and uses those. It does this by running west list to get the paths of all the projects in the installation, then filters the results to just those projects which have the necessary module metadata files.

Each project in the west list output is tested like this:

- If the project contains a file named zephyr/module.yml, then the content of that file will be used to determine which files should be added to the build, as described in the previous section.
- Otherwise (i.e. if the project has no zephyr/module.yml), the build system looks for zephyr/CMakeLists.txt and zephyr/Kconfig files in the project. If both are present, the project is considered a module, and those files will be added to the build.
- If neither of those checks succeed, the project is not considered a module, and is not added to ZEPHYR_MODULES.

Without West If you don’t have west installed or don’t want the build system to use it to find Zephyr modules, you can set ZEPHYR_MODULES yourself using one of the following options. Each of the directories in the list must contain either a zephyr/module.yml file or the files zephyr/CMakeLists.txt and Kconfig, as described in the previous section.

1. At the CMake command line, like this:
   
   ```
   cmake -DZEPHYR_MODULES=<path-to-module1>[:<path-to-module2>[:...]] ...
   ```

2. At the top of your application’s top level CMakeLists.txt, like this:
   
   ```
   set(ZEPHYR_MODULES <path-to-module1> <path-to-module2> [...] )
   find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
   ```
   
   If you choose this option, make sure to set the variable before calling find_package(Zephyr ...), as shown above.

3. In a separate CMake script which is pre-loaded to populate the CMake cache, like this:
   
   ```
   # Put this in a file with a name like "zephyr-modules.cmake"
   set(ZEPHYR_MODULES <path-to-module1> <path-to-module2> 
   CACHE STRING "pre-cached modules")
   ```
   
   You can tell the build system to use this file by adding -C zephyr-modules.cmake to your CMake command line.

Not using modules If you don’t have west installed and don’t specify ZEPHYR_MODULES yourself, then no additional modules are added to the build. You will still be able to build any applications that don’t require code or Kconfig options defined in an external repository.
2.10.10 Submitting changes to modules

When submitting new or making changes to existing modules the main repository Zephyr needs a reference to the changes to be able to verify the changes. In the main tree this is done using revisions. For code that is already merged and part of the tree we use the commit hash, a tag, or a branch name. For pull requests however, we require specifying the pull request number in the revision field to allow building the zephyr main tree with the changes submitted to the module.

To avoid merging changes to master with pull request information, the pull request should be marked as DNM (Do Not Merge) or preferably a draft pull request to make sure it is not merged by mistake and to allow for the module to be merged first and be assigned a permanent commit hash. Drafts reduce noise by not automatically notifying anyone until marked as “Ready for review”. Once the module is merged, the revision will need to be changed either by the submitter or by the maintainer to the commit hash of the module which reflects the changes.

Note that multiple and dependent changes to different modules can be submitted using exactly the same process. In this case you will change multiple entries of all modules that have a pull request against them.

Process for submitting a new module

Please follow the process in Submission and review process and obtain the TSC approval to integrate the external source code as a module.

If the request is approved, a new repository will created by the project team and initialized with basic information that would allow submitting code to the module project following the project contribution guidelines.

If a module is maintained as a fork of another project on Github, the Zephyr module related files and changes in relation to upstream need to be maintained in a special branch named zephyr.

Maintainers from the Zephyr project will create the repository and initialize it. You will be added as a collaborator in the new repository. Submit the module content (code) to the new repository following the guidelines described here, and then add a new entry to the west.yml with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add my_module to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the my_module repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

Process for submitting changes to existing modules

1. Submit the changes using a pull request to an existing repository following the contribution guidelines and expectations.

2. Submit a pull request changing the entry referencing the module into the west.yml of the main Zephyr tree with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```
For example, to add `my_module` to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the `my_module` repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

### 2.11 West (Zephyr’s meta-tool)

The Zephyr project includes a swiss-army knife command line tool named `west`. West is developed in its own repository.

West’s built-in commands provide a multiple repository management system with features inspired by Google’s Repo tool and Git submodules. West is also “pluggable”: you can write your own west extension commands which add additional features to west. Zephyr uses this to provide conveniences for building applications, flashing and debugging them, and more.

Like git and docker, the top-level `west` command takes some common options, a sub-command to run, and then options and arguments for that sub-command:

```
west [common-opts] <command> [opts] <args>
```

Since west v0.8, you can also run west like this:

```
python3 -m west [common-opts] <command> [opts] <args>
```

You can run `west --help` (or `west -h` for short) to get top-level help for available west commands, and `west <command> -h` for detailed help on each command.

The following pages document west’s v1.0.y releases, and provide additional context about the tool.

#### 2.11.1 Installing west

West is written in Python 3 and distributed through PyPI. Use `pip3` to install or upgrade west:

On Linux:

```
pip3 install --user -U west
```

On Windows and macOS:

```
pip3 install -U west
```

**Note:** See `Python and pip` for additional clarification on using the `--user` switch.

Afterwards, you can run `pip3 show -f west` for information on where the west binary and related files were installed.

Once west is installed, you can use it to `clone the Zephyr repositories`.

---

1 Zephyr is an English name for the Latin Zephyrus, the ancient Greek god of the west wind.
Structure

West's code is distributed via PyPI in a Python package named `west`. This distribution includes a launcher executable, which is also named `west` (or `west.exe` on Windows).

When `west` is installed, the launcher is placed by `pip3` somewhere in the user's filesystem (exactly where depends on the operating system, but should be on the `PATH` environment variable). This launcher is the command-line entry point to running both built-in commands like `west init`, `west update`, along with any extensions discovered in the workspace.

In addition to its command-line interface, you can also use `west`'s Python APIs directly. See `west-apis` for details.

Enabling shell completion

`West` currently supports shell completion in the following combinations of platform and shell:

- Linux: `bash`
- macOS: `bash`
- Windows: not available

In order to enable shell completion, you will need to obtain the corresponding completion script and have it sourced every time you enter a new shell session.

To obtain the completion script you can use the `west completion` command:

```bash
cd /path/to/zephyr/
west completion bash > ~/.west-completion.bash
```

**Note:** Remember to update your local copy of the completion script using `west completion` when you update Zephyr.

Next, you need to import `west-completion.bash` into your bash shell.

On Linux, you have the following options:

- Copy `west-completion.bash` to `/etc/bash_completion.d/`.
- Copy `west-completion.bash` to `/usr/share/bash-completion/completions/`.
- Copy `west-completion.bash` to a local folder and source it from your `~/.bashrc`.

On macOS, you have the following options:

- Copy `west-completion.bash` to a local folder and source it from your `~/.bash_profile`
- Install the `bash-completion` package with `brew`:

```
brew install bash-completion
```

then source the main bash completion script in your `~/.bash_profile`:

```
source /usr/local/etc/profile.d/bash_completion.sh
```

and finally copy `west-completion.bash` to `/usr/local/etc/bash_completion.d/`.

2.11.2 West Release Notes
v1.1.0

Major changes:

- west compare: new command that compares the state of the workspace against the manifest.
- Support for a new manifest.project-filter configuration option. See Built-in Configuration Options for details. The west manifest --freeze and west manifest --resolve commands currently cannot be used when this option is set. This restriction can be removed in a later release.
- Project names which contain comma (,) or whitespace now generate warnings. These warnings are errors if the new manifest.project-filter configuration option is set. The warnings may be promoted to errors in a future major version of west.

Other changes:

- west forall now takes a --group argument that can be used to restrict the command to only run in one or more groups. Run west help forall for details.
- All west commands will now output log messages from west API modules at warning level or higher. In addition, the --verbose argument to west can be used once to include informational messages, or twice to include debug messages, from all commands.

Bug fixes:

- Various improvements to error messages, debug logging, and error handling.

API changes:

- west.manifest.Manifest.is_active() now respects the manifest.project-filter configuration option's value.

v1.0.1

Major changes:

- Manifest schema version “1.0” is now available for use in this release. This is identical to the “0.13” schema version in terms of features, but can be used by applications that do not wish to use a “0.x” manifest “version:” field. See Version for details on this feature.

Bug fixes:

- West no longer exits with a successful error code when sent an interrupt signal. Instead, it exits with a platform-specific error code and signals to the calling environment that the process was interrupted.

v1.0.0

Major changes in this release:

- The west-apis are now declared stable. Any breaking changes will be communicated by a major version bump from v1.x.y to v2.x.y.
- West v1.0 no longer works with the Zephyr v1.14 LTS releases. This LTS has long been obsoleted by Zephyr v2.7 LTS. If you need to use Zephyr v1.14, you must use west v0.14 or earlier.
- Like the rest of Zephyr, west now requires Python v3.8 or later
- West commands no longer accept abbreviated command line arguments. For example, you must now specify west update --keep-descendants instead of using an abbreviation like west update --keep-d. This is part of a change applied to all of Zephyr's Python scripts' command-line interfaces. The abbreviations were causing problems in practice when commands were updated to add new options with similar names but different behavior to existing ones.

Other changes:
Zephyr Project Documentation, Release 3.5.0-rc1

- All built-in west functions have stopped using `west.log`
- `west update` now has a new `--submodule-init-config` option. See commit `9ba92b05` for details.

**Bug fixes:**
- West extension commands that failed to load properly sometimes dumped stack. This has been fixed, and west now prints a sensible error message in this case.
- `west config` now fails on malformed configuration option arguments which lack a `.` in the option name.

**API changes:**
- The `west` package now contains the metadata files necessary for some static analyzers (such as `mypy`) to auto-detect its type annotations. See commit `d9f00e24` for details.
- The deprecated `west.build` module used for Zephyr v1.14 LTS compatibility was removed.
- The deprecated `west.cmake` module used for Zephyr v1.14 LTS compatibility was removed.
- The `west.log` module is now deprecated. This module uses global state, which can make it awkward to use it as an API which multiple different python modules may rely on.
- The `west.apis-commands` module got some new APIs which lay groundwork for a future change to add a global verbosity control to a command's output, and work to remove global state from the `west` package's API:
  - New `west.commands.WestCommand.__init__()` keyword argument: `verbosity`
  - New `west.commands.WestCommand` property: `color_ui`
  - New `west.commands.WestCommand` methods, which should be used to print output from extension commands instead of writing directly to `sys.stdout` or `sys.stderr`: `inf()`, `wrn()`, `err()`, `die()`, `banner()`, `small_banner()`
  - New `west.commands.VERBOSITY` enum

**v0.14.0**

**Bug fixes:**
- West commands that were run with a bad local configuration file dumped stack in a confusing way. This has been fixed, and west now prints a sensible error message in this case.
- A bug in the way west looks for the zephyr repository was fixed. The bug itself usually appeared when running an extension command like `west build` in a new workspace for the first time; this used to fail (just for the first time, not on subsequent command invocations) unless you ran the command in the workspace's top level directory.
- West now prints sensible error messages when the user lacks permission to open the manifest file instead of dumping stack traces.

**API changes:**
- The `west.manifest.MalformedConfig` exception type has been moved to the `west.configuration` module.
- The `west.manifest.MalformedConfig` exception type has been moved to the `west.configuration` module.
- The `west.configuration.Configuration` class now raises `MalformedConfig` instead of `RuntimeError` in some cases.
v0.13.1

Bug fix:

- When calling `west.manifest.Manifest.from_file()` when outside of a workspace, west again falls back on the `ZEPHYR_BASE` environment variable to locate the workspace.

v0.13.0

New features:

- You can now associate arbitrary user data with the manifest repository itself in the `manifest:
  self: userdata: value, like so:

```yaml
manifest:
  self: userdata: <any YAML value can go here>
```

Bug fixes:

- The path to the manifest repository reported by west could be incorrect in certain circumstances detailed in [issue #572](https://github.com/zephyrproject-rtos/west/issues/572). This has been fixed as part of a larger overhaul of path handling support in the `west.manifest` API module.

- The `west.Manifest.ManifestProject._repr_.` return value was fixed

API changes:

- `west.configuration.Configuration`: new object-oriented interface to the current configuration. This reflects the system, global, and workspace-local configuration values, and allows you to read, write, and delete configuration options from any or all of these locations.

- `west.commands.WestCommand`:
  - `config`: new attribute, returns a `Configuration` object or aborts the program if none is set. This is always usable from within extension command `do_run()` implementations.
  - `has_config`: new boolean attribute, which is `True` if and only if reading `self.config` will abort the program.

- The path handling in the `west.manifest` package has been overhauled in a backwards-incompatible way. For more details, see commit [56cfe8d1d1f](https://github.com/zephyrproject-rtos/west/commit/56cfe8d1d1f3c9b45de3e793c738acd62db52aca).

- `west.manifest.Manifest.validate()`: this now returns the validated data as a Python dict. This can be useful if the value passed to this function was a str, and the dict is desired.

- `west.manifest.Manifest`: new:
  - `path` attributes `abspath`, `posixpath`, `relative_path`, `yaml_path`, `repo_path`, `repo_posixpath`
  - `userdata` attribute, which contains the parsed value from `manifest: self: userdata:`, or is `None`
  - `from_topdir()` factory method

- `west.manifest.ManifestProject`: new `userdata` attribute, which also contains the parsed value from `manifest: self: userdata:`, or is `None`

- `west.manifest.ManifestImportFailed`: the constructor can now take any value; this can be used to reflect failed imports from a `map` or other compound value.

- Deprecated configuration APIs:
The following APIs are now deprecated in favor of using a Configuration object. Usually this will be done via `self.config` from a WestCommand instance, but this can be done directly by instantiating a Configuration object for other usages.

- `west.configuration.config`
- `west.configuration.read_config`
- `west.configuration.update_config`
- `west.configuration.delete_config`

v0.12.0

New features:
- West now works on the MSYS2 platform.
- West manifest files can now contain arbitrary user data associated with each project. See Repository user data for details.

Bug fixes:
- The `west list` command's `{sha}` format key has been fixed for the manifest repository; it now prints `N/A` ("not applicable") as expected.

API changes:
- The `west.manifest.Project.userdata` attribute was added to support project user data.

v0.11.1

New features:
- `west status` now only prints output for projects which have a nonempty status.

Bug fixes:
- The manifest file parser was incorrectly allowing project names which contain the path separator characters `/` and `\`. These invalid characters are now rejected.

  Note: if you need to place a project within a subdirectory of the workspace topdir, use the `path:` key. If you need to customize a project's fetch URL relative to its remote `url-base:`, use `repo-path:`. See Projects for examples.

- The changes made in west v0.10.1 to the `west init --manifest-rev` option which selected the default branch name were leaving the manifest repository in a detached HEAD state. This has been fixed by using `git clone` internally instead of `git init` and `git fetch`. See issue #522 for details.

- The `WEST_CONFIG_LOCAL` environment variable now correctly overrides the default location, `<workspace topdir>/.west/config`.

- `west update --fetch=smart` (smart is the default) now correctly skips fetches for project revisions which are lightweight tags (it already worked correctly for annotated tags; only lightweight tags were unnecessarily fetched).

Other changes:
- The fix for issue #522 mentioned above introduces a new restriction. The `west init --manifest-rev` option value, if given, must now be either a branch or a tag. In particular, “pseudo-branches” like GitHub’s `pull/1234/head` references which could previously be used to fetch a pull request can no longer be passed to --manifest-rev. Users must now fetch and check out such revisions manually after running `west init`.

API changes:
• `west.manifest.Manifest.get_projects()` avoids incorrect results in some edge cases described in issue #523.

• `west.manifest.Project.sha()` now works correctly for tag revisions. (This applies to both lightweight and annotated tags.)

v0.11.0

New features:

• `west update` now supports `--narrow`, `--name-cache`, and `--path-cache` options. These can be influenced by the `update.narrow`, `update.name-cache`, and `update.path-cache` Configuration options. These can be used to optimize the speed of the update.

• `west update` now supports a `--fetch-opt` option that will be passed to the `git fetch` command used to fetch remote revisions when updating each project.

Bug fixes:

• `west update` now synchronizes Git submodules in projects by default. This avoids issues if the URL changes in the manifest file from when the submodule was first initialized. This behavior can be disabled by setting the `update.sync-submodules` configuration option to `false`.

Other changes:

• the `west-apis-manifest` module has fixed docstrings for the `Project` class

v0.10.1

New features:

• The `west init` command's `--manifest-rev` (`--mr`) option no longer defaults to `master`. Instead, the command will query the repository for its default branch name and use that instead. This allows users to move from `master` to `main` without breaking scripts that do not provide this option.

v0.10.0

New features:

• The `name` key in a project's `submodules list` is now optional.

Bug fixes:

• West now checks that the manifest schema version is one of the explicitly allowed values documented in `Version`. The old behavior was just to check that the schema version was newer than the west version where the `manifest: version:` key was introduced. This incorrectly allowed invalid schema versions, like 0.8.2.

Other changes:

• A manifest file's `group-filter` is now propagated through an import. This is a change from how west v0.9.x handled this. In west v0.9.x, only the top level manifest file's `group-filter` had any effect; the group filter lists from any imported manifests were ignored.

Starting with west v0.10.0, the group filter lists from imported manifests are also imported. For details, see `Group Filters and Imports`.

The new behavior will take effect if `manifest: version:` is not given or is at least 0.10. The old behavior is still available in the top level manifest file only with an explicit `manifest: version: 0.9`. See `Version` for more information on schema versions.

See `west pull request #482` for the motivation for this change and additional context.

2.11. West (Zephyr's meta-tool)
v0.9.1

Bug fixes:

- Commands like `west manifest --resolve` now correctly include group and group filter information.

Other changes:

- West now warns if you combine `import` with `group-filter`. Semantics for this combination have changed starting with v0.10.x. See the v0.10.0 release notes above for more information.

v0.9.0

**Warning:** The `west config` fix described below comes at a cost: any comments or other manual edits in configuration files will be removed when setting a configuration option via that command or the `west.configuration` API.

**Warning:** Combining the `group-filter` feature introduced in this release with manifest imports is discouraged. The resulting behavior has changed in west v0.10.

New features:

- West manifests now support *Git Submodules in Projects*. This allows you to clone *Git submodules* into a west project repository in addition to the project repository itself.
- West manifests now support *Project Groups*. Project groups can be enabled and disabled to determine what projects are “active”, and therefore will be acted upon by the following commands: `west update`, `west list`, `west diff`, `west status`, `west forall`.
- `west update` no longer updates inactive projects by default. It now supports a `--group-filter` option which allows for one-time modifications to the set of enabled and disabled project groups.
- Running `west list`, `west diff`, `west status`, or `west forall` with no arguments does not print information for inactive projects by default. If the user specifies a list of projects explicitly at the command line, output for them is included regardless of whether they are active. These commands also now support `--all` arguments to include all projects, even inactive ones.
- `west list` now supports a `{groups}` format string key in its `--format` argument.

Bug fixes:

- The `west config` command and `west.configuration` API did not correctly store some configuration values, such as strings which contain commas. This has been fixed; see commit 36f3f91e for details.
- A manifest file with an empty `manifest: self: path: value` is invalid, but west used to let it pass silently. West now rejects such manifests.
- A bug affecting the behavior of the `west init -l` command was fixed; see issue #435.

API changes:

- added `west.manifest.Manifest.is_active()`
- added `west.manifest.Manifest.group_filter`
- added `submodules` attribute to `west.manifest.Project`, which has newly added type `west.manifest.Submodule`

Other changes:
• The Manifest Imports feature now supports the terms allowlist and blocklist instead of whitelist and blacklist, respectively.

The old terms are still supported for compatibility, but the documentation has been updated to use the new ones exclusively.

v0.8.0

This is a feature release which changes the manifest schema by adding support for a path-prefix: key in an import: mapping, along with some other features and fixes.

• Manifest import mappings now support a path-prefix: key, which places the project and its imported repositories in a subdirectory of the workspace. See Example 3.4: Import into a subdirectory for an example.

• The west command line application can now also be run using python3 -m west. This makes it easier to run west under a particular Python interpreter without modifying the PATH environment variable.

• west manifest --path prints the absolute path to west.yml

• west init now supports an --mf foo.yml option, which initializes the workspace using foo.yml instead of west.yml.

• west list now prints the manifest repository's path using the manifest.path configuration option, which may differ from the self: path value in the manifest data. The old behavior is still available, but requires passing a new --manifest-path-from-yaml option.

• Various Python API changes; see west-apis for details.

v0.7.3

This is a bugfix release.

• Fix an error where a failed import could leave the workspace in an unusable state (see [PR #415](https://github.com/zephyrproject-rtos/west/pull/415) for details)

v0.7.2

This is a bugfix and minor feature release.

• Filter out duplicate extension commands brought in by manifest imports

• Fix west.Manifest.get_projects() when finding the manifest repository by path

v0.7.1

This is a bugfix and minor feature release.

• west update --stats now prints timing for operations which invoke a subprocess, time spent in west's Python process for each project, and total time updating each project.

• west todir always prints a POSIX style path

• minor console output changes
v0.7.0

The main user-visible feature in west 0.7 is the Manifest Imports feature. This allows users to load west manifest data from multiple different files, resolving the results into a single logical manifest.

Additional user-visible changes:

- The idea of a “west installation” has been renamed to “west workspace” in this documentation and in the west API documentation. The new term seems to be easier for most people to work with than the old one.
- West manifests now support a schema version.
- The “west config” command can now be run outside of a workspace, e.g. to run west config --global section.key value to set a configuration option's value globally.
- There is a new west todir command, which prints the root directory of the current west workspace.
- The west -vv init command now prints the git operations being performed, and their results.
- The restriction that no project can be named “manifest” is now enforced; the name “manifest” is reserved for the manifest repository, and is usable as such in commands like west list manifest, instead of west list path-to-manifest-repository being the only way to say that
- It’s no longer an error if there is no project named “zephyr”. This is part of an effort to make west generally usable for non-Zephyr use cases.
- Various bug fixes.

The developer-visible changes to the west-apis are:

- west.build and west.cmake: deprecated; this is Zephyr-specific functionality and should never have been part of west. Since Zephyr v1.14 LTS relies on it, it will continue to be included in the distribution, but will be removed when that version of Zephyr is obsoleted.
- west.commands:
  - WestCommand.requires_installation: deprecated; use requires_workspace instead
  - WestCommand.requires_workspace: new
  - WestCommand.has_manifest: new
  - WestCommand.manifest: this is now settable
- west.configuration: callers can now identify the workspace directory when reading and writing configuration files
- west.log:
  - msg(): new
- west.manifest:
  - The module now uses the standard logging module instead of west.log
  - QUAL_REFS_WEST: new
  - SCHEMA_VERSION: new
  - Defaults: removed
  - Manifest.as_dict(): new
  - Manifest.as_frozen_yaml(): new
  - Manifest.as_yaml(): new
  - Manifest.from_file() and from_data(): these factory methods are more flexible to use and less reliant on global state
  - Manifest.validate(): new
- ManifestImportFailed: new
- ManifestProject: semi-deprecated and will likely be removed later.
- Project: the constructor now takes a topdir argument
- Project.format() and its callers are removed. Use f-strings instead.
- Project.name_and_path: new
- Project.remote_name: new
- Project.sha() now captures stderr
- Remote: removed

West now requires Python 3.6 or later. Additionally, some features may rely on Python dictionaries being insertion-ordered; this is only an implementation detail in CPython 3.6, but is part of the language specification as of Python 3.7.

v0.6.3

This point release fixes an error in the behavior of the deprecated west.cmake module.

v0.6.2

This point release fixes an error in the behavior of west update --fetch=smart, introduced in v0.6.1. All v0.6.1 users must upgrade.

v0.6.1

**Warning:** Do not use this point release. Make sure to use v0.6.2 instead.

The user-visible features in this point release are:

- The `west update` command has a new `--fetch` command line flag and `update.fetch` configuration option. The default value, "smart", skips fetching SHAs and tags which are available locally.
- Better and more consistent error-handling in the `west diff`, `west status`, `west forall`, and `west update` commands. Each of these commands can operate on multiple projects; if a subprocess related to one project fails, these commands now continue to operate on the rest of the projects. All of them also now report a nonzero error code from the west process if any of these subprocesses fails (this was previously not true of `west forall` in particular).
- The `west manifest` command also handles errors better.
- The `west list` command now works even when the projects are not cloned, as long as its format string only requires information which can be read from the manifest file. It still fails if the format string requires data stored in the project repository, e.g. if it includes the `{sha}` format string key.
- Commands and options which operate on git revisions now accept abbreviated SHAs. For example, `west init --mr SHA_PREFIX` now works. Previously, the --mr argument needed to be the entire 40 character SHA if it wasn't a branch or a tag.

The developer-visible changes to the west-apis are:

- `west.log.banner()`: new
- `west.log.small_banner()`: new
- `west.manifest.Manifest.get_projects()`: new
• west.manifest.Project.is_cloned(): new
• west.commands.WestCommand instances can now access the parsed Manifest object via a new self.manifest property during the do_run() call. If read, it returns the Manifest object or aborts the command if it could not be parsed.
• west.manifest.Project.git() now has a capture_stderr kwarg

v0.6.0

• No separate bootstrapper

In west v0.5.x, the program was split into two components, a bootstrapper and a per-installation clone. See Multiple Repository Management in the v1.14 documentation for more details.

This is similar to how Google's Repo tool works, and lets west iterate quickly at first. It caused confusion, however, and west is now stable enough to be distributed entirely as one piece via PyPI.

From v0.6.x onwards, all of the core west commands and helper classes are part of the west package distributed via PyPI. This eliminates complexity and makes it possible to import west modules from anywhere in the system, not just extension commands.

• The selfupdate command still exists for backwards compatibility, but now simply exits after printing an error message.

• Manifest syntax changes

  – A west manifest file's projects elements can now specify their fetch URLs directly, like so:

    ```yaml
    manifest:
      projects:
        - name: example-project-name
          url: https://github.com/example/example-project
    ```

    Project elements with url attributes set in this way may not also have remote attributes.

  – Project names must be unique: this restriction is needed to support future work, but was not possible in west v0.5.x because distinct projects may have URLs with the same final pathname component, like so:

    ```yaml
    manifest:
      remotes:
        - name: remote-1
          url-base: https://github.com/remote-1
        - name: remote-2
          url-base: https://github.com/remote-2
      projects:
        - name: project
          remote: remote-1
          path: remote-1-project
        - name: project
          remote: remote-2
          path: remote-2-project
    ```

    These manifests can now be written with projects that use url instead of remote, like so:

    ```yaml
    manifest:
      projects:
        - name: remote-1-project
          url: https://github.com/remote-1/project
        - name: remote-2-project
          url: https://github.com/remote-2/project
    ```
• The `west list` command now supports a `{sha}` format string key
• The default format string for `west list` was changed to `"{name:12} {path:28} {revision:40} {url}"`.
• The command `west manifest --validate` can now be run to load and validate the current manifest file, among other error-handling fixes related to manifest parsing.
• Incompatible API changes were made to west’s APIs. Further changes are expected until API stability is declared in west v1.0.
  – The `west.manifest.Project` constructor’s `remote` and `defaults` positional arguments are now kwargs. A new `url` kwarg was also added; if given, the `Project` URL is set to that value, and the `remote` kwarg is ignored.
  – `west.manifest.MANIFEST_SECTIONS` was removed. There is only one section now, namely `manifest`. The `sections` kwarg in the `west.manifest.Manifest` factory methods and constructor were also removed.
  – The `west.manifest.SpecialProject` class was removed. Use `west.manifest.ManifestProject` instead.

v0.5.x

West v0.5.x is the first version used widely by the Zephyr Project as part of its v1.14 Long-Term Support (LTS) release. The `west v0.5.x` documentation is available as part of the Zephyr’s v1.14 documentation.

West’s main features in v0.5.x are:
• Multiple repository management using Git repositories, including self-update of west itself
• Hierarchical configuration files
• Extension commands

Versions Before v0.5.x

Tags in the west repository before v0.5.x are prototypes which are of historical interest only.

2.11.3 Troubleshooting West

This page covers common issues with west and how to solve them.

`west update` fetching failures

One good way to troubleshoot fetching issues is to run `west update` in verbose mode, like this:

```
west -v update
```

The output includes Git commands run by west and their outputs. Look for something like this:

```
=== updating your_project (path/to/your/project):
west.manifest: your_project: checking if cloned
[...other west.manifest logs...]
--- your_project: fetching, need revision SOME_SHA
west.manifest: running 'git fetch ... https://github.com/your-username/your_project ..
--.' in /some/directory
```
The `git fetch` command example in the last line above is what needs to succeed.

One strategy is to go to `/path/to/your/project`, copy/paste and run the entire `git fetch` command, then debug from there using the documentation for your credential storage helper.

If you're behind a corporate firewall and may have proxy or other issues, `curl -v FETCH_URL` (for HTTPS URLs) or `ssh -v FETCH_URL` (for SSH URLs) may be helpful.

If you can get the `git fetch` command to run successfully without prompting for a password when you run it directly, you will be able to run `west update` without entering your password in that same shell.

"'west' is not recognized as an internal or external command, operable program or batch file."

On Windows, this means that either west is not installed, or your `PATH` environment variable does not contain the directory where `pip` installed `west.exe`.

First, make sure you've installed west; see `Installing west`. Then try running `west` from a new `cmd.exe` window. If that still doesn't work, keep reading.

You need to find the directory containing `west.exe`, then add it to your `PATH`. (This `PATH` change should have been done for you when you installed Python and `pip`, so ordinarily you should not need to follow these steps.)

Run this command in `cmd.exe`:

```
pip3 show west
```

Then:

1. Look for a line in the output that looks like `Location: C:\foo\python\python38\lib\site-packages`. The exact location will be different on your computer.

2. Look for a file named `west.exe` in the `scripts` directory `C:\foo\python\python38\scripts`.

**Important:** Notice how `lib\site-packages` in the `pip3 show` output was changed to `scripts`!

3. If you see `west.exe` in the `scripts` directory, add the full path to `scripts` to your `PATH` using a command like this:

   ```
   setx PATH "%PATH%;C:\foo\python\python38\scripts"
   ```

   **Do not just copy/paste this command.** The `scripts` directory location will be different on your system.

4. Close your `cmd.exe` window and open a new one. You should be able to run `west`.

"Error: unexpected keyword argument 'requires_workspace'"

This error occurs on some Linux distributions after upgrading to west 0.7.0 or later from 0.6.x. For example:

```
$ west update
[... stack trace ...]
TypeError: __init__() got an unexpected keyword argument 'requires_workspace'
```

This appears to be a problem with the distribution's `pip`; see this comment in west issue 373 for details. Some versions of Ubuntu and Linux Mint are known to have this problem. Some users report issues on Fedora as well.

Neither macOS nor Windows users have reported this issue. There have been no reports of this issue on other Linux distributions, like Arch Linux, either.
**Workaround 1**: remove the old version, then upgrade:

```
$ pip3 show west | grep Location: | cut -f 2 -d ' ' 
/home/foo/.local/lib/python3.6/site-packages 
$ rm -r /home/foo/.local/lib/python3.6/site-packages/west 
$ pip3 install --user west==0.7.0
```

**Workaround 2**: install west in a Python virtual environment

One option is to use the **venv module** that's part of the Python 3 standard library. Some distributions remove this module from their base Python 3 packages, so you may need to do some additional work to get it installed on your system.

**“invalid choice: ‘build’” (or ‘flash’, etc.)**

If you see an unexpected error like this when trying to run a Zephyr extension command (like `west flash`, `west build`, etc.):

```
$ west build [...] 
west: error: argument <command>: invalid choice: 'build' (choose from 'init', [...])
```

```
$ west flash [...] 
west: error: argument <command>: invalid choice: 'flash' (choose from 'init', [...])
```

The most likely cause is that you’re running the command outside of a **west workspace**. West needs to know where your workspace is to find Extensions.

To fix this, you have two choices:

1. Run the command from inside a workspace (e.g. the `zephyrproject` directory you created when you **got started**).
   
   For example, create your build directory inside the workspace, or run `west flash --build-dir YOUR_BUILD_DIR` from inside the workspace.

2. Set the `ZEPHYR_BASE` environment variable and re-run the west extension command. If set, west will use `ZEPHYR_BASE` to find your workspace.

If you're unsure whether a command is built-in or an extension, run `west help` from inside your workspace. The output prints extension commands separately, and looks like this for mainline Zephyr:

```
$ west help

built-in commands for managing git repositories:
   init: create a west workspace
   [...]

other built-in commands:
   help: get help for west or a command
   [...]

extension commands from project manifest (path: zephyr):
   build: compile a Zephyr application
   flash: flash and run a binary on a board
   [...]
```

**“invalid choice: ‘post-init’”**

If you see this error when running `west init`:

```
$ west help
```

```
...extension commands from project manifest (path: zephyr):
   post-init: (choose from 'deb', 'rpm', 'post-build', 'post-flash', 'post-clean', 'post-update', 'post-maint', 'post-device')
   [...]
```

2.11. West (Zephyr's meta-tool)
Then you have an old version of west installed, and are trying to use it in a workspace that requires a more recent version.

The easiest way to resolve this issue is to upgrade west and retry as follows:

1. Install the latest west with the `-U` option for `pip3 install` as shown in *Installing west*.
2. Back up any contents of `zephyrproject/.west/config` that you want to save. (If you don’t have any configuration options set, it’s safe to skip this step.)
3. Completely remove the `zephyrproject/.west` directory (if you don’t, you will get the “already in a workspace” error message discussed next).
4. Run `west init` again.

“already in an installation”

You may see this error when running `west init` with west 0.6:

```
FATAL ERROR: already in an installation (<some directory>), aborting
```

If this is unexpected and you’re really trying to create a new west workspace, then it’s likely that west is using the `ZEPHYR_BASE` environment variable to locate a workspace elsewhere on your system.

This is intentional; it allows you to put your Zephyr applications in any directory and still use west to build, flash, and debug them, for example.

To resolve this issue, unset `ZEPHYR_BASE` and try again.

### 2.11.4 Basics

This page introduces west’s basic concepts and provides references to further reading.

West’s built-in commands allow you to work with projects (Git repositories) under a common workspace directory.

#### Example workspace

If you’ve followed the upstream Zephyr getting started guide, your workspace looks like this:

```
zephyrproject/  # west topdir
   .west/       # marks the location of the topdir
     config    # per-workspace local configuration file

# The manifest repository, never modified by west after creation:
zephyr/        # .git/ repo
   west.yml    # manifest file
     [. . . other files . . .]

# Projects managed by west:
modules/       # .git/ project
   lib/        # .git/ project
     zcbor/     # .git/ project
   net-tools/  # .git/ project
     [. . . other projects . . .]
```
Workspace concepts

Here are the basic concepts you should understand about this structure. Additional details are in Workspaces.

topdir

Above, zephyrproject is the name of the workspace's top level directory, or topdir. (The name zephyrproject is just an example – it could be anything, like z, my-zephyr-workspace, etc.)

You'll typically create the topdir and a few other files and directories using west init.

.west directory

The topdir contains the .west directory. When west needs to find the topdir, it searches for .west, and uses its parent directory. The search starts from the current working directory (and starts again from the location in the ZEPHYR_BASE environment variable as a fallback if that fails).

configuration file

The file .west/config is the workspace's local configuration file.

manifest repository

Every west workspace contains exactly one manifest repository, which is a Git repository containing a manifest file. The location of the manifest repository is given by the manifest.path configuration option in the local configuration file.

For upstream Zephyr, zephyr is the manifest repository, but you can configure west to use any Git repository in the workspace as the manifest repository. The only requirement is that it contains a valid manifest file. See Topologies supported for information on other options, and West Manifests for details on the manifest file format.

manifest file

The manifest file is a YAML file that defines projects, which are the additional Git repositories in the workspace managed by west. The manifest file is named west.yml by default; this can be overridden using the manifest.file local configuration option.

You use the west update command to update the workspace's projects based on the contents of the manifest file.

projects

Projects are Git repositories managed by west. Projects are defined in the manifest file and can be located anywhere inside the workspace. In the above example workspace, zcbor and net-tools are projects.

By default, the Zephyr build system uses west to get the locations of all the projects in the workspace, so any code they contain can be used as Modules (External projects). Note however that modules and projects are conceptually different.

extensions

Any repository known to west (either the manifest repository or any project repository) can define Extensions. Extensions are extra west commands you can run when using that workspace.

The zephyr repository uses this feature to provide Zephyr-specific commands like west build. Defining these as extensions keeps west's core agnostic to the specifics of any workspace's Zephyr version, etc.

ignored files

A workspace can contain additional Git repositories or other files and directories not managed by west. West basically ignores anything in the workspace except .west, the manifest repository, and the projects specified in the manifest file.

west init and west update

The two most important workspace-related commands are west init and west update.

**west init basics**  
This command creates a west workspace.

**Important**: West doesn’t change your manifest repository contents after `west init` is run. Use ordinary Git commands to pull new versions, etc.

You will typically run it once, like this:

```shell
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v2.5.0 zephyrproject
```

This will:

1. Create the topdir, `zephyrproject`, along with `.west` and `.west/config` inside it
2. Clone the manifest repository from `https://github.com/zephyrproject-rtos/zephyr`, placing it into `zephyrproject/zephyr`
3. Check out the `v2.5.0` git tag in your local `zephyr` clone
4. Set `manifest.path` to `zephyr` in `.west/config`
5. Set `manifest.file` to `west.yml`

Your workspace is now almost ready to use; you just need to run `west update` to clone the rest of the projects into the workspace to finish.

For more details, see `west init`.

**west update basics**  
This command makes sure your workspace contains Git repositories matching the projects in the manifest file.

**Important**: Whenever you check out a different revision in your manifest repository, you should run `west update` to make sure your workspace contains the project repositories the new revision expects.

The `west update` command reads the manifest file’s contents by:

1. Finding the topdir. In the `west init` example above, that means finding `zephyrproject`.
2. Loading `.west/config` in the topdir to read the `manifest.path` (e.g. `zephyr`) and `manifest.file` (e.g. `west.yml`) options.
3. Loading the manifest file given by these options (e.g. `zephyrproject/zephyr/west.yml`).

It then uses the manifest file to decide where missing projects should be placed within the workspace, what URLs to clone them from, and what Git revisions should be checked out locally. Project repositories which already exist are updated in place by fetching and checking out their respective Git revisions in the manifest file.

For more details, see `west update`.

**Other built-in commands**

See [Built-in commands](#).

**Zephyr Extensions**

See the following pages for information on Zephyr’s extension commands:

- *Building, Flashing and Debugging*
- *Signing Binaries*
2.11.5 Built-in commands

This page describes west's built-in commands, some of which were introduced in Basics, in more detail. Some commands are related to Git commands with the same name, but operate on the entire workspace. For example, west diff shows local changes in multiple Git repositories in the workspace.

Some commands take projects as arguments. These arguments can be project names as specified in the manifest file, or (as a fallback) paths to them on the local file system. Omitting project arguments to commands which accept them (such as west list, west forall, etc.) usually defaults to using all projects in the manifest file plus the manifest repository itself.

For additional help, run west <command> -h (e.g. west init -h).

west init

This command creates a west workspace. It can be used in two ways:

1. Cloning a new manifest repository from a remote URL
2. Creating a workspace around an existing local manifest repository

Option 1: to clone a new manifest repository from a remote URL, use:

```
west init [-m URL] [--mr REVISION] [--mf FILE] [directory]
```

The new workspace is created in the given directory, creating a new .west inside this directory. You can give the manifest URL using the -m switch, the initial revision to check out using --mr, and the location of the manifest file within the repository using --mf.

For example, running:

```
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v1.14.0 zp
```

would clone the upstream official zephyr repository into zp/zephyr, and check out the v1.14.0 release. This command creates zp/.west, and set the manifest.path configuration option to zephyr to record the location of the manifest repository in the workspace. The default manifest file location is used.

The -m option defaults to https://github.com/zephyrproject-rtos/zephyr. The --mf option defaults to west.yml. Since west v0.10.1, west will use the default branch in the manifest repository unless the --mr option is used to override it. (In prior versions, --mr defaulted to master.)

If no directory is given, the current working directory is used.

Option 2: to create a workspace around an existing local manifest repository, use:

```
west init -l [--mf FILE] directory
```

This creates .west next to directory in the file system, and sets manifest.path to directory.

As above, --mf defaults to west.yml.

Reconfiguring the workspace:
If you change your mind later, you are free to change manifest.path and manifest.file using west config after running west init. Just be sure to run west update afterwards to update your workspace to match the new manifest file.

west update

west update [-f {always,smart}] [-k] [-r] 
[--group-filter FILTER] [--stats] [PROJECT ...]

Which projects are updated:
By default, this command parses the manifest file, usually west.yml, and updates each project specified there. If your manifest uses project groups, then only the active projects are updated.

To operate on a subset of projects only, give PROJECT argument(s). Each PROJECT is either a project name as given in the manifest file, or a path that points to the project within the workspace. If you specify projects explicitly, they are updated regardless of whether they are active.

Project update procedure:
For each project that is updated, this command:
1. Initializes a local Git repository for the project in the workspace, if it does not already exist
2. Inspects the project's revision field in the manifest, and fetches it from the remote if it is not already available locally
3. Sets the project's manifest-rev branch to the commit specified by the revision in the previous step
4. Checks out manifest-rev in the local working copy as a detached HEAD
5. If the manifest file specifies a submodules key for the project, recursively updates the project's submodules as described below.

To avoid unnecessary fetches, west update will not fetch project revision values which are Git SHAs or tags that are already available locally. This is the behavior when the -f (--fetch) option has its default value, smart. To force this command to fetch from project remotes even if the revisions appear to be available locally, either use -f always or set the update.fetch configuration option to always. SHAs may be given as unique prefixes as long as they are acceptable to Git¹.

If the project revision is a Git ref that is neither a tag nor a SHA (i.e. if the project is tracking a branch), west update always fetches, regardless of -f and update.fetch.

Some branch names might look like short SHAs, like deadbeef. West treats these like SHAs. You can disambiguate by prefixing the revision value with refs/heads/, e.g. revision: refs/heads/deadbeef.

For safety, west update uses git checkout --detach to check out a detached HEAD at the manifest revision for each updated project, leaving behind any branches which were already checked out. This is typically a safe operation that will not modify any of your local branches.

However, if you had added some local commits onto a previously detached HEAD checked out by west, then git will warn you that you've left behind some commits which are no longer referred to by any branch. These may be garbage-collected and lost at some point in the future. To avoid this if you have local commits in the project, make sure you have a local branch checked out before running west update.

If you would rather rebase any locally checked out branches instead, use the -r (--rebase) option.

If you would like west update to keep local branches checked out as long as they point to commits that are descendants of the new manifest-rev, use the -k (--keep-descendants) option.

¹ West may fetch all refs from the Git server when given a SHA as a revision. This is because some Git servers have historically not allowed fetching SHAs directly.
Note: west update --rebase will fail in projects that have git conflicts between your branch and new commits brought in by the manifest. You should immediately resolve these conflicts as you usually do with git, or you can use git -C <project_path> rebase --abort to ignore incoming changes for the moment.

With a clean working tree, a plain west update never fails because it does not try to hold on to your commits and simply leaves them aside.

west update --keep-descendants offers an intermediate option that never fails either but does not treat all projects the same:

- in projects where your branch diverged from the incoming commits, it does not even try to rebase and leaves your branches behind just like a plain west update does;
- in all other projects where no rebase or merge is needed it keeps your branches in place.

One-time project group manipulation:

The --group-filter option can be used to change which project groups are enabled or disabled for the duration of a single west update command. See Project Groups for details on the project group feature.

The west update command behaves as if the --group-filter option's value were appended to the manifest.group-filter configuration option.

For example, running west update --group-filter=+foo,-bar would behave the same way as if you had temporarily appended the string "+foo,-bar" to the value of manifest.group-filter, run west update, then restored manifest.group-filter to its original value.

Note that using the syntax --group-filter=VALUE instead of --group-filter VALUE avoids issues parsing command line options if you just want to disable a single group, e.g. --group-filter=-bar.

Submodule update procedure:

If a project in the manifest has a submodules key, the submodules are updated as follows, depending on the value of the submodules key.

If the project has submodules: true, west first synchronizes the project's submodules with:

```
git submodule sync --recursive
```

West then runs one of the following in the project repository, depending on whether you run west update with the --rebase option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive
```

Otherwise, the project has submodules: <list-of-submodules>. In this case, west synchronizes the project's submodules with:

```
git submodule sync --recursive -- <submodule-path>
```

Then it updates each submodule in the list as follows, depending on whether you run west update with the --rebase option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive <submodule-path>

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive <submodule-path>
```
The `git submodule sync` commands are skipped if the `update.sync-submodules` configuration option is false.

**Other project commands**

West has a few more commands for managing the projects in the workspace, which are summarized here. Run `west <command> -h` for detailed help.

- `west list`: print a line of information about each project in the manifest, according to a format string
- `west manifest`: manage the manifest file. See *Manifest Command*.
- `west diff`: run `git diff` in local project repositories
- `west status`: run `git status` in local project repositories
- `west forall`: run an arbitrary command in local project repositories
- `west compare`: compare the state of the workspace against the manifest

**Other built-in commands**

Finally, here is a summary of other built-in commands.

- `west config`: get or set configuration options
- `west todir`: print the top level directory of the west workspace
- `west help`: get help about a command, or print information about all commands in the workspace, including *Extensions*

### 2.11.6 Workspaces

This page describes the *west workspace* concept introduced in *Basics* in more detail.

**The manifest-rev branch**

West creates and controls a Git branch named `manifest-rev` in each project. This branch points to the revision that the manifest file specified for the project at the time `west update` was last run. Other workspace management commands may use `manifest-rev` as a reference point for the upstream revision as of this latest update. Among other purposes, the `manifest-rev` branch allows the manifest file to use SHAs as project revisions.

Although `manifest-rev` is a normal Git branch, west will recreate and/or reset it on the next update. For this reason, it is **dangerous** to check it out or otherwise modify it yourself. For instance, any commits you manually add to this branch may be lost the next time you run `west update`. Instead, check out a local branch with another name, and either rebase it on top of a new `manifest-rev`, or merge `manifest-rev` into it.

**Note:** West does not create a `manifest-rev` branch in the manifest repository, since west does not manage the manifest repository's branches or revisions.
The \texttt{refs/west/} Git refs

West also reserves all Git refs that begin with \texttt{refs/west/} (such as \texttt{refs/west/foo}) for itself in local project repositories. Unlike \texttt{manifest-rev}, these refs are not regular branches. West's behavior here is an implementation detail; users should not rely on these refs' existence or behavior.

Private repositories

You can use west to fetch from private repositories. There is nothing west-specific about this.

The \texttt{west update} command essentially runs \texttt{git fetch YOUR_PROJECT_URL} when a project's \texttt{manifest-rev} branch must be updated to a newly fetched commit. It's up to your environment to make sure the fetch succeeds.

You can either enter the password manually or use any of the credential helpers built in to Git. Since Git has credential storage built in, there is no need for a west-specific feature.

The following sections cover common cases for running \texttt{west update} without having to enter your password, as well as how to troubleshoot issues.

Fetching via HTTPS

On Windows when fetching from GitHub, recent versions of Git prompt you for your GitHub password in a graphical window once, then store it for future use (in a default installation). Passwordless fetching from GitHub should therefore work "out of the box" on Windows after you have done it once.

In general, you can store your credentials on disk using the "store" git credential helper. See the \texttt{git-credential-store} manual page for details.

To use this helper for all the repositories in your workspace, run:

```bash
west forall -c "git config credential.helper store"
```

To use this helper on just the projects \texttt{foo} and \texttt{bar}, run:

```bash
west forall -c "git config credential.helper store" foo bar
```

To use this helper by default on your computer, run:

```bash
git config --global credential.helper store
```

On GitHub, you can set up a personal access token to use in place of your account password. (This may be required if your account has two-factor authentication enabled, and may be preferable to storing your account password in plain text even if two-factor authentication is disabled.)

You can use the Git credential store to authenticate with a GitHub PAT (Personal Access Token) like so:

```bash
echo "https://x-access-token:$GH_TOKEN@github.com" >> ~/.git-credentials
```

If you don't want to store any credentials on the file system, you can store them in memory temporarily using \texttt{git-credential-cache} instead.

If you setup fetching via SSH, you can use Git URL rewrite feature. The following command instructs Git to use SSH URLs for GitHub instead of HTTPS ones:

```bash
git config --global url."git@github.com:".insteadOf "https://github.com/"
```

Fetching via SSH

If your SSH key has no password, fetching should just work. If it does have a password, you can avoid entering it manually every time using \texttt{ssh-agent}.

On GitHub, see Connecting to GitHub with SSH for details on configuration and key creation.
Project locations

Projects can be located anywhere inside the workspace, but they may not “escape” it.

In other words, project repositories need not be located in subdirectories of the manifest repository or as immediate subdirectories of the topdir. However, projects must have paths inside the workspace.

You may replace a project’s repository directory within the workspace with a symbolic link to elsewhere on your computer, but west will not do this for you.

Topologies supported

The following are example source code topologies supported by west.

- **T1: star topology, zephyr is the manifest repository**
  - The zephyr repository acts as the central repository and specifies its Modules (External projects) in its west.yml
  - Analogy with existing mechanisms: Git submodules with zephyr as the super-project

This is the default. See Workspace concepts for how mainline Zephyr is an example of this topology.

- **T2: star topology, application is the manifest repository**
  - Useful for those focused on a single application
  - A repository containing a Zephyr application acts as the central repository and names other projects required to build it in its west.yml. This includes the zephyr repository and any modules.
  - Analogy with existing mechanisms: Git submodules with the application as the super-project, zephyr and other projects as submodules

A workspace using this topology looks like this:

```
west-workspace/
    application/ # .git/  
    CMakeLists.txt
    prj.conf
    src/
    └── main.c
        west.yml  # main manifest with optional import(s) and override(s)
    modules/  
    └── lib/
        └── zcbor/  # .git/ project from either the main manifest or some import.
    zephyr/  
    └── west.yml  # This can be partially imported with lower precedence or ignored.
```

Here is an example application/west.yml which uses Manifest Imports, available since west 0.7, to import Zephyr v2.5.0 and its modules into the application manifest file:
You can still selectively “override” individual Zephyr modules if you use `import`: in this way; see Example 1.3: Downstream of a Zephyr release, with module fork for an example.

Another way to do the same thing is to copy/paste `zephyr/west.yml` to `application/west.yml`, adding an entry for the zephyr project itself, like this:

```
# Equivalent to the above, but with manually maintained Zephyr modules.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  defaults:
    remote: zephyrproject-rtos
  projects:
    - name: zephyr
      revision: v2.5.0
      west-commands: scripts/west-commands.yml
    - name: net-tools
      revision: some-sha-goes-here
      path: tools/net-tools
    # ... other Zephyr modules go here ...
  self:
    path: application
```

(The `west-commands` is there for Building, Flashing and Debugging and other Zephyr-specific Extensions. It’s not necessary when using `import`.)

The main advantage to using `import` is not having to track the revisions of imported projects separately. In the above example, using `import` means Zephyr’s `module` versions are automatically determined from the `zephyr/west.yml` revision, instead of having to be copy/pasted (and maintained) on their own.

**T3: Forest topology**

- Useful for those supporting multiple independent applications or downstream distributions with no “central” repository
- A dedicated manifest repository which contains no Zephyr source code, and specifies a list of projects all at the same “level”
- Analogy with existing mechanisms: Google repo-based source distribution

A workspace using this topology looks like this:

```
west-workspace/
  app1/ # .git/ project
    CMakeLists.txt
    prj.conf
```

(continues on next page)
Here is an example T3 manifest-repo/west.yml which uses Manifest Imports, available since west 0.7, to import Zephyr v2.5.0 and its modules, then add the app1 and app2 projects:

```yaml
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: your-git-server
      url-base: https://git.example.com/your-company
  defaults:
    remote: your-git-server
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
    - name: app1
      revision: SOME_SHA_OR_BRANCH_OR_TAG
    - name: app2
      revision: ANOTHER_SHA_OR_BRANCH_OR_TAG
  self:
    path: manifest-repo
```

You can also do this “by hand” by copy/pasting zephyr/west.yml as shown above for the T2 topology, with the same caveats.

### 2.11.7 West Manifests

This page contains detailed information about west’s multiple repository model, manifest files, and the west manifest command. For API documentation on the west.manifest module, see west-apis-manifest. For a more general introduction and command overview, see Basics.

#### Multiple Repository Model

West’s view of the repositories in a west workspace, and their history, looks like the following figure (though some parts of this example are specific to upstream Zephyr’s use of west):
The history of the manifest repository is the line of Git commits which is “floating” on top of the gray plane. Parent commits point to child commits using solid arrows. The plane below contains the Git commit history of the repositories in the workspace, with each project repository boxed in by a rectangle. Parent/child commit relationships in each repository are also shown with solid arrows.

The commits in the manifest repository (again, for upstream Zephyr this is the zephyr repository itself) each have a manifest file. The manifest file in each commit specifies the corresponding commits which it expects in each of the project repositories. This relationship is shown using dotted line arrows in the diagram. Each dotted line arrow points from a commit in the manifest repository to a corresponding commit in a project repository.

Notice the following important details:

- Projects can be added (like P1 between manifest repository commits D and E) and removed (P2 between the same manifest repository commits).
- Project and manifest repository histories don’t have to move forwards or backwards together:
  - P2 stays the same from A → B, as do P1 and P3 from F → G.
  - P3 moves forward from A → B.
  - P3 moves backward from C → D.

One use for moving backward in project history is to “revert” a regression by going back to a revision before it was introduced.

- Project repository commits can be “skipped”: P3 moves forward multiple commits in its history from B → C.
- In the above diagram, no project repository has two revisions “at the same time”: every manifest file refers to exactly one commit in the projects it cares about. This can be relaxed by using a branch name as a manifest revision, at the cost of being able to bisect manifest repository history.
Manifest Files

West manifests are YAML files. Manifests have a top-level manifest section with some subsections, like this:

```yaml
manifest:
  remotes:
    # short names for project URLs
  projects:
    # a list of projects managed by west
  defaults:
    # default project attributes
  self:
    # configuration related to the manifest repository itself,
    # i.e. the repository containing west.yml
  version: "<schema-version>"
  group-filter:
    # a list of project groups to enable or disable
```

In YAML terms, the manifest file contains a mapping, with a manifest key. Any other keys and their contents are ignored (west v0.5 also required a west key, but this is ignored starting with v0.6).

The manifest contains subsections, like defaults, remotes, projects, and self. In YAML terms, the value of the manifest key is also a mapping, with these “subsections” as keys. As of west v0.10, all of these “subsection” keys are optional.

The projects value is a list of repositories managed by west and associated metadata. We'll discuss it soon, but first we will describe the remotes section, which can be used to save typing in the projects list.

Remotes   The remotes subsection contains a sequence which specifies the base URLs where projects can be fetched from.

Each remotes element has a name and a “URL base”. These are used to form the complete Git fetch URL for each project. A project's fetch URL can be set by appending a project-specific path onto a remote URL base. (As we'll see below, projects can also specify their complete fetch URLs.)

For example:

```yaml
manifest:
  # ...
  remotes:
    - name: remote1
      url-base: https://git.example.com/base1
    - name: remote2
      url-base: https://git.example.com/base2
```

The remotes keys and their usage are in the following table.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Mandatory; a unique name for the remote.</td>
</tr>
<tr>
<td>url-base</td>
<td>A prefix that is prepended to the fetch URL for each project with this remote.</td>
</tr>
</tbody>
</table>

Above, two remotes are given, with names remote1 and remote2. Their URL bases are respectively https://git.example.com/base1 and https://git.example.com/base2. You can use SSH URL bases as well; for example, you might use git@example.com:base1 if remote1 supported Git over SSH as well. Anything acceptable to Git will work.
Projects  The projects subsection contains a sequence describing the project repositories in the west workspace. Every project has a unique name. You can specify what Git remote URLs to use when cloning and fetching the projects, what revisions to track, and where the project should be stored on the local file system. Note that west projects are different from modules.

Here is an example. We'll assume the remotes given above.

manifest:

```manifest
# [... same remotes as above...]
projects:
- name: proj1
  remote: remote1
  path: extra/project-1
- name: proj2
  repo-path: my-path
  remote: remote2
  revision: v1.3
- name: proj3
  url: https://github.com/user/project-three
  revision: abcde413a111
```

In this manifest:

- proj1 has remote remote1, so its Git fetch URL is https://git.example.com/base1/proj1. The remote url-base is appended with a / and the project name to form the URL.

  Locally, this project will be cloned at path extra/project-1 relative to the west workspace's root directory, since it has an explicit path attribute with this value.

  Since the project has no revision specified, master is used by default. The current tip of this branch will be fetched and checked out as a detached HEAD when west next updates this project.

- proj2 has a remote and a repo-path, so its fetch URL is https://git.example.com/base2/my-path. The repo-path attribute, if present, overrides the default name when forming the fetch URL.

  Since the project has no path attribute, its name is used by default. It will be cloned into a directory named proj2. The commit pointed to by the v1.3 tag will be checked out when west updates the project.

- proj3 has an explicit url, so it will be fetched from https://github.com/user/project-three.

  Its local path defaults to its name, proj3. Commit abcde413a111 will be checked out when it is next updated.

The available project keys and their usage are in the following table. Sometimes we'll refer to the defaults subsection; it will be described next.
Table 3: projects elements keys

<table>
<thead>
<tr>
<th>Key(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Mandatory; a unique name for the project. The name cannot be one of the reserved values “west” or “manifest”. The name must be unique in the manifest file.</td>
</tr>
<tr>
<td>remote, url</td>
<td>Mandatory (one of the two, but not both). If the project has a remote, that remote’s url-base will be combined with the project’s name (or repo-path, if it has one) to form the fetch URL instead. If the project has a url, that's the complete fetch URL for the remote Git repository. If the project has neither, the defaults section must specify a remote, which will be used as the the project’s remote. Otherwise, the manifest is invalid.</td>
</tr>
<tr>
<td>repo-path</td>
<td>Optional. If given, this is concatenated on to the remote’s url-base instead of the project’s name to form its fetch URL. Projects may not have both url and repo-path attributes.</td>
</tr>
<tr>
<td>revision</td>
<td>Optional. The Git revision that west update should check out. This will be checked out as a detached HEAD by default, to avoid conflicting with local branch names. If not given, the revision value from the defaults subsection will be used if present. A project revision can be a branch, tag, or SHA. The default revision is master if not otherwise specified. Using HEAD~0¹ as the revision will cause west to keep the current state of the project.</td>
</tr>
<tr>
<td>path</td>
<td>Optional. Relative path specifying where to clone the repository locally, relative to the top directory in the west workspace. If missing, the project’s name is used as a directory name.</td>
</tr>
<tr>
<td>clone-depth</td>
<td>Optional. If given, a positive integer which creates a shallow history in the cloned repository limited to the given number of commits. This can only be used if the revision is a branch or tag.</td>
</tr>
<tr>
<td>west-commands</td>
<td>Optional. If given, a relative path to a YAML file within the project which describes additional west commands provided by that project. This file is named west-commands.yml by convention. See Extensions for details.</td>
</tr>
<tr>
<td>import</td>
<td>Optional. If true, imports projects from manifest files in the given repository into the current manifest. See Manifest Imports for details.</td>
</tr>
<tr>
<td>groups</td>
<td>Optional, a list of groups the project belongs to. See Project Groups for details.</td>
</tr>
<tr>
<td>submodules</td>
<td>Optional. You can use this to make west update also update Git submodules defined by the project. See Git Submodules in Projects for details.</td>
</tr>
<tr>
<td>userdata</td>
<td>Optional. The value is an arbitrary YAML value. See Repository user data.</td>
</tr>
</tbody>
</table>

Defaults The defaults subsection can provide default values for project attributes. In particular, the default remote name and revision can be specified here. Another way to write the same manifest we have been describing so far using defaults is:

```yaml
manifest:
  defaults:
    remote: remote1
    revision: v1.3

remotes:
- name: remote1
  url-base: https://git.example.com/base1
- name: remote2
  url-base: https://git.example.com/base2
```

¹ In git, HEAD is a reference, whereas HEAD~<n> is a valid revision but not a reference. West fetches references, such as refs/heads/main or HEAD, and commits not available locally, but will not fetch commits if they are already available. HEAD~0 is resolved to a specific commit that is locally available, and therefore west will simply checkout the locally available commit, identified by HEAD~0.
The available defaults keys and their usage are in the following table.

Table 4: defaults keys

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>remote</td>
<td>Optional. This will be used for a project's remote if it does not have a url or remote key set.</td>
</tr>
<tr>
<td>revision</td>
<td>Optional. This will be used for a project's revision if it does not have one set. If not given, the default is master.</td>
</tr>
</tbody>
</table>

Self The self subsection can be used to control the manifest repository itself.

As an example, let's consider this snippet from the zephyr repository's west.yml:

```yaml
manifest:
  # ...
  self:
    path: zephyr
    west-commands: scripts/west-commands.yml
```

This ensures that the zephyr repository is cloned into path zephyr, though as explained above that would have happened anyway if cloning from the default manifest URL, https://github.com/zephyrproject-rtos/zephyr. Since the zephyr repository does contain extension commands, its self entry declares the location of the corresponding west-commands.yml relative to the repository root.

The available self keys and their usage are in the following table.

Table 5: self keys

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Optional. The path <code>west init</code> should clone the manifest repository into, relative to the west workspace topdir. If not given, the basename of the path component in the manifest repository URL will be used by default. For example, if the URL is <code>https://git.example.com/project-repo</code>, the manifest repository would be cloned to the directory <code>project-repo</code>.</td>
</tr>
<tr>
<td>west-commands</td>
<td>Optional. This is analogous to the same key in a project sequence element.</td>
</tr>
<tr>
<td>import</td>
<td>Optional. This is also analogous to the <code>projects</code> key, but allows importing projects from other files in the manifest repository. See Manifest Imports.</td>
</tr>
</tbody>
</table>

Version The version subsection declares that the manifest file uses features which were introduced in some version of west. Attempts to load the manifest with older versions of west will fail with an error message that explains the minimum required version of west which is needed.
Here is an example:

```yaml
manifest:
  # Marks that this file uses version 0.10 of the west manifest
  # file format.
  
  # An attempt to load this manifest file with west v0.8.0 will
  # fail with an error message saying that west v0.10.0 or
  # later is required.

version: "0.10"
```

The pykwalify schema `manifest-schema.yml` in the west source code repository is used to validate the manifest section.

Here is a table with the valid version values, along with information about the manifest file features that were introduced in that version.

<table>
<thead>
<tr>
<th>version</th>
<th>New features</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;0.7&quot;</td>
<td>Initial support for the version feature. All manifest file features that are not otherwise mentioned in this table were introduced in west v0.7.0 or earlier.</td>
</tr>
<tr>
<td>&quot;0.8&quot;</td>
<td>Support for import: path-prefix: (Option 3: Mapping)</td>
</tr>
<tr>
<td>&quot;0.9&quot;</td>
<td>Use of west v0.9.x is discouraged. This schema version is provided to allow users to explicitly request compatibility with west v0.9.0. However, west v0.10.0 and later have incompatible behavior for features that were introduced in west v0.9.0. You should ignore version “0.9” if possible.</td>
</tr>
</tbody>
</table>
| "0.10" | Support for:
|  | • submodules: in projects: (Git Submodules in Projects)
|  | • manifest: group-filter:, and groups: in projects: (Project Groups)
|  | • The import: feature now supports allowlist: and blocklist:; these are respectively recommended as replacements for older names as part of a general Zephyr-wide inclusive language change. The older key names are still supported for backwards compatibility. (Manifest Imports, Option 3: Mapping) |
| "0.12" | Support for userdata: in projects: (Repository user data) |
| "0.13" | Support for self: userdata: (Repository user data) |
| "1.0"  | Identical to "0.13", but available for use by users that do not wish to use a "0.x" version field. |

**Note:** Versions of west without any new features in the manifest file format do not change the list of valid version values. For example, version: "0.11" is not valid, because west v0.11.x did not introduce new manifest file format features.

Quoting the version value as shown above forces the YAML parser to treat it as a string. Without quotes, 0.10 in YAML is just the floating point value 0.1. You can omit the quotes if the value is the same when cast to string, but it’s best to include them. Always use quotes if you’re not sure.

If you do not include a version in your manifest, each new release of west assumes that it should try to load it using the features that were available in that release. This may result in error messages that are harder to understand if that version of west is too old to load the manifest.

**Group-filter** See [Project Groups](ch02).
Active and Inactive Projects

Projects defined in the west manifest can be inactive or active. The difference is that an inactive project is generally ignored by west. For example, west update will not update inactive projects, and west list will not print information about them by default. As another example, any Manifest Imports in an inactive project will be ignored by west.

There are two ways to make a project inactive:

1. Using the manifest.project-filter configuration option. If a project is made active or inactive using this option, then the rules related to making a project inactive using its groups: are ignored. That is, if a regular expression in manifest.project-filter applies to a project, the project's groups have no effect on whether it is active or inactive.

   See the entry for this option in Built-in Configuration Options for details.

2. Otherwise, if a project has groups, and they are all disabled, then the project is inactive.

   See the following section for details.

Project Groups

You can use the groups and group-filter keys briefly described above to place projects into groups, and to enable or disable groups.

For example, this lets you run a west forall command only on the projects in the group by using west forall --group. This can also let you make projects inactive; see the previous section for more information on inactive projects.

The next section introduces project groups. The following section describes Enabled and Disabled Project Groups. There are some basic examples in Project Group Examples. Finally, Group Filters and Imports provides a simplified overview of how group-filter interacts with the Manifest Imports feature.

Groups Basics

The groups: and group-filter: keys appear in the manifest like this:

```manifest:
  projects:
    - name: some-project
      groups: ...
      group-filter: ...
```

The groups key's value is a list of group names. Group names are strings.

You can enable or disable project groups using group-filter. Projects whose groups are all disabled, and which are not otherwise made active by a manifest.project-filter configuration option, are inactive.

For example, in this manifest fragment:

```manifest:
  projects:
    - name: project-1
      groups:
        - groupA
    - name: project-2
      groups:
        - groupB
        - groupC
    - name: project-3
```

The projects are in these groups:
Zephyr Project Documentation, Release 3.5.0-rc1

- project-1: one group, named groupA
- project-2: two groups, named groupB and groupC
- project-3: no groups

Project group names must not contain commas (,), colons (:), or whitespace.

Group names must not begin with a dash (-) or the plus sign (+), but they may contain these characters elsewhere in their names. For example, foo-bar and foo+bar are valid groups, but -foobar and +foobar are not.

Group names are otherwise arbitrary strings. Group names are case sensitive.

As a restriction, no project may use both import: and groups:.

Enabled and Disabled Project Groups  All project groups are enabled by default. You can enable or disable groups in both your manifest file and Configuration.

Within a manifest file, manifest: group-filter: is a YAML list of groups to enable and disable.

To enable a group, prefix its name with a plus sign (+). For example, groupA is enabled in this manifest fragment:

```
manifest:
  group-filter: [+groupA]
```

Although this is redundant for groups that are already enabled by default, it can be used to override settings in an imported manifest file. See Group Filters and Imports for more information.

To disable a group, prefix its name with a dash (-). For example, groupA and groupB are disabled in this manifest fragment:

```
manifest:
  group-filter: [-groupA,-groupB]
```

Note: Since group-filter is a YAML list, you could have written this fragment as follows:

```
manifest:
  group-filter:
    - -groupA
    - -groupB
```

However, this syntax is harder to read and therefore discouraged.

In addition to the manifest file, you can control which groups are enabled and disabled using the manifest.group-filter configuration option. This option is a comma-separated list of groups to enable and/or disable.

To enable a group, add its name to the list prefixed with +. To disable a group, add its name prefixed with -. For example, setting manifest.group-filter to +groupA,-groupB enables groupA, and disables groupB.

The value of the configuration option overrides any data in the manifest file. You can think of this as if the manifest.group-filter configuration option is appended to the manifest: group-filter: list from YAML, with “last entry wins’ semantics.

Project Group Examples  This section contains example situations involving project groups and active projects. The examples use both manifest: group-filter: YAML lists and manifest.group-filter configuration lists, to show how they work together.
Note that the defaults and remotes data in the following manifests isn't relevant except to make the examples complete and self-contained.

**Note:** In all of the examples that follow, the manifest.project-filter option is assumed to be unset.

**Example 1: no disabled groups**  The entire manifest file is:

```manifest:
projects:
  - name: foo
    groups:
      - groupA
  - name: bar
    groups:
      - groupA
      - groupB
  - name: baz

defaults:
  remote: example-remote
remotes:
  - name: example-remote
    url-base: https://git.example.com
```

The manifest.group-filter configuration option is not set (you can ensure this by running west config -D manifest.group-filter).

No groups are disabled, because all groups are enabled by default. Therefore, all three projects (foo, bar, and baz) are active. Note that there is no way to make project baz inactive, since it has no groups.

**Example 2: Disabling one group via manifest**  The entire manifest file is:

```manifest:
projects:
  - name: foo
    groups:
      - groupA
  - name: bar
    groups:
      - groupA
      - groupB

group-filter: [-groupA]

defaults:
  remote: example-remote
remotes:
  - name: example-remote
    url-base: https://git.example.com
```

The manifest.group-filter configuration option is not set (you can ensure this by running west config -D manifest.group-filter).

Since groupA is disabled, project foo is inactive. Project bar is active, because groupB is enabled.

**Example 3: Disabling multiple groups via manifest**  The entire manifest file is:

```manifest:
projects:
  - name: foo
    groups:
      - groupA
  - name: bar
    groups:
      - groupA
      - groupB

group-filter: [-groupA, -groupB]

defaults:
  remote: example-remote
remotes:
  - name: example-remote
    url-base: https://git.example.com
```
Example 4: Disabling a group via configuration The entire manifest file is:

```json
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  group-filter: [-groupA,-groupB]

defaults:
  remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `-groupA` (you can ensure this by running `west config manifest.group-filter -- -groupA`; the extra `--` is required so the argument parser does not treat `-groupA` as a command line option `-g` with value `roupA`).

Project `foo` is inactive because `groupA` has been disabled by the `manifest.group-filter` configuration option. Project `bar` is active because `groupB` is enabled.

Example 5: Overriding a disabled group via configuration The entire manifest file is:

```json
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
        - groupB

  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

(continues on next page)
The manifest.group-filter configuration option is set to +groupA (you can ensure this by running west config manifest.group-filter +groupA).

In this case, groupA is enabled: the manifest.group-filter configuration option has higher precedence than the manifest: group-filter: [-groupA] content in the manifest file.

Therefore, projects foo and bar are both active.

Example 6: Overriding multiple disabled groups via configuration

The entire manifest file is:

```yaml
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
      groups:
        - groupA
        - groupB
  group-filter: [-groupA,-groupB]
  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The manifest.group-filter configuration option is set to +groupA,+groupB (you can ensure this by running west config manifest.group-filter "+groupA,+groupB").

In this case, both groupA and groupB are enabled, because the configuration value overrides the manifest file for both groups.

Therefore, projects foo and bar are both active.

Example 7: Disabling multiple groups via configuration

The entire manifest file is:

```yaml
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
```

(continues on next page)
The manifest.group-filter configuration option is set to -groupA,-groupB (you can ensure this by running west config manifest.group-filter -- "-groupA,-groupB").

In this case, both groupA and groupB are disabled.

Therefore, projects foo and bar are both inactive.

**Group Filters and Imports** This section provides a simplified description of how the manifest: group-filter: value behaves when combined with Manifest Imports. For complete details, see Manifest Import Details.

**Warning:** The below semantics apply to west v0.10.0 and later. West v0.9.x semantics are different, and combining group-filter with import in west v0.9.x is discouraged.

In short:

- if you only import one manifest, any groups it disables in its group-filter are also disabled in your manifest
- you can override this in your manifest file's manifest: group-filter: value, your workspace's manifest.group-filter configuration option, or both

Here are some examples.

**Example 1: no overrides** You are using this parent/west.yml manifest:

```yaml
# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And child/west.yml contains:

```yaml
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
```

(continues on next page)
Only child and project-2 are active in the resolved manifest.
The unstable group is disabled in child/west.yml, and that is not overridden in parent/west.yml. Therefore, the final group-filter for the resolved manifest is [-unstable].
Since project-1 and project-3 are in the unstable group and are not in any other group, they are inactive.

Example 2: overriding an imported group-filter via manifest  You are using this parent/west.yml manifest:

```
# parent/west.yml:
manifest:
  group-filter: [+unstable,-optional]
projects:
  - name: child
    url: https://git.example.com/child
    import: true
  - name: project-1
    url: https://git.example.com/project-1
    groups:
      - unstable
```

And child/west.yml contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
projects:
  - name: project-2
    url: https://git.example.com/project-2
    groups:
      - optional
  - name: project-3
    url: https://git.example.com/project-3
    groups:
      - unstable
```

Only the child, project-1, and project-3 projects are active.
The [-unstable] group filter in child/west.yml is overridden in parent/west.yml, so the unstable group is enabled. Since project-1 and project-3 are in the unstable group, they are active.
The same parent/west.yml file disables the optional group, so project-2 is inactive.
The final group filter specified by parent/west.yml is [+unstable,-optional].

Example 3: overriding an imported group-filter via configuration  You are using this parent/west.yml manifest:

```
# parent/west.yml:
manifest:
  projects:
```

(continues on next page)
And `child/west.yml` contains:

```yaml
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

If you run:

```
west config manifest.group-filter +unstable,-optional
```

Then only the `child`, `project-1`, and `project-3` projects are active.

The `-unstable` group filter in `child/west.yml` is overridden in the `manifest.group-filter` configuration option, so the unstable group is enabled. Since `project-1` and `project-3` are in the `unstable` group, they are active.

The same configuration option disables the `optional` group, so `project-2` is inactive.

The final group filter specified by `parent/west.yml` and the `manifest.group-filter` configuration option is ` [+unstable,-optional]`.

### Git Submodules in Projects

You can use the `submodules` keys briefly described above to force `west update` to also handle any Git submodules configured in project's git repository. The `submodules` key can appear inside `projects`, like this:

```yaml
manifest:
  projects:
    - name: some-project
      submodules: ...
```

The `submodules` key can be a boolean or a list of mappings. We’ll describe these in order.

**Option 1: Boolean**  
This is the easiest way to use submodules.

If `submodules` is true as a `projects` attribute, `west update` will recursively update the project's Git submodules whenever it updates the project itself. If it's false or missing, it has no effect.

For example, let's say you have a source code repository `foo`, which has some submodules, and you want `west update` to keep all of them them in sync, along with another project named `bar` in the same workspace.
You can do that with this manifest file:

```yaml
manifest:
  projects:
  - name: foo
    submodules: true
  - name: bar
```

Here, `west update` will initialize and update all submodules in `foo`. If `bar` has any submodules, they are ignored, because `bar` does not have a `submodules` value.

Option 2: List of mappings The `submodules` key may be a list of mappings, one list element for each desired submodule. Each submodule listed is updated recursively. You can still track and update unlisted submodules with `git` commands manually; present or not they will be completely ignored by `west`.

The `path` key must match exactly the path of one submodule relative to its parent `west` project, as shown in the output of `git submodule status`. The `name` key is optional and not used by `west` for now; it’s not passed to `git submodule` commands either. The `name` key was briefly mandatory in `west` version 0.9.0, but was made optional in 0.9.1.

For example, let’s say you have a source code repository `foo`, which has many submodules, and you want `west update` to keep some but not all of them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```yaml
manifest:
  projects:
  - name: foo
    submodules:
      - path: path/to/foo-first-sub
        name: foo-second-sub
      - path: path/to/foo-second-sub
  - name: bar
```

Here, `west update` will recursively initialize and update just the submodules in `foo` with paths `path/to/foo-first-sub` and `path/to/foo-second-sub`. Any submodules in `bar` are still ignored.

Repository user data

West versions v0.12 and later support an optional `userdata` key in projects.

West versions v0.13 and later supports this key in the `manifest: self:` section.

It is meant for consumption by programs that require user-specific project metadata. Beyond parsing it as YAML, `west` itself ignores the value completely.

The key’s value is arbitrary YAML. `west` parses the value and makes it accessible to programs using `west-apis` as the `userdata` attribute of the corresponding `west.manifest.Project` object.

Example manifest fragment:

```yaml
manifest:
  projects:
  - name: foo
  - name: bar
    userdata: a-string
  - name: baz
    userdata:
      key: value
```

(continues on next page)
Example Python usage:

```python
manifest = west.manifest.Manifest.from_file()

foo, bar, baz = manifest.get_projects(['foo', 'bar', 'baz'])

foo.userdata # None
bar.userdata # 'a-string'
baz.userdata # {'key': 'value'}
manifest.userdata # 'blub'
```

Manifest Imports

You can use the `import` key briefly described above to include projects from other manifest files in your `west.yml`. This key can be either a `project` or `self` section attribute:

```yaml
manifest:
  projects:
    - name: some-project
      import: ...
  self:
    import: ...
```

You can use a “self: import:” to load additional files from the repository containing your `west.yml`. You can use a “project: ... import:” to load additional files defined in that project’s Git history.

West resolves the final manifest from individual manifest files in this order:

1. imported files in `self`
2. your `west.yml` file
3. imported files in `projects`

During resolution, west ignores projects which have already been defined in other files. For example, a project named `foo` in your `west.yml` makes west ignore other projects named `foo` imported from your `projects` list.

The `import` key can be a boolean, path, mapping, or sequence. We’ll describe these in order, using examples:

- **Boolean**
  - Example 1.1: Downstream of a Zephyr release
  - Example 1.2: “Rolling release” Zephyr downstream
  - Example 1.3: Downstream of a Zephyr release, with module fork

- **Relative path**
  - Example 2.1: Downstream of a Zephyr release with explicit path
  - Example 2.2: Downstream with directory of manifest files
  - Example 2.3: Continuous Integration overrides

- **Mapping with additional configuration**
  - Example 3.1: Downstream with name allowlist
  - Example 3.2: Downstream with path allowlist
- Example 3.3: Downstream with path blocklist
- Example 3.4: Import into a subdirectory

• Sequence of paths and mappings
  - Example 4.1: Downstream with sequence of manifest files
  - Example 4.2: Import order illustration

A more formal description of how this works is last, after the examples.

Troubleshooting Note  If you’re using this feature and find west’s behavior confusing, try resolving your manifest to see the final results after imports are done.

Option 1: Boolean  This is the easiest way to use import.

If import is true as a projects attribute, west imports projects from the west.yml file in that project’s root directory. If it’s false or missing, it has no effect. For example, this manifest would import west.yml from the p1 git repository at revision v1.0:

```
manifest:
  # ...
  projects:
    - name: p1
      revision: v1.0
      import: true  # Import west.yml from p1's v1.0 git tag
    - name: p2
      import: false  # Nothing is imported from p2.
    - name: p3
      # Nothing is imported from p3 either.
```

It’s an error to set import to either true or false inside self, like this:

```
manifest:
  # ...
  self:
    import: true  # Error
```

Example 1.1: Downstream of a Zephyr release  You have a source code repository you want to use with Zephyr v1.14.1 LTS. You want to maintain the whole thing using west. You don’t want to modify any of the mainline repositories.

In other words, the west workspace you want looks like this:

```
my-downstream/
  .west/  # west directory
  zephyr/  # mainline zephyr repository
    west.yml  # the v1.14.1 version of this file is imported
    modules/  # modules from mainline zephyr
      hal/  
        [...other directories..]
      [... other projects ...]  # other mainline repositories
  my-repo/  # your downstream repository
    west.yml  # main manifest importing zephyr/west.yml v1.14.1
    [...other files..]
```

You can do this with the following my-repo/west.yml:
# my-repo/west.yml:
manifest:
  remotes:
  - name: zephyrproject-rtos
    url-base: https://github.com/zephyrproject-rtos
  projects:
  - name: zephyr
    remote: zephyrproject-rtos
    revision: v1.14.1
    import: true

You can then create the workspace on your computer like this, assuming my-repo is hosted at https://git.example.com/my-repo:

west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update

After west init, my-downstream/my-repo will be cloned.

After west update, all of the projects defined in the zephyr repository's west.yml at revision v1.14.1 will be cloned into my-downstream as well.

You can add and commit any code to my-repo you please at this point, including your own Zephyr applications, drivers, etc. See Application Development.

Example 1.2: “Rolling release” Zephyr downstream
This is similar to Example 1.1: Downstream of a Zephyr release, except we'll use revision: main for the zephyr repository:

# my-repo/west.yml:
manifest:
  remotes:
  - name: zephyrproject-rtos
    url-base: https://github.com/zephyrproject-rtos
  projects:
  - name: zephyr
    remote: zephyrproject-rtos
    revision: main
    import: true

You can create the workspace in the same way:

west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update

This time, whenever you run west update, the special manifest-rev branch in the zephyr repository will be updated to point at a newly fetched main branch tip from the URL https://github.com/zephyrproject-rtos/zephyr.

The contents of zephyr/west.yml at the new manifest-rev will then be used to import projects from Zephyr. This lets you stay up to date with the latest changes in the Zephyr project. The cost is that running west update will not produce reproducible results, since the remote main branch can change every time you run it.

It's also important to understand that west ignores your working tree's zephyr/west.yml entirely when resolving imports. West always uses the contents of imported manifests as they were committed to the latest manifest-rev when importing from a project.
You can only import manifest from the file system if they are in your manifest repository's working tree. See *Example 2.2: Downstream with directory of manifest files* for an example.

**Example 1.3: Downstream of a Zephyr release, with module fork**  This manifest is similar to the one in *Example 1.1: Downstream of a Zephyr release*, except it:

- is a downstream of Zephyr 2.0
- includes a downstream fork of the `modules/hal/nordic` module which was included in that release

```yaml
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: my-remote
      url-base: https://git.example.com
  projects:
    - name: hal_nordic
      remote: my-remote
      revision: my-sha
      path: modules/hal/nordic
      # higher precedence
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.0.0
      import: true
      # imported projects have lower precedence

# subset of zephyr/west.yml contents at v2.0.0:
manifest:
  defaults:
    remote: zephyrproject-rtos
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    # ...
    - name: hal_nordic
      path: modules/hal/nordic
      revision: another-sha
      # lower precedence, values ignored
```

With this manifest file, the project named `hal_nordic`:

- is cloned from `https://git.example.com/hal_nordic` instead of `https://github.com/zephyrproject-rtos/hal_nordic`.
- is updated to commit `my-sha` by `west update`, instead of the mainline commit `another-sha`.

In other words, when your top-level manifest defines a project, like `hal_nordic`, `west` will ignore any other definition it finds later on while resolving imports.

This does mean you have to copy the path: `modules/hal/nordic` value into `my-repo/west.yml` when defining `hal_nordic` there. The value from `zephyr/west.yml` is ignored entirely. See *Resolving Manifests* for troubleshooting advice if this gets confusing in practice.

When you run `west update`, `west` will:

- update `zephyr`'s `manifest-rev` to point at the v2.0.0 tag
- import `zephyr/west.yml` at that `manifest-rev`
- locally check out the v2.0.0 revisions for all `zephyr` projects except `hal_nordic`
- update `hal_nordic` to `my-sha` instead of `another-sha`
Option 2: Relative path

The import value can also be a relative path to a manifest file or a directory containing manifest files. The path is relative to the root directory of the projects or self repository the import key appears in.

Here is an example:

```yaml
manifest:
  projects:
    - name: project-1
      revision: v1.0
      import: west.yml
    - name: project-2
      revision: main
      import: p2-manifests
  self:
    import: submanifests
```

This will import the following:

- the contents of project-1/west.yml at manifest-rev, which points at tag v1.0 after running west update
- any YAML files in the directory tree project-2/p2-manifests at the latest commit in the main branch, as fetched by west update, sorted by file name
- YAML files in submanifests in your manifest repository, as they appear on your file system, sorted by file name

Notice how projects imports get data from Git using manifest-rev, while self imports get data from your file system. This is because as usual, west leaves version control for your manifest repository up to you.

Example 2.1: Downstream of a Zephyr release with explicit path

This is an explicit way to write an equivalent manifest to the one in Example 1.1: Downstream of a Zephyr release.

```yaml
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: west.yml
```

The setting import: west.yml means to use the file west.yml inside the zephyr project. This example is contrived, but shows the idea.

This can be useful in practice when the name of the manifest file you want to import is not west.yml.

Example 2.2: Downstream with directory of manifest files

Your Zephyr downstream has a lot of additional repositories. So many, in fact, that you want to split them up into multiple manifest files, but keep track of them all in a single manifest repository, like this:

```
my-repo/
  [submanifests
    01-libraries.yml
    02-vendor-hals.yml
    03-applications.yml
    west.yml
```

146 Chapter 2. Developing with Zephyr
You want to add all the files in `my-repo/submanifests` to the main manifest file, `my-repo/west.yml`, in addition to projects in `zephyr/west.yml`. You want to track the latest development code in the Zephyr repository's main branch instead of using a fixed revision.

Here's how:

```yaml
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
  self:
    import: submanifests
```

Manifest files are imported in this order during resolution:

1. `my-repo/submanifests/01-libraries.yml`
2. `my-repo/submanifests/02-vendor-hals.yml`
3. `my-repo/submanifests/03-applications.yml`
4. `my-repo/west.yml`
5. `zephyr/west.yml`

**Note:** The `.yml` file names are prefixed with numbers in this example to make sure they are imported in the specified order.

You can pick arbitrary names. West sorts files in a directory by name before importing.

Notice how the manifests in `submanifests` are imported before `my-repo/west.yml` and `zephyr/west.yml`. In general, an import in the `self` section is processed before the manifest files in `projects` and the main manifest file.

This means projects defined in `my-repo/submanifests` take highest precedence. For example, if `01-libraries.yml` defines `hal_nordic`, the project by the same name in `zephyr/west.yml` is simply ignored. As usual, see `Resolving Manifests` for troubleshooting advice.

This may seem strange, but it allows you to redefine projects “after the fact”, as we'll see in the next example.

**Example 2.3: Continuous Integration overrides**  
Your continuous integration system needs to fetch and test multiple repositories in your west workspace from a developer's forks instead of your mainline development trees, to see if the changes all work well together.

Starting with **Example 2.2: Downstream with directory of manifest files**, the CI scripts add a file `00-ci.yml` in `my-repo/submanifests`, with these contents:

```yaml
# my-repo/submanifests/00-ci.yml:
manifest:
  projects:
    - name: a-vendor-hal
      url: https://github.com/a-developer/hal
      revision: a-pull-request-branch
    - name: an-application
```

(continues on next page)
The CI scripts run `west update` after generating this file in `my-repo/submanifests`. The projects defined in `00-ci.yml` have higher precedence than other definitions in `my-repo/submanifests`, because the name `00-ci.yml` comes before the other file names.

Thus, `west update` always checks out the developer's branches in the projects named `a-vendor-hal` and `an-application`, even if those same projects are also defined elsewhere.

**Option 3: Mapping** The `import` key can also contain a mapping with the following keys:

- **file**: Optional. The name of the manifest file or directory to import. This defaults to `west.yml` if not present.
- **name-allowlist**: Optional. If present, a name or sequence of project names to include.
- **path-allowlist**: Optional. If present, a path or sequence of project paths to match against. This is a shell-style globbing pattern, currently implemented with `pathlib`. Note that this means case sensitivity is platform specific.
- **name-blocklist**: Optional. Like `name-allowlist`, but contains project names to exclude rather than include.
- **path-blocklist**: Optional. Like `path-allowlist`, but contains project paths to exclude rather than include.
- **path-prefix**: Optional (new in v0.8.0). If given, this will be prepended to the project's path in the workspace, as well as the paths of any imported projects. This can be used to place these projects in a subdirectory of the workspace.

Allowlists override blocklists if both are given. For example, if a project is blocked by path, then allowed by name, it will still be imported.

**Example 3.1: Downstream with name allowlist** Here is a pair of manifest files, representing a mainline and a downstream. The downstream doesn't want to use all the mainline projects, however. We'll assume the mainline `west.yml` is hosted at `https://git.example.com/mainline/manifest`.

```yaml
# mainline west.yml:
manifest:
projects:
  - name: mainline-app # included
    path: examples/app
    url: https://git.example.com/mainline/app
  - name: lib
    path: libraries/lib
    url: https://git.example.com/mainline/lib
  - name: lib2 # included
    path: libraries/lib2
    url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
projects:
  - name: mainline
    url: https://git.example.com/mainline/manifest
import:
  name-allowlist:
    - mainline-app
```

(continues on next page)
- lib2
  - name: downstream-app
    url: https://git.example.com/downstream/app
- name: lib3
  path: libraries/lib3
  url: https://git.example.com/downstream/lib3

An equivalent manifest in a single file would be:

```yaml
manifest:
  projects:
  - name: mainline
    url: https://git.example.com/mainline/manifest
  - name: downstream-app
    url: https://git.example.com/downstream/app
  - name: lib3
    path: libraries/lib3
    url: https://git.example.com/downstream/lib3
  - name: mainline-app
    path: examples/app
    url: https://git.example.com/mainline/app
  - name: lib2
    path: libraries/lib2
    url: https://git.example.com/mainline/lib2
```

If an allowlist had not been used, the lib project from the mainline manifest would have been imported.

**Example 3.2: Downstream with path allowlist**

Here is an example showing how to allowlist mainline's libraries only, using path-allowlist.

```yaml
# mainline west.yml:
manifest:
  projects:
  - name: app
    path: examples/app
    url: https://git.example.com/mainline/app
  - name: lib
    path: libraries/lib
    url: https://git.example.com/mainline/lib
  - name: lib2
    path: libraries/lib2
    url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
  - name: mainline
    url: https://git.example.com/mainline/manifest
  import:
    path-allowlist: libraries/*
  - name: app
    url: https://git.example.com/downstream/app
  - name: lib3
    path: libraries/lib3
    url: https://git.example.com/downstream/lib3
```

An equivalent manifest in a single file would be:
manifest:
  projects:
  - name: lib
    path: libraries/lib
    url: https://git.example.com/mainline/lib
  - name: lib2
    path: libraries/lib2
    url: https://git.example.com/mainline/lib2
  - name: mainline
    url: https://git.example.com/mainline/manifest
  - name: app
    path: libraries/lib3
    url: https://git.example.com/downstream/app
  - name: lib3
    path: libraries/lib3
    url: https://git.example.com/downstream/lib3

Example 3.3: Downstream with path blocklist Here's an example showing how to block all vendor HALs from mainline by common path prefix in the workspace, add your own version for the chip you're targeting, and keep everything else.

# mainline west.yml:
manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app
    - name: lib
      path: libraries/lib
    - name: lib2
      path: libraries/lib2
    - name: hal_foo
      path: modules/hals/foo # excluded
    - name: hal_bar
      path: modules/hals/bar # excluded
    - name: hal_baz
      path: modules/hals/baz # excluded

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        path-blocklist: modules/hals/*
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo

An equivalent manifest in a single file would be:

manifest:
  defaults:
    remote: mainline
remotes:
- name: mainline
  url-base: https://git.example.com/mainline
projects:
- name: app
- name: lib
  path: libraries/lib
- name: lib2
  path: libraries/lib2
- name: mainline
  repo-path: https://git.example.com/mainline/manifest
- name: hal_foo
  path: modules/hals/foo
  url: https://git.example.com/downstream/halFoo

Example 3.4: Import into a subdirectory  You want to import a manifest and its projects, placing everything into a subdirectory of your west workspace.

For example, suppose you want to import this manifest from project foo, adding this project and its projects bar and baz to your workspace:

```
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
  - name: example
    url-base: https://git.example.com
  projects:
    - name: bar
    - name: baz
```

Instead of importing these into the top level workspace, you want to place all three project repositories in an external-code subdirectory, like this:

```
workspace/
  └── external-code/
      └── foo/
      └── bar/
      └── baz/
```

You can do this using this manifest:

```
manifest:
  projects:
    - name: foo
      url: https://git.example.com/foo
      import:
        path-prefix: external-code
```

An equivalent manifest in a single file would be:

```
# foo/west.yml:
manifest:
  defaults:
    remote: example
```

(continues on next page)
remotes:
  - name: example
    url-base: https://git.example.com

projects:
  - name: foo
    path: external-code/foo
  - name: bar
    path: external-code/bar
  - name: baz
    path: external-code/baz

Option 4: Sequence  The import key can also contain a sequence of files, directories, and mappings.

Example 4.1: Downstream with sequence of manifest files  This example manifest is equivalent to the manifest in Example 2.2: Downstream with directory of manifest files, with a sequence of explicitly named files.

```yaml
# my-repo/west.yml:
manifest:
  projects:
    - name: zephyr
      url: https://github.com/zephyrproject-rtos/zephyr
      import: west.yml
  self:
    import:
      - submanifests/01-libraries.yml
      - submanifests/02-vendor-hals.yml
      - submanifests/03-applications.yml
```

Example 4.2: Import order illustration  This more complicated example shows the order that west imports manifest files:

```yaml
# my-repo/west.yml
manifest:
  # ...
  projects:
    - name: my-library
    - name: my-app
    - name: zephyr
      import: true
    - name: another-manifest-repo
      import: submanifests
  self:
    import:
      - submanifests/libraries.yml
      - submanifests/vendor-hals.yml
      - submanifests/applications.yml
  defaults:
    remote: my-remote
```

For this example, west resolves imports in this order:

1. the listed files in my-repo/submanifests are first, in the order they occur (e.g. libraries.yml comes before applications.yml, since this is a sequence of files), since the self: import: is always imported first
2. `my-repo/west.yml` is next (with projects `my-library` etc. as long as they weren’t already defined somewhere in submanifests)

3. `zephyr/west.yml` is after that, since that’s the first import key in the `projects` list in `my-repo/west.yml`

4. files in `another-manifest-repo/submanifests` are last (sorted by file name), since that’s the final project import

**Manifest Import Details**  This section describes how west resolves a manifest file that uses `import` a bit more formally.

**Overview** The `import` key can appear in a west manifest’s `projects` and `self` sections. The general case looks like this:

```yaml
# Top-level manifest file.
manifest:
  projects:
    - name: foo
      import:
        ... # import-1
    - name: bar
      import:
        ... # import-2
    # ...
    - name: baz
      import:
        ... # import-N
  self:
    import:
      ... # self-import
```

Import keys are optional. If any of `import-1`, ..., `import-N` are missing, west will not import additional manifest data from that project. If `self-import` is missing, no additional files in the manifest repository (beyond the top-level file) are imported.

The ultimate outcomes of resolving manifest imports are:

- a `projects` list, which is produced by combining the `projects` defined in the top-level file with those defined in imported files
- a set of extension commands, which are drawn from the `west-commands` keys in the top-level file and any imported files
- a `group-filter` list, which is produced by combining the top-level and any imported filters

Importing is done in this order:

1. Manifests from `self-import` are imported first.
2. The top-level manifest file’s definitions are handled next.
3. Manifests from `import-1, ..., import-N`, are imported in that order.

When an individual `import` key refers to multiple manifest files, they are processed in this order:

- If the value is a relative path naming a directory (or a map whose `file` is a directory), the manifest files it contains are processed in lexicographic order – i.e., sorted by file name.
- If the value is a sequence, its elements are recursively imported in the order they appear.

This process recurses if necessary. E.g., if `import-1` produces a manifest file that contains an `import` key, it is resolved recursively using the same rules before its contents are processed further.
The following sections describe these outcomes.

Projects This section describes how the final projects list is created.

Projects are identified by name. If the same name occurs in multiple manifests, the first definition is used, and subsequent definitions are ignored. For example, if import-1 contains a project named bar, that is ignored, because the top-level west.yml has already defined a project by that name.

The contents of files named by import-1 through import-N are imported from Git at the latest manifest-rev revisions in their projects. These revisions can be updated to the values rev-1 through rev-N by running west update. If any manifest-rev reference is missing or out of date, west update also fetches project data from the remote fetch URL and updates the reference.

Also note that all imported manifests, from the root manifest to the repository which defines a project P, must be up to date in order for west to update P itself. For example, this means west update P would update manifest-rev in the baz project if baz/west.yml defines P, as well as updating the manifest-rev branch in the local git clone of P. Confusingly, updating baz may result in the removal of P from baz/west.yml, which “should” cause west update P to fail with an unrecognized project!

For this reason, it’s not possible to run west update P if P is defined in an imported manifest; you must update this project along with all the others with a plain west update.

By default, west won’t fetch any project data over the network if a project’s revision is a SHA or tag which is already available locally, so updating the extra projects shouldn’t take too much time unless it’s really needed. See the documentation for the update.fetch configuration option for more information.

Extensions All extension commands defined using west-commands keys discovered while handling imports are available in the resolved manifest.

If an imported manifest file has a west-commands: definition in its self: section, the extension commands defined there are added to the set of available extensions at the time the manifest is imported. They will thus take precedence over any extension commands with the same names added later on.

Group filters The resolved manifest has a group-filter value which is the result of concatenating the group-filter values in the top-level manifest and any imported manifests.

Manifest files which appear earlier in the import order have higher precedence and are therefore concatenated later into the final group-filter.

In other words, let:

- the submanifest resolved from self-import have group filter self-filter
- the top-level manifest file have group filter top-filter
- the submanifests resolved from import-1 through import-N have group filters filter-1 through filter-N respectively

The final resolved group-filter value is then filterN + ... + filter-2 + filter-1 + top-filter + self-filter, where + here refers to list concatenation.

Important: The order that filters appear in the above list matters.

The last filter element in the final concatenated list “wins” and determines if the group is enabled or disabled.

For example, in [-foo] + [+foo], group foo is enabled. However, in [+foo] + [-foo], group foo is disabled.

For simplicity, west and this documentation may elide concatenated group filter elements which are redundant using these rules. For example, [+foo] + [-foo] could be written more simply as [-foo],
for the reasons given above. As another example, [-foo] + [+foo] could be written as the empty list [], since all groups are enabled by default.

**Manifest Command**

The `west manifest` command can be used to manipulate manifest files. It takes an action, and action-specific arguments.

The following sections describe each action and provides a basic signature for simple uses. Run `west manifest --help` for full details on all options.

**Resolving Manifests** The `--resolve` action outputs a single manifest file equivalent to your current manifest and all its imported manifests:

```bash
west manifest --resolve [-o outfile]
```

The main use for this action is to see the “final” manifest contents after performing any imports.

To print detailed information about each imported manifest file and how projects are handled during manifest resolution, set the maximum verbosity level using `-v`:

```bash
west -v manifest --resolve
```

**Freezing Manifests** The `--freeze` action outputs a frozen manifest:

```bash
west manifest --freeze [-o outfile]
```

A “frozen” manifest is a manifest file where every project's revision is a SHA. You can use `--freeze` to produce a frozen manifest that's equivalent to your current manifest file. The `-o` option specifies an output file; if not given, standard output is used.

**Validating Manifests** The `--validate` action either succeeds if the current manifest file is valid, or fails with an error:

```bash
west manifest --validate
```

The error message can help diagnose errors.

Here, “invalid” means that the syntax of the manifest file doesn't follow the rules documented on this page.

If your manifest is valid but it's not working the way you want it to, turning up the verbosity with `-v` is a good way to get detailed information about what decisions west made about your manifest, and why:

```bash
west -v manifest --validate
```

**Get the manifest path** The `--path` action prints the path to the top level manifest file:

```bash
west manifest --path
```

The output is something like `/path/to/workspace/west.yml`. The path format depends on your operating system.
2.11.8 Configuration

This page documents west's configuration file system, the `west config` command, and configuration options used by built-in commands. For API documentation on the `west.configuration` module, see `west-apis-configuration`.

West Configuration Files

West's configuration file syntax is INI-like; here is an example file:

```plaintext
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

Above, the `manifest` section has option `path` set to `zephyr`. Another way to say the same thing is that `manifest.path` is `zephyr` in this file.

There are three types of configuration file:

1. **System**: Settings in this file affect west's behavior for every user logged in to the computer. Its location depends on the platform:
   - Linux: `/etc/westconfig`
   - macOS: `/usr/local/etc/westconfig`
   - Windows: `%PROGRAMDATA%\west\config`

2. **Global** (per user): Settings in this file affect how west behaves when run by a particular user on the computer.
   - All platforms: the default is `.westconfig` in the user's home directory.
   - Linux note: if the environment variable `XDG_CONFIG_HOME` is set, then `$XDG_CONFIG_HOME/west/config` is used.
   - Windows note: the following environment variables are tested to find the home directory: `%HOME%`, then `%USERPROFILE%`, then a combination of `%HOMEDRIVE%` and `%HOMEPATH%`.

3. **Local**: Settings in this file affect west's behavior for the current west workspace. The file is `.west/config`, relative to the workspace's root directory.

A setting in a file which appears lower down on this list overrides an earlier setting. For example, if `color.ui` is `true` in the system's configuration file, but `false` in the workspace's, then the final value is `false`. Similarly, settings in the user configuration file override system settings, and so on.

`west config`

The built-in `config` command can be used to get and set configuration values. You can pass `west config` the options `--system`, `--global`, or `--local` to specify which configuration file to use. Only one of these can be used at a time. If none is given, then writes default to `--local`, and reads show the final value after applying overrides.

Some examples for common uses follow; run `west config -h` for detailed help, and see `Built-in Configuration Options` for more details on built-in options.

To set `manifest.path` to `some-other-manifest`:

```
w west config manifest.path some-other-manifest
```
Doing the above means that commands like `west update` will look for the west manifest inside the `some-other-manifest` directory (relative to the workspace root directory) instead of the directory given to `west init`, so be careful!

To read `zephyr.base`, the value which will be used as `ZEPHYR_BASE` if it is unset in the calling environment (also relative to the workspace root):

```
w west config zephyr.base
```

You can switch to another zephyr repository without changing `manifest.path` – and thus the behavior of commands like `west update` – using:

```
w west config zephyr.base some-other-zephyr
```

This can be useful if you use commands like `git worktree` to create your own zephyr directories, and want commands like `west build` to use them instead of the zephyr repository specified in the manifest. (You can go back to using the directory in the upstream manifest by running `west config zephyr.base zephyr`.)

To set `color.ui` to `false` in the global (user-wide) configuration file, so that west will no longer print colored output for that user when run in any workspace:

```
w west config --global color.ui false
```

To undo the above change:

```
w west config --global color.ui true
```

**Built-in Configuration Options**

The following table documents configuration options supported by west’s built-in commands. Configuration options supported by Zephyr’s extension commands are documented in the pages for those commands.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color.ui</td>
<td>Boolean. If true (the default), then west output is colorized when stdout is</td>
</tr>
<tr>
<td></td>
<td>a terminal.</td>
</tr>
<tr>
<td>commands.extend</td>
<td>Boolean, default true, disables Extensions if false</td>
</tr>
<tr>
<td>allow_extensions</td>
<td>String, default west.yml. Relative path from the manifest repository root</td>
</tr>
<tr>
<td></td>
<td>directory to the manifest file used by west init and other commands which</td>
</tr>
<tr>
<td></td>
<td>parse the manifest.</td>
</tr>
<tr>
<td>manifest.file</td>
<td>String, default west.yml. Relative path from the manifest repository root</td>
</tr>
<tr>
<td></td>
<td>directory to the manifest file used by west init and other commands which</td>
</tr>
<tr>
<td></td>
<td>parse the manifest.</td>
</tr>
<tr>
<td>manifest.group-filter</td>
<td>String, default empty. A comma-separated list of project groups to enable</td>
</tr>
<tr>
<td></td>
<td>and disable within the workspace. Prefix enabled groups with + and disabled</td>
</tr>
<tr>
<td></td>
<td>groups with -. For example, the value &quot;+foo,-bar&quot; enables group foo and</td>
</tr>
<tr>
<td></td>
<td>disables bar. See Project Groups.</td>
</tr>
<tr>
<td>manifest.path</td>
<td>String, relative path from the west workspace root directory to the</td>
</tr>
<tr>
<td></td>
<td>manifest repository used by west update and other commands which parse the</td>
</tr>
<tr>
<td></td>
<td>manifest. Set locally by west init.</td>
</tr>
<tr>
<td>manifest.project-filter</td>
<td>Comma-separated list of strings. The option's value is a</td>
</tr>
<tr>
<td></td>
<td>comma-separated list of regular expressions, each prefixed with + or -,</td>
</tr>
<tr>
<td></td>
<td>like this: +re1,-re2,-re3</td>
</tr>
<tr>
<td></td>
<td>Project names are matched against each regular expression (re1, re2, re3,</td>
</tr>
<tr>
<td></td>
<td>...) in the list, in order. If the entire project name matches the regular</td>
</tr>
<tr>
<td></td>
<td>expression, that element of the list either deactivates or activates the</td>
</tr>
<tr>
<td></td>
<td>project. The project is deactivated if the element begins with -. The</td>
</tr>
<tr>
<td></td>
<td>project is activated if the element begins with +. (Project names cannot</td>
</tr>
<tr>
<td></td>
<td>contain , if this option is used, so the regular expressions do not need</td>
</tr>
<tr>
<td></td>
<td>to contain a literal , character.)</td>
</tr>
<tr>
<td></td>
<td>If a project's name matches multiple regular expressions in the list, the</td>
</tr>
<tr>
<td></td>
<td>result from the last regular expression is used. For example, if manifest.</td>
</tr>
<tr>
<td></td>
<td>project-filter is:</td>
</tr>
<tr>
<td></td>
<td>-hal_.*,+hal_foo</td>
</tr>
<tr>
<td></td>
<td>Then a project named hal_bar is inactive, but a project named hal_foo is</td>
</tr>
<tr>
<td></td>
<td>active.</td>
</tr>
<tr>
<td></td>
<td>If a project is made inactive or active by a list element, the project is</td>
</tr>
<tr>
<td></td>
<td>active or not regardless of whether any or all of its groups are disabled.</td>
</tr>
<tr>
<td></td>
<td>(This is currently the only way to make a project that has no groups</td>
</tr>
<tr>
<td></td>
<td>inactive.) If a project does not match any regular expressions in the list,</td>
</tr>
<tr>
<td></td>
<td>it is active or inactive according to the usual rules related to its groups</td>
</tr>
<tr>
<td></td>
<td>(see Project Group Examples for examples in that case). Within an element of</td>
</tr>
<tr>
<td></td>
<td>a manifest.project-filter list, leading and trailing whitespace are ignored.</td>
</tr>
<tr>
<td></td>
<td>That means these example values are equivalent:</td>
</tr>
<tr>
<td></td>
<td>+foo,-bar</td>
</tr>
<tr>
<td></td>
<td>+foo , -bar</td>
</tr>
<tr>
<td></td>
<td>Any empty elements are ignored. That means these example values are</td>
</tr>
<tr>
<td></td>
<td>equivalent:</td>
</tr>
<tr>
<td></td>
<td>+foo,-bar</td>
</tr>
<tr>
<td></td>
<td>+foo,-bar</td>
</tr>
<tr>
<td>update.fetch</td>
<td>String, one of &quot;smart&quot; (the default behavior starting in v0.6.1) or &quot;always&quot;</td>
</tr>
<tr>
<td></td>
<td>(the previous behavior). If set to &quot;smart&quot;, the west update command will</td>
</tr>
<tr>
<td></td>
<td>skip fetching from project remotes when those projects' revisions in the</td>
</tr>
<tr>
<td></td>
<td>manifest file are SHAs or tags which are already available locally. The</td>
</tr>
<tr>
<td></td>
<td>&quot;always&quot; behavior is to unconditionally fetch from the remote.</td>
</tr>
<tr>
<td>update.name-cache</td>
<td>String. If non-empty, west update will use its value as the --name-cache</td>
</tr>
<tr>
<td></td>
<td>option's value if not given on the command line.</td>
</tr>
<tr>
<td>update.narrow</td>
<td>Boolean. If true, west update behaves as if --narrow was given on the</td>

<tr>
<td></td>
<td>command line. The default is false.</td>
</tr>
<tr>
<td>update.path-cache</td>
<td>String. If non-empty, west update will use its value as the --path-cache</td>
</tr>
<tr>
<td></td>
<td>option's value if not given on the command line.</td>
</tr>
<tr>
<td>update.sync-submodules</td>
<td>Boolean. If true (the default), west update will synchronize Git submodules</td>
</tr>
<tr>
<td></td>
<td>before updating them.</td>
</tr>
<tr>
<td>zephyr.base</td>
<td>String, default value to set for the ZEPHYR_BASE environment variable while</td>
</tr>
<tr>
<td></td>
<td>the west command is running.</td>
</tr>
<tr>
<td>zephyr.base-prefer</td>
<td>String, one the values &quot;env&quot; and &quot;configfile&quot;. If set to &quot;env&quot; (the default)</td>
</tr>
</tbody>
</table>
2.11.9 Extensions

West is “pluggable”: you can add your own commands to west without editing its source code. These are called west extension commands, or just “extensions” for short. Extensions show up in the west --help output in a special section for the project which defines them. This page provides general information on west extension commands, and has a tutorial for writing your own.

Some commands you can run when using west with Zephyr, like the ones used to build, flash, and debug and the ones described here, are extensions. That’s why help for them shows up like this in west --help:

<table>
<thead>
<tr>
<th>commands from project at &quot;zephyr&quot;:</th>
</tr>
</thead>
<tbody>
<tr>
<td>completion: display shell completion scripts</td>
</tr>
<tr>
<td>boards: display information about supported boards</td>
</tr>
<tr>
<td>build: compile a Zephyr application</td>
</tr>
<tr>
<td>sign: sign a Zephyr binary for bootloader chain-loading</td>
</tr>
<tr>
<td>flash: flash and run a binary on a board</td>
</tr>
<tr>
<td>debug: flash and interactively debug a Zephyr application</td>
</tr>
<tr>
<td>debugserver: connect to board and launch a debug server</td>
</tr>
<tr>
<td>attach: interactively debug a board</td>
</tr>
</tbody>
</table>

See zephyr/scripts/west-commands.yml and the zephyr/scripts/west_commands directory for the implementation details.

Disabling Extension Commands

To disable support for extension commands, set the commands.allow_extensions configuration option to false. To set this globally for whenever you run west, use:

```
west config --global commands.allow_extensions false
```

If you want to, you can then re-enable them in a particular west workspace with:

```
west config --local commands.allow_extensions true
```

Note that the files containing extension commands are not imported by west unless the commands are explicitly run. See below for details.

Adding a West Extension

There are three steps to adding your own extension:

1. Write the code implementing the command.
2. Add information about it to a west-commands.yml file.
3. Make sure the west-commands.yml file is referenced in the west manifest.

Note that west ignores extension commands whose names are the same as a built-in command.

Step 1: Implement Your Command

Create a Python file to contain your command implementation (see the “Meta > Requires” information on the west PyPI page for details on the currently supported versions of Python). You can put it in anywhere in any project tracked by your west manifest, or the manifest repository itself. This file must contain a subclass of the west.commands.WestCommand class; this class will be instantiated and used when your extension is run.

Here is a basic skeleton you can use to get started. It contains a subclass of WestCommand, with implementations for all the abstract methods. For more details on the west APIs you can use, see west-apis.
Basic example of a west extension.''

```python
from textwrap import dedent  # just for nicer code indentation
from west.commands import WestCommand  # your extension must subclass this
from west import log  # use this for user output

class MyCommand(WestCommand):

    def __init__(self):
        super().__init__(
            'my-command-name',  # gets stored as self.name
            'one-line help for what my-command-name does',  # self.help
            # self.description:
            dedent('A multi-line description of my-command.
You can split this up into multiple paragraphs and they'll get
reflowed for you. You can also pass
formatter_class=argparse.RawDescriptionHelpFormatter when calling
parser_adder.add_parser() below if you want to keep your line
endings."
)

    def do_add_parser(self, parser_adder):
        # This is a bit of boilerplate, which allows you full control over the
        # type of argparse handling you want. The "parser_adder" argument is
        # the return value of an argparse.ArgumentParser.add_subparsers() call.
        parser = parser_adder.add_parser(self.name,
                                       help=self.help,
                                       description=self.description)

        # Add some example options using the standard argparse module API.
        parser.add_argument('--optional', help='an optional argument')
        parser.add_argument('required', help='a required argument')

        return parser  # gets stored as self.parser

    def do_run(self, args, unknown_args):
        # This gets called when the user runs the command, e.g.:
        #
        # $ west my-command-name -o FOO BAR
        # --optional is FOO
        # required is BAR
        log.inf('--optional is', args.optional)
        log.inf('required is', args.required)
```

You can ignore the second argument to `do_run()` (unknown_args above), as `WestCommand` will reject
unknown arguments by default. If you want to be passed a list of unknown arguments instead, add
`accepts_unknown_args=True` to the `super().__init__()` arguments.

Step 2: Add or Update Your `west-commands.yml` You now need to add a `west-commands.yml` file to
your project which describes your extension to west.

Here is an example for the above class definition, assuming it's in `my_west_extension.py` at the project
root directory:
west-commands:
  - file: my_west_extension.py
    commands:
      - name: my-command-name
        class: MyCommand
        help: one-line help for what my-command-name does

The top level of this YAML file is a map with a west-commands key. The key's value is a sequence of "command descriptors". Each command descriptor gives the location of a file implementing west extensions, along with the names of those extensions, and optionally the names of the classes which define them (if not given, the class value defaults to the same thing as name).

Some information in this file is redundant with definitions in the Python code. This is because west won’t import my_west_extension.py until the user runs west my-command-name, since:

• It allows users to run west update with a manifest from an untrusted source, then use other west commands without your code being imported along the way. Since importing a Python module is shell-equivalent, this provides some peace of mind.

• It's a small optimization, since your code will only be imported if it is needed.

So, unless your command is explicitly run, west will just load the west-commands.yml file to get the basic information it needs to display information about your extension to the user in west --help output, etc.

If you have multiple extensions, or want to split your extensions across multiple files, your west-commands.yml will look something like this:

west-commands:
  - file: my_west_extension.py
    commands:
      - name: my-command-name
        class: MyCommand
        help: one-line help for what my-command-name does
  - file: another_file.py
    commands:
      - name: command2
        help: another cool west extension
      - name: a-third-command
        class: ThirdCommand
        help: a third command in the same file as command2

Above:

• my_west_extension.py defines extension my-command-name with class MyCommand

• another_file.py defines two extensions:
  1. command2 with class command2
  2. a-third-command with class ThirdCommand

See the file west-commands-schema.yml in the west repository for a schema describing the contents of a west-commands.yml.

Step 3: Update Your Manifest   Finally, you need to specify the location of the west-commands.yml you just edited in your west manifest. If your extension is in a project, add it like this:

manifest:
  # [... other contents ...]
  projects:

(continues on next page)
Where path/to/west-commands.yml is relative to the root of the project. Note that the name west-commands.yml, while encouraged, is just a convention; you can name the file something else if you need to.

Alternatively, if your extension is in the manifest repository, just do the same thing in the manifest’s self section, like this:

```yaml
manifest:
  # [...] other contents ...
  self:
    west-commands: path/to/west-commands.yml
```

That’s it; you can now run west my-command-name. Your command’s name, help, and the project which contains its code will now also show up in the west --help output. If you share the updated repositories with others, they’ll be able to use it, too.

## 2.11.10 Building, Flashing and Debugging

Zephyr provides several west extension commands for building, flashing, and interacting with Zephyr programs running on a board: build, flash, debug, debugserver and attach.

For information on adding board support for the flashing and debugging commands, see Flash and debug support in the board porting guide.

**Building:** west build

**Tip:** Run west build -h for a quick overview.

The build command helps you build Zephyr applications from source. You can use west config to configure its behavior.

Its default behavior tries to “do what you mean”:

- If there is a Zephyr build directory named build in your current working directory, it is incrementally re-compiled. The same is true if you run west build from a Zephyr build directory.
- Otherwise, if you run west build from a Zephyr application’s source directory and no build directory is found, a new one is created and the application is compiled in it.

**Basics** The easiest way to use west build is to go to an application’s root directory (i.e. the folder containing the application’s CMakeLists.txt) and then run:

```bash
west build -b <BOARD>
```

Where <BOARD> is the name of the board you want to build for. This is exactly the same name you would supply to CMake if you were to invoke it with: cmake -DBOARD=<BOARD>.

**Tip:** You can use the west boards command to list all supported boards.
A build directory named build will be created, and the application will be compiled there after west build runs CMake to create a build system in that directory. If west build finds an existing build directory, the application is incrementally re-compiled there without re-running CMake. You can force CMake to run again with --cmake.

You don't need to use the --board option if you've already got an existing build directory; west build can figure out the board from the CMake cache. For new builds, the --board option, BOARD environment variable, or build.board configuration option are checked (in that order).

**Sysbuild (multi-domain builds)** Sysbuild (System build) can be used to create a multi-domain build system combining multiple images for a single or multiple boards.

Use --sysbuild to select the Sysbuild (System build) build infrastructure with west build to build multiple domains.

More detailed information regarding the use of sysbuild can be found in the Sysbuild (System build) guide.

**Tip:** The build.sysbuild configuration option can be enabled to tell west build to default build using sysbuild. --no-sysbuild can be used to disable sysbuild for a specific build.

west build will build all domains through the top-level build folder of the domains specified by sysbuild. A single domain from a multi-domain project can be built by using --domain argument.

**Examples** Here are some west build usage examples, grouped by area.

**Forcing CMake to Run Again** To force a CMake re-run, use the --cmake (or -c) option:

```
west build -c
```

**Setting a Default Board** To configure west build to build for the reel_board by default:

```
west config build.board reel_board
```

(You can use any other board supported by Zephyr here; it doesn't have to be reel_board.)

**Setting Source and Build Directories** To set the application source directory explicitly, give its path as a positional argument:

```
west build -b <BOARD> path/to/source/directory
```

To set the build directory explicitly, use --build-dir (or -d):

```
west build -b <BOARD> --build-dir path/to/build/directory
```

To change the default build directory from build, use the build.dir-fmt configuration option. This lets you name build directories using format strings, like this:

```
west config build.dir-fmt "build/\{board\}/\{app\}"
```

With the above, running west build -b reel_board samples/hello_world will use build directory build/reel_board/hello_world. See Configuration Options for more details on this option.
Setting the Build System Target  To specify the build system target to run, use --target (or -t).

For example, on host platforms with QEMU, you can use the run target to build and run the hello_world sample for the emulated qemu_x86 board in one command:

```
west build -b qemu_x86 -t run samples/hello_world
```

As another example, to use -t to list all build system targets:

```
west build -t help
```

As a final example, to use -t to run the pristine target, which deletes all the files in the build directory:

```
west build -t pristine
```

Pristine Builds  A pristine build directory is essentially a new build directory. All byproducts from previous builds have been removed.

To force `west build` make the build directory pristine before re-running CMake to generate a build system, use the --pristine=always (or -p=always) option.

Giving --pristine or -p without a value has the same effect as giving it the value always. For example, these commands are equivalent:

```
west build -p -b reel_board samples/hello_world
west build -p=always -b reel_board samples/hello_world
```

By default, `west build` applies a heuristic to detect if the build directory needs to be made pristine. This is the same as using --pristine=auto.

**Tip:** You can run `west config build.pristine always` to always do a pristine build, or `west config build.pristine never` to disable the heuristic. See the `west build` Configuration Options for details.

Verbose Builds  To print the CMake and compiler commands run by `west build`, use the global `west` verbosity option, -v:

```
wst -v build -b reel_board samples/hello_world
```

One-Time CMake Arguments  To pass additional arguments to the CMake invocation performed by `west build`, pass them after a -- at the end of the command line.

**Important:** Passing additional CMake arguments like this forces `west build` to re-run the CMake build configuration step, even if a build system has already been generated. This will make incremental builds slower (but still much faster than building from scratch).

After using -- once to generate the build directory, use `west build -d <build-dir>` on subsequent runs to do incremental builds.

Alternatively, make your CMake arguments permanent as described in the next section; it will not slow down incremental builds.

For example, to use the Unix Makefiles CMake generator instead of Ninja (which `west build` uses by default), run:

```
west build -b reel_board -- -G'Unix Makefiles'
```
To use Unix Makefiles and set `CMAKE_VERBOS MAKEFILE` to ON:

```
west build -b reel_board -- -G 'Unix Makefiles' -DCMAKE_VERBOS MAKEFILE=ON
```

Notice how the `--` only appears once, even though multiple CMake arguments are given. All command-line arguments to `west build` after a `--` are passed to CMake.

To set `DTC_OVERLAY_FILE` to enable-modem.overlay, using that file as a devicetree overlay:

```
west build -b reel_board -- -DDTC_OVERLAY_FILE=enable-modem.overlay
```

To merge the `file.conf` Kconfig fragment into your build's `.config`:

```
w west build -- -DEXTRA_CONF_FILE=file.conf
```

### Permanent CMake Arguments

The previous section describes how to add CMake arguments for a single `west build` command. If you want to save CMake arguments for `west build` to use every time it generates a new build system instead, you should use the `build.cmake-args` configuration option. Whenever `west build` runs CMake to generate a build system, it splits this option's value according to shell rules and includes the results in the `cmake` command line.

Remember that, by default, `west build` **tries to avoid generating a new build system if one is present** in your build directory. Therefore, you need to either delete any existing build directories or do a pristine build after setting `build.cmake-args` to make sure it will take effect.

For example, to always enable `CMAKE_EXPORT_COMPILE_COMMANDS`, you can run:

```
w west config build.cmake-args -- -DCMAKE_EXPORT_COMPILE_COMMANDS=ON
```

(The extra `--` is used to force the rest of the command to be treated as a positional argument. Without it, `west config` would treat the `-DVAR=VAL` syntax as a use of its `-D` option.)

To enable `CMAKE_VERBOS MAKEFILE`, so CMake always produces a verbose build system:

```
w west config build.cmake-args -- -DCMAKE_VERBOS MAKEFILE=ON
```

To save more than one argument in `build.cmake-args`, use a single string whose value can be split into distinct arguments (`west build` uses the Python function `shlex.split()` internally to split the value).

For example, to enable both `CMAKE_EXPORT_COMPILE_COMMANDS` and `CMAKE_VERBOS MAKEFILE`:

```
w west config build.cmake-args -- "-DCMAKE_EXPORT_COMPILE_COMMANDS=ON -DCMAKE_VERBOS ...
```

If you want to save your CMake arguments in a separate file instead, you can combine CMake's `-C <initial-cache>` option with `build.cmake-args`. For instance, another way to set the options used in the previous example is to create a file named `~/my-cache.cmake` with the following contents:

```
set(CMAKE_EXPORT_COMPILE_COMMANDS ON CACHE BOOL "")
set(CMAKE_VERBOS MAKEFILE ON CACHE BOOL "")
```

Then run:

```
w west config build.cmake-args "-C ~/my-cache.cmake"
```

See the `cmake(1)` manual page and the `set()` command documentation for more details.

### Build tool arguments

Use `-o` to pass options to the underlying build tool.

This works with both `ninja` (**the default**) and `make` based build systems.

For example, to pass `-dexplain` to `ninja`:

```
2.11. West (Zephyr's meta-tool) 165
```
west build -o=-dexplain

As another example, to pass --keep-going to make:
west build -o=--keep-going

Note that using -o=--foo instead of -o --foo is required to prevent --foo from being treated as a west build option.

**Build parallelism**  By default, ninja uses all of your cores to build, while make uses only one. You can control this explicitly with the -j option supported by both tools.

For example, to build with 4 cores:
west build -o=-j4

The -o option is described further in the previous section.

**Build a single domain**  In a multi-domain build with hello_world and MCUboot, you can use --domain hello_world to only build this domain:
west build --sysbuild --domain hello_world

The --domain argument can be combined with the --target argument to build the specific target for the target, for example:
west build --sysbuild --domain hello_world --target help

**Use a snippet**  See Using Snippets.

**Configuration Options**  You can configure west build using these options.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>build.board</td>
<td>String. If given, this the board used by <code>west build</code> when <code>--board</code> is not given and BOARD is unset in the environment.</td>
</tr>
<tr>
<td>build.board_warn</td>
<td>Boolean, default true. If false, disables warnings when <code>west build</code> can’t figure out the target board.</td>
</tr>
<tr>
<td>build.cmake-args</td>
<td>String. If present, the value will be split according to shell rules and passed to CMake whenever a new build system is generated. See Permanent CMake Arguments.</td>
</tr>
<tr>
<td>build.dir-fmt</td>
<td>String, default build. The build folder format string, used by west whenever it needs to create or locate a build folder. The currently available arguments are:</td>
</tr>
</tbody>
</table>
|                   |   • board: The board name
|                   |   • source_dir: The relative path from the current working directory to the source directory. If the current working directory is inside the source directory this will be set to an empty string.
|                   |   • app: The name of the source directory.                                                                                                   |
| build.generator   | String, default Ninja. The CMake Generator to use to create a build system. (To set a generator for a single build, see the above example)   |
| build.guess-dir   | String, instructs west whether to try to guess what build folder to use when `build.dir-fmt` is in use and not enough information is available to resolve the build folder name. Can take these values: |
|                   |   • never (default): Never try to guess, bail out instead and require the user to provide a build folder with `-d`.                        |
|                   |   • runners: Try to guess the folder when using any of the ‘runner’ commands. These are typically all commands that invoke an external tool, such as flash and debug. |
| build.pristine    | String. Controls the way in which `west build` may clean the build folder before building. Can take the following values:                   |
|                   |   • never (default): Never automatically make the build folder pristine.                                                                      |
|                   |   • auto: `west build` will automatically make the build folder pristine before building, if a build system is present and the build would fail otherwise (e.g. the user has specified a different board or application from the one previously used to make the build directory). |
|                   |   • always: Always make the build folder pristine before building, if a build system is present.                                             |
| build.sysbuild    | Boolean, default false. If true, build application using the sysbuild infrastructure.                                                      |

**Flashing:** `west flash`

**Tip:** Run `west flash -h` for additional help.

**Basics**  From a Zephyr build directory, re-build the binary and flash it to your board:

```
w west flash
```

Without options, the behavior is the same as `ninja flash` (or `make flash`, etc.).

To specify the build directory, use `--build-dir` (or `-d`):
west flash --build-dir path/to/build/directory

If you don’t specify the build directory, west flash searches for one in build, then the current working directory. If you set the build-dir-fmt configuration option (see Setting Source and Build Directories), west flash searches there instead of build.

Choosing a Runner If your board’s Zephyr integration supports flashing with multiple programs, you can specify which one to use using the --runner (or -r) option. For example, if West flashes your board with nrfjprog by default, but it also supports JLink, you can override the default with:

west flash --runner jlink

You can override the default flash runner at build time by using the BOARD_FLASH_RUNNER CMake variable, and the debug runner with BOARD_DEBUG_RUNNER.

For example:

```
# Set the default runner to "jlink", overriding the board's # usual default.
west build [...] -- -DBOARD_FLASH_RUNNER=jlink
```

See One-Time CMake Arguments and Permanent CMake Arguments for more information on setting CMake arguments.

See Flash and debug runners below for more information on the runner library used by West. The list of runners which support flashing can be obtained with west flash -H; if run from a build directory or with --build-dir, this will print additional information on available runners for your board.

Configuration Overrides The CMake cache contains default values West uses while flashing, such as where the board directory is on the file system, the path to the zephyr binaries to flash in several formats, and more. You can override any of this configuration at runtime with additional options.

For example, to override the HEX file containing the Zephyr image to flash (assuming your runner expects a HEX file), but keep other flash configuration at default values:

```
west flash --hex-file path/to/some/other.hex
```

The west flash -h output includes a complete list of overrides supported by all runners.

Runner-Specific Overrides Each runner may support additional options related to flashing. For example, some runners support an --erase flag, which mass-erases the flash storage on your board before flashing the Zephyr image.

To view all of the available options for the runners your board supports, as well as their usage information, use --context (or -H):

```
wes  ```

```
```

Important: Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, west flash -H just prints a list of runners. You can use west flash -H -r <runner-name> to print usage information for options supported by that runner.

For example, to print usage information about the jlink runner:

```
```

168 Chapter 2. Developing with Zephyr
Multi-domain flashing  When a *Sysbuild (multi-domain builds)* folder is detected, then *west flash* will flash all domains in the order defined by sysbuild.

It is possible to flash the image from a single domain in a multi-domain project by using *--domain*.

For example, in a multi-domain build with `hello_world` and *MCUboot*, you can use the *--domain* `hello_world` domain to only flash only the image from this domain:

```
west flash --domain hello_world
```

**Debugging:** *west debug, west debugserver*

**Tip:** Run *west debug -h* or *west debugserver -h* for additional help.

**Basics**  From a Zephyr build directory, to attach a debugger to your board and open up a debug console (e.g. a GDB session):

```
w west debug
```

To attach a debugger to your board and open up a local network port you can connect a debugger to (e.g. an IDE debugger):

```
w west debugserver
```

Without options, the behavior is the same as *ninja debug* and *ninja debugserver* (or *make debug*, etc.).

To specify the build directory, use *--build-dir* (or *-d*):

```
w west debug --build-dir path/to/build/directory
west debugserver --build-dir path/to/build/directory
```

If you don't specify the build directory, these commands search for one in *build*, then the current working directory. If you set the *build.dir-fmt* configuration option (see *Setting Source and Build Directories*), *west debug* searches there instead of *build*.

**Choosing a Runner**  If your board's Zephyr integration supports debugging with multiple programs, you can specify which one to use using the *--runner* (or *-r*) option. For example, if West debugs your board with *pyocd-gdbserver* by default, but it also supports JLInk, you can override the default with:

```
w west debug --runner jlink
west debugserver --runner jlink
```

See *Flash and debug runners* below for more information on the *runner* library used by West. The list of runners which support debugging can be obtained with *west debug -H*; if run from a build directory or with *--build-dir*, this will print additional information on available runners for your board.

**Configuration Overrides**  The CMake cache contains default values West uses for debugging, such as where the board directory is on the file system, the path to the zephyr binaries containing symbol tables, and more. You can override any of this configuration at runtime with additional options.
For example, to override the ELF file containing the Zephyr binary and symbol tables (assuming your runner expects an ELF file), but keep other debug configuration at default values:

```plaintext
west debug --elf-file path/to/some/other.elf
west debugserver --elf-file path/to/some/other.elf
```

The `west debug -h` output includes a complete list of overrides supported by all runners.

**Runner-Specific Overrides** Each runner may support additional options related to debugging. For example, some runners support flags which allow you to set the network ports used by debug servers.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):

```plaintext
west debug --context
```

(The command `west debugserver --context` will print the same output.)

**Important:** Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, `west debug -H` just prints a list of runners. You can use `west debug -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the jlink runner:

```plaintext
west debug -H -r jlink
```

**Multi-domain debugging** `west debug` can only debug a single domain at a time. When a `Sysbuild (multi-domain builds)` folder is detected, `west debug` will debug the default domain specified by sysbuild.

The default domain will be the application given as the source directory. See the following example:

```plaintext
west build --sysbuild path/to/source/directory
```

For example, when building `hello_world` with `MCUboot` using sysbuild, `hello_world` becomes the default domain:

```plaintext
west build --sysbuild samples/hello_world
```

So to debug `hello_world` you can do:

```plaintext
west debug
```

or:

```plaintext
west debug --domain hello_world
```

If you wish to debug MCUboot, you must explicitly specify MCUboot as the domain to debug:

```plaintext
west debug --domain mcuboot
```

**Flash and debug runners**

The flash and debug commands use Python wrappers around various `Flash & Debug Host Tools`. These wrappers are all defined in a Python library at `scripts/west_commands/runners`. Each wrapper is called a runner. Runners can flash and/or debug Zephyr programs.
The central abstraction within this library is \texttt{ZephyrBinaryRunner}, an abstract class which represents runners. The set of available runners is determined by the imported subclasses of \texttt{ZephyrBinaryRunner}. \texttt{ZephyrBinaryRunner} is available in the \texttt{runners.core} module; individual runner implementations are in other submodules, such as \texttt{runners.nrfjprog}, \texttt{runners.openocd}, etc.

\section*{Hacking}

This section documents the \texttt{runners.core} module used by the flash and debug commands. This is the core abstraction used to implement support for these features.

\textbf{Warning:} These APIs are provided for reference, but they are more “shared code” used to implement multiple extension commands than a stable API.

Developers can add support for new ways to flash and debug Zephyr programs by implementing additional runners. To get this support into upstream Zephyr, the runner should be added into a new or existing \texttt{runners} module, and imported from \texttt{runners/__init__.py}.

\textbf{Note:} The test cases in \texttt{scripts/west\_commands/tests} add unit test coverage for the runners package and individual runner classes.

Please try to add tests when adding new runners. Note that if your changes break existing test cases, CI testing on upstream pull requests will fail.

\section*{Zephyr binary runner core interfaces}

This provides the core \texttt{ZephyrBinaryRunner} class meant for public use, as well as some other helpers for concrete runner classes.

\begin{Verbatim}
\texttt{class runners.core.BuildConfiguration(build\_dir: str)}
\end{Verbatim}

This helper class provides access to build-time configuration.

Configuration options can be read as if the object were a dict, either object[‘CONFIG\_FOO’] or object.get(‘CONFIG\_FOO’).

\begin{Verbatim}
\texttt{Kconfig configuration values are available (parsed from .config).}
\end{Verbatim}

\begin{Verbatim}
\texttt{getboolean(option)}
\end{Verbatim}

If a boolean option is explicitly set to \texttt{y} or \texttt{n}, returns its value. Otherwise, falls back to \texttt{False}.

\begin{Verbatim}
\texttt{class runners.core.DeprecatedAction(option\_strings, dest, nargs=\textit{None}, const=\textit{None}, default=\textit{None}, type=\textit{None}, choices=\textit{None}, required=\textit{False}, help=\textit{None}, metavar=\textit{None})}
\end{Verbatim}

\begin{Verbatim}
\texttt{class runners.core.FileType(value, names=\textit{None}, *, module=\textit{None}, qualname=\textit{None}, type=\textit{None}, start=1, boundary=\textit{None})}
\end{Verbatim}

\begin{Verbatim}
\texttt{exception runners.core.MissingProgram(program)}
\end{Verbatim}

FileNotFoundError subclass for missing program dependencies.

No significant changes from the parent \texttt{FileNotFoundError}; this is useful for explicitly signaling that the file in question is a program that some class requires to proceed.

The filename attribute contains the missing program.

\begin{Verbatim}
\texttt{class runners.core.NetworkPortHelper}
\end{Verbatim}

Helper class for dealing with local IP network ports.
get_unused_ports(starting_from)

Find unused network ports, starting at given values.

starting_from is an iterable of ports the caller would like to use.

The return value is an iterable of ports, in the same order, using the given values if they were
unused, or the next sequentially available unused port otherwise.

Ports may be bound between this call's check and actual usage, so callers still need to handle
errors involving returned ports.

class runners.core.RunnerCaps(commands: ~typing.Set[str] = <factory>, dev_id: bool = False,
 flash_addr: bool = False, erase: bool = False, reset: bool = False,
 tool_opt: bool = False, file: bool = False)

This class represents a runner class's capabilities.

Each capability is represented as an attribute with the same name. Flag attributes are True or False.

Available capabilities:

• commands: set of supported commands; default is {'flash', 'debug', 'debugserver', 'attach'}.

• dev_id: whether the runner supports device identifiers, in the form of an -i, --dev-id option.
  This is useful when the user has multiple debuggers connected to a single computer, in order
  to select which one will be used with the command provided.

• flash_addr: whether the runner supports flashing to an arbitrary address. Default is False. If
  true, the runner must honor the --dt-flash option.

• erase: whether the runner supports an --erase option, which does a mass-erase of the entire
  addressable flash on the target before flashing. On multi-core SoCs, this may only erase
  portions of flash specific the actual target core. (This option can be useful for things like
  clearing out old settings values or other subsystem state that may affect the behavior of the
  zephyr image. It is also sometimes needed by SoCs which have flash-like areas that can’t be
  sector erased by the underlying tool before flashing; UICR on nRF SoCs is one example.)

• reset: whether the runner supports a --reset option, which resets the device after a flash
  operation is complete.

• tool_opt: whether the runner supports a --tool-opt (-O) option, which can be given multiple
  times and is passed on to the underlying tool that the runner wraps.

• file: whether the runner supports a --file option, which specifies exactly the file that should be
  used to flash, overriding any default discovered in the build directory.

class runners.core.RunnerConfig(build_dir: str, board_dir: str, elf_file: str | None, hex_file: str |
 None, bin_file: str | None, uf2_file: str | None, file_type: FileType | None = FileType.OTHER, gdb: str | None =
 None, openocd: str | None = None, openocd_search: List[str] = [])

Runner execution-time configuration.

This is a common object shared by all runners. Individual runners can register specific configuration
options using their do_add_parser() hooks.

uf2_file: str | None
   Alias for field number 5

class runners.core.ZephyrBinaryRunner(cfg: RunnerConfig)
   Abstract superclass for binary runners (flashers, debuggers).

   Note: this class's API has changed relatively rarely since it as added, but it is not considered a stable Zephyr API, and may change without notice.

With some exceptions, boards supported by Zephyr must provide generic means to be flashed (have a Zephyr firmware binary permanently installed on the device for running) and debugged (have a breakpoint debugger and program loader on a host workstation attached to a running target).

This is supported by four top-level commands managed by the Zephyr build system:

   • ‘flash’: flash a previously configured binary to the board, start execution on the target, then return.
   • ‘debug’: connect to the board via a debugging protocol, program the flash, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits.
   • ‘debugserver’: connect via a board-specific debugging protocol, then reset and halt the target. Ensure the user is now able to connect to a debug server with symbol tables loaded from the binary.
   • ‘attach’: connect to the board via a debugging protocol, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits. Unlike ‘debug’, this command does not program the flash.

This class provides an API for these commands. Every subclass is called a ‘runner’ for short. Each runner has a name (like ‘pyocd’), and declares commands it can handle (like ‘flash’). Boards (like ‘nrf52dk nrf52832’) declare which runner(s) are compatible with them to the Zephyr build system, along with information on how to configure the runner to work with the board.

The build system will then place enough information in the build directory to create and use runners with this class’s create() method, which provides a command line argument parsing API. You can also create runners by instantiating subclasses directly.

In order to define your own runner, you need to:

   1. Define a ZephyrBinaryRunner subclass, and implement its abstract methods. You may need to override capabilities().
   2. Make sure the Python module defining your runner class is imported, e.g. by editing this package's __init__.py (otherwise, get_runners() won't work).
   3. Give your runner's name to the Zephyr build system in your board's board.cmake.
Additional advice:

- If you need to import any non-standard-library modules, make sure to catch ImportError and defer complaints about it to a RuntimeError if one is missing. This avoids affecting users that don’t require your runner, while still making it clear what went wrong to users that do require it that don’t have the necessary modules installed.

- If you need to ask the user something (e.g. using input()), do it in your create() classmethod, not do_run(). That ensures your __init__() really has everything it needs to call do_run(), and also avoids calling input() when not instantiating within a command line application.

- Use self.logger to log messages using the standard library’s logging API; your logger is named “runner.<your-runner-name()>”

For command-line invocation from the Zephyr build system, runners define their own argparse-based interface through the common add_parser() (and runner-specific do_add_parser() it delegates to), and provide a way to create instances of themselves from a RunnerConfig and parsed runner-specific arguments via create().

Runners use a variety of host tools and configuration values, the user interface to which is abstracted by this class. Each runner subclass should take any values it needs to execute one of these commands in its constructor. The actual command execution is handled in the run() method.

```python
classmethod add_parser(parser)
    Adds a sub-command parser for this runner.

    The given object, parser, is a sub-command parser from the argparse module. For more details, refer to the documentation for argparse.ArgumentParser.add_subparsers().

    The lone common optional argument is:
    • –dt-flash (if the runner capabilities includes flash_addr)

    Runner-specific options are added through the do_add_parser() hook.
```

```python
property build_conf: BuildConfiguration
    Get a BuildConfiguration for the build directory.
```

```python
call(cmd: List[str], **kwargs) → int
    Subclass subprocess.call() wrapper.

    Subclasses should use this method to run command in a subprocess and get its return code, rather than using subprocess directly, to keep accurate debug logs.
```

```python
classmethod capabilities() → RunnerCaps
    Returns a RunnerCaps representing this runner’s capabilities.

    This implementation returns the default capabilities.

    Subclasses should override appropriately if needed.
```

```python
cfg
    RunnerConfig for this instance.
```

```python
check_call(cmd: List[str], **kwargs)
    Subclass subprocess.check_call() wrapper.

    Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.
```

```python
check_output(cmd: List[str], **kwargs) → bytes
    Subclass subprocess.check_output() wrapper.

    Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.
```
classmethod create(cfg: RunnerConfig, args: Namespace) → ZephyrBinaryRunner

Create an instance from command-line arguments.

- cfg: runner configuration (pass to superclass __init__)
- args: arguments parsed from execution environment, as specified by add_parser().

classmethod dev_id_help() → str

Get the ArgParse help text for the --dev-id option.

abstract classmethod do_add_parser(parser)

Hook for adding runner-specific options.

abstract classmethod do_create(cfg: RunnerConfig, args: Namespace) → ZephyrBinaryRunner

Hook for instance creation from command line arguments.

abstract do_run(command: str, **kwargs)

Concrete runner; run() delegates to this. Implement in subclasses.

In case of an unsupported command, raise a ValueError.

ensure_output(output_type: str) → None

Ensure self.cfg has a particular output artifact.

For example, ensure_output('bin') ensures that self.cfg.bin_file refers to an existing file. Errors out if it's missing or undefined.

Parameters

output_type -- string naming the output type

static flash_address_from_build_conf(build_conf: BuildConfiguration)

If CONFIG_HAS_FLASH_LOAD_OFFSET is n in build_conf, return the CONFIG_FLASH_BASE_ADDRESS value. Otherwise, return CONFIG_FLASH_BASE_ADDRESS + CONFIG_FLASH_LOAD_OFFSET.

static get_flash_address(args: Namespace, build_conf: BuildConfiguration, default: int = 0) → int

Helper method for extracting a flash address.

If args.dt_flash is true, returns the address obtained from ZephyrBinaryRunner.flash_address_from_build_conf(build_conf).

Otherwise (when args.dt_flash is False), the default value is returned.

static get_runners() → List[Type[ZephyrBinaryRunner]]

Get a list of all currently defined runner classes.

logger

logging.Logger for this instance.

abstract classmethod name() → str

Return this runner's user-visible name.

When choosing a name, pick something short and lowercase, based on the name of the tool (like openocd, jlink, etc.) or the target architecture/board (like xtensa etc.).

popen_ignore_int(cmd: List[str], **kwargs) → Popen

Spawn a child command, ensuring it ignores SIGINT.

The returned subprocess.Popen object must be manually terminated.

static require(program: str) → str

Require that a program is installed before proceeding.

Parameters

program -- name of the program that is required, or path to a program binary.
If `program` is an absolute path to an existing program binary, this call succeeds. Otherwise, try to find the program by name on the system PATH.

If the program can be found, its path is returned. Otherwise, raises MissingProgram.

```python
run(command: str, **kwargs)
```

Runs command (`flash`, `debug`, `debugserver`, `attach`).

This is the main entry point to this runner.

```python
run_client(client)
```

Run a client that handles SIGINT.

```python
run_server_and_client(server, client)
```

Run a server that ignores SIGINT, and a client that handles it.

This routine portably:

- creates a Popen object for the `server` command which ignores SIGINT
- runs `client` in a subprocess while temporarily ignoring SIGINT
- cleans up the server after the client exits.

It’s useful to e.g. open a GDB server and client.

```python
property thread_info_enabled: bool
```

Returns True if self.build_conf has `CONFIG_DEBUG_THREAD_INFO` enabled.

```python
classmethod tool_opt_help() → str
```

Get the ArgParse help text for the `-tool-opt` option.

### Doing It By Hand

If you prefer not to use West to flash or debug your board, simply inspect the build directory for the binaries output by the build system. These will be named something like `zephyr/zephyr.elf`, `zephyr/zephyr.hex`, etc., depending on your board’s build system integration. These binaries may be flashed to a board using alternative tools of your choice, or used for debugging as needed, e.g. as a source of symbol tables.

By default, these West commands rebuild binaries before flashing and debugging. This can of course also be accomplished using the usual targets provided by Zephyr’s build system (in fact, that’s how these commands do it).

### 2.11.11 Signing Binaries

The `west sign` extension command can be used to sign a Zephyr application binary for consumption by a bootloader using an external tool. In some configurations, `west sign` is also used to invoke an external, post-processing tool that “stitches” the final components of the image together. Run `west sign -h` for command line help.

#### MCUboot / imgtool

The Zephyr build system has special support for signing binaries for use with the MCUboot bootloader using the `imgtool` program provided by its developers. You can both build and sign this type of application binary in one step by setting some Kconfig options. If you do, `west flash` will use the signed binaries.

If you use this feature, you don’t need to run `west sign` yourself; the build system will do it for you.

Here is an example workflow, which builds and flashes MCUboot, as well as the hello_world application for chain-loading by MCUboot. Run these commands from the `zephyrproject` workspace you created in the Getting Started Guide.
west build -b YOUR_BOARD bootloader/mcuboot/boot/zephyr -d build-mcuboot
west build -b YOUR_BOARD zephyr/samples/hello_world -d build-hello-signed  -- \   
   -DCONFIG_BOOTLOADER_MCUBOOT=y \   
   -DCONFIG_MCUBOOT_SIGNATURE_KEY_FILE="bootloader/mcuboot/root-rsa-2048.pem" 

west flash -d build-mcuboot
west flash -d build-hello-signed

Notes on the above commands:

- YOUR_BOARD should be changed to match your board
- The CONFIG_MCUBOOT_SIGNATURE_KEY_FILE value is the insecure default provided and used by MCUboot for development and testing
- You can change the hello_world application directory to any other application that can be loaded by MCUboot, such as the smp-svr sample.

For more information on these and other related configuration options, see:

- CONFIG_BOOTLOADER_MCUBOOT: build the application for loading by MCUboot
- CONFIG_MCUBOOT_SIGNATURE_KEY_FILE: the key file to use with west sign. If you have your own key, change this appropriately
- CONFIG_MCUBOOT_EXTRA_IMGTOOL_ARGS: optional additional command line arguments for imgtool
- CONFIG_MCUBOOT_GENERATE_CONFIRMED_IMAGE: also generate a confirmed image, which may be more useful for flashing in production environments than the OTA-able default image
- On Windows, if you get “Access denied” issues, the recommended fix is to run pip3 install imgtool, then retry with a pristine build directory.

If your west flash runner uses an image format supported by imgtool, you should see something like this on your device's serial console when you run west flash -d build-mcuboot:

*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1 ***
[00:00:00.004,669] <inf> mcuboot: Starting bootloader
[00:00:00.011,169] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1, copy_done=0x3, image_ok=0x3
[00:00:00.021,636] <inf> mcuboot: Boot source: none
[00:00:00.027,313] <wrn> mcuboot: Failed reading image headers; Image=0
[00:00:00.035,064] <err> mcuboot: Unable to find bootable image

Then, you should see something like this when you run west flash -d build-hello-signed:

*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1 ***
[00:00:00.004,669] <inf> mcuboot: Starting bootloader
[00:00:00.011,169] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1, copy_done=0x3, image_ok=0x3
[00:00:00.021,636] <inf> mcuboot: Boot source: none
[00:00:00.027,374] <inf> mcuboot: Swap type: none
[00:00:00.115,142] <inf> mcuboot: Bootloader chainload address offset: 0xc000
[00:00:00.123,168] <inf> mcuboot: Jumping to the first image slot
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1 ***
Hello World! nrf52840dk_nrf52840

Whether west flash supports this feature depends on your runner. The nrfjprog and pyocd runners work with the above flow. If your runner does not support this flow and you would like it to, please send a patch or file an issue for adding support.
Extending signing externally

The signing script used when running `west flash` can be extended or replaced to change features or introduce different signing mechanisms. By default with MCUboot enabled, signing is setup by the `cmake/mcuboot.cmake` file in Zephyr which adds extra post build commands for generating the signed images. The file used for signing can be replaced by adjusting the `SIGNING_SCRIPT` property on the `zephyr_property_target`, ideally done by a module using:

```cmake
if(CONFIG_BOOTLOADER_MCUBOOT)
  set_target_properties(zephyr_property_target PROPERTIES SIGNING_SCRIPT
                        ${CMAKE_CURRENT_LIST_DIR}/custom_signing.cmake)
endif()
```

This will include the custom signing CMake file instead of the default Zephyr one when projects are built with MCUboot signing support enabled. The base Zephyr MCUboot signing file can be used as a reference for creating a new signing system or extending the default behaviour.

rimage

rimage configuration uses a different approach that does not rely on Kconfig or CMake but on `west config` instead, similar to Permanent CMake Arguments.

Signing involves a number of “wrapper” scripts stacked on top of each other: `west flash` invokes `west build` which invokes `cmake` and `ninja` which invokes `west sign` which invokes `imgtool` or `rimage`. As long as the signing parameters desired are the default ones and fairly static, these indirections are not a problem. On the other hand, passing `imgtool` or `rimage` options through all these layers can causes issues typical when the layers don't abstract anything. First, this usually requires boilerplate code in each layer. Quoting whitespace or other special characters through all the wrappers can be difficult. Reproducing a lower `west sign` command to debug some build-time issue can be very time-consuming: it requires at least enabling and searching verbose build logs to find which exact options were used. Copying these options from the build logs can be unreliable: it may produce different results because of subtle environment differences. Last and worst: new signing feature and options are impossible to use until more boilerplate code has been added in each layer.

To avoid these issues, rimage parameters can be set in `west config` instead. Here's a `workspace/.west/config` example:

```
[sign]
# Not needed when invoked from CMake
tool = rimage

[rimage]
# Quoting is optional and works like in Unix shells
# Not needed when rimage can be found in the default PATH
path = "~/home/me/zworkspace/build-rimage/rimage"

# Not needed when using the default development key
extra-args = -i 4 -k 'keys/key argument with space.pem'
```

In order to support quoting, values are parsed by Python's `shlex.split()` like in One-Time CMake Arguments.

The `extra-args` are passed directly to the `rimage` command. The example above has the same effect as appending them on command line after `--` like this: `west sign --tool rimage -- -i 4 -k 'keys/key argument with space.pem'`. In case both are used, the command-line arguments go last.
2.11.12 Additional Zephyr extension commands

This page documents miscellaneous Zephyr Extensions.

Listing boards: west boards

The `boards` command can be used to list the boards that are supported by Zephyr without having to resort to additional sources of information.

It can be run by typing:

```
wester boards
```

This command lists all supported boards in a default format. If you prefer to specify the display format yourself you can use the `--format` (or `-f`) flag:

```
wester boards -f "\{arch\}:\{name\}"
```

Additional help about the formatting options can be found by running:

```
wester boards -h
```

Shell completion scripts: west completion

The `completion` extension command outputs shell completion scripts that can then be used directly to enable shell completion for the supported shells.

It currently supports the following shells:

- bash
- zsh

Additional instructions are available in the command’s help:

```
wester help completion
```

Installing CMake packages: west zephyr-export

This command registers the current Zephyr installation as a CMake config package in the CMake user package registry.

In Windows, the CMake user package registry is found in `HKEY_CURRENT_USER\Software\Kitware\CMake\Packages`.

In Linux and MacOS, the CMake user package registry is found in `~/.cmake/packages`.

You may run this command when setting up a Zephyr workspace. If you do, application CMakeLists.txt files that are outside of your workspace will be able to find the Zephyr repository with the following:

```
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

See `share/zephyr-package/cmake` for details.
**Software bill of materials**: `west spdx`

This command generates SPDX 2.2 tag-value documents, creating relationships from source files to the corresponding generated build files. **SPDX-License-Identifier** comments in source files are scanned and filled into the SPDX documents.

To use this command:

1. Pre-populate a build directory `BUILD_DIR` like this:
   ```
   west spdx --init -d BUILD_DIR
   ```
   This step ensures the build directory contains CMake metadata required for SPDX document generation.

2. Build your application using this pre-created build directory, like so:
   ```
   west build -d BUILD_DIR [...]
   ```

3. Generate SPDX documents using this build directory:
   ```
   west spdx -d BUILD_DIR
   ```

This generates the following SPDX bill-of-materials (BOM) documents in `BUILD_DIR/spdx/`:

- `app.spdx`: BOM for the application source files used for the build
- `zephyr.spdx`: BOM for the specific Zephyr source code files used for the build
- `build.spdx`: BOM for the built output files

Each file in the bill-of-materials is scanned, so that its hashes (SHA256 and SHA1) can be recorded, along with any detected licenses if an **SPDX-License-Identifier** comment appears in the file.

SPDX Relationships are created to indicate dependencies between CMake build targets, build targets that are linked together, and source files that are compiled to generate the built library files.

`west spdx` accepts these additional options:

- `-n PREFIX`: a prefix for the Document Namespaces that will be included in the generated SPDX documents. See SPDX specification clause 6 for details. If `-n` is omitted, a default namespace will be generated according to the default format described in section 2.5 using a random UUID.
- `-s SPDX_DIR`: specifies an alternate directory where the SPDX documents should be written instead of `BUILD_DIR/spdx/`.
- `--analyze-includes`: in addition to recording the compiled source code files (e.g. `.c`, `.S`) in the bills-of-materials, also attempt to determine the specific header files that are included for each `.c` file.
  This takes longer, as it performs a dry run using the C compiler for each `.c` file using the same arguments that were passed to it for the actual build.
- `--include-sdk`: with `--analyze-includes`, also create a fourth SPDX document, `sdk.spdx`, which lists header files included from the SDK.

**Working with binary blobs**: `west blobs`

The `blobs` command allows users to interact with **binary blobs** declared in one or more `modules` via their `module.yml` file.

The `blobs` command has three sub-commands, used to list, fetch or clean (i.e. delete) the binary blobs themselves.

You can list binary blobs while specifying the format of the output:
west blobs list -f '{module}: {type} {path}'

For the full set of variables available in -f/--format run west blobs -h.

Fetching blobs works in a similar manner:
west blobs fetch

Note that, as described in the modules section, fetched blobs are stored in a zephyr/lobs/ folder relative to the root of the corresponding module repository.

As does deleting them:
west blobs clean

Additionally the tool allows you to specify the modules you want to list, fetch or clean blobs for by typing the module names as a command-line parameter.

**Twister wrapper:** west twister

This command is a wrapper for twister.

Twister can then be invoked via west as follows:

```
west twister -help
west twister -T tests/ztest/base
```

**Working with binary descriptors:** west bindesc

The bindesc command allows users to read binary descriptors of executable files. It currently supports .bin, .hex, .elf and .uf2 files as input.

You can search for a specific descriptor in an image, for example:

```
west bindesc search KERNEL_VERSION_STRING build/zephyr/zephyr.bin
```

You can search for a custom descriptor by type and ID, for example:

```
west bindesc custom_search STR 0x200 build/zephyr/zephyr.bin
```

You can dump all of the descriptors in an image using:

```
west bindesc dump build/zephyr/zephyr.bin
```

You can list all known standard descriptor names using:

```
west bindesc list
```

### 2.11.13 History and Motivation

West was added to the Zephyr project to fulfill two fundamental requirements:

- The ability to work with multiple Git repositories
- The ability to provide an extensible and user-friendly command-line interface for basic Zephyr workflows

During the development of west, a set of Design Constraints were identified to avoid the common pitfalls of tools of this kind.
Requirements

Although the motivation behind splitting the Zephyr codebase into multiple repositories is outside of the scope of this page, the fundamental requirements, along with a clear justification of the choice not to use existing tools and instead develop a new one, do belong here.

The basic requirements are:

- **R1**: Keep externally maintained code in separately maintained repositories outside of the main zephyr repository, without requiring users to manually clone each of the external repositories
- **R2**: Provide a tool that both Zephyr users and distributors can make use of to benefit from and extend
- **R3**: Allow users and downstream distributions to override or remove repositories without having to make changes to the zephyr repository
- **R4**: Support both continuous tracking and commit-based (bisectable) project updating

Rationale for a custom tool

Some of west's features are similar to those provided by Git Submodules and Google's repo.

Existing tools were considered during west's initial design and development. None were found suitable for Zephyr's requirements. In particular, these were examined in detail:

- **Google repo**
  - Does not cleanly support using zephyr as the manifest repository (R4)
  - Python 2 only
  - Does not play well with Windows
  - Assumes Gerrit is used for code review
- **Git submodules**
  - Does not fully support R1, since the externally maintained repositories would still need to be inside the main zephyr Git tree
  - Does not support R3, since downstream copies would need to either delete or replace sub-module definitions
  - Does not support continuous tracking of the latest HEAD in external repositories (R4)
  - Requires hardcoding of the paths/locations of the external repositories

Multiple Git Repositories

Zephyr intends to provide all required building blocks needed to deploy complex IoT applications. This in turn means that the Zephyr project is much more than an RTOS kernel, and is instead a collection of components that work together. In this context, there are a few reasons to work with multiple Git repositories in a standardized manner within the project:

- Clean separation of Zephyr original code and imported projects and libraries
- Avoidance of license incompatibilities between original and imported code
- Reduction in size and scope of the core Zephyr codebase, with additional repositories containing optional components instead of being imported directly into the tree
- Safety and security certifications
- Enforcement of modularization of the components
- Out-of-tree development based on subsets of the supported boards and SoCs
See Basics for information on how west workspaces manage multiple git repositories.

**Design Constraints**

West is:

- **Optional**: it is always possible to drop back to “raw” command-line tools, i.e. use Zephyr without using west (although west itself might need to be installed and accessible to the build system). It may not always be convenient to do so, however. (If all of west's features were already conveniently available, there would be no reason to develop it.)

- **Compatible with CMake**: building, flashing and debugging, and emulator support will always remain compatible with direct use of CMake.

- **Cross-platform**: West is written in Python 3, and works on all platforms supported by Zephyr.

- **Usable as a Library**: whenever possible, west features are implemented as libraries that can be used standalone in other programs, along with separate command line interfaces that wrap them. West itself is a Python package named west; its libraries are implemented as subpackages.

- **Conservative about features**: no features will be accepted without strong and compelling motivation.

- **Clearly specified**: West's behavior in cases where it wraps other commands is clearly specified and documented. This enables interoperability with third party tools, and means Zephyr developers can always find out what is happening “under the hood” when using west.

See Zephyr issue #6205 and for more details and discussion.

### 2.11.14 Moving to West

To convert a “pre-west” Zephyr setup on your computer to west, follow these steps. If you are starting from scratch, use the Getting Started Guide instead. See Troubleshooting West for advice on common issues.

1. Install west.
   - On Linux:
     ```bash
     pip3 install --user -U west
     ```
   - On Windows and macOS:
     ```bash
     pip3 install -U west
     ```
   For details, see Installing west.

2. Move your zephyr repository to a new zephyrproject parent directory, and change directory there.
   - On Linux and macOS:
     ```bash
     mkdir zephyrproject
     mv zephyr zephyrproject
     cd zephyrproject
     ```
   - On Windows cmd.exe:
     ```bash
     mkdir zephyrproject
     move zephyr zephyrproject
     chdir zephyrproject
     ```
   The name zephyrproject is recommended, but you can choose any name with no spaces anywhere in the path.
3. Create a `west workspace` using the zephyr repository as a local manifest repository:

```
west init -l zephyr
```

This creates `zephyrproject/.west`, marking the root of your workspace, and does some other setup. It will not change the contents of the zephyr repository in any way.

4. Clone the rest of the repositories used by zephyr:

```
w west update
```

**Make sure to run this command whenever you pull zephyr.** Otherwise, your local repositories will get out of sync. (Run `west list` for current information on these repositories.)

You are done: `zephyrproject` is now set up to use west.

### 2.11.15 Using Zephyr without west

This page provides information on using Zephyr without west. This is not recommended for beginners due to the extra effort involved. In particular, you will have to do work “by hand” to replace these features:

- cloning the additional source code repositories used by Zephyr in addition to the main `zephyr` repository, and keeping them up to date
- specifying the locations of these repositories to the Zephyr build system
- flashing and debugging without understanding detailed usage of the relevant host tools

**Note:** If you have previously installed west and want to stop using it, uninstall it first:

```
pip3 uninstall west
```

Otherwise, Zephyr's build system will find it and may try to use it.

### Getting the Source

In addition to downloading the zephyr source code repository itself, you will need to manually clone the additional projects listed in the `west manifest file` inside that repository.

```
mkdir zephyrproject
cd zephyrproject
git clone https://github.com/zephyrproject-rtos/zephyr
# clone additional repositories listed in zephyr/west.yml, # and check out the specified revisions as well.
```

As you pull changes in the zephyr repository, you will also need to maintain those additional repositories, adding new ones as necessary and keeping existing ones up to date at the latest revisions.

### Building applications

You can build a Zephyr application using CMake and Ninja (or make) directly without west installed if you specify any modules manually.

```
cmake -Bbuild -GNinja -DZEPHYR_MODULES=module1;module2;... samples/hello_world
ninja -Cbuild
```
When building with west installed, the Zephyr build system will use it to set `ZEPHYR_MODULES`.

If you don’t have west installed and your application does not need any of these repositories, the build will still work.

If you don’t have west installed and your application does need one of these repositories, you must set `ZEPHYR_MODULES` yourself as shown above.

See [Modules (External projects)](https://zephyr-project.org/docs/modules/) for more details.

Similarly, if your application requires binary blobs and you are not using west, you will need to download and place those blobs in the right places instead of using `west blobs`. See [Binary Blobs](https://zephyr-project.org/docs/binary-blobs/) for more details.

### Flashing and Debugging

Running build system targets like `ninja flash`, `ninja debug`, etc. is just a call to the corresponding west command. For example, `ninja flash` calls `west flash`\(^1\). If you don't have west installed on your system, running those targets will fail. You can of course still flash and debug using any Flash & Debug Host Tools which work for your board (and which those west commands wrap).

If you want to use these build system targets but do not want to install west on your system using pip, it is possible to do so by manually creating a west workspace:

```
# cd into zephyrproject if not already there
git clone https://github.com/zephyrproject-rtos/west.git .west/west
```

Then create a file `.west/config` with the following contents:

```
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

After that, and in order for `ninja` to be able to invoke `west` to flash and debug, you must specify the west directory. This can be done by setting the environment variable `WEST_DIR` to point to `zephyrproject/`. `west/west` before running CMake to set up a build directory.

For details on west's Python APIs, see `west-apis`.

### 2.12 Testing

#### 2.12.1 Test Framework

The Zephyr Test Framework (Ztest) provides a simple testing framework intended to be used during development. It provides basic assertion macros and a generic test structure.

The framework can be used in two ways, either as a generic framework for integration testing, or for unit testing specific modules.

To enable support for the latest Ztest API, set `CONFIG_ZTEST_NEW_API` to `y`. There is also a legacy API that is deprecated and will eventually be removed.

---

\(^1\) Note that `west build` invokes `ninja`, among other tools. There's no recursive invocation of either `west` or `ninja` involved by default, however, as `west build` does not invoke `ninja flash`, `debug`, etc. The one exception is if you specifically run one of these build system targets with a command line like `west build -t flash`. In that case, `west` is run twice: once for `west build`, and in a subprocess, again for `west flash`. Even in this case, `ninja` is only run once, as `ninja flash`. This is because these build system targets depend on an up to date build of the Zephyr application, so it's compiled before `west flash` is run.
Creating a test suite

Using Ztest to create a test suite is as easy as calling the `ZTEST_SUITE`. The macro accepts the following arguments:

- **suite_name** - The name of the suite. This name must be unique within a single binary.
- **ztest_suite_predicate_t** - An optional predicate function to allow choosing when the test will run. The predicate will get a pointer to the global state passed in through `ztest_run_all()` and should return a boolean to decide if the suite should run.
- **ztest_suite_setup_t** - An optional setup function which returns a test fixture. This will be called and run once per test suite run.
- **ztest_suite_before_t** - An optional before function which will run before every single test in this suite.
- **ztest_suite_after_t** - An optional after function which will run after every single test in this suite.
- **ztest_suite_teardown_t** - An optional teardown function which will run at the end of all the tests in the suite.

Below is an example of a test suite using a predicate:

```c
#include <zephyr/ztest.h>
#include "test_state.h"

static bool predicate(const void *global_state)
{
    return ((const struct test_state*)global_state)->x == 5;
}

ZTEST_SUITE(alternating_suite, predicate, NULL, NULL, NULL, NULL);
```

Adding tests to a suite

There are 4 macros used to add a test to a suite, they are:

- **ZTEST** (suite_name, test_name) - Which can be used to add a test by test_name to a given suite by suite_name.
- **ZTEST_USER** (suite_name, test_name) - Which behaves the same as ZTEST, only that when `CONFIG_USERSPACE` is enabled, then the test will be run in a userspace thread.
- **ZTEST_F** (suite_name, test_name) - Which behaves the same as ZTEST, only that the test function will already include a variable named fixture with the type `<suite_name>_fixture`.
- **ZTEST_USER_F** (suite_name, test_name) - Which combines the fixture feature of ZTEST_F with the userspace threading for the test.

Test fixtures - Test fixtures can be used to help simplify repeated test setup operations. In many cases, tests in the same suite will require some initial setup followed by some form of reset between each test. This is achieved via fixtures in the following way:

```c
#include <zephyr/ztest.h>

struct my_suite_fixture {
    size_t max_size;
    size_t size;
    uint8_t buff[1];
}
```
static void *my_suite_setup(void)
{
    /* Allocate the fixture with 256 byte buffer */
    struct my_suite_fixture *fixture = malloc(sizeof(struct my_suite_fixture) + 255);

    zassert_not_null(fixture, NULL);
    fixture->max_size = 256;

    return fixture;
}

static void my_suite_before(void *f)
{
    struct my_suite_fixture *fixture = (struct my_suite_fixture *)f;
    memset(fixture->buff, 0, fixture->max_size);
    fixture->size = 0;
}

static void my_suite_teardown(void *f)
{
    free(f);
}

ZTEST_SUITE(my_suite, NULL, my_suite_setup, my_suite_before, NULL, my_suite_teardown);

ZTEST_F(my_suite, test_feature_x)
{
    zassert_equal(0, fixture->size);
    zassert_equal(256, fixture->max_size);
}

Using memory allocated by a test fixture in a userspace thread, such as during execution of ZTEST_USER or ZTEST_USER_F, requires that memory to be declared userspace accessible. This is because the fixture memory is owned and initialized by kernel space. The Ztest framework provides the ZTEST_DMEM and ZTEST_BMEM macros for use of such user/kernel space shared memory.

Advanced features

Test result expectations Some tests were made to be broken. In cases where the test is expected to fail or skip due to the nature of the code, it's possible to annotate the test as such. For example:

```c
#include <zephyr/ztest.h>

ZTEST_SUITE(my_suite, NULL, NULL, NULL, NULL, NULL);

ZTEST_EXPECT_FAIL(my_suite, test_fail);
ZTEST(my_suite, test_fail)
{
    /** This will fail the test */
    zassert_true(false, NULL);
}

ZTEST_EXPECT_SKIP(my_suite, test_skip);
```
In this example, the above tests should be marked as failed and skipped respectively. Instead, Ztest will mark both as passed due to the expectation.

### Test rules

Test rules are a way to run the same logic for every test and every suite. There are a lot of cases where you might want to reset some state for every test in the binary (regardless of which suite is currently running). As an example, this could be to reset mocks, reset emulators, flush the UART, etc.:

```c
#include <zephyr/fff.h>
#include <zephyr/ztest.h>
#include "test_mocks.h"

DEFINE_FFF_GLOBALS;
DEFINE_FAKE_VOID_FUN(my_weak_func);

static void fff_reset_rule_before(const struct ztest_unit_test *test, void *fixture)
{
    ARG_UNUSED(test);
    ARG_UNUSED(fixture);
    RESET_FAKE(my_weak_func);
}

ZTEST_RULE(fff_reset_rule, fff_reset_rule_before, NULL);
```

### A custom test_main

While the Ztest framework provides a default `test_main()` function, it's possible that some applications will want to provide custom behavior. This is particularly true if there's some global state that the tests depend on and that state either cannot be replicated or is difficult to replicate without starting the process over. For example, one such state could be a power sequence. Assuming there's a board with several steps in the power-on sequence a test suite can be written using the predicate to control when it would run. In that case, the `test_main()` function can be written as follows:

```c
#include <zephyr/ztest.h>
#include "my_test.h"

void test_main(void)
{
    struct power_sequence_state state;

    /* Only suites that use a predicate checking for phase == PWR_PHASE_0 will run. */
    state.phase = PWR_PHASE_0;
    ztest_run_all(&state);

    /* Only suites that use a predicate checking for phase == PWR_PHASE_1 will run. */
    state.phase = PWR_PHASE_1;
    ztest_run_all(&state);
}
```
state.phase = PWR_PHASE_1;
ztest_run_all(&state);

/* Only suites that use a predicate checking for phase == PWR_PHASE_2 will run. */
state.phase = PWR_PHASE_2;
ztest_run_all(&state);

/* Check that all the suites in this binary ran at least once. */
ztest_verify_all_test_suites_ran();
}

Quick start - Integration testing

A simple working base is located at samples/subsys/testsuite/integration. Just copy the files to tests/ and edit them for your needs. The test will then be automatically built and run by the twister script. If you are testing the bar component of foo, you should copy the sample folder to tests/foo/bar. It can then be tested with:

```bash
./scripts/twister -s tests/foo/bar/test-identifier
```

In the example above tests/foo/bar signifies the path to the test and the test-identifier references a test defined in the testcase.yaml file.

To run all tests defined in a test project, run:

```bash
./scripts/twister -T tests/foo/bar/
```

The sample contains the following files:

CMakeLists.txt

```bash
# SPDX-License-Identifier: Apache-2.0

cmake_minimum_required(VERSION 3.20.0)
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
project(integration)

FILE(GLOB app_sources src/*.c)
target_sources(app PRIVATE ${app_sources})
```

testcase.yaml

```yaml
tests:
  subsection.
  sample.testing.ztest:
    build_only: true
    platform_allow: native_posix
    integration_platforms:
      - native_posix
    tags: test_framework
```

prj.conf

```bash
CONFIG_ZTEST=y
CONFIG_ZTEST_NEW_API=y
```

csrc/main.c (see best practices)

2.12. Testing
/*
 * Copyright (c) 2016 Intel Corporation
 *
 * SPDX-License-Identifier: Apache-2.0
 */

#include <zephyr/ztest.h>

ZTEST_SUITE(framework_tests, NULL, NULL, NULL, NULL, NULL);

/**
 * @brief Test Asserts
 *
 * This test verifies various assert macros provided by ztest.
 *
 */
ZTEST(framework_tests, test_assert)
{
    zassert_true(1, "1 was false");
    zassert_false(0, "0 was true");
    zassert_is_null(NULL, "NULL was not NULL");
    zassert_not_null("foo", "\"foo\" was NULL");
    zassert_equal(1, 1, "1 was not equal to 1");
    zassert_equal_ptr(NULL, NULL, "NULL was not equal to NULL");
}

• Listing Tests

• Skipping Tests

A test case project may consist of multiple sub-tests or smaller tests that either can be testing functionality or APIs. Functions implementing a test should follow the guidelines below:

• Test cases function names should be prefix with test_
• Test cases should be documented using doxygen
• Test function names should be unique within the section or component being tested

For example:

/**
 * @brief Test Asserts
 *
 * This test verifies the zassert_true macro.
 *
 */
ZTEST(my_suite, test_assert)
{
    zassert_true(1, "1 was false");
}

Listing Tests  Tests (test projects) in the Zephyr tree consist of many testcases that run as part of a project and test similar functionality, for example an API or a feature. The twister script can parse the testcases in all test projects or a subset of them, and can generate reports on a granular level, i.e. if cases have passed or failed or if they were blocked or skipped.
Twister parses the source files looking for test case names, so you can list all kernel test cases, for example, by running:

```
twister --list-tests -T tests/kernel
```

**Skipping Tests** Special- or architecture-specific tests cannot run on all platforms and architectures, however we still want to count those and report them as being skipped. Because the test inventory and the list of tests is extracted from the code, adding conditionals inside the test suite is sub-optimal. Tests that need to be skipped for a certain platform or feature need to explicitly report a skip using `ztest_test_skip()` or `Z_TEST_SKIP_IFDEF`. If the test runs, it needs to report either a pass or fail. For example:

```
#ifndef CONFIG_TEST1
ZTEST(common, test_test1)
{
    zassert_true(1, "true");
}
#else
ZTEST(common, test_test1)
{
    ztest_test_skip();
}
#endif
ZTEST(common, test_test2)
{
    Z_TEST_SKIP_IFDEF(CONFIG_BUGxxxxx);
    zassert_equal(1, 0, NULL);
}
ZTEST_SUITE(common, NULL, NULL, NULL, NULL, NULL);
```

**Quick start - Unit testing**

Ztest can be used for unit testing. This means that rather than including the entire Zephyr OS for testing a single function, you can focus the testing efforts into the specific module in question. This will speed up testing since only the module will have to be compiled in, and the tested functions will be called directly.

Since you won’t be including basic kernel data structures that most code depends on, you have to provide function stubs in the test. Ztest provides some helpers for mocking functions, as demonstrated below.

In a unit test, mock objects can simulate the behavior of complex real objects and are used to decide whether a test failed or passed by verifying whether an interaction with an object occurred, and if required, to assert the order of that interaction.

**Best practices for declaring the test suite** `twister` and other validation tools need to obtain the list of subcases that a Zephyr `ztest` test image will expose.

**Rationale**

This all is for the purpose of traceability. It’s not enough to have only a semaphore test project. We also need to show that we have testpoints for all APIs and functionality, and we trace back to documentation of the API, and functional requirements.
The idea is that test reports show results for every sub-testcase as passed, failed, blocked, or skipped. Reporting on only the high-level test project level, particularly when tests do too many things, is too vague.

Other questions:

- Why not pre-scan with CPP and then parse? or post scan the ELF file?
  
  If C pre-processing or building fails because of any issue, then we won’t be able to tell the subcases.

- Why not declare them in the YAML testcase description?
  
  A separate testcase description file would be harder to maintain than just keeping the information in the test source files themselves – only one file to update when changes are made eliminates duplication.

**Stress test framework**

Zephyr stress test framework (Ztress) provides an environment for executing user functions in multiple priority contexts. It can be used to validate that code is resilient to preemptions. The framework tracks the number of executions and preemptions for each context. Execution can have various completion conditions like timeout, number of executions or number of preemptions.

The framework is setting up the environment by creating the requested number of threads (each on different priority), optionally starting a timer. For each context, a user function (different for each context) is called and then the context sleeps for a randomized amount of system ticks. The framework is tracking CPU load and adjusts sleeping periods to achieve higher CPU load. In order to increase the probability of preemptions, the system clock frequency should be relatively high. The default 100 Hz on QEMU x86 is much too low and it is recommended to increase it to 100 kHz.

The stress test environment is setup and executed using `ZTRESS_EXECUTE` which accepts a variable number of arguments. Each argument is a context that is specified by `ZTRESS_TIMER` or `ZTRESS_THREAD` macros. Contexts are specified in priority descending order. Each context specifies completion conditions by providing the minimum number of executions and preemptions. When all conditions are met and the execution has completed, an execution report is printed and the macro returns. Note that while the test is executing, a progress report is periodically printed.

Execution can be prematurely completed by specifying a test timeout (`ztress_set_timeout()`) or an explicit abort (`ztress_abort()`).

User function parameters contains an execution counter and a flag indicating if it is the last execution.

The example below presents how to setup and run 3 contexts (one of which is k_timer interrupt handler context). Completion criteria is set to at least 10000 executions of each context and 1000 preemptions of the lowest priority context. Additionally, the timeout is configured to complete after 10 seconds if those conditions are not met. The last argument of each context is the initial sleep time which will be adjusted throughout the test to achieve the highest CPU load.

```c
ztress_set_timeout(K_MSEC(10000));
ZTRESS_EXECUTE(ZTRESS_TIMER(foo_0, user_data_0, 10000, Z_TIMEOUT_TICKS(20)),
    ZTRESS_THREAD(foo_1, user_data_1, 10000, 0, Z_TIMEOUT TICKS(20)),
    ZTRESS_THREAD(foo_2, user_data_2, 10000, 1000, Z_TIMEOUT TICKS(20)));
```

**Configuration**

Static configuration of Ztress contains:

- `ZTRESS_MAX_THREADS` - number of supported threads.
- `ZTRESS_STACK_SIZE` - Stack size of created threads.
- `ZTRESS_REPORT_PROGRESS_MS` - Test progress report interval.
API reference

Running tests

`group ztest_test`

This module eases the testing process by providing helpful macros and other testing structures.

Defines

`ZTEST(suite, fn)`

Create and register a new unit test.

Calling this macro will create a new unit test and attach it to the declared `suite`. The `suite` does not need to be defined in the same compilation unit.

**Parameters**

- `suite` – The name of the test suite to attach this test
- `fn` – The test function to call.

`ZTEST_USER(suite, fn)`

Define a test function that should run as a user thread.

This macro behaves exactly the same as `ZTEST`, but calls the test function in user space if `CONFIG_USERSPACE` was enabled.

**Parameters**

- `suite` – The name of the test suite to attach this test
- `fn` – The test function to call.

`ZTEST_F(suite, fn)`

Define a test function.

This macro behaves exactly the same as `ZTEST()`, but the function takes an argument for the fixture of type `struct suite##_fixture*` named `this`.

**Parameters**

- `suite` – The name of the test suite to attach this test
- `fn` – The test function to call.

`ZTEST_USER_F(suite, fn)`

Define a test function that should run as a user thread.

If `CONFIG_USERSPACE` is not enabled, this is functionally identical to `ZTEST_F()`. The test function takes a single fixture argument of type `struct suite##_fixture*` named `this`.

**Parameters**

- `suite` – The name of the test suite to attach this test
- `fn` – The test function to call.

`ZTEST_RULE(name, before_each_fn, after_each_fn)`

Define a test rule that will run before/after each unit test.

Functions defined here will run before/after each unit test for every test suite. Along with the callback, the test functions are provided a pointer to the test being run, and the data. This provides a mechanism for tests to perform custom operations depending on the specific test or the data (for example logging may use the test's name).

**Ordering:**
• Test rule's `before` function will run before the suite's `before` function. This is done to allow the test suite's customization to take precedence over the rule which is applied to all suites.

• Test rule's `after` function is not guaranteed to run in any particular order.

**Parameters**

- `name` – The name for the test rule (must be unique within the compilation unit)
- `before_each_fn` – The callback function (`ztest_rule_cb`) to call before each test (may be NULL)
- `after_each_fn` – The callback function (`ztest_rule_cb`) to call after each test (may be NULL)

`ztest_run_test_suite(suite)`

Run the specified test suite.

**Parameters**

- `suite` – Test suite to run.

**Typedefs**

typedef void (*ztest_rule_cb)(const struct ztest_unit_test *test, void *data)

Test rule callback function signature.

The function signature that can be used to register a test rule's before/after callback. This provides access to the test and the fixture data (if provided).

**Param test**

- Pointer to the unit test in context

**Param data**

- Pointer to the test's fixture data (may be NULL)

**Functions**

`void ztest_test_fail(void)`

Fail the currently running test.

This is the function called from failed assertions and the like. You probably don't need to call it yourself.

`void ztest_test_pass(void)`

Pass the currently running test.

Normally a test passes just by returning without an assertion failure. However, if the success case for your test involves a fatal fault, you can call this function from `k_sys_fatal_error_handler` to indicate that the test passed before aborting the thread.

`void ztest_test_skip(void)`

Skip the current test.

`void ztest_skip_failed_assumption(void)`

`void ztest_simple_1cpu_before(void *data)`

A 'before' function to use in test suites that just need to start 1cpu.

Ignores data, and calls `z_test_1cpu_start()`
Parameters

• data – The test suite’s data

```c
void ztest_simple_1cpu_after(void *data)
A 'after' function to use in test suites that just need to stop 1cpu.
Ignores data, and calls z_test_1cpu_stop()
```

Parameters

• data – The test suite’s data

```c
struct ztest_test_rule
```

```c
struct ztest_arch_api
#include <ztest_test_new.h> Structure for architecture specific APIs.
```

Assertions

These macros will instantly fail the test if the related assertion fails. When an assertion
fails, it will print the current file, line and function, alongside a reason for the failure and an optional
message. If the config CONFIG_ZTEST_ASSERT_VERBOSE is 0, the assertions will only print the file and
line numbers, reducing the binary size of the test.

Example output for a failed macro from zassert_equal(buf->ref, 2, "Invalid refcount"):

```
Assertion failed at main.c:62: test_get_single_buffer: Invalid refcount (buf->ref not →
˓equal to 2)
Aborted at unit test function
```

```c
group ztest_assert
This module provides assertions when using Ztest.
```

Defines

```c
zassert(cond, default_msg, ...)
zassume(cond, default_msg, ...)
zexpect(cond, default_msg, ...)
zassert_unreachable(...)
```

Assert that this function call won’t be reached.

```c
zassert_true(cond, ...)
```

Assert that `cond` is true.

```c
zassert_false(cond, ...)
```

Assert that `cond` is false.

Parameters

• cond – Condition to check

Parameters

• cond – Condition to check
•... – Optional message and variables to print if the assertion fails

assert_ok(cond, ...)

Assert that cond is 0 (success)

Parameters
• cond – Condition to check
• ... – Optional message and variables to print if the assertion fails

assert_is_null(ptr, ...)

Assert that ptr is NULL.

Parameters
• ptr – Pointer to compare
• ... – Optional message and variables to print if the assertion fails

assert_not_null(ptr, ...)

Assert that ptr is not NULL.

Parameters
• ptr – Pointer to compare
• ... – Optional message and variables to print if the assertion fails

assert_equal(a, b, ...)

Assert that a equals b.

a and b won’t be converted and will be compared directly.

Parameters
• a – Value to compare
• b – Value to compare
• ... – Optional message and variables to print if the assertion fails

assert_not_equal(a, b, ...)

Assert that a does not equal b.

a and b won’t be converted and will be compared directly.

Parameters
• a – Value to compare
• b – Value to compare
• ... – Optional message and variables to print if the assertion fails

assert_equal_ptr(a, b, ...)

Assert that a equals b.

a and b will be converted to void * before comparing.

Parameters
• a – Value to compare
• b – Value to compare
• ... – Optional message and variables to print if the assertion fails
zassert_within(a, b, d, ...)
  Assert that \( a \) is within \( b \) with delta \( d \).

Parameters
  • \( a \) – Value to compare
  • \( b \) – Value to compare
  • \( d \) – Delta
  • \( ... \) – Optional message and variables to print if the assertion fails

zassert_between_inclusive(a, l, u, ...)
  Assert that \( a \) is greater than or equal to \( l \) and less than or equal to \( u \).

Parameters
  • \( a \) – Value to compare
  • \( l \) – Lower limit
  • \( u \) – Upper limit
  • \( ... \) – Optional message and variables to print if the assertion fails

zassert_mem_equal(...)
  Assert that 2 memory buffers have the same contents.

This macro calls the final memory comparison assertion macro. Using double expansion allows providing some arguments by macros that would expand to more than one values (ANSI-C99 defines that all the macro arguments have to be expanded before macro call).

Parameters
  • \( ... \) – Arguments, see \texttt{zassert\_mem\_equal\_} for real arguments accepted.

zassert_mem_equal__(buf, exp, size, ...)
  Internal assert that 2 memory buffers have the same contents.

Parameters
  • \( buf \) – Buffer to compare
  • \( exp \) – Buffer with expected contents
  • \( size \) – Size of buffers
  • \( ... \) – Optional message and variables to print if the assertion fails

Note: This is internal macro, to be used as a second expansion. See \texttt{zassert\_mem\_equal}.

Expectations These macros will continue test execution if the related expectation fails and subsequently fail the test at the end of its execution. When an expectation fails, it will print the current file, line, and function, alongside a reason for the failure and an optional message but continue executing the test. If the config \texttt{CONFIG:\_\_\_ZTEST\_\_\_ASSERT\_\_\_VERBOSE} is 0, the expectations will only print the file and line numbers, reducing the binary size of the test.

For example, if the following expectations fail:

\begin{verbatim}
zexpect_equal(buf->ref, 2, "Invalid refcount");
zexpect_equal(buf->ref, 1337, "Invalid refcount");
\end{verbatim}

The output will look something like:
group ztest_expect

This module provides expectations when using Ztest.

Defines

zexpect_true(cond, ...)

Expect that cond is true, otherwise mark test as failed but continue its execution.

Parameters

• cond – Condition to check
• ... – Optional message and variables to print if the expectation fails

zexpect_false(cond, ...)

Expect that cond is false, otherwise mark test as failed but continue its execution.

Parameters

• cond – Condition to check
• ... – Optional message and variables to print if the expectation fails

zexpect_ok(cond, ...)

Expect that cond is 0 (success), otherwise mark test as failed but continue its execution.

Parameters

• cond – Condition to check
• ... – Optional message and variables to print if the expectation fails

zexpect_is_null(ptr, ...)

Expect that ptr is NULL, otherwise mark test as failed but continue its execution.

Parameters

• ptr – Pointer to compare
• ... – Optional message and variables to print if the expectation fails

zexpect_not_null(ptr, ...)

Expect that ptr is not NULL, otherwise mark test as failed but continue its execution.

Parameters

• ptr – Pointer to compare
• ... – Optional message and variables to print if the expectation fails

zexpect_equal(a, b, ...)

Expect that a equals b, otherwise mark test as failed but continue its execution.

expectation fails, the test will be marked as “skipped”.

Parameters

• a – Value to compare
• b – Value to compare
• ... – Optional message and variables to print if the expectation fails

zexpect_not_equal(a, b, ...)  
Expect that \( a \) does not equal \( b \), otherwise mark test as failed but continue its execution.

\( a \) and \( b \) won’t be converted and will be compared directly.

Parameters
• a – Value to compare
• b – Value to compare
• ... – Optional message and variables to print if the expectation fails

zexpect_equal_ptr(a, b, ...)  
Expect that \( a \) equals \( b \), otherwise mark test as failed but continue its execution.

\( a \) and \( b \) will be converted to \( \text{void} * \) before comparing.

Parameters
• a – Value to compare
• b – Value to compare
• ... – Optional message and variables to print if the expectation fails

zexpect_within(a, b, delta, ...)  
Expect that \( a \) is within \( b \) with delta \( d \), otherwise mark test as failed but continue its execution.

Parameters
• a – Value to compare
• b – Value to compare
• delta – Difference between \( a \) and \( b \)
• ... – Optional message and variables to print if the expectation fails

zexpect_between_inclusive(a, lower, upper, ...)  
Expect that \( a \) is greater than or equal to \( l \) and less than or equal to \( u \), otherwise mark test as failed but continue its execution.

Parameters
• a – Value to compare
• lower – Lower limit
• upper – Upper limit
• ... – Optional message and variables to print if the expectation fails

zexpect_mem_equal(buf, exp, size, ...)  
Expect that 2 memory buffers have the same contents, otherwise mark test as failed but continue its execution.

Parameters
• buf – Buffer to compare
• exp – Buffer with expected contents
• size – Size of buffers
• ... – Optional message and variables to print if the expectation fails
Assumptions These macros will instantly skip the test or suite if the related assumption fails. When an assumption fails, it will print the current file, line, and function, alongside a reason for the failure and an optional message. If the config CONFIG_ZTEST_ASSERT_VERBOSE is 0, the assumptions will only print the file and line numbers, reducing the binary size of the test.

Example output for a failed macro from zassert_equal(buf->ref, 2, "Invalid refcount"):

group ztest_assume
This module provides assumptions when using Ztest.

Defines

zassume_true(cond, ...)
Assume that cond is true.
If the assumption fails, the test will be marked as “skipped”.

Parameters
• cond – Condition to check
• ... – Optional message and variables to print if the assumption fails

zassume_false(cond, ...)
Assume that cond is false.
If the assumption fails, the test will be marked as “skipped”.

Parameters
• cond – Condition to check
• ... – Optional message and variables to print if the assumption fails

zassume_ok(cond, ...)
Assume that cond is 0 (success)
If the assumption fails, the test will be marked as “skipped”.

Parameters
• cond – Condition to check
• ... – Optional message and variables to print if the assumption fails

zassume_is_null(ptr, ...)
Assume that ptr is NULL.
If the assumption fails, the test will be marked as “skipped”.

Parameters
• ptr – Pointer to compare
• ... – Optional message and variables to print if the assumption fails

zassume_not_null(ptr, ...)
Assume that ptr is not NULL.
If the assumption fails, the test will be marked as “skipped”.

Parameters
• ptr – Pointer to compare
• ... – Optional message and variables to print if the assumption fails
zassume_equal(a, b, ...)  
Assume that a equals b. 

a and b won’t be converted and will be compared directly. If the assumption fails, the test will 
be marked as “skipped”.

Parameters
• a – Value to compare 
• b – Value to compare 
• ... – Optional message and variables to print if the assumption fails 

zassume_not_equal(a, b, ...)  
Assume that a does not equal b. 

a and b won’t be converted and will be compared directly. If the assumption fails, the test will 
be marked as “skipped”.

Parameters
• a – Value to compare 
• b – Value to compare 
• ... – Optional message and variables to print if the assumption fails 

zassume_equal_ptr(a, b, ...)  
Assume that a equals b. 

a and b will be converted to void * before comparing. If the assumption fails, the test will be 
marked as “skipped”.

Parameters
• a – Value to compare 
• b – Value to compare 
• ... – Optional message and variables to print if the assumption fails 

zassume_within(a, b, d, ...)  
Assume that a is within b with delta d. 

If the assumption fails, the test will be marked as “skipped”.

Parameters
• a – Value to compare 
• b – Value to compare 
• d – Delta 
• ... – Optional message and variables to print if the assumption fails 

zassume_between_inclusive(a, l, u, ...)  
Assume that a is greater than or equal to l and less than or equal to u. 

If the assumption fails, the test will be marked as “skipped”.

Parameters
• a – Value to compare 
• l – Lower limit 
• u – Upper limit 
• ... – Optional message and variables to print if the assumption fails
zassume_mem_equal(...)  
Assume that 2 memory buffers have the same contents. 
This macro calls the final memory comparison assumption macro. Using double expansion allows providing some arguments by macros that would expand to more than one values (ANSI-C99 defines that all the macro arguments have to be expanded before macro call). 

Parameters  
• ... – Arguments, see zassume_mem_equal__ for real arguments accepted.

zassume_mem_equal__(buf, exp, size, ...)  
Internal assume that 2 memory buffers have the same contents.  
If the assumption fails, the test will be marked as “skipped”.  

Note: This is internal macro, to be used as a second expansion. See zassume_mem_equal.

Parameters  
• buf – Buffer to compare  
• exp – Buffer with expected contents  
• size – Size of buffers  
• ... – Optional message and variables to print if the assumption fails

Ztress  
group ztest_ztress  
This module provides test stress when using Ztest.

Defines  

ZTRESS_TIMER(handler, user_data, exec_cnt, init_timeout)  
Descriptor of a k_timer handler execution context.  
The handler is executed in the k_timer handler context which typically means interrupt context. This context will preempt any other used in the set.

Note: There can only be up to one k_timer context in the set and it must be the first argument of ZTRESS_EXECUTE.

Parameters  
• handler – User handler of type stress_handler.  
• user_data – User data passed to the handler.  
• exec_cnt – Number of handler executions to complete the test. If 0 then this is not included in completion criteria.  
• init_timeout – Initial backoff time base (given in k_timeout_t). It is adjusted during the test to optimize CPU load. The actual timeout used for the timer is randomized.
ZTRESS_THREAD(handler, user_data, exec_cnt, preempt_cnt, init_timeout)

Descriptor of a thread execution context.

The handler is executed in the thread context. The priority of the thread is determined based on the order in which contexts are listed in ZTRESS_EXECUTE.

**Note:** thread sleeps for random amount of time. Additionally, the thread busy-waits for a random length of time to further increase randomization in the test.

**Parameters**

- **handler** – User handler of type `ztress_handler`.
- **user_data** – User data passed to the handler.
- **exec_cnt** – Number of handler executions to complete the test. If 0 then this is not included in completion criteria.
- **preempt_cnt** – Number of preemptions of that context to complete the test. If 0 then this is not included in completion criteria.
- **init_timeout** – Initial backoff time base (given in `k_timeout_t`). It is adjusted during the test to optimize CPU load. The actual timeout used for sleeping is randomized.

ZTRESS_CONTEXT_INITIALIZER(_handler, _user_data, _exec_cnt, _preempt_cnt, _t)

Initialize context structure.

For argument types see `ztress_context_data`. For more details see ZTRESS_THREAD.

**Parameters**

- **_handler** – Handler.
- **_user_data** – User data passed to the handler.
- **_exec_cnt** – Execution count limit.
- **_preempt_cnt** – Preemption count limit.
- **_t** – Initial timeout.

ZTRESS_EXECUTE(…)

Setup and run stress test.

It initialises all contexts and calls `stress_execute`.

**Parameters**

- **…”** – List of contexts. Contexts are configured using ZTRESS_TIMER and ZTRESSTHREAD macros. ZTRESS_TIMER must be the first argument if used.

Each thread context has an assigned priority. The priority is assigned in a descending order (first listed thread context has the highest priority). The maximum number of supported thread contexts, including the timer context, is configurable in Kconfig (ZTRESS_MAX_THREADS).

**Typedefs**

typedef bool (*ztress_handler)(void *user_data, uint32_t cnt, bool last, int prio)

User handler called in one of the configured contexts.

**Param user_data**

User data provided in the context descriptor.
Param cnt
Current execution counter. Counted from 0.

Param last
Flag set to true indicates that it is the last execution because completion criteria are met, test timed out or was aborted.

Param prio
Context priority counting from 0 which indicates the highest priority.

Retval true
continue test.

Retval false
stop executing the current context.

Functions

int zstress_execute(struct stress_context_data *timer_data, struct stress_context_data *thread_data, size_t cnt)
Execute contexts.

The test runs until all completion requirements are met or until the test times out (use zstress_set_timeout to configure timeout) or until the test is aborted (zstress_abort).

on test completion a report is printed (zstress_report is called internally).

Parameters

• timer_data – Timer context. NULL if timer context is not used.
• thread_data – List of thread contexts descriptors in priority descending order.
• cnt – Number of thread contexts.

Return values

• -EINVAL – If configuration is invalid.
• 0 – if test is successfully performed.

void zstress_abort(void)
Abort ongoing stress test.

void zstress_set_timeout(k_timeout_t t)
Set test timeout.

Test is terminated after timeout disregarding completion criteria. Setting is persistent between executions.

Parameters

• t – Timeout.

void zstress_report(void)
Print last test report.

Report contains number of executions and preemptions for each context, initial and adjusted timeouts and CPU load during the test.

int zstress_exec_count(uint32_t id)
Get number of executions of a given context in the last test.

Parameters

• id – Context id. 0 means the highest priority.
Returns
Number of executions.

int zstress_preempt_count(uint32_t id)
Get number of preemptions of a given context in the last test.

Parameters
• id – Context id. 0 means the highest priority.

Returns
Number of preemptions.

uint32_t zstress_optimized_ticks(uint32_t id)
Get optimized timeout base of a given context in the last test.
Optimized value can be used to update initial value. It will improve the test since optimal CPU load will be reach immediately.

Parameters
• id – Context id. 0 means the highest priority.

Returns
Optimized timeout base.

struct zstress_context_data
#include <ztress.h>

Mocking via FFF  Zephyr has integrated with FFF for mocking. See FFF for documentation. To use it, include the relevant header:

#include <zephyr/fff.h>

Zephyr provides several FFF-based fake drivers which can be used as either stubs or mocks. Fake driver instances are configured via Devicetree and Configuration System (Kconfig). See the following devicetree bindings for more information:
• zephyr,fake-can
• zephyr,fake-eeprom

Zephyr also has defined extensions to FFF for simplified declarations of fake functions. See FFF Extensions.

Customizing Test Output

The way output is presented when running tests can be customized. An example can be found in tests/ztest/custom_output.

Customization is enabled by setting CONFIG_ZTEST_TC_UTIL_USER_OVERRIDE to “y” and adding a file tc_util_user_override.h with your overrides.

Add the line zephyr_include_directories(my_folder) to your project’s CMakeLists.txt to let Zephyr find your header file during builds.

See the file subsys/testsuite/include/zephyr/tc_util.h to see which macros and/or defines can be overridden. These will be surrounded by blocks such as:

 ifndef SOMETHING
 #define SOMETHING <default implementation>
 #endif /* SOMETHING */
Shuffling Test Sequence

By default the tests are sorted and run in alphanumerical order. Test cases may be dependent on this sequence. Enable `CONFIG_ZTEST_SHUFFLE` to randomize the order. The output from the test will display the seed for failed tests. For native posix builds you can provide the seed as an argument to twister with `--seed`.

Static configuration of ZTEST_SHUFFLE contains:

- `CONFIG_ZTEST_SHUFFLE_SUITE_REPEAT_COUNT` - Number of iterations the test suite will run.
- `CONFIG_ZTEST_SHUFFLE_TEST_REPEAT_COUNT` - Number of iterations the test will run.

Test Selection

For POSIX enabled builds with ZTEST_NEW_API use command line arguments to list or select tests to run. The test argument expects a comma separated list of `suite::test`. You can substitute the test name with an `*` to run all tests within a suite.

For example:

```bash
$ zephyr.exe -list
$ zephyr.exe -test="fixture_tests::test_fixture_pointer,framework_tests::test_assert_mem_equal"
$ zephyr.exe -test="framework_tests::*"
```

FFF Extensions

`group fff_extensions`

This module provides extensions to FFF for simplifying the configuration and usage of fakes.

**Defines**

```
RETURN_HANDLED_CONTEXT(FUNCNAME, CONTEXTTYPE, RESULTFIELD, CONTEXTPTRNAME, HANDLERBODY)
```

Wrap custom fake body to extract defined context struct.

Add extension macro for simplified creation of fake functions needing call-specific context data.

This macro enables a fake to be implemented as follows and requires no familiarity with the inner workings of FFF.

```c
struct FUNCNAME##_custom_fake_context
{
    struct instance * const instance;
    int result;
};

int FUNCNAME##_custom_fake(
    const struct instance **instance_out)
{
    RETURN_HANDLED_CONTEXT(
        FUNCNAME,
        struct FUNCNAME##_custom_fake_context,
        result,
```
context,
{
    if (context != NULL)
    {
        if (context->result == 0)
        {
            if (instance_out != NULL)
            {
                *instance_out = context->instance;
            }
        }
        return context->result;
    }
    return FUNCNAME##_fake.return_val;
}

Parameters

- FUNCNAME – Name of function being faked
- CONTEXTTYPE – Type of custom defined fake context struct
- RESULTFIELD – Name of field holding the return type & value
- CONTEXTPTRNAME – Expected name of pointer to custom defined fake context struct
- HANDLERBODY – In-line custom fake handling logic

2.12.2 Test Runner (Twister)

This script scans for the set of unit test applications in the git repository and attempts to execute them. By default, it tries to build each test case on boards marked as default in the board definition file.

The default options will build the majority of the tests on a defined set of boards and will run in an emulated environment if available for the architecture or configuration being tested.

In normal use, twister runs a limited set of kernel tests (inside an emulator). Because of its limited test execution coverage, twister cannot guarantee local changes will succeed in the full build environment, but it does sufficient testing by building samples and tests for different boards and different configurations to help keep the complete code tree buildable.

When using (at least) one \-v option, twister's console output shows for every test how the test is run (qemu, native_posix, etc.) or whether the binary was just built. There are a few reasons why twister only builds a test and doesn't run it:

- The test is marked as build_only: true in its .yaml configuration file.
- The test configuration has defined a harness but you don't have it or haven't set it up.
- The target device is not connected and not available for flashing.
- You or some higher level automation invoked twister with --build-only.

To run the script in the local tree, follow the steps below:

**Linux**

```
$ source zephyr-env.sh
$ ./scripts/twister
```
Windows

```
zephyr-env.cmd
python .\scripts\twister
```

If you have a system with a large number of cores and plenty of free storage space, you can build and run all possible tests using the following options:

Linux

```
$ ./scripts/twister --all --enable-slow
```

Windows

```
python .\scripts\twister --all --enable-slow
```

This will build for all available boards and run all applicable tests in a simulated (for example QEMU) environment.

If you want to run tests on one or more specific platforms, you can use the `--platform` option, it is a platform filter for testing, with this option, test suites will only be built/run on the platforms specified. This option also supports different revisions of one same board, you can use `--platform board@revision` to test on a specific revision.

The list of command line options supported by twister can be viewed using:

Linux

```
$ ./scripts/twister --help
```

Windows

```
python .\scripts\twister --help
```

**Board Configuration**

To build tests for a specific board and to execute some of the tests on real hardware or in an emulation environment such as QEMU a board configuration file is required which is generic enough to be used for other tasks that require a board inventory with details about the board and its configuration that is only available during build time otherwise.

The board metadata file is located in the board directory and is structured using the YAML markup language. The example below shows a board with a data required for best test coverage for this specific board:

```
identifier: frdm_k64f
name: NXP FRDM-K64F
type: mcu
arch: arm
toolchain:
  - zephyr
  - gnuarmemb
  - xtools
supported:
  - arduino_gpio
  - arduino_i2c
  - netif:eth
  - adc
  - i2c
  - nvs
```

(continues on next page)
- spi
- gpio
- usb_device
- watchdog
- can
- pwm

**testing:**

default: true

**identifier:**

A string that matches how the board is defined in the build system. This same string is used when building, for example when calling `west build` or `cmake`:

```
# with west
west build -b reel_board
# with cmake
cmake -DBOARD=reel_board ..
```

**name:**

The actual name of the board as it appears in marketing material.

**type:**

Type of the board or configuration, currently we support 2 types: mcu, qemu

**simulation:**

Simulator used to simulate the platform, e.g. qemu.

**arch:**

Architecture of the board

**toolchain:**

The list of supported toolchains that can build this board. This should match one of the values used for 'ZEPHYR_TOOLCHAIN_VARIANT' when building on the command line

**ram:**

Available RAM on the board (specified in KB). This is used to match testcase requirements. If not specified we default to 128KB.

**flash:**

Available FLASH on the board (specified in KB). This is used to match testcase requirements. If not specified we default to 512KB.

**supported:**

A list of features this board supports. This can be specified as a single word feature or as a variant of a feature class. For example:

```
supported:
- pci
```

This indicates the board does support PCI. You can make a testcase build or run only on such boards, or:

```
supported:
- netif:eth
- sensor:bmi16
```

A testcase can both depend on ‘eth’ to only test ethernet or on ‘netif’ to run on any board with a networking interface.

**testing:**

testing relating keywords to provide best coverage for the features of this board.
default: [True|False]:
This is a default board, it will be tested with the highest priority and is covered when invoking the simplified twister without any additional arguments.

ignore_tags:
Do not attempt to build (and therefore run) tests marked with this list of tags.

only_tags:
Only execute tests with this list of tags on a specific platform.

timeout_multiplier: <float> (default 1)
Multiply each test case timeout by specified ratio. This option allows to tune timeouts only for required platform. It can be useful in case naturally slow platform i.e.: HW board with power-efficient but slow CPU or simulation platform which can perform instruction accurate simulation but does it slowly.

Test Cases

Test cases are detected by the presence of a ‘testcase.yaml’ or a ‘sample.yaml’ files in the application’s project directory. This file may contain one or more entries in the test section each identifying a test scenario.

The name of each testcase needs to be unique in the context of the overall testsuite and has to follow basic rules:

1. The format of the test identifier shall be a string without any spaces or special characters (allowed characters: alphanumeric and [\-_=]) consisting of multiple sections delimited with a dot (.)
2. Each test identifier shall start with a section followed by a subsection separated by a dot. For example, a test that covers semaphores in the kernel shall start with kernel.semaphore.
3. All test identifiers within a testcase.yaml file need to be unique. For example a testcase.yaml file covering semaphores in the kernel can have:
   - kernel.semaphore: For general semaphore tests
   - kernel.semaphore.stress: Stress testing semaphores in the kernel.
4. Depending on the nature of the test, an identifier can consist of at least two sections:
   - Ztest tests: The individual testcases in the ztest testsuite will be concatenated to identifier in the testcase.yaml file generating unique identifiers for every testcase in the suite.
   - Standalone tests and samples: This type of test should at least have 3 sections in the test identifier in the testcase.yaml (or sample.yaml) file. The last section of the name shall signify the test itself.

Test cases are written using the YAML syntax and share the same structure as samples. The following is an example test with a few options that are explained in this document.

tests:
    bluetooth.gatt:
        build_only: true
        platform_allow: qemu_cortex_m3 qemu_x86
        tags: bluetooth
    bluetooth.gatt.br:
        build_only: true
        extra_args: CONF_FILE="prj_br.conf"
        filter: not CONFIG_DEBUG
        platform_exclude: up_squared
        platform_allow: qemu_cortex_m3 qemu_x86
        tags: bluetooth
A sample with tests will have the same structure with additional information related to the sample and what is being demonstrated:

```json
sample:
  name: hello world
  description: Hello World sample, the simplest Zephyr application

tests:
  sample.basic.hello_world:
    build_only: true
    tags: tests
    min_ram: 16
  sample.basic.hello_world.singlethread:
    build_only: true
    extra_args: CONF_FILE=prj_single.conf
    filter: not CONFIG_BT
    tags: tests
    min_ram: 16
```

The full canonical name for each test case is:

```
<path to test case>/<test entry>
```

Each test block in the testcase meta data can define the following key/value pairs:

- **tags**: `<list of tags>` (required)
  A set of string tags for the testcase. Usually pertains to functional domains but can be anything. Command line invocations of this script can filter the set of tests to run based on tag.

- **skip**: `<True|False>` (default False)
  skip testcase unconditionally. This can be used for broken tests.

- **slow**: `<True|False>` (default False)
  Don’t run this test case unless –enable-slow or –enable-slow-only was passed in on the command line. Intended for time-consuming test cases that are only run under certain circumstances, like daily builds. These test cases are still compiled.

- **extra_args**: `<list of extra arguments>`
  Extra arguments to pass to Make when building or running the test case.

- **extra_configs**: `<list of extra configurations>`
  Extra configuration options to be merged with a master prj.conf when building or running the test case. For example:

```json
common:
  tags: drivers adc
tests:
  test:
    depends_on: adc
test_async:
    extra_configs:
      - CONFIG_ADC_ASYNC=y
```

Using namespaces, it is possible to apply a configuration only to some hardware. Currently both architectures and platforms are supported:
extra_configs:
- arch:x86:CONFIG_ADC_ASYNC=y
- platform:qemu_x86:CONFIG_DEBUG=y

build_only: <True|False> (default False)
If true, twister will not try to run the test even if the test is runnable on the platform.
This keyword is reserved for tests that are used to test if some code actually builds. A build_only test is not
designed to be run in any environment and should not be testing any functionality, it only verifies that the code builds.
This option is often used to test drivers and the fact that they are correctly enabled in Zephyr and that the code builds,
for example sensor drivers. Such test shall not be used to verify the functionality of the driver.

build_on_all: <True|False> (default False)
If true, attempt to build test on all available platforms. This is mostly used in CI for increased coverage.
Do not use this flag in new tests.

depends_on: <list of features>
A board or platform can announce what features it supports, this option will enable the test only those
platforms that provide this feature.

levels: <list of levels”
Test levels this test should be part of. If a level is present, this test will be selectable using the
command line option --level <level name>

min_ram: <integer>
minimum amount of RAM in KB needed for this test to build and run. This is compared with
information provided by the board metadata.

min_flash: <integer>
minimum amount of ROM in KB needed for this test to build and run. This is compared with
information provided by the board metadata.

timeout: <number of seconds>
Length of time to run test before automatically killing it. Default to 60 seconds.

arch_allow: <list of arches, such as x86, arm, arc>
Set of architectures that this test case should only be run for.

arch_exclude: <list of arches, such as x86, arm, arc>
Set of architectures that this test case should not run on.

platform_allow: <list of platforms>
Set of platforms that this test case should only be run for. Do not use this option to limit testing or
building in CI due to time or resource constraints, this option should only be used if the test or sample
only can be run on the allowed platform and nothing else.

integration_platforms: <YML list of platforms/boards>
This option limits the scope to the listed platforms when twister is invoked with the –integration
option. Use this instead of platform_allow if the goal is to limit scope due to timing or resource
constraints.

platform_exclude: <list of platforms>
Set of platforms that this test case should not run on.

extra_sections: <list of extra binary sections>
When computing sizes, twister will report errors if it finds extra, unexpected sections in the Zephyr
binary unless they are named here. They will not be included in the size calculation.

sysbuild: <True|False> (default False)
Build the project using sysbuild infrastructure. Only the main project’s generated devicetree and
Kconfig will be used for filtering tests. on device testing must use the hardware map, or west flash
to load the images onto the target. The –erase option of west flash is not supported with this option. Usage of unsupported options will result in tests requiring sysbuild support being skipped.

**harness:** `<string>`
A harness keyword in the `testcase.yaml` file identifies a Twister harness needed to run a test successfully. A harness is a feature of Twister and implemented by Twister, some harnesses are defined as placeholders and have no implementation yet.

A harness can be seen as the handler that needs to be implemented in Twister to be able to evaluate if a test passes criteria. For example, a keyboard harness is set on tests that require keyboard interaction to reach verdict on whether a test has passed or failed, however, Twister lack this harness implementation at the moment.

Supported harnesses:

- `ztest`
- `test`
- `console`
- `pytest`
- `gtest`
- `robot`

Harnesses `ztest`, `gtest` and `console` are based on parsing of the output and matching certain phrases. `ztest` and `gtest` harnesses look for pass/fail/etc. frames defined in those frameworks. Use `gtest` harness if you’ve already got tests written in the gTest framework and do not wish to update them to zTest. The `console` harness tells Twister to parse a test's text output for a regex defined in the test's YAML file. The `robot` harness is used to execute Robot Framework test suites in the Renode simulation framework.

Some widely used harnesses that are not supported yet:

- `keyboard`
- `net`
- `bluetooth`

**platform_key:** `<list of platform attributes>`
Often a test needs to only be built and run once to qualify as passing. Imagine a library of code that depends on the platform architecture where passing the test on a single platform for each arch is enough to qualify the tests and code as passing. The `platform_key` attribute enables doing just that.

For example to key on (arch, simulation) to ensure a test is run once per arch and simulation (as would be most common):

```yaml
platform_key:
  - arch
  - simulation
```

Adding platform (board) attributes to include things such as soc name, soc family, and perhaps sets of IP blocks implementing each peripheral interface would enable other interesting uses. For example, this could enable building and running SPI tests once for each unique IP block.

**harness_config:** `<harness configuration options>`
Extra harness configuration options to be used to select a board and/or for handling generic Console with regex matching. Config can announce what features it supports. This option will enable the test to run on only those platforms that fulfill this external dependency.

The following options are currently supported:

- **type:** `<one_line|multi_line>` *(required)*
  Depends on the regex string to be matched
record: <recording options>

regex: <expression> (required)
Any string that the particular test case prints to record test results.

regex: <expression> (required)
Any string that the particular test case prints to confirm test runs as expected.

ordered: <True|False> (default False)
Check the regular expression strings in orderly or randomly fashion

repeat: <integer>
Number of times to validate the repeated regex expression

fixture: <expression>
Specify a test case dependency on an external device (e.g., sensor), and identify setups that fulfill this dependency. It depends on specific test setup and board selection logic to pick the particular board(s) out of multiple boards that fulfill the dependency in an automation setup based on “fixture” keyword. Some sample fixture names are i2c_hts221, i2c_bme280, i2c_FRAM, ble_fw and gpio_loop.

Only one fixture can be defined per testcase and the fixture name has to be unique across all tests in the test suite.

pytest_root: <list of pytest testpaths> (default pytest)
Specify a list of pytest directories, files or subtests that need to be executed when test case begin to running, default pytest directory is pytest. After pytest finished, twister will check if this case pass or fail according to the pytest report.

pytest_args: <list of arguments> (default empty)
Specify a list of additional arguments to pass to pytest.

robot_test_path: <robot file path> (default empty)
Specify a path to a file containing a Robot Framework test suite to be run.

The following is an example yaml file with a few harness_config options.

```yaml
sample:
  name: HTS221 Temperature and Humidity Monitor
common:
tags: sensor
harness: console
harness_config:
type: multi_line
ordered: false
regex:
  - "Temperature:(.*)C"
  - "Relative Humidity:(.*)%"
fixture: i2c_hts221
tests:
test:
tags: sensors
depends_on: i2c
```

The following is an example yaml file with pytest harness_config options, default pytest_root name “pytest” will be used if pytest_root not specified. Please refer the examples in samples/subsys/testsuite/pytest/.

```yaml
common:
harness: pytest
tests:
  pytest.example.directories:
    harness_config:
```
(continues on next page)
pytest_root:
- pytest_dir1
- $ENV_VAR/samples/test/pytest_dir2

pytest.example.files_and_subtests:
  harness_config:
    pytest_root:
    - pytest/test_file_1.py
    - test_file_2.py::test_A
    - test_file_2.py::test_B[param_a]

The following is an example yaml file with robot harness_config options.

tests:
  robot.example:
    harness: robot
    harness_config:
      robot_test_path: [robot file path]

filter: <expression>

Filter whether the testcase should be run by evaluating an expression against an environment containing the following values:

```
{ ARCH : <architecture>,
 PLATFORM : <platform>,
 <all CONFIG_* key/value pairs in the test's generated defconfig>,
 *<env>: any environment variable available
}
```

Twister will first evaluate the expression to find if a “limited” cmake call, i.e. using package_helper cmake script, can be done. Existence of “dt_” entries indicates devicetree is needed. Existence of “CONFIG*” entries indicates kconfig is needed. If there are no other types of entries in the expression a filtration can be done without creating a complete build system. If there are entries of other types a full cmake is required.

The grammar for the expression language is as follows:

```
exression ::= expression “and” expression

  “or” expression
  “not” expression
  “(” expression “)”

  symbol “==” constant
  symbol “!=” constant
  symbol “<” number
  symbol “>” number
  symbol “>=” number
  symbol “<=” number
  symbol “in” list
  symbol “:” string

list ::= “[” list_contents “]”

list_contents ::= constant
```

2.12. Testing
constant ::= number

string

For the case where expression ::= symbol, it evaluates to true if the symbol is defined to a non-empty string.

Operator precedence, starting from lowest to highest:

or (left associative) and (left associative) not (right associative) all comparison operators (non-associative)

arch_allow, arch_exclude, platform_allow, platform_exclude are all syntactic sugar for these expressions. For instance

arch_exclude = x86 arc

Is the same as:

filter = not ARCH in ["x86", "arc"]

The ‘:’ operator compiles the string argument as a regular expression, and then returns a true value only if the symbol's value in the environment matches. For example, if CONFIG_SOC="stm32f107xc" then

filter = CONFIG_SOC : "stm.*"

Would match it.

required_snippets: <list of needed snippets>

Snippets are supported in twister for test cases that require them. As with normal applications, twister supports using the base zephyr snippet directory and test application directory for finding snippets. Listed snippets will filter supported tests for boards (snippets must be compatible with a board for the test to run on them, they are not optional).

The following is an example yaml file with 2 required snippets.

```yaml
tests:
  snippet.example:
    required_snippets:
    - cdc-acm-console
    - user-snippet-example
```

The set of test cases that actually run depends on directives in the testcase filed and options passed in on the command line. If there is any confusion, running with -v or examining the discard report (twister_discard.csv) can help show why particular test cases were skipped.

Metrics (such as pass/fail state and binary size) for the last code release are stored in scripts/release/twister_last_release.csv. To update this, pass the –all –release options.

To load arguments from a file, write ‘+’ before the file name, e.g., +file_name. File content must be one or more valid arguments separated by line break instead of white spaces.

Most everyday users will run with no arguments.

Managing tests timeouts

There are several parameters which control tests timeouts on various levels:

- timeout option in each test case. See here for more details.
- timeout_multiplier option in board configuration. See here for more details.
- --timeout-multiplier twister option which can be used to adjust timeouts in exact twister run.

It can be useful in case of simulation platform as simulation time may depend on the host speed & load or we may select different simulation method (i.e. cycle accurate but slower one), etc…
Overall test case timeout is a multiplication of these three parameters.

**Running in Integration Mode**

This mode is used in continuous integration (CI) and other automated environments used to give developers fast feedback on changes. The mode can be activated using the `--integration` option of twister and narrows down the scope of builds and tests if applicable to platforms defined under the integration keyword in the testcase definition file (testcase.yaml and sample.yaml).

**Running tests on custom emulator**

Apart from the already supported QEMU and other simulated environments, Twister supports running any out-of-tree custom emulator defined in the board’s `board.cmake`. To use this type of simulation, add the following properties to `custom_board/custom_board.yaml`:

```yaml
simulation: custom
simulation_exec: <name_of_emu_binary>
```

This tells Twister that the board is using a custom emulator called `<name_of_emu_binary>`, make sure this binary exists in the PATH.

Then, in `custom_board/board.cmake`, set the supported emulation platforms to custom:

```cmake
set(SUPPORTED_EMU_PLATFORMS custom)
```

Finally, implement the `run_custom` target in `custom_board/board.cmake`. It should look something like this:

```cmake
add_custom_target(run_custom
    COMMAND
    <name_of_emu_binary to invoke during 'run'>
    <any args to be passed to the command, i.e. ${BOARD}, ${APPLICATION_BINARY_DIR}/zephyr/zephyr.elf>
    WORKING_DIRECTORY ${APPLICATION_BINARY_DIR}
    DEPENDS ${logical_target_for_zephyr_elf}
    USES_TERMINAL
)
```

**Running Tests on Hardware**

Beside being able to run tests in QEMU and other simulated environments, twister supports running most of the tests on real devices and produces reports for each run with detailed FAIL/PASS results.

**Executing tests on a single device**

To use this feature on a single connected device, run twister with the following new options:

**Linux**

```bash
scripts/twister --device-testing --device-serial /dev/ttyACM0 --device-serial-baud 115200 -p frdm_k64f -T tests/kernel
```

**Windows**

```bash
python .\scripts\twister --device-testing --device-serial COM1 --device-serial-baud 115200 -p frdm_k64f -T tests/kernel
```
The \texttt{--device-serial} option denotes the serial device the board is connected to. This needs to be accessible by the user running \texttt{twister}. You can run this on only one board at a time, specified using the \texttt{--platform} option.

The \texttt{--device-serial-baud} option is only needed if your device does not run at 115200 baud.

To support devices without a physical serial port, use the \texttt{--device-serial-pty} option. In this cases, log messages are captured for example using a script. In this case you can run \texttt{twister} with the following options:

\texttt{Linux}

\begin{verbatim}
scripts/twister --device-testing --device-serial-pty "script.py" \n-p intel_adsp_cavs25 -T tests/kernel
\end{verbatim}

\texttt{Windows}

\begin{verbatim}
Note: Not supported on Windows OS
\end{verbatim}

The script is user-defined and handles delivering the messages which can be used by \texttt{twister} to determine the test execution status.

The \texttt{--device-flash-timeout} option allows to set explicit timeout on the device flash operation, for example when device flashing takes significantly large time.

The \texttt{--device-flash-with-test} option indicates that on the platform the flash operation also executes a test case, so the flash timeout is increased by a test case timeout.

\textbf{Executing tests on multiple devices}  To build and execute tests on multiple devices connected to the host PC, a hardware map needs to be created with all connected devices and their details such as the serial device, baud and their IDs if available. Run the following command to produce the hardware map:

\texttt{Linux}

\begin{verbatim}
./scripts/twister --generate-hardware-map map.yml
\end{verbatim}

\texttt{Windows}

\begin{verbatim}
python .\scripts\twister --generate-hardware-map map.yml
\end{verbatim}

The generated hardware map file (map.yml) will have the list of connected devices, for example:

\texttt{Linux}

\begin{verbatim}
- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: unknown
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
- connected: true
  id: 000683759358
  platform: unknown
  product: J-Link
  runner: unknown
  serial: /dev/cu.usbmodem0006837593581
\end{verbatim}

\texttt{Windows}
Any options marked as ‘unknown’ need to be changed and set with the correct values, in the above example the platform names, the products and the runners need to be replaced with the correct values corresponding to the connected hardware. In this example we are using a reel_board and an nrf52840dk_nrf52840:

Linux

- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
  baud: 9600
- connected: true
  id: 000683759358
  platform: nrf52840dk_nrf52840
  product: J-Link
  runner: nrfjprog
  serial: /dev/cu.usbmodem0006837593581
  baud: 9600

Windows

- connected: true
  id: OSHW000032254e4500128002ab98002784d1000097969900
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: COM1
  baud: 9600
- connected: true
  id: 000683759358
  platform: nrf52840dk_nrf52840
  product: J-Link
  runner: nrfjprog
  serial: COM2
  baud: 9600

The baud entry is only needed if not running at 115200.

If the map file already exists, then new entries are added and existing entries will be updated. This way you can use one single master hardware map and update it for every run to get the correct serial devices and status of the devices.

With the hardware map ready, you can run any tests by pointing to the map

2.12. Testing
The above command will result in twister building tests for the platforms defined in the hardware map and subsequently flashing and running the tests on those platforms.

**Note:** Currently only boards with support for both pyocd and nrfjprog are supported with the hardware map features. Boards that require other runners to flash the Zephyr binary are still work in progress.

Hardware map allows to set `--device-flash-timeout` and `--device-flash-with-test` command line options as `flash-timeout` and `flash-with-test` fields respectively. These hardware map values override command line options for the particular platform.

Serial PTY support using `--device-serial-pty` can also be used in the hardware map:

```
- connected: true
  id: None
  platform: intel_adsp_cavs25
  product: None
  runner: intel_adsp
  serial_pty: path/to/script.py
  runner_params:
    - --remote-host=remote_host_ip_addr
    - --key=/path/to/key.pem
```

The runner_params field indicates the parameters you want to pass to the west runner. For some boards the west runner needs some extra parameters to work. It is equivalent to following west and twister commands.

**Linux**

```
west flash --remote-host remote_host_ip_addr --key /path/to/key.pem
twister -p intel_adsp_cavs25 --device-testing --device-serial-pty script.py
--west-flash="--remote-host=remote_host_ip_addr,--key=/path/to/key.pem"
```

**Windows**

**Note:** Not supported on Windows OS

**Note:** For serial PTY, the “--generate-hardware-map” option cannot scan it out and generate a correct hardware map automatically. You have to edit it manually according to above example. This is because the serial port of the PTY is not fixed and being allocated in the system at runtime.

**Fixtures** Some tests require additional setup or special wiring specific to the test. Running the tests without this setup or test fixture may fail. A testcase can specify the fixture it needs which can then be matched with hardware capability of a board and the fixtures it supports via the command line or using the hardware map file.

Fixtures are defined in the hardware map file as a list:
When running `twister` with `--device-testing`, the configured fixture in the hardware map file will be matched to testcases requesting the same fixtures and these tests will be executed on the boards that provide this fixture.

Fixtures can also be provided via `twister` command option `--fixture`, this option can be used multiple times and all given fixtures will be appended as a list. And the given fixtures will be assigned to all boards, this means that all boards set by current `twister` command can run those testcases which request the same fixtures.

**Notes**  It may be useful to annotate board descriptions in the hardware map file with additional information. Use the “notes” keyword to do this. For example:

```
- connected: false
  fixtures:
```

(continues on next page)
- gpio_loopback
id: 000683290670
notes: An nrf5340dk_nrf5340 is detected as an nrf52840dk_nrf52840 with no serial port, and three serial ports with an unknown platform. The board id of the serial ports is not the same as the board id of the development kit. If you regenerate this file you will need to update serial to reference the third port, and platform to nrf5340dk_nrf5340_cpuapp or another supported board target.

platform: nrf52840dk_nrf52840
product: J-Link
runner: jlink
serial: null

Overriding Board Identifier When (re-)generated the hardware map file will contain an “id” keyword that serves as the argument to --board-id when flashing. In some cases the detected ID is not the correct one to use, for example when using an external J-Link probe. The “probe_id” keyword overrides the “id” keyword for this purpose. For example:

- connected: false
  id: 0229000005d9ebc600000000000000000000000097969905
  platform: mimxrt1060_evk
  probe_id: 000609301751
  product: DAPLink CMSIS-DAP
  runner: jlink
  serial: null

Quarantine Twister allows user to provide configuration files defining a list of tests or platforms to be put under quarantine. Such tests will be skipped and marked accordingly in the output reports. This feature is especially useful when running larger test suits, where a failure of one test can affect the execution of other tests (e.g. putting the physical board in a corrupted state).

To use the quarantine feature one has to add the argument --quarantine-list <PATH_TO_QUARANTINE_YAML> to a twister call. Multiple quarantine files can be used. The current status of tests on the quarantine list can also be verified by adding --quarantine-verify to the above argument. This will make twister skip all tests which are not on the given list.

A quarantine yaml has to be a sequence of dictionaries. Each dictionary has to have “scenarios” and “platforms” entries listing combinations of scenarios and platforms to put under quarantine. In addition, an optional entry “comment” can be used, where some more details can be given (e.g. link to a reported issue). These comments will also be added to the output reports.

When quarantining a class of tests or many scenarios in a single testsuite or when dealing with multiple issues within a subsystem, it is possible to use regular expressions, for example, kernel.* would quarantine all kernel tests.

An example of entries in a quarantine yaml:

- scenarios:
  - sample.basic.helloworld
  comment: "Link to the issue: https://github.com/zephyrproject-rtos/zephyr/pull/33287"

- scenarios:
  - kernel.common
  - kernel.common.(misra|tls)
  - kernel.common.nano64

(continues on next page)
To exclude a platform, use the following syntax:

```
- platforms:
  - qemu_x86
  comment: "broken qemu"
```

Additionally you can quarantine entire architectures or a specific simulator for executing tests.

**Test Configuration**

A test configuration can be used to customize various aspects of twister and the default enabled options and features. This allows tweaking the filtering capabilities depending on the environment and makes it possible to adapt and improve coverage when targeting different sets of platforms.

The test configuration also adds support for test levels and the ability to assign a specific test to one or more levels. Using command line options of twister it is then possible to select a level and just execute the tests included in this level.

Additionally, the test configuration allows defining level dependencies and additional inclusion of tests into a specific level if the test itself does not have this information already.

In the configuration file you can include complete components using regular expressions and you can specify which test level to import from the same file, making management of levels easier.

To help with testing outside of upstream CI infrastructure, additional options are available in the configuration file, which can be hosted locally. As of now, those options are available:

- Ability to ignore default platforms as defined in board definitions (Those are mostly emulation platforms used to run tests in upstream CI)
- Option to specify your own list of default platforms overriding what upstream defines.
- Ability to override build_onl_all options used in some testcases. This will treat tests or sample as any other just build for default platforms you specify in the configuration file or on the command line.
- Ignore some logic in twister to expand platform coverage in cases where default platforms are not in scope.

**Platform Configuration**

The following options control platform filtering in twister:

- **override_default_platforms**: override default key a platform sets in board configuration and instead use the list of platforms provided in the configuration file as the list of default platforms. This option is set to False by default.
- **increased_platform_scope**: This option is set to True by default, when disabled, twister will not increase platform coverage automatically and will only build and run tests on the specified platforms.
- **default_platforms**: A list of additional default platforms to add. This list can either be used to replace the existing default platforms or can extend it depending on the value of **override_default_platforms**.

And example platforms configuration:

```
platforms:
  - platforms: true
  increased_platform_scope: false
```

(continues on next page)
Test Level Configuration  The test configuration allows defining test levels, level dependencies and additional inclusion of tests into a specific test level if the test itself does not have this information already.

In the configuration file you can include complete components using regular expressions and you can specify which test level to import from the same file, making management of levels simple.

And example test level configuration:

```yaml
levels:
  - name: my-test-level
    description: >
      my custom test level
    adds:
      - kernel.threads.*
      - kernel.timer.behavior
      - arch.interrupt
      - boards.*
```

Combined configuration  To mix the Platform and level configuration, you can take an example as below:

And example platforms plus level configuration:

```yaml
platforms:
  override_default_platforms: true
  default_platforms:
    - frdm_k64f
levels:
  - name: smoke
    description: >
      A plan to be used verifying basic zephyr features.
  - name: unit
    description: >
      A plan to be used verifying unit test.
  - name: integration
    description: >
      A plan to be used verifying integration.
  - name: acceptance
    description: >
      A plan to be used verifying acceptance.
  - name: system
    description: >
      A plan to be used verifying system.
  - name: regression
    description: >
      A plan to be used verifying regression.
```

To run with above test_config.yaml file, only default_platforms with given test level test cases will run.

```bash
scripts/twister --test-config=<path to>/test_config.yaml -T tests --level="smoke"
```
Running in Tests in Random Order

Enable ZTEST framework's `CONFIG_ZTEST_SHUFFLE` config option to run your tests in random order. This can be beneficial for identifying dependencies between test cases. For native_posix platforms, you can provide the seed to the random number generator by providing `-seed=value` as an argument to twister. See `Shuffling Test Sequence` for more details.

Robot Framework Tests

Zephyr supports Robot Framework as one of solutions for automated testing.

Robot files allow you to express interactive test scenarios in human-readable text format and execute them in simulation or against hardware. At this moment Zephyr integration supports running Robot tests in the Renode simulation framework.

To execute a Robot test suite with twister, run the following command:

**Linux**

```
$ ./scripts/twister --platform hifive1 --test samples/subsys/shell/shell_module/samples/shell.shell.shell_module.robot
```

**Windows**

```
python .\scripts\twister --platform hifive1 --test samples/subsys/shell/shell_module/samples/shell.shell.shell_module.robot
```

It's also possible to run it by `west` directly, with:

```
$ ROBOT_FILES=shell_module.robot west build -p -b hifive1 -s samples/subsys/shell/shell_module -t run_renode_test
```

Writing Robot tests  For the list of keywords provided by the Robot Framework itself, refer to the official Robot documentation.

Information on writing and running Robot Framework tests in Renode can be found in the testing section of Renode documentation. It provides a list of the most commonly used keywords together with links to the source code where those are defined.

It's possible to extend the framework by adding new keywords expressed directly in Robot test suite files, as an external Python library or, like Renode does it, dynamically via XML-RPC. For details see the extending Robot Framework section in the official Robot documentation.

2.12.3 Integration with pytest test framework

*Please mind that integration of twister with pytest is still work in progress. Not every platform type is supported in pytest (yet). If you find any issue with the integration or have an idea for an improvement, please, let us know about it and open a GitHub issue/enhancement.*

Introduction

Pytest is a python framework that “makes it easy to write small, readable tests, and can scale to support complex functional testing for applications and libraries” ([https://docs.pytest.org/en/7.3.x/](https://docs.pytest.org/en/7.3.x/)). Python is known for its free libraries and ease of using it for scripting. In addition, pytest utilizes the concept of plugins and fixtures, increasing its expendability and reusability. A pytest plugin `pytest-twister-harness` was introduced to provide an integration between pytest and twister, allowing Zephyr's community to utilize pytest functionality with keeping twister as the main framework.
Integration with twister

By default, there is nothing to be done to enable pytest support in twister. The plugin is developed as a part of Zephyr's tree. To enable install-less operation, twister first extends PYTHONPATH with path to this plugin, and then during pytest call, it appends the command with -p `twister_harness.plugin` argument. If one prefers to use the installed version of the plugin, they must add `--allow-installed-plugin` flag to twister's call.

Pytest-based test suites are discovered the same way as other twister tests, i.e., by a presence of testcase/sample.yaml. Inside, a keyword `harness` tells twister how to handle a given test. In the case of `harness: pytest`, most of twister workflow (test suites discovery, parallelization, building and reporting) remains the same as for other harnesses. The change happens during the execution step. The below picture presents a simplified overview of the integration.

If `harness: pytest` is used, twister delegates the test execution to pytest, by calling it as a subprocess. Required parameters (such as build directory, device to be used, etc.) are passed through a CLI command. When pytest is done, twister looks for a pytest report (results.xml) and sets the test result accordingly.
How to create a pytest test

An example of a pytest test is given at samples/subsys/testsuite/pytest/shell/pytest/test_shell.py. Twister calls pytest for each configuration from the .yaml file which uses harness: pytest. By default, it points to pytest directory, located next to a directory with binary sources. A keyword pytest_root placed under harness_config section can be used to point to other files, directories or subtests.

Pytest scans the given locations looking for tests, following its default discovery rules. One can also pass some extra arguments to the pytest from yaml file using pytest_args keyword under harness_config, e.g.: pytest_args: ['-k=test_method', '--log-level=DEBUG'].

Helpers & fixtures

dut  Give access to a DeviceAdapter type object, that represents Device Under Test. This fixture is the core of pytest harness plugin. It is required to launch DUT (initialize logging, flash device, connect serial etc). This fixture yields a device prepared according to the requested type (native posix, qemu, hardware, etc.). All types of devices share the same API. This allows for writing tests which are device-type-agnostic.

    from twister_harness import DeviceAdapter
    def test_sample(dut: DeviceAdapter):
        dut.readlines_until('Hello world')

shell  Provide an object with methods used to interact with shell application. It calls wait_for_prompt method, to not start scenario until DUT is ready. Note that it uses dut fixture, so dut can be skipped when shell is used.

    from twister_harness import Shell
    def test_shell(shell: Shell):
        shell.exec_command('help')

mcumgr  Sample fixture to wrap mcumgr command-line tool used to manage remote devices. More information about MCUmgr can be found here MCUmgr.

Note: This fixture requires the mcumgr available in the system PATH

Only selected functionality of MCUmgr is wrapped by this fixture. For example, here is a test with a fixture mcumgr

    from twister_harness import DeviceAdapter, Shell, McuMgr
    def test_upgrade(dut: DeviceAdapter, shell: Shell, mcumgr: McuMgr):
        # free the serial port for mcumgr
        dut.disconnect()
        # upload the signed image
        mcumgr.image_upload('path/to/zephyr.signed.bin')
        # obtain the hash of uploaded image from the device
        second_hash = mcumgr.get_hash_to_test()
        # test a new upgrade image
        mcumgr.image_test(second_hash)
        # reset the device remotely
        mcumgr.reset_device()
        # continue test scenario, check version etc.
Limitations

- Not every platform type is supported in the plugin (yet).

2.12.4 Generating coverage reports

With Zephyr, you can generate code coverage reports to analyze which parts of the code are covered by a given test or application.

You can do this in two ways:

- In a real embedded target or QEMU, using Zephyr’s gcov integration
- Directly in your host computer, by compiling your application targeting the POSIX architecture

Test coverage reports in embedded devices or QEMU

Overview

GCC GCOV is a test coverage program used together with the GCC compiler to analyze and create test coverage reports for your programs, helping you create more efficient, faster running code and discovering untested code paths.

In Zephyr, gcov collects coverage profiling data in RAM (and not to a file system) while your application is running. Support for gcov collection and reporting is limited by available RAM size and so is currently enabled only for QEMU emulation of embedded targets.

Details

There are 2 parts to enable this feature. The first is to enable the coverage for the device and the second to enable in the test application. As explained earlier the code coverage with gcov is a function of RAM available. Therefore ensure that the device has enough RAM when enabling the coverage for it. For example a small device like frdm_k64f can run a simple test application but the more complex test cases which consume more RAM will crash when coverage is enabled.

To enable the device for coverage, select CONFIG_HAS_COVERAGE_SUPPORT in the Kconfig.board file.

To report the coverage for the particular test application set CONFIG_COVERAGE.

Steps to generate code coverage reports

These steps will produce an HTML coverage report for a single application.

1. Build the code with CONFIG_COVERAGE=y.

```bash
west build -b mps2_an385 -- -DCONFIG_COVERAGE=y -DCONFIG_COVERAGE_DUMP=y
```

2. Capture the emulator output into a log file. You may need to terminate the emulator with Ctrl-A X for this to complete after the coverage dump has been printed:

```bash
ninja -Cbuild run | tee log.log
```

3. Generate the gcov .gcda and .gcno files from the log file that was saved:

```bash
$ python3 scripts/gen_gcov_files.py -i log.log
```

4. Find the gcov binary placed in the SDK. You will need to pass the path to the gcov binary for the appropriate architecture when you later invoke gcovr:
$ find $ZEPHYR_SDK_INSTALL_DIR -iregex ".*gcov"

5. Create an output directory for the reports:

$ mkdir -p gcov_report

6. Run gcovr to get the reports:

$ gcovr -r $ZEPHYR_BASE . --html -o gcov_report/coverage.html --html-details --gcov-executable <gcov_path_in_SDK>

Coverage reports using the POSIX architecture

When compiling for the POSIX architecture, you utilize your host native tooling to build a native executable which contains your application, the Zephyr OS, and some basic HW emulation.

That means you can use the same tools you would while developing any other desktop application.

To build your application with gcc's gcov, simply set CONFIG_COVERAGE before compiling it. When you run your application, gcov coverage data will be dumped into the respective gcda and gcno files. You may postprocess these with your preferred tools. For example:

west build -b native_posix samples/hello_world -- -DCONFIG_COVERAGE=y

$ ./build/zephyr/zephyr.exe
# Press Ctrl+C to exit
lcov --capture --directory ./ --output-file lcov.info -q --rc lcov_branch_coverage=1
genhtml lcov.info --output-directory lcov_html -q --ignore-errors source --branch-coverage --highlight --legend

Note: You need a recent version of lcov (at least 1.14) with support for intermediate text format. Such packages exist in recent Linux distributions.
Alternatively, you can use gcovr (at least version 4.2).

Coverage reports using Twister

Zephyr's twister script can automatically generate a coverage report from the tests which were executed. You just need to invoke it with the --coverage command line option.

For example, you may invoke:

$ twister --coverage -p qemu_x86 -T tests/kernel

or:

$ twister --coverage -p native_posix -T tests/bluetooth

which will produce twister-out/coverage/index.html with the report.

The process differs for unit tests, which are built with the host toolchain and require a different board:

$ twister --coverage -p unit_testing -T tests/unit

which produces a report in the same location as non-unit testing.
Using different toolchains  Twister looks at the environment variable ZEPHYR_TOOLCHAIN_VARIANT to check which gcov tool to use by default. The following are used as the default for the Twister --gcov-tool argument default:

<table>
<thead>
<tr>
<th>Toolchain</th>
<th>--gcov-tool value</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>gcov</td>
</tr>
<tr>
<td>llvm</td>
<td>llvm-cov gcov</td>
</tr>
<tr>
<td>zephyr</td>
<td>gcov</td>
</tr>
</tbody>
</table>

2.12.5 BabbleSim

BabbleSim and Zephyr

In the Zephyr project we use the Babblesim simulator to test some of the Zephyr radio protocols, including the BLE stack, 802.15.4, and some of the networking stack.

BabbleSim is a physical layer simulator, which in combination with the Zephyr bsim boards can be used to simulate a network of BLE and 15.4 devices. When we build Zephyr targeting an nrf52_bsim board we produce a Linux executable, which includes the application, Zephyr OS, and models of the HW.

When there is radio activity, this Linux executable will connect to the BabbleSim Phy simulation to simulate the radio channel.

In the BabbleSim documentation you can find more information on how to get and build the simulator. In the nrf52_bsim board documentation you can find more information about how to build Zephyr targeting that particular board, and a few examples.

Types of tests

Tests without radio activity: bsim tests with twister  The bsim boards can be used without radio activity, and in that case, it is not necessary to connect them to a physical layer simulation. Thanks to this, this target boards can be used just like native_posix with twister, to run all standard Zephyr twister tests, but with models of a real SOC HW, and their drivers.

Tests with radio activity  When there is radio activity, BabbleSim tests require at least a physical layer simulation running, and most, more than 1 simulated device. Due to this, these tests are not build and run with twister, but with a dedicated set of tests scripts.

These tests are kept in the tests/bsim/ folder. There you can find a README with more information about how to build and run them, as well as the convention they follow.

There are two main sets of tests of these type:

- Self checking embedded application/tests: In which some of the simulated devices applications are built with some checks which decide if the test is passing or failing. These embedded applications tests use the bs_tests system to report the pass or failure, and in many cases to build several tests into the same binary.

- Test using the EDTT tool, in which a EDTT (python) test controls the embedded applications over an RPC mechanism, and decides if the test passes or not. Today these tests include a very significant subset of the BT qualification test suite.

More information about how different tests types relate to BabbleSim and the bsim boards can be found in the bsim boards tests section.
Test coverage and BabbleSim

As the nrf52_bsim is based on the POSIX architecture, you can easily collect test coverage information. You can use the script tests/bsim/generate_coverage_report.sh to generate an html coverage report from tests. Check the page on coverage generation for more info.

2.12.6 ZTest Deprecated APIs

Ztest is currently being migrated to a new API, this documentation provides information about the deprecated APIs which will eventually be removed. See Test Framework for the new API. Similarly, ZTest's mocking framework is also deprecated (see Mocking via FFF).

Quick start - Unit testing

Ztest can be used for unit testing. This means that rather than including the entire Zephyr OS for testing a single function, you can focus the testing efforts into the specific module in question. This will speed up testing since only the module will have to be compiled in, and the tested functions will be called directly.

Since you won’t be including basic kernel data structures that most code depends on, you have to provide function stubs in the test. Ztest provides some helpers for mocking functions, as demonstrated below.

In a unit test, mock objects can simulate the behavior of complex real objects and are used to decide whether a test failed or passed by verifying whether an interaction with an object occurred, and if required, to assert the order of that interaction.

Best practices for declaring the test suite

twister and other validation tools need to obtain the list of subcases that a Zephyr ztest test image will expose.

Rationale

This all is for the purpose of traceability. It’s not enough to have only a semaphore test project. We also need to show that we have testpoints for all APIs and functionality, and we trace back to documentation of the API, and functional requirements.

The idea is that test reports show results for every sub-testcase as passed, failed, blocked, or skipped. Reporting on only the high-level test project level, particularly when tests do too many things, is too vague.

There exist two alternatives to writing tests. The first, and more verbose, approach is to directly declare and run the test suites. Here is a generic template for a test showing the expected use of ztest_test_suite():

```
#include <zephyr/ztest.h>

extern void test_sometest1(void);
extern void test_sometest2(void);
#endif /* Conditionally skip test_sometest3 */
void test_sometest3(void)
{
    ztest_test_skip();
}
#endif
extern void test_sometest3(void);
```

(continues on next page)
# endif
extern void test_sometest4(void);
...

void test_main(void)
{
    ztest_test_suite(common,
                     ztest_unit_test(test_sometest1),
                     ztest_unit_test(test_sometest2),
                     ztest_unit_test(test_sometest3),
                     ztest_unit_test(test_sometest4)
    );
    ztest_run_test_suite(common);
}

Alternatively, it is possible to split tests across multiple files using ztest_register_test_suite() which bypasses the need for extern:

```
#include <zephyr/ztest.h>

void test_sometest1(void) {
    zassert_true(1, "true");
}

ztest_register_test_suite(common, NULL,
                          ztest_unit_test(test_sometest1)
                          );
```

The above sample simple registers the test suite and uses a NULL pragma function (more on that later). It is important to note that the test suite isn’t directly run in this file. Instead two alternatives exist for running the suite. First, if to do nothing. A default test_main function is provided by ztest. This is the preferred approach if the test doesn’t involve a state and doesn’t require use of the pragma.

In cases of an integration test it is possible that some general state needs to be set between test suites. This can be thought of as a state diagram in which test_main simply goes through various actions that modify the board’s state and different test suites need to run. This is achieved in the following:

```
#include <zephyr/ztest.h>

struct state {
    bool is_hibernating;
    bool is_usb_connected;
}

static bool pragma_always(const void *state)
{
    return true;
}

static bool pragma_not_hibernating_not_connected(const void *s)
{
    struct state *state = s;
    return !state->is_hibernating && !state->is_usb_connected;
}

static bool pragma_usb_connected(const void *s)
{
```

(continues on next page)
return ((struct state *)s)->is_usb_connected;
}
ztest_register_test_suite(baseline, pragma_always,
    ztest_unit_test(test_case0));
ztest_register_test_suite(before_usb, pragma_not_hibernating_not_connected,
    ztest_unit_test(test_case1),
    ztest_unit_test(test_case2));
ztest_register_test_suite(with_usb, pragma_usb_connected,,
    ztest_unit_test(test_case3),
    ztest_unit_test(test_case4));

void test_main(void)
{
    struct state state;

    /* Should run `baseline' test suite only. */
    ztest_run_registered_test_suites(&state);

    /* Simulate power on and update state. */
    emulate_power_on();
    /* Should run `baseline' and `before_usb' test suites. */
    ztest_run_registered_test_suites(&state);

    /* Simulate plugging in a USB device. */
    emulate_plugging_in_usb();
    /* Should run `baseline' and `with_usb' test suites. */
    ztest_run_registered_test_suites(&state);

    /* Verify that all the registered test suites actually ran. */
    ztest_verify_all_registered_test_suites_ran();
}

For twister to parse source files and create a list of subcases, the declarations of ztest_test_suite() and ztest_register_test_suite() must follow a few rules:

- one declaration per line
- conditional execution by using ztest_test_skip()

What to avoid:

- packing multiple testcases in one source file

```c
void test_main(void)
{
    #ifdef TEST_feature1
    ztest_test_suite(feature1,
        ztest_unit_test(test_1a),
        ztest_unit_test(test_1b),
        ztest_unit_test(test_1c)
    );
    ztest_run_test_suite(feature1);
    #endif

    #ifdef TEST_feature2
    ztest_test_suite(feature2,
        ztest_unit_test(test_2a),
        ...
    #endif

    (continues on next page)
• Do not use `#if`

```c
ztest_test_suite(common,
    ztest_unit_test(test_sometest1),
    ztest_unit_test(test_sometest2),
#ifdef CONFIG_WHATEVER
    ztest_unit_test(test_sometest3),
#endif
    ztest_unit_test(test_sometest4),
```...

• Do not add comments on lines with a call to `ztest_unit_test()`:

```c
ztest_test_suite(common,
    ztest_unit_test(test_sometest1),
    ztest_unit_test(test_sometest2) /* will fail */,
    /* will fail! */ ztest_unit_test(test_sometest3),
    ztest_unit_test(test_sometest4),
```...

• Do not define multiple definitions of unit / user unit test case per line

```c
ztest_test_suite(common,
    ztest_unit_test(test_sometest1), ztest_unit_test(test_˓
>sometest2),
    ztest_unit_test(test_sometest3),
    ztest_unit_test(test_sometest4),
```...

Other questions:

• Why not pre-scan with CPP and then parse? or post scan the ELF file?

If C pre-processing or building fails because of any issue, then we won’t be able to tell the subcases.

• Why not declare them in the YAML testcase description?

A separate testcase description file would be harder to maintain than just keeping the information in the test source files themselves – only one file to update when changes are made eliminates duplication.

Mocking

These functions allow abstracting callbacks and related functions and controlling them from specific tests. You can enable the mocking framework by setting `CONFIG_ZTEST_MOCKING` to “y” in the configuration file of the test. The amount of concurrent return values and expected parameters is limited by `CONFIG_ZTEST_PARAMETER_COUNT`.

Here is an example for configuring the function `expect_two_parameters` to expect the values `a=2` and `b=3`, and telling `returns_int` to return 5:

```
#include <zephyr/ztest.h>
```
```c
static void expect_two_parameters(int a, int b)
{
    ztest_check_expected_value(a);
    ztest_check_expected_value(b);
}

static void parameter_tests(void)
{
    ztest_expect_value(expect_two_parameters, a, 2);
    ztest_expect_value(expect_two_parameters, b, 3);
    expect_two_parameters(2, 3);
}

static int returns_int(void)
{
    return ztest_get_return_value();
}

static void return_value_tests(void)
{
    ztest_returns_value(returns_int, 5);
    zassert_equal(returns_int(), 5, NULL);
}

void test_main(void)
{
    ztest_test_suite(mock_framework_tests,
        ztest_unit_test(parameter_test),
        ztest_unit_test(return_value_test)
    );
    ztest_run_test_suite(mock_framework_tests);
}
```

group ztest_mock

This module provides simple mocking functions for unit testing.
These need CONFIG_ZTEST_MOCKING=y.

Defines

`ztest_expect_value(func, param, value)`

Tell function `func` to expect the value `value` for `param`.

When using `ztest_check_expected_value()`, tell that the value of `param` should be `value`. The value will internally be stored as an `uintptr_t`.

Parameters

- `func` – Function in question
- `param` – Parameter for which the value should be set
- `value` – Value for `param`

`ztest_check_expected_value(param)`

If `param` doesn’t match the value set by `ztest_expect_value()`, fail the test.
This will first check that does `param` have a value to be expected, and then checks whether the value of the parameter is equal to the expected value. If either of these checks fail, the current test will fail. This must be called from the called function.

**Parameters**
- `param` – Parameter to check

`ztest_expect_data(func, param, data)`

Tell function `func` to expect the data `data` for `param`.

When using `ztest_check_expected_data()`, the data pointed to by `param` should be same `data` in this function. Only data pointer is stored by this function, so it must still be valid when `ztest_check_expected_data` is called.

**Parameters**
- `func` – Function in question
- `param` – Parameter for which the data should be set
- `data` – pointer for the data for parameter `param`

`ztest_check_expected_data(param, length)`

If data pointed by `param` don’t match the data set by `ztest_expect_data()`, fail the test.

This will first check that `param` is expected to be null or non-null and then check whether the data pointed by parameter is equal to expected data. If either of these checks fail, the current test will fail. This must be called from the called function.

**Parameters**
- `param` – Parameter to check
- `length` – Length of the data to compare

`ztest_return_data(func, param, data)`

Tell function `func` to return the data `data` for `param`.

When using `ztest_return_data()`, the data pointed to by `param` should be same `data` in this function. Only data pointer is stored by this function, so it must still be valid when `ztest_copy_return_data` is called.

**Parameters**
- `func` – Function in question
- `param` – Parameter for which the data should be set
- `data` – pointer for the data for parameter `param`

`ztest_copy_return_data(param, length)`

Copy the data set by `ztest_return_data` to the memory pointed by `param`.

This will first check that `param` is not null and then copy the data. This must be called from the called function.

**Parameters**
- `param` – Parameter to return data for
- `length` – Length of the data to return

`ztest_returns_value(func, value)`

Tell `func` that it should return `value`.

**Parameters**
- `func` – Function that should return `value`
- `value` – Value to return from `func`
ztest_get_return_value()
    Get the return value for current function.
    The return value must have been set previously with \texttt{ztest_returns_value()). If no return value exists, the current test will fail.

    \textbf{Returns}
    The value the current function should return

ztest_get_return_value_ptr()
    Get the return value as a pointer for current function.
    The return value must have been set previously with \texttt{ztest_returns_value()). If no return value exists, the current test will fail.

    \textbf{Returns}
    The value the current function should return as a \texttt{void *}

\section*{2.13 Static Code Analysis (SCA)}
Support for static code analysis tools in Zephyr is possible through CMake.
The build setting \texttt{ZEPHYR_SCA_VARIANT} can be used to specify the SCA tool to use. \texttt{ZEPHYR_SCA_VARIANT} is also supported as \texttt{environment variable}.
Use \texttt{-DZEPHYR_SCA_VARIANT=<tool>}, for example \texttt{-DZEPHYR_SCA_VARIANT=sparse} to enable the static analysis tool \texttt{sparse}.

\subsection*{2.13.1 SCA Tool infrastructure}
Support for an SCA tool is implemented in a file: \texttt{sca.cmake} file. The file: \texttt{sca.cmake} must be placed under file: \texttt{<SCA_ROOT>/cmake/sca/<tool>/sca.cmake}. Zephyr itself is always added as an \texttt{SCA_ROOT} but the build system offers the possibility to add additional folders to the \texttt{SCA_ROOT} setting.
You can provide support for out of tree SCA tools by creating the following structure:

\begin{verbatim}
<scra_root>/
  cmake/
    sca/
      <tool>/ # Name of SCA tool, this is the value given to ZEPHYR_SCA_VARIANT
      \-- \_VARIANT
      \-- sca.cmake # CMake code that configures the tool to be used with Zephyr
  \-- Zephyr
\end{verbatim}

To add \texttt{foo} under \texttt{/path/to/my_tools/cmake/sca} create the following structure:

\begin{verbatim}
/path/to/my_tools
  cmake/
    sca/
      foo/
      \-- sca.cmake
\end{verbatim}

To use \texttt{foo} as SCA tool you must then specify \texttt{-DZEPHYR_SCA_VARIANT=foo}.
Remember to add \texttt{/path/to/my_tools} to \texttt{SCA_ROOT}.
\texttt{SCA_TOOL} can be set as a regular CMake setting using \texttt{-DSACA_ROOT=<sca_root>}, or added by a Zephyr module in its \texttt{module.yml} file, see \textit{Zephyr Modules - Build settings}. 

\section*{2.13. Static Code Analysis (SCA)
## 2.13.2 Native SCA Tool support

The following is a list of SCA tools natively supported by Zephyr build system.

### CodeChecker support

CodeChecker is a static analysis infrastructure. It executes analysis tools available on the build system, such as Clang-Tidy, Clang Static Analyzer and Cppcheck. Refer to the analyzer's websites for installation instructions.

#### Installing CodeChecker

CodeChecker itself is a python package available on pypi.

```
pip install codechecker
```

#### Running with CodeChecker

To run CodeChecker, `west build` should be called with a `-DZEPHYR_SCA_VARIANT=codechecker` parameter, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=codechecker
```

#### Configuring CodeChecker

To configure CodeChecker or analyzers used, arguments can be passed using the `CODECHECKER_ANALYZE_OPTS` parameter, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=codechecker
-DCODECHECKER_ANALYZE_OPTS="--config;$CODECHECKER_CONFIG_FILE;--timeout;60"
```

#### Storing CodeChecker results

If a CodeChecker server is active the results can be uploaded and stored for tracking purposes. Storing is done using the optional `CODECHECKER_STORE=y` or `CODECHECKER_STORE_OPTS="arg;list"` parameters, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=codechecker
-DCODECHECKER_STORE_OPTS="--name;build;--url=localhost:8001/Default"
```

**Note:** If `--name` isn't passed to either `CODECHECKER_ANALYZE_OPTS` or `CODECHECKER_STORE_OPTS`, the default `zephyr` is used.

#### Exporting CodeChecker reports

Optional reports can be generated using the CodeChecker results, when passing a `-DCODECHECKER_EXPORT=<type>` parameter. Allowed types are: html, json, codeclimate, gerrit, baseline. Multiple types can be passed as comma-separated arguments.

Optional parser configuration arguments can be passed using the `CODECHECKER_PARSE_OPTS` parameter, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=codechecker
-DCODECHECKER_EXPORT=html,json -DCODECHECKER_PARSE_OPTS="--trim-path-prefix;$PWD"
```
Sparse support

Sparse is a static code analysis tool. Apart from performing common code analysis tasks it also supports an address_space attribute, which allows introduction of distinct address spaces in C code with subsequent verification that pointers to different address spaces do not get confused. Additionally it supports a force attribute which should be used to cast pointers between different address spaces. At the moment Zephyr introduces a single custom address space __cache used to identify pointers from the cached address range on the Xtensa architecture. This helps identify cases where cached and uncached addresses are confused.

Running with sparse To run a sparse verification build west build should be called with a -DZEPHYR_SCA_VARIANT=sparse parameter, e.g.

```
w west build -d hello -b intel_adsp_cavs25 zephyr/samples/hello_world -- -DZEPHYR_SCA_VARIANT=sparse
```

2.14 Toolchains

Guides on how to set up toolchains for Zephyr development.

2.14.1 Zephyr SDK

The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr’s supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).

Supported architectures

The Zephyr SDK supports the following target architectures:

- ARC (32-bit and 64-bit; ARCv1, ARCv2, ARCv3)
- ARM (32-bit and 64-bit; ARMv6, ARMv7, ARMv8; A/R/M Profiles)
- MIPS (32-bit and 64-bit)
- Nios II
- RISC-V (32-bit and 64-bit; RV32I, RV32E, RV64I)
- x86 (32-bit and 64-bit)
- Xtensa

Installation bundle and variables

The Zephyr SDK bundle supports all major operating systems (Linux, macOS and Windows) and is delivered as a compressed file. The installation consists of extracting the file and running the included setup script. Additional OS-specific instructions are described in the sections below.

If no toolchain is selected, the build system looks for Zephyr SDK and uses the toolchain from there. You can enforce this by setting the environment variable ZEPHYR_TOOLCHAIN_VARIANT to zephyr.

If you install the Zephyr SDK outside any of the default locations (listed in the operating system specific instructions below) and you want automatic discovery of the Zephyr SDK, then you must register the
Zephyr SDK in the CMake package registry by running the setup script. If you decide not to register the Zephyr SDK in the CMake registry, then the `ZEPHYR_SDK_INSTALL_DIR` can be used to point to the Zephyr SDK installation directory.

You can also set `ZEPHYR_SDK_INSTALL_DIR` to point to a directory containing multiple Zephyr SDKs, allowing for automatic toolchain selection. For example, you can set `ZEPHYR_SDK_INSTALL_DIR` to `/company/tools`, where the `company/tools` folder contains the following subfolders:

- `/company/tools/zephyr-sdk-0.13.2`
- `/company/tools/zephyr-sdk-a.b.c`
- `/company/tools/zephyr-sdk-x.y.z`

This allows the Zephyr build system to choose the correct version of the SDK, while allowing multiple Zephyr SDKs to be grouped together at a specific path.

**Zephyr SDK version compatibility**

In general, the Zephyr SDK version referenced in this page should be considered the recommended version for the corresponding Zephyr version.

For the full list of compatible Zephyr and Zephyr SDK versions, refer to the Zephyr SDK Version Compatibility Matrix.

**Install Zephyr SDK on Linux**

1. Download and verify the Zephyr SDK bundle:

   ```bash
   wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/zephyr-sdk-0.16.3_linux-x86_64.tar.xz
   wget -o - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/sha256.sum | shasum --check --ignore-missing
   ```

   You can change `0.16.3` to another version if needed; the Zephyr SDK Releases page contains all available SDK releases.

   If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace `x86_64` with `aarch64` in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

   ```bash
   cd <sdk download directory>
   tar xvf zephyr-sdk-0.16.3_linux-x86_64.tar.xz
   ```

3. Run the Zephyr SDK bundle setup script:

   ```bash
   cd zephyr-sdk-0.16.3
   ./setup.sh
   ```

   If this fails, make sure Zephyr's dependencies were installed as described in *Install Requirements and Dependencies*.

If you want to uninstall the SDK, remove the directory where you installed it. If you relocate the SDK directory, you need to re-run the setup script.

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following default locations:

- `$HOME`
- `$HOME/.local`
- `$HOME/.local/opt`
$HOME/bin
$HOME/.local
$HOME/.local/opt
$HOME/bin
/opt
/usr/local

The Zephyr SDK bundle archive contains the zephyr-sdk-0.16.3 directory and, when extracted under $HOME, the resulting installation path will be $HOME/zephyr-sdk-0.16.3.

Install Zephyr SDK on macOS

1. Download and verify the Zephyr SDK bundle:

```bash
cd ~
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/zephyr-sdk-0.16.3_macos-x86_64.tar.xz
wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v0.16.3/sha256.sum | shasum --check --ignore-missing
```

If your host architecture is 64-bit ARM (Apple Silicon, also known as M1), replace x86_64 with aarch64 in order to download the 64-bit ARM macOS SDK.

2. Extract the Zephyr SDK bundle archive:

```bash
tar xvf zephyr-sdk-0.16.3_macos-x86_64.tar.xz
```

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following default locations:

- $HOME
- $HOME/.local
- $HOME/.local/opt
- $HOME/bin
- /opt
- /usr/local

The Zephyr SDK bundle archive contains the zephyr-sdk-0.16.3 directory and, when extracted under $HOME, the resulting installation path will be $HOME/zephyr-sdk-0.16.3.

3. Run the Zephyr SDK bundle setup script:

```bash
cd zephyr-sdk-0.16.3
./setup.sh
```

**Note:** You only need to run the setup script once after extracting the Zephyr SDK bundle.

You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

Install Zephyr SDK on Windows

1. Open a cmd.exe window by pressing the Windows key typing “cmd.exe”.
2. Download the Zephyr SDK bundle:
3. Extract the Zephyr SDK bundle archive:

```bash
7z x zephyr-sdk-0.16.3_windows-x86_64.7z
```

**Note:** It is recommended to extract the Zephyr SDK bundle at one of the following default locations:

- `%HOMEPATH%`
- `%PROGRAMFILES%`

The Zephyr SDK bundle archive contains the `zephyr-sdk-0.16.3` directory and, when extracted under `%HOMEPATH%`, the resulting installation path will be `%HOMEPATH%\zephyr-sdk-0.16.3`.

4. Run the Zephyr SDK bundle setup script:

```bash
cd zephyr-sdk-0.16.3
setup.cmd
```

**Note:** You only need to run the setup script once after extracting the Zephyr SDK bundle. You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

### 2.14.2 Arm Compiler 6

1. Download and install a development suite containing the Arm Compiler 6 for your operating system.

2. **Set these environment variables:**

   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `armclang`.
   - Set `ARMCLANG_TOOLCHAIN_PATH` to the toolchain installation directory.

3. The Arm Compiler 6 needs the `ARMLMD_LICENSE_FILE` environment variable to point to your license file or server.

   For example:

   ```
   # Linux, macOS, license file:
   export ARMLMD_LICENSE_FILE=/<path>/license_armds.dat
   # Linux, macOS, license server:
   export ARMLMD_LICENSE_FILE=8224@myserver
   # Windows, license file:
   set ARMLMD_LICENSE_FILE=c:\<path>\license_armds.dat
   # Windows, license server:
   set ARMLMD_LICENSE_FILE=8224@myserver
   ```

   1. If the Arm Compiler 6 was installed as part of an Arm Development Studio, then you must set the `ARM_PRODUCT_DEF` to point to the product definition file. See also: Product and toolkit configuration. For example if the Arm Development Studio is installed in: `/opt/armds-2020-1` with a Gold license, then set `ARM_PRODUCT_DEF` to point to `/opt/armds-2020-1/gold.elmap`. 

242 Chapter 2. Developing with Zephyr
**Note:** The Arm Compiler 6 uses `armlink` for linking. This is incompatible with Zephyr's linker script template, which works with GNU ld. Zephyr's Arm Compiler 6 supports Zephyr's CMake linker script generator, which supports generating scatter files. Basic scatter file support is in place, but there are still areas covered in ld templates which are not fully supported by the CMake linker script generator.

Some Zephyr subsystems or modules may also contain C or assembly code that relies on GNU intrinsics and have not yet been updated to work fully with `armclang`.

### 2.14.3 Cadence Tensilica Xtensa C/C++ Compiler (XCC)

1. Obtain Tensilica Software Development Toolkit targeting the specific SoC on hand. This usually contains two parts:
   - The Xtensa Xplorer which contains the necessary executables and libraries.
   - A SoC-specific add-on to be installed on top of Xtensa Xplorer.
     - This add-on allows the compiler to generate code for the SoC on hand.
2. Install Xtensa Xplorer and then the SoC add-on.
   - Follow the instruction from Cadence on how to install the SDK.
   - Depending on the SDK, there are two sets of compilers:
     - GCC-based compiler: `xt-xcc` and its friends.
     - Clang-based compiler: `xt-clang` and its friends.
3. Make sure you have obtained a license to use the SDK, or have access to a remote licensing server.
4. **Set these environment variables**:
   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `xcc` or `xt-clang`.
   - Set `XTENSA_TOOLCHAIN_PATH` to the toolchain installation directory.
   - Set `XTENSA_CORE` to the SoC ID where application is being targeting.
   - Set `TOOLCHAIN_VER` to the Xtensa SDK version.
5. For example, assuming the SDK is installed in `/opt/xtensa`, and using the SDK for application development on `intel_adsp_cavs15`, setup the environment using:

   ```bash
   # Linux
   export ZEPHYR_TOOLCHAIN_VARIANT=xcc
   export XTENSA_TOOLCHAIN_PATH=/opt/xtensa/XtDevTools/install/tools/
   export XTENSA_CORE=X6H3SUE_RI_2018_0
   export TOOLCHAIN_VER=RI-2018.0-linux
   ```
6. To use Clang-based compiler:
   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `xt-clang`.
   - Note that the Clang-based compiler may contain an old LLVM bug which results in the following error:

   ```
   /tmp/file.s: Assembler messages:
   /tmp/file.s:20: Error: file number 1 already allocated
   clang-3.9: error: Xtensa-as command failed with exit code 1
   ```

   If this happens, set `XCC_NO_G_FLAG` to 1.
   - For example:
# Linux

```bash
export XCC_NO_G_FLAG=1
```

- Also note that setting `XCC_USE_CLANG` to 1 and `ZEPHYR_TOOLCHAIN_VARIANT` to `xcc` is deprecated. Set `ZEPHYR_TOOLCHAIN_VARIANT` to `xt-clang` instead.

## 2.14.4 DesignWare ARC MetaWare Development Toolkit (MWDT)

1. You need to have `ARC MWDT` installed on your host.
2. You need to have `Zephyr SDK` installed on your host.

**Note:** A Zephyr SDK is used as a source of tools like device tree compiler (DTC), QEMU, etc... Even though ARC MWDT toolchain is used for Zephyr RTOS build, still the GNU preprocessor & GNU objcopy might be used for some steps like device tree preprocessing and `.bin` file generation. We used Zephyr SDK as a source of these ARC GNU tools as well.

3. Set these environment variables:
   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `arcmwdt`.
   - Set `ARCMWDT_TOOLCHAIN_PATH` to the toolchain installation directory. MWDT installation provides `METAWARE_ROOT` so simply set `ARCMWDT_TOOLCHAIN_PATH` to `$METAWARE_ROOT/../` (Linux) or `%METAWARE_ROOT%../` (Windows).

**Tip:** If you have only one ARC MWDT toolchain version installed on your machine you may skip setting `ARCMWDT_TOOLCHAIN_PATH` - it would be detected automatically.

4. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `ARCMWDT_TOOLCHAIN_PATH` values may be different on your system):

```bash
# Linux:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
arcmwdt
$ echo $ARCMWDT_TOOLCHAIN_PATH
/home/you/ARC/MWDT_2023.03/

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
arcmwdt
> echo %ARCMWDT_TOOLCHAIN_PATH%
C:\ARC\MWDT_2023.03
```

## 2.14.5 GNU Arm Embedded

1. Download and install a GNU Arm Embedded build for your operating system and extract it on your file system.

**Note:** On Windows, we'll assume for this guide that you install into the directory `C:\gnu_arm_embedded`. You can also choose the default installation path used by the ARM GCC installer, in which case you will need to adjust the path accordingly in the guide below.
**Warning:** On macOS Catalina or later you might need to change a security policy for the toolchain to be able to run from the terminal.

2. **Set these environment variables:**
   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `gnuarmemb`.
   - Set `GNUARMEMB_TOOLCHAIN_PATH` to the toolchain installation directory.

3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `GNUARMEMB_TOOLCHAIN_PATH` values may be different on your system):

   ```bash
   # Linux, macOS:
   $ echo $ZEPHYR_TOOLCHAIN_VARIANT
   gnuarmemb
   $ echo $GNUARMEMB_TOOLCHAIN_PATH
   /home/you/Downloads/gnu_arm_embedded
   # Windows:
   > echo %ZEPHYR_TOOLCHAIN_VARIANT%
   gnuarmemb
   > echo %GNUARMEMB_TOOLCHAIN_PATH%
   C:\gnu_arm_embedded
   ``

**Warning:** On macOS, if you are having trouble with the suggested procedure, there is an unofficial package on brew that might help you. Run `brew install gcc-arm-embedded` and configure the variables

   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `gnuarmemb`.
   - Set `GNUARMEMB_TOOLCHAIN_PATH` to the brew installation directory (something like `/usr/local`)

### 2.14.6 Intel oneAPI Toolkit

1. Download Intel oneAPI Base Toolkit

2. Assuming the toolkit is installed in `/opt/intel/oneapi`, set environment using:

   ```bash
   # Linux, macOS:
   export ONEAPI_TOOLCHAIN_PATH=/opt/intel/oneapi
   source $ONEAPI_TOOLCHAIN_PATH/compiler/latest/env/vars.sh
   # Windows:
   > set ONEAPI_TOOLCHAIN_PATH=C:\Users\Intel\oneapi
   ``

   To setup the complete oneApi environment, use:

   ```bash
   source /opt/intel/oneapi/setvars.sh
   ``

   The above will also change the python environment to the one used by the toolchain and might conflict with what Zephyr uses.

3. Set `ZEPHYR_TOOLCHAIN_VARIANT` to `oneApi`. 

---

2.14. Toolchains 245
2.14.7 Crosstool-NG (Deprecated)

**Warning:** `xtools` toolchain variant is deprecated. The *cross-compile toolchain variant* should be used when using a custom toolchain built with Crosstool-NG.

You can build toolchains from source code using crosstool-NG.

1. Follow the steps on the crosstool-NG website to **prepare your host**.
2. Follow the Zephyr SDK with Crosstool NG instructions to build your toolchain. Repeat as necessary to build toolchains for multiple target architectures.

You will need to clone the `sdk-ng` repo and run the following command:

```
./go.sh <arch>
```

**Note:** Currently, only i586 and Arm toolchain builds are verified.

3. **Set these environment variables**:
   - Set `ZEPHYR_TOOLCHAIN_VARIANT` to `xtools`.
   - Set `XTOOLS_TOOLCHAIN_PATH` to the toolchain build directory.

4. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `XTOOLS_TOOLCHAIN_PATH` values may be different on your system):

   ```
   # Linux, macOS:
   $ echo $ZEPHYR_TOOLCHAIN_VARIANT
   xtools
   $ echo $XTOOLS_TOOLCHAIN_PATH
   /Volumes/CrossToolNGNew/build/output/
   ```

2.14.8 Host Toolchains

In some specific configurations, like when building for non-MCU x86 targets on a Linux host, you may be able to re-use the native development tools provided by your operating system.

To use your host gcc, set the `ZEPHYR_TOOLCHAIN_VARIANT environment variable` to `host`. To use clang, set `ZEPHYR_TOOLCHAIN_VARIANT` to `llvm`.

2.14.9 Other Cross Compilers

This toolchain variant is borrowed from the Linux kernel build system's mechanism of using a `CROSS_COMPILE` environment variable to set up a GNU-based cross toolchain.

Examples of such “other cross compilers” are cross toolchains that your Linux distribution packaged, that you compiled on your own, or that you downloaded from the net. Unlike toolchains specifically listed in Toolchains, the Zephyr build system may not have been tested with them, and doesn’t officially support them. (Nonetheless, the toolchain set-up mechanism itself is supported.)

Follow these steps to use one of these toolchains.

1. Install a cross compiler suitable for your host and target systems.

   For example, you might install the `gcc-arm-none-eabi` package on Debian-based Linux systems, or `arm-none-eabi-newlib` on Fedora or Red Hat:
2. Set these environment variables:

- Set `ZEPHYR_TOOLCHAIN_VARIANT` to `cross-compile`.
- Set `CROSS_COMPILE` to the common path prefix which your toolchain's binaries have, e.g. the path to the directory containing the compiler binaries plus the target triplet and trailing dash.

3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `CROSS_COMPILE` value may be different on your system):

```bash
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
cross-compile
$ echo $CROSS_COMPILE
/usr/bin/arm-none-eabi-
```

You can also set `CROSS_COMPILE` as a CMake variable. When using this option, all of your toolchain binaries must reside in the same directory and have a common file name prefix. The `CROSS_COMPILE` variable is set to the directory concatenated with the file name prefix. In the Debian example above, the `gcc-arm-none-eabi` package installs binaries such as `arm-none-eabi-gcc` and `arm-none-eabi-ld` in directory `/usr/bin/`, so the common prefix is `/usr/bin/arm-none-eabi-` (including the trailing dash, `-`). If your toolchain is installed in `/opt/mytoolchain/bin` with binary names based on target triplet `myarch-none-elf`, `CROSS_COMPILE` would be set to `/opt/mytoolchain/bin/myarch-none-elf-`

### 2.14.10 Custom CMake Toolchains

To use a custom toolchain defined in an external CMake file, set these environment variables:

- Set `ZEPHYR_TOOLCHAIN_VARIANT` to your toolchain's name
- Set `TOOLCHAIN_ROOT` to the path to the directory containing your toolchain's CMake configuration files.

Zephyr will then include the toolchain cmake files located in the `TOOLCHAIN_ROOT` directory:

- `cmake/toolchain/<toolchain name>/generic.cmake`: configures the toolchain for “generic” use, which mostly means running the C preprocessor on the generated `Devicetree` file.
- `cmake/toolchain/<toolchain name>/target.cmake`: configures the toolchain for “target” use, i.e. building Zephyr and your application’s source code.

Here `<toolchain name>` is the same as the name provided in `ZEPHYR_TOOLCHAIN_VARIANT` See the zephyr files `cmake/modules/FindHostTools.cmake` and `cmake/modules/FindTargetTools.cmake` for more details on what your `generic.cmake` and `target.cmake` files should contain.

You can also set `ZEPHYR_TOOLCHAIN_VARIANT` and `TOOLCHAIN_ROOT` as CMake variables when generating a build system for a Zephyr application, like so:

```bash
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

```bash
cmake -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

If you do this, `-C <initial-cache> cmake option` may useful. If you save your `ZEPHYR_TOOLCHAIN_VARIANT`, `TOOLCHAIN_ROOT`, and other settings in a file named `my-toolchain.cmake`, you can then invoke cmake as `cmake -C my-toolchain.cmake ...` to save typing.

### 2.14. Toolchains
Zephyr includes `include/toolchain.h` which again includes a toolchain specific header based on the compiler identifier, such as `__llvm__` or `__GNUC__`. Some custom compilers identify themselves as the compiler on which they are based, for example `llvm` which then gets the `toolchain/llvm.h` included. This included file may though not be right for the custom toolchain. In order to solve this, and thus to get the `include/other.h` included instead, add the `set(TOOLCHAIN_USE_CUSTOM 1)` cmake line to the generic.cmake and/or target.cmake files located under `<TOOLCHAIN_ROOT>/cmake/toolchain/ <toolchain name>/`.

When `TOOLCHAIN_USE_CUSTOM` is set, the `other.h` must be available out-of-tree and it must include the correct header for the custom toolchain. A good location for the `other.h` header file, would be a directory under the directory specified in `TOOLCHAIN_ROOT` as `include/toolchain`. To get the toolchain header included in zephyr's build, the `USERINCLUDE` can be set to point to the include directory, as shown here:

```
west build -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=... -DUSERINCLUDE=...
```

## 2.15 Tools and IDEs

### 2.15.1 Coccinelle

Coccinelle is a tool for pattern matching and text transformation that has many uses in kernel development, including the application of complex, tree-wide patches and detection of problematic programming patterns.

**Note:** Linux and macOS development environments are supported, but not Windows.

### Getting Coccinelle

The semantic patches included in the kernel use features and options which are provided by Coccinelle version 1.0.0-rc11 and above. Using earlier versions will fail as the option names used by the Coccinelle files and `coccicheck` have been updated.

Coccinelle is available through the package manager of many distributions, e.g.:

- Debian
- Fedora
- Ubuntu
- OpenSUSE
- Arch Linux
- NetBSD
- FreeBSD

Some distribution packages are obsolete and it is recommended to use the latest version released from the Coccinelle homepage at [http://coccinelle.lip6.fr/](http://coccinelle.lip6.fr/)

Or from Github at:
[https://github.com/coccinelle/coccinelle](https://github.com/coccinelle/coccinelle)

Once you have it, run the following commands:

```
./autogen
./configure
make
```
as a regular user, and install it with:

```
sudo make install
```

More detailed installation instructions to build from source can be found at:

https://github.com/coccinelle/coccinelle/blob/master/install.txt

**Supplemental documentation**

For Semantic Patch Language (SmPL) grammar documentation refer to:

https://coccinelle.gitlabpages.inria.fr/website/documentation.html

**Using Coccinelle on Zephyr**

coccicheck checker is the front-end to the Coccinelle infrastructure and has various modes:

Four basic modes are defined: patch, report, context, and org. The mode to use is specified by setting `--mode=<mode>` or `-m=<mode>`.

- **patch** proposes a fix, when possible.
- **report** generates a list in the following format: file:line:column-column: message
- **context** highlights lines of interest and their context in a diff-like style. Lines of interest are indicated with `-`
- **org** generates a report in the Org mode format of Emacs.

Note that not all semantic patches implement all modes. For easy use of Coccinelle, the default mode is `report`.

Two other modes provide some common combinations of these modes.

- **chain** tries the previous modes in the order above until one succeeds.
- **rep+ctxt** runs successively the report mode and the context mode. It should be used with the `C` option (described later) which checks the code on a file basis.

**Examples**

To make a report for every semantic patch, run the following command:

```
./scripts/coccicheck --mode=report
```

To produce patches, run:

```
./scripts/coccicheck --mode=patch
```

The `coccicheck` target applies every semantic patch available in the sub-directories of `scripts/coccinelle` to the entire source code tree.

For each semantic patch, a commit message is proposed. It gives a description of the problem being checked by the semantic patch, and includes a reference to Coccinelle.

As any static code analyzer, Coccinelle produces false positives. Thus, reports must be carefully checked, and patches reviewed.

To enable verbose messages set `--verbose=1` option, for example:

```
./scripts/coccicheck --mode=report --verbose=1
```
Coccinelle parallelization

By default, coccicheck tries to run as parallel as possible. To change the parallelism, set the --jobs=<number> option. For example, to run across 4 CPUs:

```
./scripts/coccicheck --mode=report --jobs=4
```

As of Coccinelle 1.0.2 Coccinelle uses Ocaml parmap for parallelization, if support for this is detected you will benefit from parmap parallelization.

When parmap is enabled coccicheck will enable dynamic load balancing by using --chunksize 1 argument, this ensures we keep feeding threads with work one by one, so that we avoid the situation where most work gets done by only a few threads. With dynamic load balancing, if a thread finishes early we keep feeding it more work.

When parmap is enabled, if an error occurs in Coccinelle, this error value is propagated back, the return value of the coccicheck command captures this return value.

Using Coccinelle with a single semantic patch

The option --cocci can be used to check a single semantic patch. In that case, the variable must be initialized with the name of the semantic patch to apply.

For instance:

```
./scripts/coccicheck --mode=report --cocci=<example.cocci>
```

or:

```
./scripts/coccicheck --mode=report --cocci=./path/to/<example.cocci>
```

Controlling which files are processed by Coccinelle

By default the entire source tree is checked.

To apply Coccinelle to a specific directory, pass the path of specific directory as an argument.

For example, to check drivers/usb/ one may write:

```
./scripts/coccicheck --mode=patch drivers/usb/
```

The report mode is the default. You can select another one with the --mode=<mode> option explained above.

Debugging Coccinelle SmPL patches

Using coccicheck is best as it provides in the spatch command line include options matching the options used when we compile the kernel. You can learn what these options are by using verbose option, you could then manually run Coccinelle with debug options added.

Alternatively you can debug running Coccinelle against SmPL patches by asking for stderr to be redirected to stderr, by default stderr is redirected to /dev/null, if you’d like to capture stderr you can specify the --debug=file.err option to coccicheck. For instance:

```
rm -f cocci.err
./scripts/coccicheck --mode=patch --debug=cocci.err
```

Debugging support is only supported when using Coccinelle >= 1.0.2.
Additional Flags

Additional flags can be passed to spatch through the SPFLAGS variable. This works as Coccinelle respects the last flags given to it when options are in conflict.

```
./scripts/coccicheck --sp-flag="--use-glimpse"
```

Coccinelle supports idutils as well but requires coccinelle >= 1.0.6. When no ID file is specified coccinelle assumes your ID database file is in the file .id-utils.index on the top level of the kernel, coccinelle carries a script scripts/idutils_index.sh which creates the database with:

```
mkid -i C --output .id-utils.index
```

If you have another database filename you can also just symlink with this name.

```
./scripts/coccicheck --sp-flag="--use-idutils"
```

Alternatively you can specify the database filename explicitly, for instance:

```
./scripts/coccicheck --sp-flag="--use-idutils /full-path/to/ID"
```

Sometimes coccinelle doesn't recognize or parse complex macro variables due to insufficient definition. Therefore, to make it parsable we explicitly provide the prototype of the complex macro using the ```--macro-file-builtins <headerfile.h>``` flag.

The `<headerfile.h>` should contain the complete prototype of the complex macro from which spatch engine can extract the type information required during transformation.

For example:

`Z_SYSCALL_HANDLER` is not recognized by coccinelle. Therefore, we put its prototype in a header file, say for example `mymacros.h`.

```
$ cat mymacros.h
#define Z_SYSCALL_HANDLER int xxx
```

Now we pass the header file `mymacros.h` during transformation:

```
./scripts/coccicheck --sp-flag="--macro-file-builtins mymacros.h"
```

See spatch --help to learn more about spatch options.

Note that the ```--use-glimpse``` and ```--use-idutils``` options require external tools for indexing the code. None of them is thus active by default. However, by indexing the code with one of these tools, and according to the cocci file used, spatch could proceed the entire code base more quickly.

SmPL patch specific options

SmPL patches can have their own requirements for options passed to Coccinelle. SmPL patch specific options can be provided by providing them at the top of the SmPL patch, for instance:

```
// Options: --no-includes --include-headers
```

Proposing new semantic patches

New semantic patches can be proposed and submitted by kernel developers. For sake of clarity, they should be organized in the sub-directories of `scripts/coccinelle/`.

The cocci script should have the following properties:

- The script **must** have report mode.
• The first few lines should state the purpose of the script using /// comments. Usually, this message would be used as the commit log when proposing a patch based on the script.

Example

/// Use ARRAY_SIZE instead of dividing sizeof array with sizeof an element

• A more detailed information about the script with exceptional cases or false positives (if any) can be listed using //# comments.

Example

//# This makes an effort to find cases where ARRAY_SIZE can be used such as
//# where there is a division of sizeof the array by the sizeof its first
//# element or by any indexed element or the element type. It replaces the
//# division of the two sizeofs by ARRAY_SIZE.

• Confidence: It is a property defined to specify the accuracy level of the script. It can be either High, Moderate or Low depending upon the number of false positives observed.

Example

// Confidence: High

• Virtual rules: These are required to support the various modes framed in the script. The virtual rule specified in the script should have the corresponding mode handling rule.

Example

type T;
T[] E;
@@
( *
* (sizeof(E)/sizeof(*E))
| *
* (sizeof(E)/sizeof(E[...]))
| *
* (sizeof(E)/sizeof(T))
)

Detailed description of the report mode

report generates a list in the following format:

file:line:column-column: message

Example

Running:

./scripts/coccicheck --mode=report --cocci=scripts/coccinelle/array_size.cocci

will execute the following part of the SmPL script:
This SmPL excerpt generates entries on the standard output, as illustrated below:

```
ext/hal/nxp/mcux/drivers/lpc/fsl_wwdt.c:66:49-50: WARNING: Use ARRAY_SIZE
ext/hal/nxp/mcux/drivers/lpc/fsl_ctimer.c:74:53-54: WARNING: Use ARRAY_SIZE
ext/hal/nxp/mcux/drivers/imx/fsl_dcp.c:944:45-46: WARNING: Use ARRAY_SIZE
```

**Detailed description of the patch mode**

When the patch mode is available, it proposes a fix for each problem identified.

**Example**  Running:

```
./scripts/coccicheck --mode=patch --cocci=scripts/coccinelle/misc/array_size.cocci
```

will execute the following part of the SmPL script:

```
<smpl>
@depends on patch@
    type T;
    T[] E;
    @
    ( (sizeof(E)p /sizeof(*E))
 | (sizeof(E)p /sizeof(E[...]))
 | (sizeof(E)p /sizeof(T))
   )

@script:python depends on report@
    p << r.p;
    @
    msg="WARNING: Use ARRAY_SIZE"
    coccilib.report.print_report(p[0], msg)
</smpl>
```
This SmPL excerpt generates patch hunks on the standard output, as illustrated below:

```diff

Deep description of the context mode

context highlights lines of interest and their context in a diff-like style.

Note: The diff-like output generated is NOT an applicable patch. The intent of the context mode is to highlight the important lines (annotated with minus, -) and gives some surrounding context lines around. This output can be used with the diff mode of Emacs to review the code.

Example  Running:

```
./scripts/coccicheck --mode=context --coci=scripts/coccinelle/array_size.coci
```

will execute the following part of the SmPL script:

```<smpl>
@depends on context@
type T;
T[] E;
@@
(  *(sizeof(E)/sizeof(*E))
    *(sizeof(E)/sizeof(E[...]))
    *(sizeof(E)/sizeof(T))
)
</smpl>
```

This SmPL excerpt generates diff hunks on the standard output, as illustrated below:
diff -u -p ext/lib/encoding/tinycbor/src/cborvalidation.c /tmp/nothing/ext/lib/encoding/tinycbor/src/cborvalidation.c
--- ext/lib/encoding/tinycbor/src/cborvalidation.c
+++ /tmp/nothing/ext/lib/encoding/tinycbor/src/cborvalidation.c
@@ -325,7 +325,6 @@ static inline CborError validate_number(

Detailed description of the org mode

org generates a report in the Org mode format of Emacs.

Example  Running:

./scripts/coccicheck --mode=org --cocci=scripts/coccinelle/misc/array_size.cocci

will execute the following part of the SmPL script:

```smpl
@r depends on (org || report)@ type T; T[] E; position p; @@
(#endif)
    (sizeof(E)@p /sizeof(*E))
    | (sizeof(E)@p /sizeof(E[...]))
    | (sizeof(E)@p /sizeof(T))
@script:python depends on org@
p << r.p;
    coccilib.org.print_todo(p[0], "WARNING should use ARRAY_SIZE")
</smpl>
```

This SmPL excerpt generates Org entries on the standard output, as illustrated below:

* TODO [[view:ext/lib/encoding/tinycbor/src/cborvalidation.c::face=ovl-face1::linb=328::colb=52::cole=53][WARNING should use ARRAY_SIZE]]

Chapter 3

Kernel

3.1 Kernel Services

The Zephyr kernel lies at the heart of every Zephyr application. It provides a low footprint, high performance, multi-threaded execution environment with a rich set of available features. The rest of the Zephyr ecosystem, including device drivers, networking stack, and application-specific code, uses the kernel’s features to create a complete application.

The configurable nature of the kernel allows you to incorporate only those features needed by your application, making it ideal for systems with limited amounts of memory (as little as 2 KB!) or with simple multi-threading requirements (such as a set of interrupt handlers and a single background task). Examples of such systems include: embedded sensor hubs, environmental sensors, simple LED wearable, and store inventory tags.

Applications requiring more memory (50 to 900 KB), multiple communication devices (like Wi-Fi and Bluetooth Low Energy), and complex multi-threading, can also be developed using the Zephyr kernel. Examples of such systems include: fitness wearables, smart watches, and IoT wireless gateways.

3.1.1 Scheduling, Interrupts, and Synchronization

These pages cover basic kernel services related to thread scheduling and synchronization.

Note: There is also limited support for using Operation without Threads.

- Lifecycle
  - Thread Creation
  - Thread Termination
  - Thread Aborting
  - Thread Suspension
- Thread States
- Thread Stack objects
  - Kernel-only Stacks
This section describes kernel services for creating, scheduling, and deleting independently executable threads of instructions.

A thread is a kernel object that is used for application processing that is too lengthy or too complex to be performed by an ISR.

Any number of threads can be defined by an application (limited only by available RAM). Each thread is referenced by a thread id that is assigned when the thread is spawned.

A thread has the following key properties:

- A stack area, which is a region of memory used for the thread's stack. The size of the stack area can be tailored to conform to the actual needs of the thread's processing. Special macros exist to create and work with stack memory regions.
- A thread control block for private kernel bookkeeping of the thread's metadata. This is an instance of type k_thread.
- An entry point function, which is invoked when the thread is started. Up to 3 argument values can be passed to this function.
- A scheduling priority, which instructs the kernel's scheduler how to allocate CPU time to the thread. (See Scheduling.)
- A set of thread options, which allow the thread to receive special treatment by the kernel under specific circumstances. (See Thread Options.)
- A start delay, which specifies how long the kernel should wait before starting the thread.
- An execution mode, which can either be supervisor or user mode. By default, threads run in supervisor mode and allow access to privileged CPU instructions, the entire memory address space, and peripherals. User mode threads have a reduced set of privileges. This depends on the CONFIG_USERSPACE option. See User Mode.

Lifecycle

Thread Creation A thread must be created before it can be used. The kernel initializes the thread control block as well as one end of the stack portion. The remainder of the thread's stack is typically left uninitialized.
Specifying a start delay of `K_NO_WAIT` instructs the kernel to start thread execution immediately. Alternatively, the kernel can be instructed to delay execution of the thread by specifying a timeout value – for example, to allow device hardware used by the thread to become available.

The kernel allows a delayed start to be canceled before the thread begins executing. A cancellation request has no effect if the thread has already started. A thread whose delayed start was successfully canceled must be re-spawned before it can be used.

**Thread Termination** Once a thread is started it typically executes forever. However, a thread may synchronously end its execution by returning from its entry point function. This is known as termination.

A thread that terminates is responsible for releasing any shared resources it may own (such as mutexes and dynamically allocated memory) prior to returning, since the kernel does not reclaim them automatically.

In some cases a thread may want to sleep until another thread terminates. This can be accomplished with the `k_thread_join()` API. This will block the calling thread until either the timeout expires, the target thread self-exits, or the target thread aborts (either due to a `k_thread_abort()` call or triggering a fatal error).

Once a thread has terminated, the kernel guarantees that no use will be made of the thread struct. The memory of such a struct can then be re-used for any purpose, including spawning a new thread. Note that the thread must be fully terminated, which presents race conditions where a thread's own logic signals completion which is seen by another thread before the kernel processing is complete. Under normal circumstances, application code should use `k_thread_join()` or `k_thread_abort()` to synchronize on thread termination state and not rely on signaling from within application logic.

**Thread Aborting** A thread may asynchronously end its execution by aborting. The kernel automatically aborts a thread if the thread triggers a fatal error condition, such as dereferencing a null pointer.

A thread can also be aborted by another thread (or by itself) by calling `k_thread_abort()`. However, it is typically preferable to signal a thread to terminate itself gracefully, rather than aborting it.

As with thread termination, the kernel does not reclaim shared resources owned by an aborted thread.

**Note:** The kernel does not currently make any claims regarding an application's ability to respawn a thread that aborts.

**Thread Suspension** A thread can be prevented from executing for an indefinite period of time if it becomes suspended. The function `k_thread_suspend()` can be used to suspend any thread, including the calling thread. Suspending a thread that is already suspended has no additional effect.

Once suspended, a thread cannot be scheduled until another thread calls `k_thread_resume()` to remove the suspension.

**Note:** A thread can prevent itself from executing for a specified period of time using `k_sleep()`. However, this is different from suspending a thread since a sleeping thread becomes executable automatically when the time limit is reached.

**Thread States** A thread that has no factors that prevent its execution is deemed to be ready, and is eligible to be selected as the current thread.

A thread that has one or more factors that prevent its execution is deemed to be unready, and cannot be selected as the current thread.

The following factors make a thread unready:
- The thread has not been started.
- The thread is waiting for a kernel object to complete an operation. (For example, the thread is taking a semaphore that is unavailable.)
- The thread is waiting for a timeout to occur.
- The thread has been suspended.
- The thread has terminated or aborted.

**Note:** Although the diagram above may appear to suggest that both **Ready** and **Running** are distinct thread states, that is not the correct interpretation. **Ready** is a thread state, and **Running** is a schedule state that only applies to **Ready** threads.

---

**Thread Stack objects** Every thread requires its own stack buffer for the CPU to push context. Depending on configuration, there are several constraints that must be met:

- There may need to be additional memory reserved for memory management structures
- If guard-based stack overflow detection is enabled, a small write-protected memory management region must immediately precede the stack buffer to catch overflows.
- If userspace is enabled, a separate fixed-size privilege elevation stack must be reserved to serve as a private kernel stack for handling system calls.
- If userspace is enabled, the thread’s stack buffer must be appropriately sized and aligned such that a memory protection region may be programmed to exactly fit.

The alignment constraints can be quite restrictive, for example some MPUs require their regions to be of some power of two in size, and aligned to its own size.

Because of this, portable code can’t simply pass an arbitrary character buffer to `k_thread_create()`. Special macros exist to instantiate stacks, prefixed with `K_KERNEL_STACK` and `K_THREAD_STACK`.

**Kernel-only Stacks** If it is known that a thread will never run in user mode, or the stack is being used for special contexts like handling interrupts, it is best to define stacks using the `K_KERNEL_STACK` macros.
These stacks save memory because an MPU region will never need to be programmed to cover the stack buffer itself, and the kernel will not need to reserve additional room for the privilege elevation stack, or memory management data structures which only pertain to user mode threads.

Attempts from user mode to use stacks declared in this way will result in a fatal error for the caller.

If CONFIG_USERSPACE is not enabled, the set of K_THREAD_STACK macros have an identical effect to the K_KERNEL_STACK macros.

Thread stacks If it is known that a stack will need to host user threads, or if this cannot be determined, define the stack with K_THREAD_STACK macros. This may use more memory but the stack object is suitable for hosting user threads.

If CONFIG_USERSPACE is not enabled, the set of K_THREAD_STACK macros have an identical effect to the K_KERNEL_STACK macros.

Thread Priorities A thread’s priority is an integer value, and can be either negative or non-negative. Numerically lower priorities takes precedence over numerically higher values. For example, the scheduler gives thread A of priority 4 higher priority over thread B of priority 7; likewise thread C of priority -2 has higher priority than both thread A and thread B.

The scheduler distinguishes between two classes of threads, based on each thread’s priority.

- A cooperative thread has a negative priority value. Once it becomes the current thread, a cooperative thread remains the current thread until it performs an action that makes it unready.
- A preemptible thread has a non-negative priority value. Once it becomes the current thread, a preemptible thread may be supplanted at any time if a cooperative thread, or a preemptible thread of higher or equal priority, becomes ready.

A thread’s initial priority value can be altered up or down after the thread has been started. Thus it is possible for a preemptible thread to become a cooperative thread, and vice versa, by changing its priority.

Note: The scheduler does not make heuristic decisions to re-prioritize threads. Thread priorities are set and changed only at the application’s request.

The kernel supports a virtually unlimited number of thread priority levels. The configuration options CONFIG_NUM_COOP_PRIORITIES and CONFIG_NUM_PREEMPT_PRIORITIES specify the number of priority levels for each class of thread, resulting in the following usable priority ranges:

- cooperative threads: (-CONFIG_NUM_COOP_PRIORITIES) to -1
- preemptive threads: 0 to (CONFIG_NUM_PREEMPT_PRIORITIES - 1)

For example, configuring 5 cooperative priorities and 10 preemptive priorities results in the ranges -5 to -1 and 0 to 9, respectively.
**Meta-IRQ Priorities** When enabled (see `CONFIG_NUM_METAIRQ_PRIORITIES`), there is a special subclass of cooperative priorities at the highest (numerically lowest) end of the priority space: meta-IRQ threads. These are scheduled according to their normal priority, but also have the special ability to preempt all other threads (and other meta-IRQ threads) at lower priorities, even if those threads are cooperative and/or have taken a scheduler lock. Meta-IRQ threads are still threads, however, and can still be interrupted by any hardware interrupt.

This behavior makes the act of unblocking a meta-IRQ thread (by any means, e.g. creating it, calling `k_sem_give()`, etc.) into the equivalent of a synchronous system call when done by a lower priority thread, or an ARM-like “pended IRQ” when done from true interrupt context. The intent is that this feature will be used to implement interrupt “bottom half” processing and/or “tasklet” features in driver subsystems. The thread, once woken, will be guaranteed to run before the current CPU returns into application code.

Unlike similar features in other OSes, meta-IRQ threads are true threads and run on their own stack (which must be allocated normally), not the per-CPU interrupt stack. Design work to enable the use of the IRQ stack on supported architectures is pending.

Note that because this breaks the promise made to cooperative threads by the Zephyr API (namely that the OS won’t schedule other thread until the current thread deliberately blocks), it should be used only with great care from application code. These are not simply very high priority threads and should not be used as such.

**Thread Options** The kernel supports a small set of *thread options* that allow a thread to receive special treatment under specific circumstances. The set of options associated with a thread are specified when the thread is spawned.

A thread that does not require any thread option has an option value of zero. A thread that requires a thread option specifies it by name, using the `|` character as a separator if multiple options are needed (i.e. combine options using the bitwise OR operator).

The following thread options are supported.

- **K_ESSENTIAL**
  This option tags the thread as an *essential thread*. This instructs the kernel to treat the termination or aborting of the thread as a fatal system error.
  
  By default, the thread is not considered to be an essential thread.

- **K_SSE_REGS**
  This x86-specific option indicate that the thread uses the CPU's SSE registers. Also see `K_FP_REGS`.
  
  By default, the kernel does not attempt to save and restore the contents of these registers when scheduling the thread.

- **K_FP_REGS**
  This option indicate that the thread uses the CPU’s floating point registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. (For more information see [Floating Point Services](#).)
  
  By default, the kernel does not attempt to save and restore the contents of this register when scheduling the thread.

- **K_USER**
  If `CONFIG_USERSPACE` is enabled, this thread will be created in user mode and will have reduced privileges. See [User Mode](#). Otherwise this flag does nothing.

- **K_INHERIT_PERMS**
  If `CONFIG_USERSPACE` is enabled, this thread will inherit all kernel object permissions that the parent thread had, except the parent thread object. See [User Mode](#).
Thread Custom Data  Every thread has a 32-bit custom data area, accessible only by the thread itself, and may be used by the application for any purpose it chooses. The default custom data value for a thread is zero.

Note: Custom data support is not available to ISRs because they operate within a single shared kernel interrupt handling context.

By default, thread custom data support is disabled. The configuration option CONFIG_THREAD_CUSTOM_DATA can be used to enable support.

The k_thread_custom_data_set() and k_thread_custom_data_get() functions are used to write and read a thread’s custom data, respectively. A thread can only access its own custom data, and not that of another thread.

The following code uses the custom data feature to record the number of times each thread calls a specific routine.

Note: Obviously, only a single routine can use this technique, since it monopolizes the use of the custom data feature.

```c
int call_tracking_routine(void)
{
    uint32_t call_count;

    if (k_is_in_isr()) {
        /* ignore any call made by an ISR */
    } else {
        call_count = (uint32_t)k_thread_custom_data_get();
        call_count++;
        k_thread_custom_data_set((void *)call_count);
    }

    /* do rest of routine's processing */
    ...
}
```

Use thread custom data to allow a routine to access thread-specific information, by using the custom data as a pointer to a data structure owned by the thread.

Implementation

Spawning a Thread  A thread is spawned by defining its stack area and its thread control block, and then calling k_thread_create().

The stack area must be defined using K_THREAD_STACK_DEFINE or K_KERNEL_STACK_DEFINE to ensure it is properly set up in memory.

The size parameter for the stack must be one of three values:

- The original requested stack size passed to K_THREAD_STACK or K_KERNEL_STACK family of stack instantiation macros.
- For a stack object defined with the K_THREAD_STACK family of macros, the return value of K_THREAD_STACK_SIZEOF() for that object.
- For a stack object defined with the K_KERNEL_STACK family of macros, the return value of K_KERNEL_STACK_SIZEOF() for that object.
The thread spawning function returns its thread id, which can be used to reference the thread. The following code spawns a thread that starts immediately.

```c
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5
extern void my_entry_point(void *, void *, void *);
K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);
struct k_thread my_thread_data;
k_tid_t my_tid = k_thread_create(&my_thread_data, my_stack_area,
                                 K_THREAD_STACK_SIZEOF(my_stack_area),
                                 my_entry_point,
                                 NULL, NULL, NULL,
                                 MY_PRIORITY, 0, K_NO_WAIT);
```

Alternatively, a thread can be declared at compile time by calling `K_THREAD_DEFINE`. Observe that the macro defines the stack area, control block, and thread id variables automatically. The following code has the same effect as the code segment above.

```c
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5
extern void my_entry_point(void *, void *, void *);
K_THREAD_DEFINE(my_tid, MY_STACK_SIZE,
                my_entry_point, NULL, NULL, NULL,
                MY_PRIORITY, 0, 0);
```

**Note:** The delay parameter to `k_thread_create()` is a `k_timeout_t` value, so `K_NO_WAIT` means to start the thread immediately. The corresponding parameter to `K_THREAD_DEFINE` is a duration in integral milliseconds, so the equivalent argument is 0.

**User Mode Constraints** This section only applies if `CONFIG_USERSPACE` is enabled, and a user thread tries to create a new thread. The `k_thread_create()` API is still used, but there are additional constraints which must be met or the calling thread will be terminated:

- The calling thread must have permissions granted on both the child thread and stack parameters; both are tracked by the kernel as kernel objects.
- The child thread and stack objects must be in an uninitialized state, i.e. it is not currently running and the stack memory is unused.
- The stack size parameter passed in must be equal to or less than the bounds of the stack object when it was declared.
- The `K_USER` option must be used, as user threads can only create other user threads.
- The `K_ESSENTIAL` option must not be used, user threads may not be considered essential threads.
- The priority of the child thread must be a valid priority value, and equal to or lower than the parent thread.

**Dropping Permissions** If `CONFIG_USERSPACE` is enabled, a thread running in supervisor mode may perform a one-way transition to user mode using the `k_thread_user_mode_enter()` API. This is a one-
way operation which will reset and zero the thread’s stack memory. The thread will be marked as non-essential.

**Terminating a Thread**  A thread terminates itself by returning from its entry point function.

The following code illustrates the ways a thread can terminate.

```c
void my_entry_point(int unused1, int unused2, int unused3)
{
    while (1) {
        ...
        if (<some condition>) {
            return; /* thread terminates from mid-entry point function */
        }
        ...
    }
    /* thread terminates at end of entry point function */
}
```

If CONFIG_USERSPACE is enabled, aborting a thread will additionally mark the thread and stack objects as uninitialized so that they may be re-used.

**Runtime Statistics**  Thread runtime statistics can be gathered and retrieved if CONFIG_THREAD_RUNTIME_STATS is enabled, for example, total number of execution cycles of a thread.

By default, the runtime statistics are gathered using the default kernel timer. For some architectures, SoCs or boards, there are timers with higher resolution available via timing functions. Using of these timers can be enabled via CONFIG_THREAD_RUNTIME_STATS_USE_TIMING_FUNCTIONS.

Here is an example:

```c
k_thread_runtime_stats_t rt_stats_thread;
k_thread_runtime_stats_get(k_current_get(), &rt_stats_thread);
printk("Cycles: %llu\n", rt_stats_thread.execution_cycles);
```

**Suggested Uses**  Use threads to handle processing that cannot be handled in an ISR.

Use separate threads to handle logically distinct processing operations that can execute in parallel.

**Configuration Options**  Related configuration options:

- CONFIG_MAIN_THREAD_PRIORITY
- CONFIG_MAIN_STACK_SIZE
- CONFIG_IDLE_STACK_SIZE
- CONFIG_THREAD_CUSTOM_DATA
- CONFIG_NUM_COOP_PRIORITIES
- CONFIG_NUM_PREEMPT_PRIORITIES
- CONFIG_TIMESLICING
- CONFIG_TIMESLICE_SIZE
• CONFIG_TIMESLICE_PRIORITY
• CONFIG_USERSPACE

API Reference

• Basic thread manipulation - Spawn multiple threads that blink LEDs and print information to the console.
• Dumb HTTP server (multi-threaded) - Implement a simple HTTP server supporting simultaneous connections using BSD sockets.

**group thread APIs**

**Defines**

**K_ESSENTIAL**

system thread that must not abort

**K_FP_IDX**

FPU registers are managed by context switch.

This option indicates that the thread uses the CPU’s floating point registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. No effect if `CONFIG_FPU_SHARING` is not enabled.

**K_FP_REGS**

**K_USER**

user mode thread

This thread has dropped from supervisor mode to user mode and consequently has additional restrictions

**K_INHERIT_PERMS**

Inherit Permissions.

Indicates that the thread being created should inherit all kernel object permissions from the thread that created it. No effect if `CONFIG_USERSPACE` is not enabled.

**K_CALLBACK_STATE**

Callback item state.

This is a single bit of state reserved for “callback manager” utilities (p4wq initially) who need to track operations invoked from within a user-provided callback they have been invoked. Effectively it serves as a tiny bit of zero-overhead TLS data.

**k_thread_access_grant**(thread, ...)

Grant a thread access to a set of kernel objects.

This is a convenience function. For the provided thread, grant access to the remaining arguments, which must be pointers to kernel objects.
The thread object must be initialized (i.e. running). The objects don’t need to be. Note that NULL shouldn’t be passed as an argument.

Parameters

- thread – Thread to grant access to objects
- ... – list of kernel object pointers

K_THREAD_DEFINE(name, stack_size, entry, p1, p2, p3, prio, options, delay)

Statically define and initialize a thread.

The thread may be scheduled for immediate execution or a delayed start.

Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using “|” (the logical OR operator).

The ID of the thread can be accessed using:

extern const k_tid_t <name>;

Note: Static threads with zero delay should not normally have MetaIRQ priority levels. This can preempt the system initialization handling (depending on the priority of the main thread) and cause surprising ordering side effects. It will not affect anything in the OS per se, but consider it bad practice. Use a SYS_INIT() callback if you need to run code before entrance to the application main().

Parameters

- name – Name of the thread.
- stack_size – Stack size in bytes.
- entry – Thread entry function.
- p1 – 1st entry point parameter.
- p2 – 2nd entry point parameter.
- p3 – 3rd entry point parameter.
- prio – Thread priority.
- options – Thread options.
- delay – Scheduling delay (in milliseconds), zero for no delay.

K_KERNEL_THREAD_DEFINE(name, stack_size, entry, p1, p2, p3, prio, options, delay)

Statically define and initialize a thread intended to run only in kernel mode.

The thread may be scheduled for immediate execution or a delayed start.

Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using “|” (the logical OR operator).

The ID of the thread can be accessed using:

extern const k_tid_t <name>;

Note: Threads defined by this can only run in kernel mode, and cannot be transformed into user thread via k_thread_user_mode_enter().
Warning: Depending on the architecture, the stack size (stack_size) may need to be multiples of CONFIG_MMU_PAGE_SIZE (if MMU) or in power-of-two size (if MPU).

Parameters

- **name** – Name of the thread.
- **stack_size** – Stack size in bytes.
- **entry** – Thread entry function.
- **p1** – 1st entry point parameter.
- **p2** – 2nd entry point parameter.
- **p3** – 3rd entry point parameter.
- **prio** – Thread priority.
- **options** – Thread options.
- **delay** – Scheduling delay (in milliseconds), zero for no delay.

Typedefs

typedef void (*k_thread_user_cb_t)(const struct k_thread *thread, void *user_data)

Functions

void k_thread_foreach(k_thread_user_cb_t user_cb, void *user_data)
Iterate over all the threads in the system.

This routine iterates over all the threads in the system and calls the user_cb function for each thread.

**Note:** CONFIG_THREAD_MONITOR must be set for this function to be effective.

**Note:** This API uses k_spin_lock to protect the _kernel.threads list which means creation of new threads and terminations of existing threads are blocked until this API returns.

Parameters

- **user_cb** – Pointer to the user callback function.
- **user_data** – Pointer to user data.

void k_thread_foreach_unlocked(k_thread_user_cb_t user_cb, void *user_data)
Iterate over all the threads in the system without locking.

This routine works exactly the same like k_thread_foreach but unlocks interrupts when user_cb is executed.

**Note:** CONFIG_THREAD_MONITOR must be set for this function to be effective.
**Note:** This API uses \texttt{k\_spin\_lock} only when accessing the \_kernel.threads queue elements. It unlocks it during user callback function processing. If a new task is created when this \texttt{foreach} function is in progress, the added new task would not be included in the enumeration. If a task is aborted during this enumeration, there would be a race here and there is a possibility that this aborted task would be included in the enumeration.

**Note:** If the task is aborted and the memory occupied by its \texttt{k\_thread} structure is reused when this \texttt{k\_thread\_foreach\_unlocked} is in progress it might even lead to the system behave unstable. This function may never return, as it would follow some next task pointers treating given pointer as a pointer to the \texttt{k\_thread} structure while it is something different right now. Do not reuse the memory that was occupied by \texttt{k\_thread} structure of aborted task if it was aborted after this function was called in any context.

### Parameters
- \texttt{user\_cb} – Pointer to the user callback function.
- \texttt{user\_data} – Pointer to user data.

\texttt{k\_thread\_stack\_t *k\_thread\_stack\_alloc(size\_t size, int flags)}

Dynamically allocate a thread stack.

Relevant stack creation flags include:
- \texttt{K\_USER} allocate a userspace thread (requires \texttt{CONFIG\_USERSPACE=y})

**See also:**
\texttt{CONFIG\_DYNAMIC\_THREAD}

### Parameters
- \texttt{size} – Stack size in bytes.
- \texttt{flags} – Stack creation flags, or 0.

### Return values
- \texttt{the} – allocated thread stack on success.
- \texttt{NULL} – on failure.

\texttt{int k\_thread\_stack\_free(k\_thread\_stack\_t *stack)}

Free a dynamically allocated thread stack.

**See also:**
\texttt{CONFIG\_DYNAMIC\_THREAD}

### Parameters
- \texttt{stack} – Pointer to the thread stack.

### Return values
- \texttt{0} – on success.
- \texttt{-EBUSY} – if the thread stack is in use.
- \texttt{-EINVAL} – if stack is invalid.
k_tid_t k_thread_create(struct k_thread *new_thread, k_thread_stack_t *stack, size_t stack_size, k_thread_entry_t entry, void *p1, void *p2, void *p3, int prio, uint32_t options, k_timeout_t delay)

Create a thread.

This routine initializes a thread, then schedules it for execution.

The new thread may be scheduled for immediate execution or a delayed start. If the newly spawned thread does not have a delayed start the kernel scheduler may preempt the current thread to allow the new thread to execute.

Thread options are architecture-specific, and can include K_ESSENTIAL, K_FP_REGS, and K_SSE_REGS. Multiple options may be specified by separating them using “|” (the logical OR operator).

Stack objects passed to this function must be originally defined with either of these macros in order to be portable:

- K_THREAD_STACK_DEFINE() - For stacks that may support either user or supervisor threads.
- K_KERNEL_STACK_DEFINE() - For stacks that may support supervisor threads only. These stacks use less memory if CONFIG_USERSPACE is enabled.

The stack_size parameter has constraints. It must either be:

- The original size value passed to K_THREAD_STACK_DEFINE() or K_KERNEL_STACK_DEFINE()
- The return value of K_THREAD_STACK_SIZEOF(stack) if the stack was defined with K_THREAD_STACK_DEFINE()
- The return value of K_KERNEL_STACK_SIZEOF(stack) if the stack was defined with K_KERNEL_STACK_DEFINE().

Using other values, or sizeof(stack) may produce undefined behavior.

Parameters
- new_thread – Pointer to uninitialized struct k_thread
- stack – Pointer to the stack space.
- stack_size – Stack size in bytes.
- entry – Thread entry function.
- p1 – 1st entry point parameter.
- p2 – 2nd entry point parameter.
- p3 – 3rd entry point parameter.
- prio – Thread priority.
- options – Thread options.
- delay – Scheduling delay, or K_NO_WAIT (for no delay).

Returns
- ID of new thread.
FUNC_NORETURN void k_thread_user_mode_enter(k_thread_entry_t entry, void *p1, void *p2, void *p3)

Drop a thread’s privileges permanently to user mode.
This allows a supervisor thread to be re-used as a user thread. This function does not return, but control will transfer to the provided entry point as if this was a new user thread.
The implementation ensures that the stack buffer contents are erased. Any thread-local storage will be reverted to a pristine state.
Memory domain membership, resource pool assignment, kernel object permissions, priority, and thread options are preserved.

A common use of this function is to re-use the main thread as a user thread once all supervisor mode-only tasks have been completed.

Parameters
• entry – Function to start executing from
• p1 – 1st entry point parameter
• p2 – 2nd entry point parameter
• p3 – 3rd entry point parameter

static inline void k_thread_heap_assign(struct k_thread *thread, struct k_heap *heap)
Assign a resource memory pool to a thread.

By default, threads have no resource pool assigned unless their parent thread has a resource pool, in which case it is inherited. Multiple threads may be assigned to the same memory pool.

Changing a thread’s resource pool will not migrate allocations from the previous pool.

Parameters
• thread – Target thread to assign a memory pool for resource requests.
• heap – Heap object to use for resources, or NULL if the thread should no longer have a memory pool.

void k_thread_system_pool_assign(struct k_thread *thread)
Assign the system heap as a thread’s resource pool.
Similar to k_thread_heap_assign(), but the thread will use the kernel heap to draw memory.
Use with caution, as a malicious thread could perform DoS attacks on the kernel heap.

Parameters
• thread – Target thread to assign the system heap for resource requests

int k_thread_join(struct k_thread *thread, k_timeout_t timeout)
Sleep until a thread exits.
The caller will be put to sleep until the target thread exits, either due to being aborted, self-exiting, or taking a fatal error. This API returns immediately if the thread isn’t running.

This API may only be called from ISRs with a K_NO_WAIT timeout, where it can be useful as a predicate to detect when a thread has aborted.

Parameters
• thread – Thread to wait to exit
• timeout – upper bound time to wait for the thread to exit.

Return values
• 0 – success, target thread has exited or wasn’t running
-EBUSY – returned without waiting
-EAGAIN – waiting period timed out
-EDeadLK – target thread is joining on the caller, or target thread is the caller

```c
int32_t k_sleep(k_timeout_t timeout)
```

Put the current thread to sleep.

This routine puts the current thread to sleep for duration, specified as a `k_timeout_t` object.

**Note:** if `timeout` is set to `K_FOREVER` then the thread is suspended.

**Parameters**
- `timeout` – Desired duration of sleep.

**Returns**
Zero if the requested time has elapsed or the number of milliseconds left to sleep, if thread was woken up by `k_wakeup` call.

```c
static inline int32_t k_msleep(int32_t ms)
```

Put the current thread to sleep.

This routine puts the current thread to sleep for duration milliseconds.

**Parameters**
- `ms` – Number of milliseconds to sleep.

**Returns**
Zero if the requested time has elapsed or the number of milliseconds left to sleep, if thread was woken up by `k_wakeup` call.

```c
int32_t k_usleep(int32_t us)
```

Put the current thread to sleep with microsecond resolution.

This function is unlikely to work as expected without kernel tuning. In particular, because the lower bound on the duration of a sleep is the duration of a tick, `CONFIG_SYS_CLOCK_TICKS_PER_SEC` must be adjusted to achieve the resolution desired. The implications of doing this must be understood before attempting to use `k_usleep()`. Use with caution.

**Parameters**
- `us` – Number of microseconds to sleep.

**Returns**
Zero if the requested time has elapsed or the number of microseconds left to sleep, if thread was woken up by `k_wakeup` call.

```c
void k_busy_wait(uint32_t usec_to_wait)
```

Cause the current thread to busy wait.

This routine causes the current thread to execute a “do nothing” loop for `usec_to_wait` microseconds.

**Note:** The clock used for the microsecond-resolution delay here may be skewed relative to the clock used for system timeouts like `k_sleep()`. For example `k_busy_wait(1000)` may take slightly more or less time than `k_sleep(K_MSEC(1))`, with the offset dependent on clock tolerances.
bool k_can_yield(void)
   Check whether it is possible to yield in the current context.

   This routine checks whether the kernel is in a state where it is possible to yield or call blocking
API's. It should be used by code that needs to yield to perform correctly, but can feasibly be
called from contexts where that is not possible. For example in the PRE_KERNEL initialization
step, or when being run from the idle thread.

   **Returns**
   True if it is possible to yield in the current context, false otherwise.

void k_yield(void)
   Yield the current thread.

   This routine causes the current thread to yield execution to another thread of the same or
higher priority. If there are no other ready threads of the same or higher priority, the routine
returns immediately.

void k_wakeup(k_tid_t thread)
   Wake up a sleeping thread.

   This routine prematurely wakes up `thread` from sleeping.

   If `thread` is not currently sleeping, the routine has no effect.

   **Parameters**
   • `thread` – ID of thread to wake.

__attribute_const__ k_tid_t k_sched_current_thread_query(void)
   Query thread ID of the current thread.

   This unconditionally queries the kernel via a system call.

---

**Note:** Use `k_current_get()` unless absolutely sure this is necessary. This should only be used
directly where the thread local variable cannot be used or may contain invalid values if thread
local storage (TLS) is enabled. If TLS is not enabled, this is the same as `k_current_get()`.

---

__attribute_const__ static inline k_tid_t k_current_get(void)
   Get thread ID of the current thread.

   **Returns**
   ID of current thread.

void k_thread_abort(k_tid_t thread)
   Abort a thread.

   This routine permanently stops execution of `thread`. The thread is taken off all kernel queues
it is part of (i.e. the ready queue, the timeout queue, or a kernel object wait queue). However,
any kernel resources the thread might currently own (such as mutexes or memory blocks) are
not released. It is the responsibility of the caller of this routine to ensure all necessary cleanup
is performed.

   After `k_thread_abort()` returns, the thread is guaranteed not to be running or to become
runnable anywhere on the system. Normally this is done via blocking the caller (in the same
manner as `k_thread_join()`), but in interrupt context on SMP systems the implementation is
required to spin for threads that are running on other CPUs. Note that as specified, this
means that on SMP platforms it is possible for application code to create a deadlock condition
by simultaneously aborting a cycle of threads using at least one termination from interrupt
context. Zephyr cannot detect all such conditions.
Parameters

- thread – ID of thread to abort.

```c
void k_thread_start(k_tid_t thread)
```
Start an inactive thread.

If a thread was created with K_FOREVER in the delay parameter, it will not be added to the
scheduling queue until this function is called on it.

Parameters

- thread – thread to start

```c
k_ticks_t k_thread_timeout_expires_ticks(const struct k_thread *t)
```
Get time when a thread wakes up, in system ticks.

This routine computes the system uptime when a waiting thread next executes, in units of
system ticks. If the thread is not waiting, it returns current system time.

```c
k_ticks_t k_thread_timeout_remaining_ticks(const struct k_thread *t)
```
Get time remaining before a thread wakes up, in system ticks.

This routine computes the time remaining before a waiting thread next executes, in units of
system ticks. If the thread is not waiting, it returns zero.

```c
int k_thread_priority_get(k_tid_t thread)
```
Get a thread’s priority.

This routine gets the priority of thread.

Parameters

- thread – ID of thread whose priority is needed.

Returns

Priority of thread.

```c
void k_thread_priority_set(k_tid_t thread, int prio)
```
Set a thread’s priority.

This routine immediately changes the priority of thread.

Rescheduling can occur immediately depending on the priority thread is set to:

- If its priority is raised above the priority of the caller of this function, and the caller is
preemptible, thread will be scheduled in.
- If the caller operates on itself, it lowers its priority below that of other threads in the
system, and the caller is preemptible, the thread of highest priority will be scheduled in.

Priority can be assigned in the range of -CONFIG_NUM_COOP_PRIORITIES to
CONFIG_NUM_PREEMPT_PRIORITIES-1, where -CONFIG_NUM_COOP_PRIORITIES is the
highest priority.

**Warning:** Changing the priority of a thread currently involved in mutex priority inheri-
tance may result in undefined behavior.

Parameters

- thread – ID of thread whose priority is to be set.
- prio – New priority.
void k_thread_deadline_set(k_tid_t thread, int deadline)
Set deadline expiration time for scheduler.

This sets the “deadline” expiration as a time delta from the current time, in the same units
used by k_cycle_get_32(). The scheduler (when deadline scheduling is enabled) will choose
the next expiring thread when selecting between threads at the same static priority. Threads
at different priorities will be scheduled according to their static priority.

Note: Deadlines are stored internally using 32 bit unsigned integers. The number of cy-
cles between the “first” deadline in the scheduler queue and the “last” deadline must be less
than 2^31 (i.e a signed non-negative quantity). Failure to adhere to this rule may result in
scheduled threads running in an incorrect deadline order.

Note: Despite the API naming, the scheduler makes no guarantees the the thread WILL be
scheduled within that deadline, nor does it take extra metadata (like e.g. the “runtime” and
“period” parameters in Linux sched_setattr()) that allows the kernel to validate the scheduling
for achievability. Such features could be implemented above this call, which is simply input
to the priority selection logic.

Note: You should enable CONFIG_SCHED_DEADLINE in your project configuration.

Parameters
• thread – A thread on which to set the deadline
• deadline – A time delta, in cycle units

int k_thread_cpu_mask_clear(k_tid_t thread)
Sets all CPU enable masks to zero.
After this returns, the thread will no longer be schedulable on any CPUs. The thread must not
be currently runnable.

Note: You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters
• thread – Thread to operate upon

Returns
Zero on success, otherwise error code

int k_thread_cpu_mask_enable_all(k_tid_t thread)
Sets all CPU enable masks to one.
After this returns, the thread will be schedulable on any CPU. The thread must not be currently
runnable.

Note: You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters
• thread – Thread to operate upon
Returns

Zero on success, otherwise error code

int kThread_cpu_mask_enable(k_tid_t thread, int cpu)
Enable thread to run on specified CPU.
The thread must not be currently runnable.

Note: You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters

• thread – Thread to operate upon
• cpu – CPU index

Returns

Zero on success, otherwise error code

int kThread_cpu_mask_disable(k_tid_t thread, int cpu)
Prevent thread to run on specified CPU.
The thread must not be currently runnable.

Note: You should enable CONFIG_SCHED_CPU_MASK in your project configuration.

Parameters

• thread – Thread to operate upon
• cpu – CPU index

Returns

Zero on success, otherwise error code

int kThread_cpu_pin(k_tid_t thread, int cpu)
Pin a thread to a CPU.
Pin a thread to a CPU by first clearing the cpu mask and then enabling the thread on the selected CPU.

Parameters

• thread – Thread to operate upon
• cpu – CPU index

Returns

Zero on success, otherwise error code

void kThread_suspend(k_tid_t thread)
Suspend a thread.

This routine prevents the kernel scheduler from making thread the current thread. All other internal operations on thread are still performed; for example, kernel objects it is waiting on are still handed to it. Note that any existing timeouts (e.g. k_sleep(), or a timeout argument to k_sem_take() et. al.) will be canceled. On resume, the thread will begin running immediately and return from the blocked call.

If thread is already suspended, the routine has no effect.

Parameters

void k_thread_resume(k_tid_t thread)
Resume a suspended thread.

This routine allows the kernel scheduler to make thread the current thread, when it is next eligible for that role.

If thread is not currently suspended, the routine has no effect.

Parameters
- thread – ID of thread to resume.

void k_sched_time_slice_set(int32_t slice, int prio)
Set time-slicing period and scope.

This routine specifies how the scheduler will perform time slicing of preemptible threads.

To enable time slicing, slice must be non-zero. The scheduler ensures that no thread runs for more than the specified time limit before other threads of that priority are given a chance to execute. Any thread whose priority is higher than prio is exempted, and may execute as long as desired without being preempted due to time slicing.

Time slicing only limits the maximum amount of time a thread may continuously execute. Once the scheduler selects a thread for execution, there is no minimum guaranteed time the thread will execute before threads of greater or equal priority are scheduled.

When the current thread is the only one of that priority eligible for execution, this routine has no effect; the thread is immediately rescheduled after the slice period expires.

To disable timeslicing, set both slice and prio to zero.

Parameters
- slice – Maximum time slice length (in milliseconds).
- prio – Highest thread priority level eligible for time slicing.

void k_thread_time_slice_set(struct k_thread *th, int32_t slice_ticks, k_thread_timeslice_fn_t expired, void *data)
Set thread time slice.

As for k_sched_time_slice_set, but (when CONFIG_TIMESLICE_PER_THREAD=y) sets the timeslice for a specific thread. When non-zero, this timeslice will take precedence over the global value.

When such a thread’s timeslice expires, the configured callback will be called before the thread is removed/re-added to the run queue. This callback will occur in interrupt context, and the specified thread is guaranteed to have been preempted by the currently-executing ISR. Such a callback is free to, for example, modify the thread priority or slice time for future execution, suspend the thread, etc...

Note: Unlike the older API, the time slice parameter here is specified in ticks, not milliseconds. Ticks have always been the internal unit, and not all platforms have integer conversions between the two.

Note: Threads with a non-zero slice time set will be timesliced always, even if they are higher priority than the maximum timeslice priority set via k_sched_time_slice_set().

Note: The callback notification for slice expiration happens, as it must, while the thread is still “current”, and thus it happens before any registered timeouts at this tick. This has the
somewhat confusing side effect that the tick time (c.f. \texttt{k_uptime_get()}) does not yet reflect the expired ticks. Applications wishing to make fine-grained timing decisions within this callback should use the cycle API, or derived facilities like \texttt{k_thread_runtime_stats_get().}

### Parameters

- \texttt{th} – A valid, initialized thread
- \texttt{slice_ticks} – Maximum timeslice, in ticks
- \texttt{expired} – Callback function called on slice expiration
- \texttt{data} – Parameter for the expiration handler

```c
void k_sched_lock(void)
Lock the scheduler.
```

This routine prevents the current thread from being preempted by another thread by instructing the scheduler to treat it as a cooperative thread. If the thread subsequently performs an operation that makes it unready, it will be context switched out in the normal manner. When the thread again becomes the current thread, its non-preemptible status is maintained.

This routine can be called recursively.

Owing to clever implementation details, scheduler locks are extremely fast for non-userspace threads (just one byte inc/decrement in the thread struct).

---

**Note:** This works by elevating the thread priority temporarily to a cooperative priority, allowing cheap synchronization vs. other preemptible or cooperative threads running on the current CPU. It does not prevent preemption or asynchrony of other types. It does not prevent threads from running on other CPUs when \texttt{CONFIG_SMP=y}. It does not prevent interrupts from happening, nor does it prevent threads with MetaIRQ priorities from preempting the current thread. In general this is a historical API not well-suited to modern applications, use with care.

```c
void k_sched_unlock(void)
Unlock the scheduler.
```

This routine reverses the effect of a previous call to \texttt{k_sched_lock().} A thread must call the routine once for each time it called \texttt{k_sched_lock()} before the thread becomes preemptible.

```c
void k_thread_custom_data_set(void *value)
Set current thread’s custom data.
```

This routine sets the custom data for the current thread to \texttt{@ value}. Custom data is not used by the kernel itself, and is freely available for a thread to use as it sees fit. It can be used as a framework upon which to build thread-local storage.

#### Parameters

- \texttt{value} – New custom data value.

```c
void *k_thread_custom_data_get(void)
Get current thread’s custom data.
```

This routine returns the custom data for the current thread.

#### Returns

Current custom data value.
int k_thread_name_set(k_tid_t thread, const char *str)
Set current thread name.
Set the name of the thread to be used when CONFIG_THREAD_MONITOR is enabled for tracing and debugging.

Parameters
• thread – Thread to set name, or NULL to set the current thread
• str – Name string

Return values
• 0 – on success
• -EFAULT – Memory access error with supplied string
• -ENOSYS – Thread name configuration option not enabled
• -EINVAL – Thread name too long

const char *k_thread_name_get(k_tid_t thread)
Get thread name.
Get the name of a thread

Parameters
• thread – Thread ID

Return values
Thread name, or NULL if configuration not enabled

int k_thread_name_copy(k_tid_t thread, char *buf, size_t size)
Copy the thread name into a supplied buffer.

Parameters
• thread – Thread to obtain name information
• buf – Destination buffer
• size – Destination buffer size

Return values
• -ENOSPC – Destination buffer too small
• -EFAULT – Memory access error
• -ENOSYS – Thread name feature not enabled
• 0 – Success

const char *k_thread_state_str(k_tid_t thread_id, char *buf, size_t buf_size)
Get thread state string.
This routine generates a human friendly string containing the thread's state, and copies as much of it as possible into buf.

Parameters
• thread_id – Thread ID
• buf – Buffer into which to copy state strings
• buf_size – Size of the buffer

Return values
Pointer to buf if data was copied, else a pointer to "".

3.1. Kernel Services 279
struct k_thread
    
#include <thread.h>  Thread Structure.

Public Members

struct _callee_saved callee_saved
    defined by the architecture, but all archs need these

Thread Stack APIs.
Defines

K_KERNEL_STACK_DECLARE(sym, size)
Declare a reference to a thread stack.
This macro declares the symbol of a thread stack defined elsewhere in the current scope.

Parameters
• sym – Thread stack symbol name
• size – Size of the stack memory region

K_KERNEL_STACK_ARRAY_DECLARE(sym, nmemb, size)
Declare a reference to a thread stack array.
This macro declares the symbol of a thread stack array defined elsewhere in the current scope.

Parameters
• sym – Thread stack symbol name
• nmemb – Number of stacks defined
• size – Size of the stack memory region

K_KERNEL_PINNED_STACK_ARRAYDECLARE(sym, nmemb, size)
Declare a reference to a pinned thread stack array.
This macro declares the symbol of a pinned thread stack array defined elsewhere in the current scope.

Parameters
• sym – Thread stack symbol name
• nmemb – Number of stacks defined
• size – Size of the stack memory region

K_KERNEL_STACK_EXTERN(sym)
Obtain an extern reference to a stack.
This macro properly brings the symbol of a thread stack defined elsewhere into scope.

Deprecated:
Use K_KERNEL_STACK_DECLARE() instead.

Parameters
• sym – Thread stack symbol name

K_KERNEL_STACK_ARRAY_EXTERN(sym, nmemb, size)
Obtain an extern reference to a stack array.
This macro properly brings the symbol of a stack array defined elsewhere into scope.

Deprecated:
Use K_KERNEL_STACK_ARRAY_DECLARE() instead.

Parameters
• sym – Thread stack symbol name
• nmemb – Number of stacks defined
size – Size of the stack memory region

K_KERNEL_PINNED_STACK_ARRAY_EXTERN(sym, nmemb, size)

Obtain an extern reference to a pinned stack array.

This macro properly brings the symbol of a pinned stack array defined elsewhere into scope.

Deprecated:
Use K_KERNEL_PINNED_STACK_ARRAY_DECLARE() instead.

Parameters

• sym – Thread stack symbol name
• nmemb – Number of stacks defined
• size – Size of the stack memory region

K_KERNEL_STACK_DEFINE(sym, size)

Define a toplevel kernel stack memory region.

This defines a region of memory for use as a thread stack, for threads that exclusively run in supervisor mode. This is also suitable for declaring special stacks for interrupt or exception handling.

Stacks defined with this macro may not host user mode threads.

It is legal to precede this definition with the ‘static’ keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of k_thread_create(), it may not be the same as the ‘size’ parameter. Use K_KERNEL_STACK_SIZEOF() instead.

The total amount of memory allocated may be increased to accommodate fixed-size stack overflow guards.

Parameters

• sym – Thread stack symbol name
• size – Size of the stack memory region

K_KERNEL_PINNED_STACK_DEFINE(sym, size)

Define a toplevel kernel stack memory region in pinned section.

See K_KERNEL_STACK_DEFINE() for more information and constraints.

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as K_KERNEL_STACK_DEFINE().

Parameters

• sym – Thread stack symbol name
• size – Size of the stack memory region

K_KERNEL_STACK_ARRAY_DEFINE(sym, nmemb, size)

Define a toplevel array of kernel stack memory regions.

Stacks defined with this macro may not host user mode threads.

Parameters

• sym – Kernel stack array symbol name
• nmemb – Number of stacks to define
• size – Size of the stack memory region

\texttt{K\_KERNEL\_PINNED\_STACK\_ARRAY\_DEFINE(sym, nmemb, size)}

Define a toplevel array of kernel stack memory regions in pinned section.

See \texttt{K\_KERNEL\_STACK\_ARRAY\_DEFINE()} for more information and constraints.

This puts the stack into the pinned noinit linker section if \texttt{CONFIG\_LINKER\_USE\_PINNED\_SECTION} is enabled, or else it would put the stack into the same section as \texttt{K\_KERNEL\_STACK\_ARRAY\_DEFINE()}.

\textbf{Parameters}

• sym – Kernel stack array symbol name
• nmemb – Number of stacks to define
• size – Size of the stack memory region

\texttt{K\_KERNEL\_STACK\_MEMBER(sym, size)}

Define an embedded stack memory region.

Used for kernel stacks embedded within other data structures.

Stacks defined with this macro may not host user mode threads.

\textbf{Parameters}

• sym – Thread stack symbol name
• size – Size of the stack memory region

\texttt{K\_KERNEL\_STACK\_SIZEOF(sym)}

\texttt{K\_THREAD\_STACK\_DECLARE(sym, size)}

Declare a reference to a thread stack.

This macro declares the symbol of a thread stack defined elsewhere in the current scope.

\textbf{Parameters}

• sym – Thread stack symbol name
• size – Size of the stack memory region

\texttt{K\_THREAD\_STACK\_ARRAY\_DECLARE(sym, nmemb, size)}

Declare a reference to a thread stack array.

This macro declares the symbol of a thread stack array defined elsewhere in the current scope.

\textbf{Parameters}

• sym – Thread stack symbol name
• nmemb – Number of stacks defined
• size – Size of the stack memory region

\texttt{K\_THREAD\_STACK\_EXTERN(sym)}

Obtain an extern reference to a stack.

This macro properly brings the symbol of a thread stack defined elsewhere into scope.

\textit{Deprecated:}

Use \texttt{K\_THREAD\_STACK\_DECLARE()} instead.

\textbf{Parameters}

• sym – Thread stack symbol name
K_THREAD_STACK_ARRAY_EXTERN(sym, nmemb, size)

Obtain an extern reference to a thread stack array.

This macro properly brings the symbol of a stack array defined elsewhere into scope.

Deprecated:
Use K_THREAD_STACK_ARRAY_DECLARE() instead.

Parameters

• sym – Thread stack symbol name
• nmemb – Number of stacks defined
• size – Size of the stack memory region

K_THREAD_STACK_SIZEOF(sym)

Return the size in bytes of a stack memory region.

Convenience macro for passing the desired stack size to k_thread_create() since the underlying implementation may actually create something larger (for instance a guard area).

The value returned here is not guaranteed to match the ‘size’ parameter passed to K_THREAD_STACK_DEFINE and may be larger, but is always safe to pass to k_thread_create() for the associated stack object.

Parameters

• sym – Stack memory symbol

Returns

Size of the stack buffer

K_THREAD_STACK_DEFINE(sym, size)

Define a toplevel thread stack memory region.

This defines a region of memory suitable for use as a thread’s stack.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in ‘noinit’ section so that it isn’t zeroed at boot

The defined symbol will always be a k_thread_stack_t which can be passed to k_thread_create(), but should otherwise not be manipulated. If the buffer inside needs to be examined, examine thread->stack_info for the associated thread object to obtain the boundaries.

It is legal to precede this definition with the ‘static’ keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of k_thread_create(), it may not be the same as the ‘size’ parameter. Use K_THREAD_STACK_SIZEOF() instead.

Some arches may round the size of the usable stack region up to satisfy alignment constraints. K_THREAD_STACK_SIZEOF() will return the aligned size.

Parameters

• sym – Thread stack symbol name
• size – Size of the stack memory region

K_THREAD_PINNED_STACK_DEFINE(sym, size)

Define a toplevel thread stack memory region in pinned section.

This defines a region of memory suitable for use as a thread’s stack.
This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in ‘noinit’ section so that it isn’t zeroed at boot.

The defined symbol will always be a k_thread_stack_t which can be passed to k_thread_create(), but should otherwise not be manipulated. If the buffer inside needs to be examined, examine thread->stack_info for the associated thread object to obtain the boundaries.

It is legal to precede this definition with the ‘static’ keyword.

It is NOT legal to take the sizeof(sym) and pass that to the stackSize parameter of k_thread_create(), it may not be the same as the ‘size’ parameter. Use K_THREAD_STACK_SIZEOF() instead.

Some archs may round the size of the usable stack region up to satisfy alignment constraints. K_THREAD_STACK_SIZEOF() will return the aligned size.

This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as K_THREAD_STACK_DEFINE().

Parameters

- sym – Thread stack symbol name
- size – Size of the stack memory region

K_THREAD_STACK_LEN(size)

Calculate size of stacks to be allocated in a stack array.

This macro calculates the size to be allocated for the stacks inside a stack array. It accepts the indicated “size” as a parameter and if required, pads some extra bytes (e.g. for MPU scenarios). Refer K_THREAD_STACK_ARRAY_DEFINE definition to see how this is used. The returned size ensures each array member will be aligned to the required stack base alignment.

Parameters

- size – Size of the stack memory region

Returns

Appropriate size for an array member

K_THREAD_STACK_ARRAY_DEFINE(sym, nmemb, size)

Define a toplevel array of thread stack memory regions.

Create an array of equally sized stacks. See K_THREAD_STACK_DEFINE definition for additional details and constraints.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in ‘noinit’ section so that it isn’t zeroed at boot.

Parameters

- sym – Thread stack symbol name
- nmemb – Number of stacks to define
- size – Size of the stack memory region

K_THREAD_PINNED_STACK_ARRAY_DEFINE(sym, nmemb, size)

Define a toplevel array of thread stack memory regions in pinned section.

Create an array of equally sized stacks. See K_THREAD_STACK_DEFINE definition for additional details and constraints.

This is the generic, historical definition. Align to Z_THREAD_STACK_OBJ_ALIGN and put in ‘noinit’ section so that it isn’t zeroed at boot.
This puts the stack into the pinned noinit linker section if CONFIG_LINKER_USE_PINNED_SECTION is enabled, or else it would put the stack into the same section as \texttt{K_THREAD_STACK_DEFINE()}.

**Parameters**

- \texttt{sym} – Thread stack symbol name
- \texttt{nmemb} – Number of stacks to define
- \texttt{size} – Size of the stack memory region

\texttt{K_THREAD_STACK_MEMBER(sym, size)}

Define an embedded stack memory region.

Used for stacks embedded within other data structures. Use is highly discouraged but in some cases necessary. For memory protection scenarios, it is very important that any RAM preceding this member not be writable by threads else a stack overflow will lead to silent corruption. In other words, the containing data structure should live in RAM owned by the kernel.

A user thread can only be started with a stack defined in this way if the thread starting it is in supervisor mode.

This is now deprecated, as stacks defined in this way are not usable from user mode. Use \texttt{K_KERNEL_STACK_MEMBER}.

**Parameters**

- \texttt{sym} – Thread stack symbol name
- \texttt{size} – Size of the stack memory region

### Scheduling

The kernel’s priority-based scheduler allows an application’s threads to share the CPU.

**Concepts**

The scheduler determines which thread is allowed to execute at any point in time; this thread is known as the current thread.

There are various points in time when the scheduler is given an opportunity to change the identity of the current thread. These points are called reschedule points. Some potential reschedule points are:

- transition of a thread from running state to a suspended or waiting state, for example by \texttt{k_sem_take()} or \texttt{k_sleep()}.
- transition of a thread to the ready state, for example by \texttt{k_sem_give()} or \texttt{k_thread_start()}
- return to thread context after processing an interrupt
- when a running thread invokes \texttt{k_yield()}

A thread sleeps when it voluntarily initiates an operation that transitions itself to a suspended or waiting state.

Whenever the scheduler changes the identity of the current thread, or when execution of the current thread is replaced by an ISR, the kernel first saves the current thread’s CPU register values. These register values get restored when the thread later resumes execution.

**Scheduling Algorithm**

The kernel’s scheduler selects the highest priority ready thread to be the current thread. When multiple ready threads of the same priority exist, the scheduler chooses the one that has been waiting longest.

A thread’s relative priority is primarily determined by its static priority. However, when both earliest-deadline-first scheduling is enabled (\texttt{CONFIG_SCHED_DEADLINE}) and a choice of threads have equal static priority, then the thread with the earlier deadline is considered to have the higher priority. Thus, when
earliest-deadline-first scheduling is enabled, two threads are only considered to have the same priority when both their static priorities and deadlines are equal. The routine `k_thread_deadline_set()` is used to set a thread's deadline.

**Note:** Execution of ISRs takes precedence over thread execution, so the execution of the current thread may be replaced by an ISR at any time unless interrupts have been masked. This applies to both cooperative threads and preemptive threads.

The kernel can be built with one of several choices for the ready queue implementation, offering different choices between code size, constant factor runtime overhead and performance scaling when many threads are added.

- **Simple linked-list ready queue (CONFIG_SCHED_DUMB)**
  The scheduler ready queue will be implemented as a simple unordered list, with very fast constant-time performance for single threads and very low code size. This implementation should be selected on systems with constrained code size that will never see more than a small number (3, maybe) of runnable threads in the queue at any given time. On most platforms (that are not otherwise using the red/black tree) this results in a savings of ~2k of code size.

- **Red/black tree ready queue (CONFIG_SCHED_SCALABLE)**
  The scheduler ready queue will be implemented as a red/black tree. This has rather slower constant-time insertion and removal overhead, and on most platforms (that are not otherwise using the red/black tree somewhere) requires an extra ~2kb of code. The resulting behavior will scale cleanly and quickly into the many thousands of threads.
  Use this for applications needing many concurrent runnable threads (> 20 or so). Most applications won’t need this ready queue implementation.

- **Traditional multi-queue ready queue (CONFIG_SCHED_MULTIQ)**
  When selected, the scheduler ready queue will be implemented as the classic/textbook array of lists, one per priority (max 32 priorities).
  This corresponds to the scheduler algorithm used in Zephyr versions prior to 1.12.
  It incurs only a tiny code size overhead vs. the “dumb” scheduler and runs in O(1) time in almost all circumstances with very low constant factor. But it requires a fairly large RAM budget to store those list heads, and the limited features make it incompatible with features like deadline scheduling that need to sort threads more finely, and SMP affinity which need to traverse the list of threads.
  Typical applications with small numbers of runnable threads probably want the DUMB scheduler.

The wait_q abstraction used in IPC primitives to pend threads for later wakeup shares the same backend data structure choices as the scheduler, and can use the same options.

- **Scalable wait_q implementation (CONFIG_WAITQ_SCALABLE)**
  When selected, the wait_q will be implemented with a balanced tree. Choose this if you expect to have many threads waiting on individual primitives. There is a ~2kb code size increase over `CONFIG_WAITQ_DUMB` (which may be shared with `CONFIG_SCHED_SCALABLE`) if the red/black tree is not used elsewhere in the application, and pend/unpend operations on “small” queues will be somewhat slower (though this is not generally a performance path).

- **Simple linked-list wait_q (CONFIG_WAITQ_DUMB)**
  When selected, the wait_q will be implemented with a doubly-linked list. Choose this if you expect to have only a few threads blocked on any single IPC primitive.

**Cooperative Time Slicing** Once a cooperative thread becomes the current thread, it remains the current thread until it performs an action that makes it unready. Consequently, if a cooperative thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of higher priority and equal priority.
To overcome such problems, a cooperative thread can voluntarily relinquish the CPU from time to time to permit other threads to execute. A thread can relinquish the CPU in two ways:

- Calling `k_yield()` puts the thread at the back of the scheduler’s prioritized list of ready threads, and then invokes the scheduler. All ready threads whose priority is higher or equal to that of the yielding thread are then allowed to execute before the yielding thread is rescheduled. If no such ready threads exist, the scheduler immediately reschedules the yielding thread without context switching.

- Calling `k_sleep()` makes the thread unready for a specified time period. Ready threads of all priorities are then allowed to execute; however, there is no guarantee that threads whose priority is lower than that of the sleeping thread will actually be scheduled before the sleeping thread becomes ready once again.

**Preemptive Time Slicing** Once a preemptive thread becomes the current thread, it remains the current thread until a higher priority thread becomes ready, or until the thread performs an action that makes it unready. Consequently, if a preemptive thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of equal priority.
To overcome such problems, a preemptive thread can perform cooperative time slicing (as described above), or the scheduler’s time slicing capability can be used to allow other threads of the same priority to execute.

The scheduler divides time into a series of **time slices**, where slices are measured in system clock ticks. The time slice size is configurable, but this size can be changed while the application is running.

At the end of every time slice, the scheduler checks to see if the current thread is preemptible and, if so, implicitly invokes `k_yield()` on behalf of the thread. This gives other ready threads of the same priority the opportunity to execute before the current thread is scheduled again. If no threads of equal priority are ready, the current thread remains the current thread.

Threads with a priority higher than specified limit are exempt from preemptive time slicing, and are never preempted by a thread of equal priority. This allows an application to use preemptive time slicing only when dealing with lower priority threads that are less time-sensitive.

**Note:** The kernel’s time slicing algorithm does not ensure that a set of equal-priority threads receive an equitable amount of CPU time, since it does not measure the amount of time a thread actually gets to execute. However, the algorithm *does* ensure that a thread never executes for longer than a single time slice without being required to yield.

**Scheduler Locking**  A preemptible thread that does not wish to be preempted while performing a critical operation can instruct the scheduler to temporarily treat it as a cooperative thread by calling `k_sched_lock()`. This prevents other threads from interfering while the critical operation is being performed.

Once the critical operation is complete the preemptible thread must call `k_sched_unlock()` to restore its normal, preemptible status.

If a thread calls `k_sched_lock()` and subsequently performs an action that makes it unready, the scheduler will switch the locking thread out and allow other threads to execute. When the locking thread again becomes the current thread, its non-preemptible status is maintained.

**Note:** Locking out the scheduler is a more efficient way for a preemptible thread to prevent preemption than changing its priority level to a negative value.
Thread Sleeping  A thread can call \texttt{k\_sleep()} to delay its processing for a specified time period. During the time the thread is sleeping the CPU is relinquished to allow other ready threads to execute. Once the specified delay has elapsed the thread becomes ready and is eligible to be scheduled once again.

A sleeping thread can be woken up prematurely by another thread using \texttt{k\_wakeup()}. This technique can sometimes be used to permit the secondary thread to signal the sleeping thread that something has occurred \textit{without} requiring the threads to define a kernel synchronization object, such as a semaphore. Waking up a thread that is not sleeping is allowed, but has no effect.

Busy Waiting  A thread can call \texttt{k\_busy\_wait()} to perform a busy wait that delays its processing for a specified time period \textit{without} relinquishing the CPU to another ready thread.

A busy wait is typically used instead of thread sleeping when the required delay is too short to warrant having the scheduler context switch from the current thread to another thread and then back again.

Suggested Uses  Use cooperative threads for device drivers and other performance-critical work.

Use cooperative threads to implement mutually exclusion without the need for a kernel object, such as a mutex.

Use preemptive threads to give priority to time-sensitive processing over less time-sensitive processing.

CPU Idling

Although normally reserved for the idle thread, in certain special applications, a thread might want to make the CPU idle.

```c
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}
```

(continues on next page)
int main(void)
{
    k_sem_init(&my_sem, 0, 1);

    /* wait for semaphore from ISR, then do related work */
    for (;;) {
        /* wait for ISR to trigger work to perform */
        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {
            /* ... do processing */
        }

        /* put CPU to sleep to save power */
        k_cpu_idle();
    }
}

Making the CPU idle in an atomic fashion  It is possible that there is a need to do some work atomically before making the CPU idle. In such a case, k_cpu_atomic_idle() should be used instead.

In fact, there is a race condition in the previous example: the interrupt could occur between the time the semaphore is taken, finding out it is not available and making the CPU idle again. In some systems, this can cause the CPU to idle until another interrupt occurs, which might be never, thus hanging the system completely. To prevent this, k_cpu_atomic_idle() should have been used, like in this example.

static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}

int main(void)
{
    k_sem_init(&my_sem, 0, 1);

    for (;;) {

        unsigned int key = irq_lock();

        /*
         * Wait for semaphore from ISR; if acquired, do related work, then
         * go to next loop iteration (the semaphore might have been given
         * again); else, make the CPU idle.
         */

        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {
            irq_unlock(key);
            /* ... do processing */

(continues on next page)
Suggested Uses  Use `k_cpu_atomic_idle()` when a thread has to do some real work in addition to idling the CPU to wait for an event. See example above.

Use `k_cpu_idle()` only when a thread is only responsible for idling the CPU, i.e. not doing any real work, like in this example below.

```c
int main(void)
{
    /* ... do some system/application initialization */

    /* thread is only used for CPU idling from this point on */
    for (;;) {
        k_cpu_idle();
    }
}
```

**Note:** Do not use these APIs unless absolutely necessary. In a normal system, the idle thread takes care of power management, including CPU idling.

### API Reference

**group** cpu_idle_apis

#### Functions

static inline void `k_cpu_idle`(void)

Make the CPU idle.

This function makes the CPU idle until an event wakes it up.

In a regular system, the idle thread should be the only thread responsible for making the CPU idle and triggering any type of power management. However, in some more constrained systems, such as a single-threaded system, the only thread would be responsible for this if needed.

**Note:** In some architectures, before returning, the function unmask interrupts unconditionally.

static inline void `k_cpu_atomic_idle`(unsigned int key)

Make the CPU idle in an atomic fashion.

Similar to `k_cpu_idle()`, but must be called with interrupts locked.

Enabling interrupts and entering a low-power mode will be atomic, i.e. there will be no period of time where interrupts are enabled before the processor enters a low-power mode.
After waking up from the low-power mode, the interrupt lockout state will be restored as if by `irq_unlock(key)`.

**Parameters**

- `key` – Interrupt locking key obtained from `irq_lock()`.

---

**System Threads**

- **Implementation**
  - *Writing a main() function*

- **Suggested Uses**

A *system thread* is a thread that the kernel spawns automatically during system initialization. The kernel spawns the following system threads:

**Main thread**

This thread performs kernel initialization, then calls the application's `main()` function (if one is defined).

By default, the main thread uses the highest configured preemptible thread priority (i.e. 0). If the kernel is not configured to support preemptible threads, the main thread uses the lowest configured cooperative thread priority (i.e. -1).

The main thread is an essential thread while it is performing kernel initialization or executing the application's `main()` function; this means a fatal system error is raised if the thread aborts. If `main()` is not defined, or if it executes and then does a normal return, the main thread terminates normally and no error is raised.

**Idle thread**

This thread executes when there is no other work for the system to do. If possible, the idle thread activates the board's power management support to save power; otherwise, the idle thread simply performs a “do nothing” loop. The idle thread remains in existence as long as the system is running and never terminates.

The idle thread always uses the lowest configured thread priority. If this makes it a cooperative thread, the idle thread repeatedly yields the CPU to allow the application's other threads to run when they need to.

The idle thread is an essential thread, which means a fatal system error is raised if the thread aborts.

Additional system threads may also be spawned, depending on the kernel and board configuration options specified by the application. For example, enabling the system workqueue spawns a system thread that services the work items submitted to it. (See *Workqueue Threads.*)

**Implementation**

**Writing a main() function**  An application-supplied `main()` function begins executing once kernel initialization is complete. The kernel does not pass any arguments to the function.

The following code outlines a trivial `main()` function. The function used by a real application can be as complex as needed.

```c
int main(void)
{
    /* initialize a semaphore */
```

(continues on next page)
A workqueue is a kernel object that uses a dedicated thread to process work items in a first in, first out manner. Each work item is processed by calling the function specified by the work item. A workqueue is typically used by an ISR or a high-priority thread to offload non-urgent processing to a lower-priority thread so it does not impact time-sensitive processing.

Any number of workqueues can be defined (limited only by available RAM). Each workqueue is referenced by its memory address.

A workqueue has the following key properties:

- A **queue** of work items that have been added, but not yet processed.
- A **thread** that processes the work items in the queue. The priority of the thread is configurable, allowing it to be either cooperative or preemptive as required.

Regardless of workqueue thread priority the workqueue thread will yield between each submitted work item, to prevent a cooperative workqueue from starving other threads.

A workqueue must be initialized before it can be used. This sets its queue to empty and spawns the workqueue's thread. The thread runs forever, but sleeps when no work items are available.

**Note:** The behavior described here is changed from the Zephyr workqueue implementation used prior to release 2.6. Among the changes are:
• Precise tracking of the status of cancelled work items, so that the caller need not be concerned that an item may be processing when the cancellation returns. Checking of return values on cancellation is still required.
• Direct submission of delayable work items to the queue with \texttt{K\_NO\_WAIT} rather than always going through the timeout API, which could introduce delays.
• The ability to wait until a work item has completed or a queue has been drained.
• Finer control of behavior when scheduling a delayable work item, specifically allowing a previous deadline to remain unchanged when a work item is scheduled again.
• Safe handling of work item resubmission when the item is being processed on another workqueue.

Using the return values of \texttt{k\_work\_busy\_get()} or \texttt{k\_work\_is\_pending()}, or measurements of remaining time until delayable work is scheduled, should be avoided to prevent race conditions of the type observed with the previous implementation. See also \textit{Workqueue Best Practices}.

\textbf{Work Item Lifecycle}  \hspace{2em} Any number of \textbf{work items} can be defined. Each work item is referenced by its memory address.

A work item is assigned a \textbf{handler function}, which is the function executed by the workqueue's thread when the work item is processed. This function accepts a single argument, which is the address of the work item itself. The work item also maintains information about its status.

A work item must be initialized before it can be used. This records the work item's handler function and marks it as not pending.

A work item may be \textbf{queued} (\texttt{K\_WORK\_QUED}) by submitting it to a workqueue by an ISR or a thread. Submitting a work item appends the work item to the workqueue's queue. Once the workqueue's thread has processed all of the preceding work items in its queue the thread will remove the next work item from the queue and invoke the work item's handler function. Depending on the scheduling priority of the workqueue's thread, and the work required by other items in the queue, a queued work item may be processed quickly or it may remain in the queue for an extended period of time.

A delayable work item may be \textbf{scheduled} (\texttt{K\_WORK\_DELAYED}) to a workqueue; see \textit{Delayable Work}.

A work item will be \textbf{running} (\texttt{K\_WORK\_RUNNING}) when it is running on a work queue, and may also be \textbf{canceling} (\texttt{K\_WORK\_CANCELING}) if it started running before a thread has requested that it be cancelled.

A work item can be in multiple states; for example it can be:

• running on a queue;
• marked canceling (because a thread used \texttt{k\_work\_cancel\_sync()} to wait until the work item completed);
• queued to run again on the same queue;
• scheduled to be submitted to a (possibly different) queue

\textit{all simultaneously}. A work item that is in any of these states is \textbf{pending} (\texttt{k\_work\_is\_pending()}) or \textbf{busy} (\texttt{k\_work\_busy\_get()}).

A handler function can use any kernel API available to threads. However, operations that are potentially blocking (e.g. taking a semaphore) must be used with care, since the workqueue cannot process subsequent work items in its queue until the handler function finishes executing.

The single argument that is passed to a handler function can be ignored if it is not required. If the handler function requires additional information about the work it is to perform, the work item can be embedded in a larger data structure. The handler function can then use the argument value to compute the address of the enclosing data structure with \texttt{CONTAINER\_OF}, and thereby obtain access to the additional information it needs.

A work item is typically initialized once and then submitted to a specific workqueue whenever work needs to be performed. If an ISR or a thread attempts to submit a work item that is already queued the
work item is not affected; the work item remains in its current place in the workqueue's queue, and the work is only performed once.

A handler function is permitted to re-submit its work item argument to the workqueue, since the work item is no longer queued at that time. This allows the handler to execute work in stages, without unduly delaying the processing of other work items in the workqueue's queue.

**Important:** A pending work item must not be altered until the item has been processed by the workqueue thread. This means a work item must not be re-initialized while it is busy. Furthermore, any additional information the work item's handler function needs to perform its work must not be altered until the handler function has finished executing.

### Delayable Work

An ISR or a thread may need to schedule a work item that is to be processed only after a specified period of time, rather than immediately. This can be done by scheduling a delayable work item to be submitted to a workqueue at a future time.

A delayable work item contains a standard work item but adds fields that record when and where the item should be submitted.

A delayable work item is initialized and scheduled to a workqueue in a similar manner to a standard work item, although different kernel APIs are used. When the schedule request is made the kernel initiates a timeout mechanism that is triggered after the specified delay has elapsed. Once the timeout occurs the kernel submits the work item to the specified workqueue, where it remains queued until it is processed in the standard manner.

Note that work handler used for delayable still receives a pointer to the underlying non-delayable work structure, which is not publicly accessible from `k_work_delayable`. To get access to an object that contains the delayable work object use this idiom:

```c
static void work_handler(struct k_work *work)
{
    struct k_work_delayable *dwork = k_work_delayable_from_work(work);
    struct work_context *ctx = CONTAINER_OF(dwork, struct work_context, timed_work);
    ...
}
```

### Triggered Work

The `k_work_poll_submit()` interface schedules a triggered work item in response to a poll event (see Polling API), that will call a user-defined function when a monitored resource becomes available or poll signal is raised, or a timeout occurs. In contrast to `k_poll()`, the triggered work does not require a dedicated thread waiting or actively polling for a poll event.

A triggered work item is a standard work item that has the following added properties:

- A pointer to an array of poll events that will trigger work item submissions to the workqueue
- A size of the array containing poll events.

A triggered work item is initialized and submitted to a workqueue in a similar manner to a standard work item, although dedicated kernel APIs are used. When a submit request is made, the kernel begins observing kernel objects specified by the poll events. Once at least one of the observed kernel object's changes state, the work item is submitted to the specified workqueue, where it remains queued until it is processed in the standard manner.

**Important:** The triggered work item as well as the referenced array of poll events have to be valid and cannot be modified for a complete triggered work item lifecycle, from submission to work item execution or cancellation.
An ISR or a thread may cancel a triggered work item it has submitted as long as it is still waiting for a poll event. In such case, the kernel stops waiting for attached poll events and the specified work is not executed. Otherwise the cancellation cannot be performed.

**System Workqueue**  The kernel defines a workqueue known as the **system workqueue**, which is available to any application or kernel code that requires workqueue support. The system workqueue is optional, and only exists if the application makes use of it.

**Important:** Additional workqueues should only be defined when it is not possible to submit new work items to the system workqueue, since each new workqueue incurs a significant cost in memory footprint. A new workqueue can be justified if it is not possible for its work items to co-exist with existing system workqueue work items without an unacceptable impact; for example, if the new work items perform blocking operations that would delay other system workqueue processing to an unacceptable degree.

### How to Use Workqueues

**Defining and Controlling a Workqueue**  A workqueue is defined using a variable of type `k_work_q`. The workqueue is initialized by defining the stack area used by its thread, initializing the `k_work_q`, either zeroing its memory or calling `k_work_queue_init()`, and then calling `k_work_queue_start()`. The stack area must be defined using `K_THREAD_STACK_DEFINE` to ensure it is properly set up in memory.

The following code defines and initializes a workqueue:

```c
#define MY_STACK_SIZE 512
#define MY_PRIORITY 5

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);

struct k_work_q my_work_q;

k_work_queue_init(&my_work_q);

k_work_queue_start(&my_work_q, my_stack_area,
                   K_THREAD_STACK_SIZEOF(my_stack_area), MY_PRIORITY,
                   NULL);
```

In addition the queue identity and certain behavior related to thread rescheduling can be controlled by the optional final parameter; see `k_work_queue_start()` for details.

The following API can be used to interact with a workqueue:

- `k_work_queue_drain()` can be used to block the caller until the work queue has no items left. Work items resubmitted from the workqueue thread are accepted while a queue is draining, but work items from any other thread or ISR are rejected. The restriction on submitting more work can be extended past the completion of the drain operation in order to allow the blocking thread to perform additional work while the queue is “plugged”. Note that draining a queue has no effect on scheduling or processing delayable items, but if the queue is plugged and the deadline expires the item will silently fail to be submitted.
- `k_work_queue_unplug()` removes any previous block on submission to the queue due to a previous drain operation.

**Submitting a Work Item**  A work item is defined using a variable of type `k_work`. It must be initialized by calling `k_work_init()`, unless it is defined using `K_WORK_DEFINE` in which case initialization is performed at compile-time.
An initialized work item can be submitted to the system workqueue by calling \texttt{k\_work\_submit()}, or to a specified workqueue by calling \texttt{k\_work\_submit\_to\_queue()}.

The following code demonstrates how an ISR can offload the printing of error messages to the system workqueue. Note that if the ISR attempts to resubmit the work item while it is still queued, the work item is left unchanged and the associated error message will not be printed.

```c
struct device_info {
    struct k_work work;
    char name[16]
} my_device;

void my_isr(void *arg) {
    ...
    if (error detected) {
        k_work_submit(&my_device.work);
    }
    ...
}

void print_error(struct k_work *item) {
    struct device_info *the_device = CONTAINER_OF(item, struct device_info, work);
    printk("Got error on device %s\n", the_device->name);
}

/* initialize name info for a device */
strcpy(my_device.name, "FOO_dev");

/* initialize work item for printing device's error messages */
k_work_init(&my_device.work, print_error);

/* install my_isr() as interrupt handler for the device (not shown) */
...
```

The following API can be used to check the status of or synchronize with the work item:

- \texttt{k\_work\_busy\_get()} returns a snapshot of flags indicating work item state. A zero value indicates the work is not scheduled, submitted, being executed, or otherwise still being referenced by the workqueue infrastructure.

- \texttt{k\_work\_is\_pending()} is a helper that indicates true if and only if the work is scheduled, queued, or running.

- \texttt{k\_work\_flush()} may be invoked from threads to block until the work item has completed. It returns immediately if the work is not pending.

- \texttt{k\_work\_cancel()} attempts to prevent the work item from being executed. This may or may not be successful. This is safe to invoke from ISRs.

- \texttt{k\_work\_cancel\_sync()} may be invoked from threads to block until the work completes; it will return immediately if the cancellation was successful or not necessary (the work wasn't submitted or running). This can be used after \texttt{k\_work\_cancel()} is invoked (from an ISR) to confirm completion of an ISR-initiated cancellation.

Scheduling a Delayable Work Item  A delayable work item is defined using a variable of type \texttt{k\_work\_delayable}. It must be initialized by calling \texttt{k\_work\_init\_delayable()}.
For delayed work there are two common use cases, depending on whether a deadline should be extended if a new event occurs. An example is collecting data that comes in asynchronously, e.g. characters from a UART associated with a keyboard. There are two APIs that submit work after a delay:

- `k_work_schedule()` (or `k_work_schedule_for_queue()`) schedules work to be executed at a specific time or after a delay. Further attempts to schedule the same item with this API before the delay completes will not change the time at which the item will be submitted to its queue. Use this if the policy is to keep collecting data until a specified delay since the first unprocessed data was received;

- `k_work_reschedule()` (or `k_work_reschedule_for_queue()`) unconditionally sets the deadline for the work, replacing any previous incomplete delay and changing the destination queue if necessary. Use this if the policy is to keep collecting data until a specified delay since the last unprocessed data was received.

If the work item is not scheduled both APIs behave the same. If `K_NO_WAIT` is specified as the delay the behavior is as if the item was immediately submitted directly to the target queue, without waiting for a minimal timeout (unless `k_work_schedule()` is used and a previous delay has not completed).

Both also have variants that allow control of the queue used for submission.

The helper function `k_work_delayable_from_work()` can be used to get a pointer to the containing `k_work_delayable` from a pointer to `k_work` that is passed to a work handler function.

The following additional API can be used to check the status of or synchronize with the work item:

- `k_work_delayable_busy_get()` is the analog to `k_work_busy_get()` for delayable work.
- `k_work_delayable_is_pending()` is the analog to `k_work_is_pending()` for delayable work.
- `k_work_flush_delayable()` is the analog to `k_work_flush()` for delayable work.
- `k_work_cancel_delayable()` is the analog to `k_work_cancel()` for delayable work; similarly with `k_work_cancel_delayable_sync()`.

**Synchronizing with Work Items** While the state of both regular and delayable work items can be determined from any context using `k_work_busy_get()` and `k_work_delayable_busy_get()` some use cases require synchronizing with work items after they've been submitted. `k_work_flush()`, `k_work_cancel_sync()`, and `k_work_cancel_delayable_sync()` can be invoked from thread context to wait until the requested state has been reached.

These APIs must be provided with a `k_work_sync` object that has no application-inspectable components but is needed to provide the synchronization objects. These objects should not be allocated on a stack if the code is expected to work on architectures with CONFIG_KERNEL_COHERENCE.

**Workqueue Best Practices**

**Avoid Race Conditions** Sometimes the data a work item must process is naturally thread-safe, for example when it's put into a `k_queue` by some thread and processed in the work thread. More often external synchronization is required to avoid data races: cases where the work thread might inspect or manipulate shared state that's being accessed by another thread or interrupt. Such state might be a flag indicating that work needs to be done, or a shared object that is filled by an ISR or thread and read by the work handler.

For simple flags *Atomic Services* may be sufficient. In other cases spin locks (`k_spinlock_t`) or thread-aware locks (`k_sem, k_mutex`, . . .) may be used to ensure data races don't occur.

If the selected lock mechanism can *sleep* then allowing the work thread to sleep will starve other work queue items, which may need to make progress in order to get the lock released. Work handlers should try to take the lock with its no-wait path. For example:
static void work_handler(struct work *work)
{
    struct work_context *parent = CONTAINER_OF(work, struct work_context, work_item);

    if (k_mutex_lock(&parent->lock, K_NO_WAIT) != 0) {
        /* NB: Submit will fail if the work item is being cancelled. */
        (void)k_work_submit(work);
        return;
    }

    /* do stuff under lock */
    k_mutex_unlock(&parent->lock);
    /* do stuff without lock */
}

Be aware that if the lock is held by a thread with a lower priority than the work queue the resubmission
may starve the thread that would release the lock, causing the application to fail. Where the idiom above
is required a delayable work item is preferred, and the work should be (re-)scheduled with a non-zero
delay to allow the thread holding the lock to make progress.

Note that submitting from the work handler can fail if the work item had been cancelled. Generally this
is acceptable, since the cancellation will complete once the handler finishes. If it is not, the code above
must take other steps to notify the application that the work could not be performed.

Work items in isolation are self-locking, so you don’t need to hold an external lock just to submit or
schedule them. Even if you use external state protected by such a lock to prevent further resubmission,
it’s safe to do the resubmit as long as you’re sure that eventually the item will take its lock and check that
state to determine whether it should do anything. Where a delayable work item is being rescheduled in
its handler due to inability to take the lock some other self-locking state, such as an atomic flag set by the
application/driver when the cancel is initiated, would be required to detect the cancellation and avoid
the cancelled work item being submitted again after the deadline.

Check Return Values  All work API functions return status of the underlying operation, and in many
cases it is important to verify that the intended result was obtained.

• Submitting a work item (k_work_submit_to_queue()) can fail if the work is being cancelled or
  the queue is not accepting new items. If this happens the work will not be executed, which could
  cause a subsystem that is animated by work handler activity to become non-responsive.

• Asynchronous cancellation (k_work_cancel() or k_work_cancel_delayable()) can complete
  while the work item is still being run by a handler. Proceeding to manipulate state shared with
  the work handler will result in data races that can cause failures.

Many race conditions have been present in Zephyr code because the results of an operation were not
checked.

There may be good reason to believe that a return value indicating that the operation did not complete as
expected is not a problem. In those cases the code should clearly document this, by (1) casting the return
value to void to indicate that the result is intentionally ignored, and (2) documenting what happens in
the unexpected case. For example:

/* If this fails, the work handler will check pub->active and
 * exit without transmitting.
 */
(void)k_work_cancel_delayable(&pub->timer);

However in such a case the following code must still avoid data races, as it cannot guarantee that the
work thread is not accessing work-related state.
Don’t Optimize Prematurely  The workqueue API is designed to be safe when invoked from multiple threads and interrupts. Attempts to externally inspect a work item's state and make decisions based on the result are likely to create new problems.

So when new work comes in, just submit it. Don’t attempt to “optimize” by checking whether the work item is already submitted by inspecting snapshot state with `k_work_is_pending()` or `k_work_busy_get()`, or checking for a non-zero delay from `k_work_delayable_remaining_get()`. Those checks are fragile: a “busy” indication can be obsolete by the time the test is returned, and a “not-busy” indication can also be wrong if work is submitted from multiple contexts, or (for delayable work) if the deadline has completed but the work is still in queued or running state.

A general best practice is to always maintain in shared state some condition that can be checked by the handler to confirm whether there is work to be done. This way you can use the work handler as the standard cleanup path: rather than having to deal with cancellation and cleanup at points where items are submitted, you may be able to have everything done in the work handler itself.

A rare case where you could safely use `k_work_is_pending()` is as a check to avoid invoking `k_work_flush()` or `k_work_cancel_sync()`, if you are certain that nothing else might submit the work while you’re checking (generally because you’re holding a lock that prevents access to state used for submission).

Suggested Uses  Use the system workqueue to defer complex interrupt-related processing from an ISR to a shared thread. This allows the interrupt-related processing to be done promptly without compromising the system’s ability to respond to subsequent interrupts, and does not require the application to define and manage an additional thread to do the processing.

Configuration Options  Related configuration options:

- `CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE`
- `CONFIG_SYSTEM_WORKQUEUE_PRIORITY`
- `CONFIG_SYSTEM_WORKQUEUE_NO_YIELD`

API Reference

group workqueue_apis

**Defines**

- `K_WORK_DELAYABLE_DEFINE(work, work_handler)`
  Initialize a statically-defined delayable work item.

  This macro can be used to initialize a statically-defined delayable work item, prior to its first use. For example,

  ```
  static K_WORK_DELAYABLE_DEFINE(<dwork>, <work_handler>);
  ```

  Note that if the runtime dependencies support initialization with `k_work_init_delayable()` using that will eliminate the initialized object in ROM that is produced by this macro and copied in at system startup.

  **Parameters**

  - `work` – Symbol name for delayable work item object
  - `work_handler` – Function to invoke each time work item is processed.
K_WORK_USER_DEFINE(work, work_handler)
Initialize a statically-defined user work item.
This macro can be used to initialize a statically-defined user work item, prior to its first use. For example,

```c
static K_WORK_USER_DEFINE(<work>, <work_handler>);
```

**Parameters**
- `work` – Symbol name for work item object
- `work_handler` – Function to invoke each time work item is processed.

K_WORK_DEFINE(work, work_handler)
Initialize a statically-defined work item.
This macro can be used to initialize a statically-defined workqueue work item, prior to its first use. For example,

```c
static K_WORK_DEFINE(<work>, <work_handler>);
```

**Parameters**
- `work` – Symbol name for work item object
- `work_handler` – Function to invoke each time work item is processed.

**Typedefs**

typedef void (*k_work_handler_t)(struct k_work *work)
The signature for a work item handler function.
The function will be invoked by the thread animating a work queue.

**Param work**
the work item that provided the handler.

typedef void (*k_work_user_handler_t)(struct k_work_user *work)
Work item handler function type for user work queues.
A work item's handler function is executed by a user workqueue's thread when the work item is processed by the workqueue.

**Param work**
Address of the work item.

**Enums**

enum [anonymous]
**Values:**

enumerator K_WORK_RUNNING = BIT(K_WORK_RUNNING_BIT)
Flag indicating a work item that is running under a work queue thread.
Accessed via `k_work_busy_get()`. May co-occur with other flags.
enumerator K_WORKCANCELING = BIT(K_WORKCANCELING_BIT)
Flag indicating a work item that is being canceled.
Accessed via k_work_busy_get(). May co-occur with other flags.

enumerator K_WORKQUEUED = BIT(K_WORKQUEUED_BIT)
Flag indicating a work item that has been submitted to a queue but has not started running.
Accessed via k_work_busy_get(). May co-occur with other flags.

enumerator K_WORKDELAYED = BIT(K_WORKDELAYED_BIT)
Flag indicating a delayed work item that is scheduled for submission to a queue.
Accessed via k_work_busy_get(). May co-occur with other flags.

Functions

void k_work_init(struct k_work *work, k_work_handler_t handler)
Initialize a (non-delayable) work structure.
This must be invoked before submitting a work structure for the first time. It need not be invoked again on the same work structure. It can be re-invoked to change the associated handler, but this must be done when the work item is idle.

Function properties (list may not be complete)

isr-ok

Parameters
- work – the work structure to be initialized.
- handler – the handler to be invoked by the work item.

int k_work_busy_get(const struct k_work *work)
Busy state flags from the work item.
A zero return value indicates the work item appears to be idle.

Function properties (list may not be complete)

isr-ok

Note: This is a live snapshot of state, which may change before the result is checked. Use locks where appropriate.

Parameters
- work – pointer to the work item.

Returns
a mask of flags K_WORK_DELAYED, K_WORKQUEUED, K_WORK_RUNNING, and K_WORKCANCELING.
static inline bool k_work_is_pending(const struct k_work *work)
    Test whether a work item is currently pending.
    Wrapper to determine whether a work item is in a non-idle dstate.

Function properties (list may not be complete)
    isr-ok

Note: This is a live snapshot of state, which may change before the result is checked. Use locks where appropriate.

Parameters
    • work – pointer to the work item.

Returns
    true if and only if k_work_busy_get() returns a non-zero value.

int k_work_submit_to_queue(struct k_work_q *queue, struct k_work *work)
    Submit a work item to a queue.

Function properties (list may not be complete)
    isr-ok

Parameters
    • queue – pointer to the work queue on which the item should run. If NULL the queue from the most recent submission will be used.
    • work – pointer to the work item.

Return values
    • 0 – if work was already submitted to a queue
    • 1 – if work was not submitted and has been queued to queue
    • 2 – if work was running and has been queued to the queue that was running it
    • -EBUSY –
        – if work submission was rejected because the work item is cancelling; or
        – queue is draining; or
        – queue is plugged.
    • -EINVAL – if queue is null and the work item has never been run.
    • -ENODEV – if queue has not been started.

int k_work_submit(struct k_work *work)
    Submit a work item to the system queue.

Function properties (list may not be complete)
    isr-ok

Parameters
    • work – pointer to the work item.
Returns

as with \texttt{k\_work\_submit\_to\_queue()}.

\begin{verbatim}
bool k_work_flush(struct k_work *work, struct k_work_sync *sync)

Wait for last-submitted instance to complete.
Resubmissions may occur while waiting, including chained submissions (from within the han-
dler).

\textbf{Note:} Be careful of caller and work queue thread relative priority. If this function sleeps
it will not return until the work queue thread completes the tasks that allow this thread to
resume.

\textbf{Note:} Behavior is undefined if this function is invoked on \texttt{work} from a work queue running
\texttt{work}.
\end{verbatim}

Parameters

\begin{itemize}
\item \textit{work} – pointer to the work item.
\item \textit{sync} – pointer to an opaque item containing state related to the pending can-
cellation. The object must persist until the call returns, and be accessible from
both the caller thread and the work queue thread. The object must not be
used for any other flush or cancel operation until this one completes. On ar-
chitectures with \texttt{CONFIG\_KERNEL\_COHERENCE} the object must be allocated
in coherent memory.
\end{itemize}

Return values

\begin{itemize}
\item \texttt{true} – if call had to wait for completion
\item \texttt{false} – if work was already idle
\end{itemize}

\begin{verbatim}
int k_work_cancel(struct k_work *work)

Cancel a work item.
This attempts to prevent a pending (non-delayable) work item from being processed by re-
moving it from the work queue. If the item is being processed, the work item will continue to
be processed, but resubmissions are rejected until cancellation completes.
If this returns zero cancellation is complete, otherwise something (probably a work queue
thread) is still referencing the item.
See also \texttt{k\_work\_cancel\_sync()}.
\end{verbatim}

Function properties (list may not be complete)

\texttt{isr-ok}

Parameters

\begin{itemize}
\item \textit{work} – pointer to the work item.
\end{itemize}

Returns

the \texttt{k\_work\_busy\_get()} status indicating the state of the item after all cancellation
steps performed by this call are completed.
bool k_work_cancel_sync(struct k_work *work, struct k_work_sync *sync)
Cancel a work item and wait for it to complete.

Same as k_work_cancel() but does not return until cancellation is complete. This can be
invoked by a thread after k_work_cancel() to synchronize with a previous cancellation.

On return the work structure will be idle unless something submits it after the cancellation
was complete.

**Note:** Be careful of caller and work queue thread relative priority. If this function sleeps
it will not return until the work queue thread completes the tasks that allow this thread to
resume.

**Note:** Behavior is undefined if this function is invoked on work from a work queue running
work.

### Parameters
- **work** – pointer to the work item.
- **sync** – pointer to an opaque item containing state related to the pending can-
cellation. The object must persist until the call returns, and be accessible from
both the caller thread and the work queue thread. The object must not be
used for any other flush or cancel operation until this one completes. On ar-
chitectures with CONFIG_KERNEL_COHERENCE the object must be allocated
in coherent memory.

### Return values
- **true** – if work was pending (call had to wait for cancellation of a running
  handler to complete, or scheduled or submitted operations were cancelled);
- **false** – otherwise

void k_work_queue_init(struct k_work_q *queue)
Initialize a work queue structure.
This must be invoked before starting a work queue structure for the first time. It need not be
invoked again on the same work queue structure.

### Function properties (list may not be complete)
`isr-ok`

### Parameters
- **queue** – the queue structure to be initialized.

void k_work_queue_start(struct k_work_q *queue, k_thread_stack_t *stack, size_t stack_size, int
prio, const struct k_work_queue_config *cfg)
Initialize a work queue.
This configures the work queue thread and starts it running. The function should not be
re-invoked on a queue.

### Parameters
- **queue** – pointer to the queue structure. It must be initialized in zeroed/bss
  memory or with k_work_queue_init before use.
- **stack** – pointer to the work thread stack area.
• **stack_size** – size of the the work thread stack area, in bytes.

• **prio** – initial thread priority

• **cfg** – optional additional configuration parameters. Pass NULL if not required, to use the defaults documented in `k_work_queue_config`.

```c
static inline k_tid_t k_work_queue_thread_get(struct k_work_q *queue)
```

Access the thread that animates a work queue.

This is necessary to grant a work queue thread access to things the work items it will process are expected to use.

**Parameters**

- queue – pointer to the queue structure.

**Returns**

the thread associated with the work queue.

```c
int k_work_queue_drain(struct k_work_q *queue, bool plug)
```

Wait until the work queue has drained, optionally plugging it.

This blocks submission to the work queue except when coming from queue thread, and blocks the caller until no more work items are available in the queue.

If plug is true then submission will continue to be blocked after the drain operation completes until `k_work_queue_unplug()` is invoked.

Note that work items that are delayed are not yet associated with their work queue. They must be cancelled externally if a goal is to ensure the work queue remains empty. The plug feature can be used to prevent delayed items from being submitted after the drain completes.

**Parameters**

- queue – pointer to the queue structure.
- plug – if true the work queue will continue to block new submissions after all items have drained.

**Return values**

- 1 – if call had to wait for the drain to complete
- 0 – if call did not have to wait
- negative – if wait was interrupted or failed

```c
int k_work_queue_unplug(struct k_work_q *queue)
```

Release a work queue to accept new submissions.

This releases the block on new submissions placed when `k_work_queue_drain()` is invoked with the plug option enabled. If this is invoked before the drain completes new items may be submitted as soon as the drain completes.

**Function properties (list may not be complete)**

`isr-ok`

**Parameters**

- queue – pointer to the queue structure.

**Return values**

- 0 – if successfully unplugged
- -EALREADY – if the work queue was not plugged.
void k_work_init_delayable(struct k_work_delayable *dwork, k_work_handler_t handler)

Initialize a delayable work structure.

This must be invoked before scheduling a delayable work structure for the first time. It need not be invoked again on the same work structure. It can be re-invoked to change the associated handler, but this must be done when the work item is idle.

Function properties (list may not be complete)

- isr-ok

Parameters

- dwork – the delayable work structure to be initialized.
- handler – the handler to be invoked by the work item.

static inline struct k_work_delayable *k_work_delayable_from_work(struct k_work *work)

Get the parent delayable work structure from a work pointer.

This function is necessary when a k_work_handler_t function is passed to k_work_schedule_for_queue() and the handler needs to access data from the container of the containing k_work_delayable.

Parameters

- work – Address passed to the work handler

Returns

Address of the containing k_work_delayable structure.

int k_work_delayable_busy_get(const struct k_work_delayable *dwork)

Busy state flags from the delayable work item.

Function properties (list may not be complete)

- isr-ok

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters

- dwork – pointer to the delayable work item.

Returns

a mask of flags K_WORK_DELAYED, K_WORK_QUEUED, K_WORK_RUNNING, and K_WORK_CANCELING. A zero return value indicates the work item appears to be idle.

static inline bool k_work_delayable_is_pending(const struct k_work_delayable *dwork)

Test whether a delayed work item is currently pending.

Wrapper to determine whether a delayed work item is in a non-idle state.

Function properties (list may not be complete)

- isr-ok
Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters
• dwork – pointer to the delayable work item.

Returns
true if and only if `k_work_delayable_busy_get()` returns a non-zero value.

static inline `k_ticks_t k_work_delayable_expires_get(const struct k_work_delayable *dwork)`
Get the absolute tick count at which a scheduled delayable work will be submitted.

Function properties (list may not be complete)

`isr-ok`

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters
• dwork – pointer to the delayable work item.

Returns
the tick count when the timer that will schedule the work item will expire, or the current tick count if the work is not scheduled.

static inline `k_ticks_t k_work_delayable_remaining_get(const struct k_work_delayable *dwork)`
Get the number of ticks until a scheduled delayable work will be submitted.

Function properties (list may not be complete)

`isr-ok`

Note: This is a live snapshot of state, which may change before the result can be inspected. Use locks where appropriate.

Parameters
• dwork – pointer to the delayable work item.

Returns
the number of ticks until the timer that will schedule the work item will expire, or zero if the item is not scheduled.

int `k_work_schedule_for_queue(struct k_work_q *queue, struct k_work_delayable *dwork, k_timeout_t delay)`
Submit an idle work item to a queue after a delay.
Unlike `k_work_reschedule_for_queue()` this is a no-op if the work item is already scheduled or submitted, even if delay is `K_NO_WAIT`.

Function properties (list may not be complete)

`isr-ok`
Parameters

- queue – the queue on which the work item should be submitted after the delay.
- dwork – pointer to the delayable work item.
- delay – the time to wait before submitting the work item. If K_NO_WAIT and the work is not pending this is equivalent to \textit{k\_work\_submit\_to\_queue()}.  

Return values

- 0 – if work was already scheduled or submitted.
- 1 – if work has been scheduled.
- -EBUSY – if delay is K_NO_WAIT and \textit{k\_work\_submit\_to\_queue()} fails with this code.
- -EINVAL – if delay is K_NO_WAIT and \textit{k\_work\_submit\_to\_queue()} fails with this code.
- -ENODEV – if delay is K_NO_WAIT and \textit{k\_work\_submit\_to\_queue()} fails with this code.

\texttt{int k\_work\_schedule(struct k\_work\_delayable *dwork, k\_timeout\_t delay)}

Submit an idle work item to the system work queue after a delay.

This is a thin wrapper around \textit{k\_work\_schedule\_for\_queue()}, with all the API characteristics of that function.

Parameters

- dwork – pointer to the delayable work item.
- delay – the time to wait before submitting the work item. If K_NO_WAIT this is equivalent to \textit{k\_work\_submit\_to\_queue()}.  

Returns

as with \textit{k\_work\_schedule\_for\_queue()}.  

\texttt{int k\_work\_reschedule\_for\_queue(struct k\_work\_q *queue, struct k\_work\_delayable *dwork, k\_timeout\_t delay)}

Reschedule a work item to a queue after a delay.

Unlike \textit{k\_work\_schedule\_for\_queue()} this function can change the deadline of a scheduled work item, and will schedule a work item that is in any state (e.g. is idle, submitted, or running). This function does not affect (“unsubmit”) a work item that has been submitted to a queue.

Function properties (list may not be complete)

\texttt{isr-ok}

\underline{Note:} If delay is K_NO_WAIT (“no delay”) the return values are as with \textit{k\_work\_submit\_to\_queue()}.  

Parameters

- queue – the queue on which the work item should be submitted after the delay.
- dwork – pointer to the delayable work item.
- delay – the time to wait before submitting the work item. If K_NO_WAIT this is equivalent to \textit{k\_work\_submit\_to\_queue()} after canceling any previous scheduled submission.
Return values

- 0 – if delay is K_NO_WAIT and work was already on a queue
- 1 – if
  - delay is K_NO_WAIT and work was not submitted but has now been queued to queue; or
  - delay not K_NO_WAIT and work has been scheduled
- 2 – if delay is K_NO_WAIT and work was running and has been queued to the queue that was running it
- -EBUSY – if delay is K_NO_WAIT and k_work_submit_to_queue() fails with this code.
- -EINVAL – if delay is K_NO_WAIT and k_work_submit_to_queue() fails with this code.
- -ENODEV – if delay is K_NO_WAIT and k_work_submit_to_queue() fails with this code.

```c
int k_work_reschedule(struct k_work_delayable *dwork, k_timeout_t delay)
```
Reschedule a work item to the system work queue after a delay.

This is a thin wrapper around k_work_reschedule_for_queue(), with all the API characteristics of that function.

**Parameters**

- `dwork` – pointer to the delayable work item.
- `delay` – the time to wait before submitting the work item.

**Returns**

as with k_work_reschedule_for_queue().

```c
bool k_work_flush_delayable(struct k_work_delayable *dwork, struct k_work_sync *sync)
```
Flush delayable work.

If the work is scheduled, it is immediately submitted. Then the caller blocks until the work completes, as with k_work_flush().

**Note:** Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

**Note:** Behavior is undefined if this function is invoked on dwork from a work queue running dwork.

**Parameters**

- `dwork` – pointer to the delayable work item.
- `sync` – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.

**Return values**
- true – if call had to wait for completion
- false – if work was already idle

```c
int k_work_cancel_delayable(struct k_work_delayable *dwork)
```

Cancel delayable work.

Similar to `k_work_cancel()` but for delayable work. If the work is scheduled or submitted it is canceled. This function does not wait for the cancellation to complete.

**Function properties (list may not be complete)**

- isr-ok

**Note:** The work may still be running when this returns. Use `k_work_flush_delayable()` or `k_work_cancel_delayable_sync()` to ensure it is not running.

**Note:** Canceling delayable work does not prevent rescheduling it. It does prevent submitting it until the cancellation completes.

**Parameters**
- dwork – pointer to the delayable work item.

**Returns**
- the `k_work_delayable_busy_get()` status indicating the state of the item after all cancellation steps performed by this call are completed.

```c
bool k_work_cancel_delayable_sync(struct k_work_delayable *dwork, struct k_work_sync *sync)
```

Cancel delayable work and wait.

Like `k_work_cancel_delayable()` but waits until the work becomes idle.

**Note:** Canceling delayable work does not prevent rescheduling it. It does prevent submitting it until the cancellation completes.

**Note:** Be careful of caller and work queue thread relative priority. If this function sleeps it will not return until the work queue thread completes the tasks that allow this thread to resume.

**Note:** Behavior is undefined if this function is invoked on `dwork` from a work queue running `dwork`.

**Parameters**
- dwork – pointer to the delayable work item.
- sync – pointer to an opaque item containing state related to the pending cancellation. The object must persist until the call returns, and be accessible from both the caller thread and the work queue thread. The object must not be used for any other flush or cancel operation until this one completes. On architectures with CONFIG_KERNEL_COHERENCE the object must be allocated in coherent memory.
Return values

- true – if work was not idle (call had to wait for cancellation of a running handler to complete, or scheduled or submitted operations were cancelled);
- false – otherwise

static inline void k_work_user_init(struct k_work_user *work, k_work_user_handler_t handler)

Initialize a userspace work item.

This routine initializes a user workqueue work item, prior to its first use.

Parameters

- work – Address of work item.
- handler – Function to invoke each time work item is processed.

static inline bool k_work_user_is_pending(struct k_work_user *work)

Check if a userspace work item is pending.

This routine indicates if user work item work is pending in a workqueue’s queue.

Function properties (list may not be complete)

isr-ok

Note: Checking if the work is pending gives no guarantee that the work will still be pending when this information is used. It is up to the caller to make sure that this information is used in a safe manner.

Parameters

- work – Address of work item.

Returns

true if work item is pending, or false if it is not pending.

static inline int k_work_user_submit_to_queue(struct k_work_user_q *work_q, struct k_work_user *work)

Submit a work item to a user mode workqueue.

Submits a work item to a workqueue that runs in user mode. A temporary memory allocation is made from the caller’s resource pool which is freed once the worker thread consumes the k_work item. The workqueue thread must have memory access to the k_work item being submitted. The caller must have permission granted on the work_q parameter’s queue object.

Function properties (list may not be complete)

isr-ok

Parameters

- work_q – Address of workqueue.
- work – Address of work item.

Return values

- EBUSY – if the work item was already in some workqueue
- ENOMEM – if no memory for thread resource pool allocation
- 0 – Success
void k_work_user_queue_start(struct k_work_user_q *work_q, k_thread_stack_t *stack, size_t stack_size, int prio, const char *name)

Start a workqueue in user mode.

This works identically to \texttt{k_work_queue_start()} except it is callable from user mode, and the worker thread created will run in user mode. The caller must have permissions granted on both the \texttt{work_q} parameter's thread and queue objects, and the same restrictions on priority apply as \texttt{k_thread_create()}. 

\textbf{Parameters}

- \texttt{work_q} – Address of workqueue.
- \texttt{stack} – Pointer to work queue thread’s stack space, as defined by \texttt{K_THREAD_STACK_DEFINE()}
- \texttt{stack_size} – Size of the work queue thread's stack (in bytes), which should either be the same constant passed to \texttt{K_THREAD_STACK_DEFINE()} or the value of \texttt{K_THREAD_STACK_SIZEOF()}
- \texttt{prio} – Priority of the work queue’s thread.
- \texttt{name} – optional thread name. If not null a copy is made into the thread's name buffer.

\textbf{static inline} k_tid_t k_work_user_queue_thread_get(struct k_work_user_q *work_q)

Access the user mode thread that animates a work queue.

This is necessary to grant a user mode work queue thread access to things the work items it will process are expected to use.

\textbf{Parameters}

- \texttt{work_q} – pointer to the user mode queue structure.

\textbf{Returns}

the user mode thread associated with the work queue.

void k_work_poll_init(struct k_work_poll *work, k_work_handler_t handler)

Initialize a triggered work item.

This routine initializes a workqueue triggered work item, prior to its first use.

\textbf{Parameters}

- \texttt{work} – Address of triggered work item.
- \texttt{handler} – Function to invoke each time work item is processed.

\textbf{int k_work_poll_submit_to_queue(struct k_work_q *work_q, struct k_work_poll *work, struct k_poll_event *events, int num_events, k_timeout_t timeout)}

Submit a triggered work item.

This routine schedules work item \texttt{work} to be processed by workqueue \texttt{work_q} when one of the given \texttt{events} is signaled. The routine initiates internal poller for the work item and then returns to the caller. Only when one of the watched events happen the work item is actually submitted to the workqueue and becomes pending.

Submitting a previously submitted triggered work item that is still waiting for the event cancels the existing submission and reschedules it the using the new event list. Note that this behavior is inherently subject to race conditions with the pre-existing triggered work item and work queue, so care must be taken to synchronize such resubmissions externally.

\textbf{Function properties (list may not be complete)}

\texttt{isr-ok}
Warning: Provided array of events as well as a triggered work item must be placed in persistent memory (valid until work handler execution or work cancellation) and cannot be modified after submission.

Parameters
- `work_q` – Address of workqueue.
- `work` – Address of delayed work item.
- `events` – An array of events which trigger the work.
- `num_events` – The number of events in the array.
- `timeout` – Timeout after which the work will be scheduled for execution even if not triggered.

Return values
- 0 – Work item started watching for events.
- `-EINVAL` – Work item is being processed or has completed its work.
- `-EADDRINUSE` – Work item is pending on a different workqueue.

```c
int k_work_poll_submit(struct k_work_poll *work, struct k_poll_event *events, int num_events, k_timeout_t timeout)
```

Submit a triggered work item to the system workqueue.

This routine schedules work item `work` to be processed by system workqueue when one of the given `events` is signaled. The routine initiates internal poller for the work item and then returns to the caller. Only when one of the watched events happen the work item is actually submitted to the workqueue and becomes pending.

Submitting a previously submitted triggered work item that is still waiting for the event cancels the existing submission and reschedules it the using the new event list. Note that this behavior is inherently subject to race conditions with the pre-existing triggered work item and work queue, so care must be taken to synchronize such resubmissions externally.

Function properties (list may not be complete)
- `isr-ok`

Warning: Provided array of events as well as a triggered work item must not be modified until the item has been processed by the workqueue.

Parameters
- `work` – Address of delayed work item.
- `events` – An array of events which trigger the work.
- `num_events` – The number of events in the array.
- `timeout` – Timeout after which the work will be scheduled for execution even if not triggered.

Return values
- 0 – Work item started watching for events.
- `-EINVAL` – Work item is being processed or has completed its work.
- `-EADDRINUSE` – Work item is pending on a different workqueue.
int k_work_poll_cancel(struct k_work_poll *work)
    Cancel a triggered work item.
    This routine cancels the submission of triggered work item work. A triggered work item can only be canceled if no event triggered work submission.

Function properties (list may not be complete)

isr-ok

Parameters

• work – Address of delayed work item.

Return values

• 0 – Work item canceled.
• -EINVAL – Work item is being processed or has completed its work.

struct k_work
    #include <kernel.h> A structure used to submit work.

struct k_work_delayable
    #include <kernel.h> A structure used to submit work after a delay.

struct k_work_sync
    #include <kernel.h> A structure holding internal state for a pending synchronous operation on a work item or queue.
    Instances of this type are provided by the caller for invocation of k_work_flush(), k_work_cancel_sync() and sibling flush and cancel APIs. A referenced object must persist until the call returns, and be accessible from both the caller thread and the work queue thread.

    Note: If CONFIG_KERNEL_COHERENCE is enabled the object must be allocated in coherent memory; see arch_mem_coherent(). The stack on these architectures is generally not coherent. be stack-allocated. Violations are detected by runtime assertion.

struct k_work_queue_config
    #include <kernel.h> A structure holding optional configuration items for a work queue.
    This structure, and values it references, are not retained by k_work_queue_start().

Public Members

const char *name
    The name to be given to the work queue thread.
    If left null the thread will not have a name.

bool no_yield
    Control whether the work queue thread should yield between items.
    Yielding between items helps guarantee the work queue thread does not starve other threads, including cooperative ones released by a work item. This is the default behavior.
Set this to `true` to prevent the work queue thread from yielding between items. This may be appropriate when a sequence of items should complete without yielding control.

```c
struct k_work_q
#include <kernel.h> A structure used to hold work until it can be processed.
```

**Operation without Threads**

Thread support is not necessary in some applications:

- Bootloaders
- Simple event-driven applications
- Examples intended to demonstrate core functionality

Thread support can be disabled by setting `CONFIG_MULTITHREADING` to `n`. Since this configuration has a significant impact on Zephyr's functionality and testing of it has been limited, there are conditions on what can be expected to work in this configuration.

**What Can be Expected to Work** These core capabilities shall function correctly when `CONFIG_MULTITHREADING` is disabled:

- The **build system**
- The ability to boot the application to `main()`
- **Interrupt management**
- The system clock including `k_uptime_get()`
- Timers, i.e. `k_timer()`
- Non-sleeping delays e.g. `k_busy_wait()`.
- Sleeping `k_cpu_idle()`.
- Pre `main()` drivers and subsystems initialization e.g. `SYS_INIT`.
- **Memory Management**
- Specifically identified drivers in certain subsystems, listed below.

The expectations above affect selection of other features; for example `CONFIG_SYS_CLOCK_EXISTS` cannot be set to `n`.

**What Cannot be Expected to Work** Functionality that will not work with `CONFIG_MULTITHREADING` includes majority of the kernel API:

- **Threads**
- **Scheduling**
- **Workqueue Threads**
- **Polling API**
- **Semaphores**
- **Mutexes**
- **Condition Variables**
- **Data Passing**

---

**3.1. Kernel Services**
Subsystem Behavior Without Thread Support  The sections below list driver and functional subsystems that are expected to work to some degree when CONFIG_MULTITHREADING is disabled. Subsystems that are not listed here should not be expected to work.

Some existing drivers within the listed subsystems do not work when threading is disabled, but are within scope based on their subsystem, or may be sufficiently isolated that supporting them on a particular platform is low-impact. Enhancements to add support to existing capabilities that were not originally implemented to work with threads disabled will be considered.

Flash  The **Flash** is expected to work for all SoC flash peripheral drivers. Bus-accessed devices like serial memories may not be supported.

_list/table of supported drivers to go here_

GPIO  The **General-Purpose Input/Output (GPIO)** is expected to work for all SoC GPIO peripheral drivers. Bus-accessed devices like GPIO extenders may not be supported.

_list/table of supported drivers to go here_

UART  A subset of the **Universal Asynchronous Receiver-Transmitter (UART)** is expected to work for all SoC UART peripheral drivers.

- Applications that select **CONFIG_UART_INTERRUPT_DRIVEN** may work, depending on driver implementation.
- Applications that select **CONFIG_UART_ASYNC_API** may work, depending on driver implementation.
- Applications that do not select either **CONFIG_UART_ASYNC_API** or **CONFIG_UART_INTERRUPT_DRIVEN** are expected to work.

_list/table of supported drivers to go here, including which API options are supported_

Interrupts

An **interrupt service routine** (ISR) is a function that executes asynchronously in response to a hardware or software interrupt. An ISR normally preempts the execution of the current thread, allowing the response to occur with very low overhead. Thread execution resumes only once all ISR work has been completed.

- **Concepts**
  - Multi-level Interrupt handling
  - Preventing Interruptions
  - Offloading ISR Work
  - Sharing interrupt lines
- **Implementation**
  - Defining a regular ISR
  - Defining a ‘direct’ ISR
  - Sharing an interrupt line
  - Dynamically disconnecting an ISR
  - Implementation Details
- **Suggested Uses**
- **Configuration Options**
An ISR has the following key properties:

- An interrupt request (IRQ) signal that triggers the ISR.
- A priority level associated with the IRQ.
- An interrupt handler function that is invoked to handle the interrupt.
- An argument value that is passed to that function.

An IDT (Interrupt Descriptor Table) or a vector table is used to associate a given interrupt source with a given ISR. Only a single ISR can be associated with a specific IRQ at any given time.

Multiple ISRs can utilize the same function to process interrupts, allowing a single function to service a device that generates multiple types of interrupts or to service multiple devices (usually of the same type). The argument value passed to an ISR's function allows the function to determine which interrupt has been signaled.

The kernel provides a default ISR for all unused IDT entries. This ISR generates a fatal system error if an unexpected interrupt is signaled.

The kernel supports interrupt nesting. This allows an ISR to be preempted in mid-execution if a higher priority interrupt is signaled. The lower priority ISR resumes execution once the higher priority ISR has completed its processing.

An ISR's interrupt handler function executes in the kernel's interrupt context. This context has its own dedicated stack area (or, on some architectures, stack areas). The size of the interrupt context stack must be capable of handling the execution of multiple concurrent ISRs if interrupt nesting support is enabled.

**Important:** Many kernel APIs can be used only by threads, and not by ISRs. In cases where a routine may be invoked by both threads and ISRs the kernel provides the `k_is_in_isr()` API to allow the routine to alter its behavior depending on whether it is executing as part of a thread or as part of an ISR.

### Multi-level Interrupt handling

A hardware platform can support more interrupt lines than natively-provided through the use of one or more nested interrupt controllers. Sources of hardware interrupts are combined into one line that is then routed to the parent controller.

If nested interrupt controllers are supported, `CONFIG_MULTI_LEVEL_INTERRUPTS` should be set to 1, and `CONFIG_2ND_LEVEL_INTERRUPTS` and `CONFIG_3RD_LEVEL_INTERRUPTS` configured as well, based on the hardware architecture.

A unique 32-bit interrupt number is assigned with information embedded in it to select and invoke the correct Interrupt Service Routine (ISR). Each interrupt level is given a byte within this 32-bit number, providing support for up to four interrupt levels using this arch, as illustrated and explained below:

<table>
<thead>
<tr>
<th>9</th>
<th>2</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>A</td>
<td></td>
</tr>
<tr>
<td>-</td>
<td>C</td>
<td>B</td>
</tr>
<tr>
<td>-</td>
<td>D</td>
<td></td>
</tr>
</tbody>
</table>

(LEVEL 1) (LEVEL 2) (LEVEL 3)

There are three interrupt levels shown here.

- '-' means interrupt line and is numbered from 0 (right most).
- **LEVEL 1** has 12 interrupt lines, with two lines (2 and 9) connected to nested controllers and one device 'A' on line 4.
- One of the **LEVEL 2** controllers has interrupt line 5 connected to a **LEVEL 3** nested controller and one device 'C' on line 3.
- The other **LEVEL 2** controller has no nested controllers but has one device 'B' on line 2.
- The **LEVEL 3** controller has one device ‘D’ on line 2.

Here’s how unique interrupt numbers are generated for each hardware interrupt. Let’s consider four interrupts shown above as A, B, C, and D:

<table>
<thead>
<tr>
<th>Interrupt</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0x00000004</td>
</tr>
<tr>
<td>B</td>
<td>0x00000302</td>
</tr>
<tr>
<td>C</td>
<td>0x00000409</td>
</tr>
<tr>
<td>D</td>
<td>0x00030609</td>
</tr>
</tbody>
</table>

**Note:** The bit positions for **LEVEL 2** and onward are offset by 1, as 0 means that interrupt number is not present for that level. For our example, the **LEVEL 3** controller has device D on line 2, connected to the **LEVEL 2** controller’s line 5, that is connected to the **LEVEL 1** controller’s line 9 (2 -> 5 -> 9). Because of the encoding offset for **LEVEL 2** and onward, device D is given the number 0x00030609.

### Preventing Interruptions

In certain situations it may be necessary for the current thread to prevent ISRs from executing while it is performing time-sensitive or critical section operations.

A thread may temporarily prevent all IRQ handling in the system using an **IRQ lock**. This lock can be applied even when it is already in effect, so routines can use it without having to know if it is already in effect. The thread must unlock its IRQ lock the same number of times it was locked before interrupts can be once again processed by the kernel while the thread is running.

**Important:** The IRQ lock is thread-specific. If thread A locks out interrupts then performs an operation that puts itself to sleep (e.g. sleeping for N milliseconds), the thread’s IRQ lock no longer applies once thread A is swapped out and the next ready thread B starts to run.

This means that interrupts can be processed while thread B is running unless thread B has also locked out interrupts using its own IRQ lock. (Whether interrupts can be processed while the kernel is switching between two threads that are using the IRQ lock is architecture-specific.)

When thread A eventually becomes the current thread once again, the kernel re-establishes thread A’s IRQ lock. This ensures thread A won’t be interrupted until it has explicitly unlocked its IRQ lock.

If thread A does not sleep but does make a higher-priority thread B ready, the IRQ lock will inhibit any preemption that would otherwise occur. Thread B will not run until the next reschedule point reached after releasing the IRQ lock.

Alternatively, a thread may temporarily **disable** a specified IRQ so its associated ISR does not execute when the IRQ is signaled. The IRQ must be subsequently **enabled** to permit the ISR to execute.

**Important:** Disabling an IRQ prevents all threads in the system from being preempted by the associated ISR, not just the thread that disabled the IRQ.

### Zero Latency Interrupts

Preventing interruptions by applying an IRQ lock may increase the observed interrupt latency. A high interrupt latency, however, may not be acceptable for certain low-latency use-cases.
The kernel addresses such use-cases by allowing interrupts with critical latency constraints to execute at a priority level that cannot be blocked by interrupt locking. These interrupts are defined as zero-latency interrupts. The support for zero-latency interrupts requires CONFIG_ZERO_LATENCYIRQS to be enabled. In addition to that, the flag IRQ_ZERO_LATENCY must be passed to IRQ_CONNECT or IRQ_DIRECT_CONNECT macros to configure the particular interrupt with zero latency.

Zero-latency interrupts are expected to be used to manage hardware events directly, and not to inter-operate with the kernel code at all. They should treat all kernel APIs as undefined behavior (i.e., an application that uses the APIs inside a zero-latency interrupt context is responsible for directly verifying correct behavior). Zero-latency interrupts may not modify any data inspected by kernel APIs invoked from normal Zephyr contexts and shall not generate exceptions that need to be handled synchronously (e.g., kernel panic).

**Important:** Zero-latency interrupts are supported on an architecture-specific basis. The feature is currently implemented in the ARM Cortex-M architecture variant.

**Offloading ISR Work** An ISR should execute quickly to ensure predictable system operation. If time-consuming processing is required the ISR should offload some or all processing to a thread, thereby restoring the kernel’s ability to respond to other interrupts.

The kernel supports several mechanisms for offloading interrupt-related processing to a thread.

- An ISR can signal a helper thread to do interrupt-related processing using a kernel object, such as a FIFO, LIFO, or semaphore.
- An ISR can instruct the system workqueue thread to execute a work item. (See Workqueue Threads.)

When an ISR offloads work to a thread, there is typically a single context switch to that thread when the ISR completes, allowing interrupt-related processing to continue almost immediately. However, depending on the priority of the thread handling the offload, it is possible that the currently executing cooperative thread or other higher-priority threads may execute before the thread handling the offload is scheduled.

**Sharing interrupt lines** In the case of some hardware platforms, the same interrupt lines may be used by different IPs. For example, interrupt 17 may be used by a DMA controller to signal that a data transfer has been completed or by a DAI controller to signal that the transfer FIFO has reached its watermark. To make this work, one would have to either employ some special logic or find a workaround (for example, using the shared_irq interrupt controller), which doesn’t scale very well.

To solve this problem, one may use shared interrupts, which can be enabled using CONFIG_SHARED_INTERRUPTS. Whenever an attempt to register a second ISR/argument pair on the same interrupt line is made (using IRQ_CONNECT or irq_connect_dynamic()), the interrupt line will become shared, meaning the two ISR/argument pairs (previous one and the one that has just been registered) will be invoked each time the interrupt is triggered. The entities that make use of an interrupt line in the shared interrupt context are known as clients. The maximum number of allowed clients for an interrupt is controlled by SHARED_IRQ_MAX_NUM_CLIENTS.

Interrupt sharing is transparent to the user. As such, the user may register interrupts using IRQ_CONNECT and irq_connect_dynamic() as they normally would. The interrupt sharing is taken care of behind the scenes.

Enabling the shared interrupt support and dynamic interrupt support will allow users to dynamically disconnect ISRs using irq_disconnect_dynamic(). After an ISR is disconnected, whenever the interrupt line for which it was registered gets triggered, the ISR will no longer get invoked.

Please note that enabling CONFIG_SHARED_INTERRUPTS will result in a non-negligible increase in the binary size. Use with caution.

**Implementation**
Defining a regular ISR  An ISR is defined at runtime by calling \texttt{IRQ\_CONNECT}. It must then be enabled by calling \texttt{irq\_enable()}. 

\textbf{Important:}  \texttt{IRQ\_CONNECT()} is not a C function and does some inline assembly magic behind the scenes. All its arguments must be known at build time. Drivers that have multiple instances may need to define per-instance config functions to configure each instance of the interrupt.

The following code defines and enables an ISR.

```c
#define MY_DEV_IRQ 24 /* device uses IRQ 24 */
#define MY_DEV_PRIO 2 /* device uses interrupt priority 2 */ /* argument passed to my_isr(), in this case a pointer to the device */
#define MY_ISR_ARG DEVICE_GET(my_device)
#define MY_IRQ_FLAGS 0 /* IRQ flags */

void my_isr(void *arg)
{
    ... /* ISR code */
}

void my_isr_installer(void)
{
    ...
    IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG, MY_IRQ_FLAGS);
    irq_enable(MY_DEV_IRQ);
    ...
}
```

Since the \texttt{IRQ\_CONNECT} macro requires that all its parameters be known at build time, in some cases this may not be acceptable. It is also possible to install interrupts at runtime with \texttt{irq\_connect\_dynamic()}. It is used in exactly the same way as \texttt{IRQ\_CONNECT}:

```c
void my_isr_installer(void)
{
    ...
    irq_connect_dynamic(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG, MY_IRQ_FLAGS);
    irq_enable(MY_DEV_IRQ);
    ...
}
```

Dynamic interrupts require the \texttt{CONFIG\_DYNAMIC\_INTERRUPTS} option to be enabled. Removing or re-configuring a dynamic interrupt is currently unsupported.

\textbf{Defining a ‘direct’ ISR}  Regular Zephyr interrupts introduce some overhead which may be unacceptable for some low-latency use-cases. Specifically:

- The argument to the ISR is retrieved and passed to the ISR
- If power management is enabled and the system was idle, all the hardware will be resumed from low-power state before the ISR is executed, which can be very time-consuming
- Although some architectures will do this in hardware, other architectures need to switch to the interrupt stack in code
- After the interrupt is serviced, the OS then performs some logic to potentially make a scheduling decision.
Zephyr supports so-called 'direct' interrupts, which are installed via `IRQ_DIRECT_CONNECT`. These direct interrupts have some special implementation requirements and a reduced feature set; see the definition of `IRQ_DIRECT_CONNECT` for details.

The following code demonstrates a direct ISR:

```c
#define MY_DEV_IRQ 24 /* device uses IRQ 24 */
#define MY_DEV_PRIO 2 /* device uses interrupt priority 2 */
/* argument passed to my_isr(), in this case a pointer to the device */
#define MY_IRQ_FLAGS 0 /* IRQ flags */

ISR_DIRECT_DECLARE(my_isr)
{
    do_stuff();
    ISR_DIRECT_PM(); /* PM done after servicing interrupt for best latency */
    return 1; /* We should check if scheduling decision should be made */
}

void my_isr_installer(void)
{
    ...
    IRQ_DIRECT_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_IRQ_FLAGS);
    irq_enable(MY_DEV_IRQ);
    ...
}
```

Installation of dynamic direct interrupts is supported on an architecture-specific basis. (The feature is currently implemented in ARM Cortex-M architecture variant. Dynamic direct interrupts feature is exposed to the user via an ARM-only API.)

**Sharing an interrupt line** The following code defines two ISRs using the same interrupt number.

```c
#define MY_DEV_IRQ 24 /* device uses INTID 24 */
#define MY_DEV_PRIO 2 /* device uses interrupt priority 2 */
/* this argument may be anything */
#define MY_FST_ISR_ARG INT_TO_POINTER(1)
/* this argument may be anything */
#define MY_SND_ISR_ARG INT_TO_POINTER(2)
#define MY_IRQ_FLAGS 0 /* IRQ flags */

void my_first_isr(void *arg)
{
    ... /* some magic happens here */
}

void my_second_isr(void *arg)
{
    ... /* even more magic happens here */
}

void my_isr_installer(void)
{
    ...
    IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_first_isr, MY_FST_ISR_ARG, MY_IRQ_FLAGS);
    IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_second_isr, MY_SND_ISR_ARG, MY_IRQ_FLAGS);
}
```

(continues on next page)
The same restrictions regarding `IRQ_CONNECT` described in Defining a regular ISR are applicable here. If `CONFIG_SHARED_INTERRUPTS` is disabled, the above code will generate a build error. Otherwise, the above code will result in the two ISRs being invoked each time interrupt 24 is triggered.

If `CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS` is set to a value lower than 2 (current number of clients), a build error will be generated.

If dynamic interrupts are enabled, `irq_connect_dynamic` will allow sharing interrupts during runtime. Exceeding the configured maximum number of allowed clients will result in a failed assertion.

---

**Dynamically disconnecting an ISR**  The following code defines two ISRs using the same interrupt number. The second ISR is disconnected during runtime.

```c
#define MY_DEV_IRQ 24 /* device uses INTID 24 */
#define MY_DEV_IRQ_PRIO 2 /* device uses interrupt priority 2 */
/* this argument may be anything */
#define MY_FST_ISR_ARG INT_TO_POINTER(1)
/* this argument may be anything */
#define MY_SND_ISR_ARG INT_TO_POINTER(2)
#define MY_IRQ_FLAGS 0 /* IRQ flags */

void my_first_isr(void *arg)
{
    ... /* some magic happens here */
}

void my_second_isr(void *arg)
{
    ... /* even more magic happens here */
}

void my_isr_installer(void)
{
    ...
    IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr, MY_FST_ISR_ARG, MY_IRQ_FLAGS);
    IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_second_isr, MY_SND_ISR_ARG, MY_IRQ_FLAGS);
    ...
}

void my_isr_uninstaller(void)
{
    ...
    irq_disconnect_dynamic(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr, MY_FST_ISR_ARG, MY_IRQ_FLAGS);
    ...
}
```

The `irq_disconnect_dynamic()` call will result in interrupt 24 becoming unshared, meaning the system will act as if the first `IRQ_CONNECT` call never happened. This behaviour is only allowed if `CONFIG_DYNAMIC_INTERRUPTS` is enabled, otherwise a linker error will be generated.
Implementation Details Interrupt tables are set up at build time using some special build tools. The details laid out here apply to all architectures except x86, which are covered in the x86 Details section below.

Any invocation of `IRQ_CONNECT` will declare an instance of `struct _isr_list` which is placed in a special `.intList` section:

```c
struct _isr_list {
    /**< IRQ line number */
    int32_t irq;
    /**< Flags for this IRQ, see ISR_FLAG_* definitions */
    int32_t flags;
    /**< ISR to call */
    void *func;
    /**< Parameter for non-direct IRQs */
    void *param;
};
```

Zephyr is built in two phases; the first phase of the build produces `${ZEPHYR_PREBUILT_EXECUTABLE}.elf` which contains all the entries in the `.intList` section preceded by a header:

```c
struct {
    void *spurious_irq_handler;
    void *sw_irq_handler;
    uint32_t num_isrs;
    uint32_t num_vectors;
    struct _isr_list isrs[];  /**< of size num_isrs
};
```

This data consisting of the header and instances of `struct _isr_list` inside `${ZEPHYR_PREBUILT_EXECUTABLE}.elf` is then used by the `gen_isr_tables.py` script to generate a C file defining a vector table and software ISR table that are then compiled and linked into the final application.

The priority level of any interrupt is not encoded in these tables, instead `IRQ_CONNECT` also has a runtime component which programs the desired priority level of the interrupt to the interrupt controller. Some architectures do not support the notion of interrupt priority, in which case the priority argument is ignored.

Vector Table A vector table is generated when `CONFIG_GEN_IRQ_VECTOR_TABLE` is enabled. This data structure is used natively by the CPU and is simply an array of function pointers, where each element $n$ corresponds to the IRQ handler for IRQ line $n$, and the function pointers are:

1. For ‘direct’ interrupts declared with `IRQ_DIRECT_CONNECT`, the handler function will be placed here.
2. For regular interrupts declared with `IRQ_CONNECT`, the address of the common software IRQ handler is placed here. This code does common kernel interrupt bookkeeping and looks up the ISR and parameter from the software ISR table.
3. For interrupt lines that are not configured at all, the address of the spurious IRQ handler will be placed here. The spurious IRQ handler causes a system fatal error if encountered.

Some architectures (such as the Nios II internal interrupt controller) have a common entry point for all interrupts and do not support a vector table, in which case the `CONFIG_GEN_IRQ_VECTOR_TABLE` option should be disabled.

Some architectures may reserve some initial vectors for system exceptions and declare this in a table elsewhere, in which case `CONFIG_GEN_IRQ_START_VECTOR` needs to be set to properly offset the indices in the table.
SW ISR Table  This is an array of struct _isr_table_entry:

```c
struct _isr_table_entry {
    void *arg;
    void (*isr)(void *);
};
```

This is used by the common software IRQ handler to look up the ISR and its argument and execute it. The active IRQ line is looked up in an interrupt controller register and used to index this table.

Shared SW ISR Table  This is an array of struct z_shared_isr_table_entry:

```c
struct z_shared_isr_table_entry {
    struct z_shared_isr_client clients[CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS];
    size_t client_num;
};
```

This table keeps track of the registered clients for each of the interrupt lines. Whenever an interrupt line becomes shared, c:func:z_shared_isr will replace the currently registered ISR in _sw_isr_table. This special ISR will iterate through the list of registered clients and invoke the ISRs.

The definition for struct z_shared_isr_client is as follows:

```c
struct z_shared_isr_client {
    void (*isr)(const void *arg);
    const void *arg;
};
```

x86 Details  The x86 architecture has a special type of vector table called the Interrupt Descriptor Table (IDT) which must be laid out in a certain way per the x86 processor documentation. It is still fundamentally a vector table, and the arch/x86/gen_idt.py tool uses the .intList section to create it. However, on APIC-based systems the indexes in the vector table do not correspond to the IRQ line. The first 32 vectors are reserved for CPU exceptions, and all remaining vectors (up to index 255) correspond to the priority level, in groups of 16. In this scheme, interrupts of priority level 0 will be placed in vectors 32-47, level 1 48-63, and so forth. When the arch/x86/gen_idt.py tool is constructing the IDT, when it configures an interrupt it will look for a free vector in the appropriate range for the requested priority level and set the handler there.

On x86 when an interrupt or exception vector is executed by the CPU, there is no foolproof way to determine which vector was fired, so a software ISR table indexed by IRQ line is not used. Instead, the IRQ_CONNECT call creates a small assembly language function which calls the common interrupt code in _interrupt_enter() with the ISR and parameter as arguments. It is the address of this assembly interrupt stub which gets placed in the IDT. For interrupts declared with IRQ_DIRECT_CONNECT the parameterless ISR is placed directly in the IDT.

On systems where the position in the vector table corresponds to the interrupt's priority level, the interrupt controller needs to know at runtime what vector is associated with an IRQ line. arch/x86/gen_idt.py additionally creates an _irq_to_interrupt_vector array which maps an IRQ line to its configured vector in the IDT. This is used at runtime by IRQ_CONNECT to program the IRQ-to-vector association in the interrupt controller.

For dynamic interrupts, the build must generate some 4-byte dynamic interrupt stubs, one stub per dynamic interrupt in use. The number of stubs is controlled by the CONFIG_X86_DYNAMIC_IRQ_STUBS option. Each stub pushes an unique identifier which is then used to fetch the appropriate handler function and parameter out of a table populated when the dynamic interrupt was connected.

Going Beyond the Default Supported Number of Interrupts  When generating interrupts in the multilevel configuration, 8-bits per level is the default mask used when determining which level a given
interrupt code belongs to. This can become a problem when dealing with CPUs that support more than 255 interrupts per single aggregator. In this case it may be desirable to override these defaults and use a custom number of bits per level. Regardless of how many bits used for each level, the sum of the total bits used between all levels must sum to be less than or equal to 32-bits, fitting into a single 32-bit integer. To modify the bit total per level, override the default 8 in `Kconfig.multilevel` by setting `CONFIG_1ST_LEVEL_INTERRUPT_BITS` for the first level, `CONFIG_2ND_LEVEL_INTERRUPT_BITS` for the second tier and `CONFIG_3RD_LEVEL_INTERRUPT_BITS` for the third tier. These masks control the length of the bit masks and shift to apply when generating interrupt values, when checking the interrupts level and converting interrupts to a different level. The logic controlling this can be found in `irq.h`.

**Suggested Uses**  Use a regular or direct ISR to perform interrupt processing that requires a very rapid response, and can be done quickly without blocking.

**Note:** Interrupt processing that is time consuming, or involves blocking, should be handed off to a thread. See *Offloading ISR Work* for a description of various techniques that can be used in an application.

**Configuration Options**  Related configuration options:

- `CONFIG_ISR_STACK_SIZE`

Additional architecture-specific and device-specific configuration options also exist.

**API Reference**

*group isr_apis*

**Defines**

**IRQ_CONNECT**(irq_p, priority_p, isr_p, isr_param_p, flags_p)

Initialize an interrupt handler.

This routine initializes an interrupt handler for an IRQ. The IRQ must be subsequently enabled before the interrupt handler begins servicing interrupts.

**Warning:** Although this routine is invoked at run-time, all of its arguments must be computable by the compiler at build time.

**Parameters**

- `irq_p` – IRQ line number.
- `priority_p` – Interrupt priority.
- `isr_p` – Address of interrupt service routine.
- `isr_param_p` – Parameter passed to interrupt service routine.
- `flags_p` – Architecture-specific IRQ configuration flags..

**IRQ_DIRECT_CONNECT**(irq_p, priority_p, isr_p, flags_p)

Initialize a 'direct' interrupt handler.

This routine initializes an interrupt handler for an IRQ. The IRQ must be subsequently enabled via `irq_enable()` before the interrupt handler begins servicing interrupts.
These ISRs are designed for performance-critical interrupt handling and do not go through common interrupt handling code. They must be implemented in such a way that it is safe to put them directly in the vector table. For ISRs written in C, the `ISR_DIRECT_DECLARE()` macro will do this automatically. For ISRs written in assembly it is entirely up to the developer to ensure that the right steps are taken.

This type of interrupt currently has a few limitations compared to normal Zephyr interrupts:

- No parameters are passed to the ISR.
- No stack switch is done, the ISR will run on the interrupted context's stack, unless the architecture automatically does the stack switch in HW.
- Interrupt locking state is unchanged from how the HW sets it when the ISR runs. On arches that enter ISRs with interrupts locked, they will remain locked.
- Scheduling decisions are now optional, controlled by the return value of ISRs implemented with the `ISR_DIRECT_DECLARE()` macro.
- The call into the OS to exit power management idle state is now optional. Normal interrupts always do this before the ISR is run, but when it runs is now controlled by the placement of a `ISR_DIRECT_PM()` macro, or omitted entirely.

**Warning:** Although this routine is invoked at run-time, all of its arguments must be computable by the compiler at build time.

**Parameters**

- `irq_p` – IRQ line number.
- `priority_p` – Interrupt priority.
- `isr_p` – Address of interrupt service routine.
- `flags_p` – Architecture-specific IRQ configuration flags.

`ISR_DIRECT_HEADER()`

Common tasks before executing the body of an ISR.

This macro must be at the beginning of all direct interrupts and performs minimal architecture-specific tasks before the ISR itself can run. It takes no arguments and has no return value.

`ISR_DIRECT_FOOTER(check_reschedule)`

Common tasks before exiting the body of an ISR.

This macro must be at the end of all direct interrupts and performs minimal architecture-specific tasks like EOI. It has no return value.

In a normal interrupt, a check is done at end of interrupt to invoke `z_swap()` logic if the current thread is preemptible and there is another thread ready to run in the kernel’s ready queue cache. This is now optional and controlled by the `check_reschedule` argument. If unsure, set to nonzero. On systems that do stack switching and nested interrupt tracking in software, `z_swap()` should only be called if this was a non-nested interrupt.

**Parameters**

- `check_reschedule` – If nonzero, additionally invoke scheduling logic

`ISR_DIRECT_PM()`

Perform power management idle exit logic.

This macro may optionally be invoked somewhere in between `IRQ_DIRECT_HEADER()` and `IRQ_DIRECT_FOOTER()` invocations. It performs tasks necessary to exit power management idle state. It takes no parameters and returns no arguments. It may be omitted, but be careful!
ISR_DIRECT_DECLARE(name)

Helper macro to declare a direct interrupt service routine.

This will declare the function in a proper way and automatically include the
ISR_DIRECT_FOOTER() and ISR_DIRECT_HEADER() macros. The function should return nonzero status if a scheduling decision should potentially be made. See ISR_DIRECT_FOOTER() for more details on the scheduling decision.

For architectures that support 'regular' and 'fast' interrupt types, where these interrupt types require different assembly language handling of registers by the ISR, this will always generate code for the 'fast' interrupt type.

Example usage:

ISR_DIRECT_DECLARE(my_isr)
{
    bool done = do_stuff();
    ISR_DIRECT_PM(); // done after do_stuff() due to latency concerns
    if (!done) {
        return 0; // don't bother checking if we have to z_swap()
    }

    k_sem_give(some_sem);
    return 1;
}

Parameters

- name – symbol name of the ISR

irq_lock()

Lock interrupts.

This routine disables all interrupts on the CPU. It returns an unsigned integer “lock-out key”, which is an architecture-dependent indicator of whether interrupts were locked prior to the call. The lock-out key must be passed to irq_unlock() to re-enable interrupts.

This routine can be called recursively, as long as the caller keeps track of each lock-out key that is generated. Interrupts are re-enabled by passing each of the keys to irq_unlock() in the reverse order they were acquired. (That is, each call to irq_lock() must be balanced by a corresponding call to irq_unlock().)

This routine can only be invoked from supervisor mode. Some architectures (for example, ARM) will fail silently if invoked from user mode instead of generating an exception.

Note: This routine must also serve as a memory barrier to ensure the uniprocessor implementation of k_spinlock_t is correct.

Note: This routine can be called by ISRs or by threads. If it is called by a thread, the interrupt lock is thread-specific; this means that interrupts remain disabled only while the thread is running. If the thread performs an operation that allows another thread to run (for example, giving a semaphore or sleeping for N milliseconds), the interrupt lock no longer applies and interrupts may be re-enabled while other processing occurs. When the thread once again becomes the current thread, the kernel re-establishes its interrupt lock; this ensures the thread won’t be interrupted until it has explicitly released the interrupt lock it established.
**Warning:** The lock-out key should never be used to manually re-enable interrupts or to inspect or manipulate the contents of the CPU’s interrupt bits.

**Returns**
An architecture-dependent lock-out key representing the “interrupt disable state” prior to the call.

```c
irq_unlock(key)
```
Unlock interrupts.

This routine reverses the effect of a previous call to `irq_lock()` using the associated lock-out key. The caller must call the routine once for each time it called `irq_lock()`, supplying the keys in the reverse order they were acquired, before interrupts are enabled.

This routine can only be invoked from supervisor mode. Some architectures (for example, ARM) will fail silently if invoked from user mode instead of generating an exception.

**Note:** This routine must also serve as a memory barrier to ensure the uniprocessor implementation of `k_spinlock_t` is correct.

**Note:** Can be called by ISRs.

### Parameters
- `key` – Lock-out key generated by `irq_lock()`.

```c
irq_enable(irq)
```
Enable an IRQ.

This routine enables interrupts from source `irq`.

**Parameters**
- `irq` – IRQ line.

```c
irq_disable(irq)
```
Disable an IRQ.

This routine disables interrupts from source `irq`.

**Parameters**
- `irq` – IRQ line.

```c
irq_is_enabled(irq)
```
Get IRQ enable state.

This routine indicates if interrupts from source `irq` are enabled.

**Parameters**
- `irq` – IRQ line.

**Returns**
interrupt enable state, true or false
Functions

static inline int irq_connect_dynamic(unsigned int irq, unsigned int priority, void (*routine)(const void *parameter), const void *parameter, uint32_t flags)

Configure a dynamic interrupt.

Use this instead of IRQ_CONNECT() if arguments cannot be known at build time.

Parameters

- irq – IRQ line number
- priority – Interrupt priority
- routine – Interrupt service routine
- parameter – ISR parameter
- flags – Arch-specific IRQ configuration flags

Returns

The vector assigned to this interrupt

static inline int irq_disconnect_dynamic(unsigned int irq, unsigned int priority, void (*routine)(const void *parameter), const void *parameter, uint32_t flags)

Disconnect a dynamic interrupt.

Use this in conjunction with shared interrupts to remove a routine/parameter pair from the list of clients using the same interrupt line. If the interrupt is not being shared then the associated _sw_isr_table entry will be replaced by (NULL, z_irq_spurious) (default entry).

Parameters

- irq – IRQ line number
- priority – Interrupt priority
- routine – Interrupt service routine
- parameter – ISR parameter
- flags – Arch-specific IRQ configuration flags

Returns

0 in case of success, negative value otherwise

static inline unsigned int irq_get_level(unsigned int irq)

Return IRQ level This routine returns the interrupt level number of the provided interrupt.

Parameters

- irq – IRQ number in its zephyr format

Returns

1 if IRQ level 1, 2 if IRQ level 2, 3 if IRQ level 3

bool k_is_in_isr(void)

Determine if code is running at interrupt level.

This routine allows the caller to customize its actions, depending on whether it is a thread or an ISR.

Function properties (list may not be complete)

  isr-ok
Returns
false if invoked by a thread.

Returns
true if invoked by an ISR.

int k_is_preempt_thread(void)
Determine if code is running in a preemptible thread.
This routine allows the caller to customize its actions, depending on whether it can be pre-
empted by another thread. The routine returns a ‘true’ value if all of the following conditions
are met:

• The code is running in a thread, not at ISR.
• The thread’s priority is in the preemptible range.
• The thread has not locked the scheduler.

Function properties (list may not be complete)
isr-ok

Returns
0 if invoked by an ISR or by a cooperative thread.

Returns
Non-zero if invoked by a preemptible thread.

static inline bool k_is_pre_kernel(void)
Test whether startup is in the before-main-task phase.
This routine allows the caller to customize its actions, depending on whether it being invoked
before the kernel is fully active.

Function properties (list may not be complete)
isr-ok

Returns
true if invoked before post-kernel initialization

Returns
false if invoked during/after post-kernel initialization

Polling API
The polling API is used to wait concurrently for any one of multiple conditions to be fulfilled.

• Concepts
• Implementation
  – Using k_poll()
  – Using k_poll_signal_raise()
• Suggested Uses
• Configuration Options
Concepts  The polling API's main function is `k_poll()`, which is very similar in concept to the POSIX `poll()` function, except that it operates on kernel objects rather than on file descriptors.

The polling API allows a single thread to wait concurrently for one or more conditions to be fulfilled without actively looking at each one individually.

There is a limited set of such conditions:

- a semaphore becomes available
- a kernel FIFO contains data ready to be retrieved
- a poll signal is raised

A thread that wants to wait on multiple conditions must define an array of poll events, one for each condition.

All events in the array must be initialized before the array can be polled on.

Each event must specify which type of condition must be satisfied so that its state is changed to signal the requested condition has been met.

Each event must specify what kernel object it wants the condition to be satisfied.

Each event can optionally specify a tag to group multiple events together, to the user's discretion.

Apart from the kernel objects, there is also a poll signal pseudo-object type that be directly signaled.

The `k_poll()` function returns as soon as one of the conditions it is waiting for is fulfilled. It is possible for more than one to be fulfilled when `k_poll()` returns, if they were fulfilled before `k_poll()` was called, or due to the preemptive multi-threading nature of the kernel. The caller must look at the state of all the poll events in the array to figure out which ones were fulfilled and what actions to take.

Currently, there is only one mode of operation available: the object is not acquired. As an example, this means that when `k_poll()` returns and the poll event states that the semaphore is available, the caller of `k_poll()` must then invoke `k_sem_take()` to take ownership of the semaphore. If the semaphore is contested, there is no guarantee that it will be still available when `k_sem_take()` is called.

Implementation

Using `k_poll()`  The main API is `k_poll()`, which operates on an array of poll events of type `k_poll_event`. Each entry in the array represents one event a call to `k_poll()` will wait for its condition to be fulfilled.

Poll events can be initialized using either the runtime initializers `K_POLL_EVENT_INITIALIZER()` or `k_poll_event_init()`, or the static initializer `K_POLL_EVENT_STATIC_INITIALIZER()`. An object that matches the type specified must be passed to the initializers. The mode must be set to `K_POLL_MODE_NOTIFY ONLY`. The state must be set to `K_POLL_STATE_NOT READY` (the initializers take care of this). The user tag is optional and completely opaque to the API: it is there to help a user to group similar events together. Being optional, it is passed to the static initializer, but not the runtime ones for performance reasons. If using runtime initializers, the user must set it separately in the `k_poll_event` data structure. If an event in the array is to be ignored, most likely temporarily, its type can be set to `K_POLL_TYPE_IGNORE`.

```c
struct k_poll_event events[2] = {
    K_POLL_EVENT_STATIC_INITIALIZER(KERN poll_type SEM AVAILABLE,
    K POLL MODE NOTIFY ONLY,
(continues on next page)```
&my_sem, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_FIFO_DATA_AVAILABLE,
    K_POLL_MODE_NOTIFY_ONLY,
    &my_fifo, 0),
};

or at runtime

    struct k_poll_event events[2];
    void some_init(void)
    {
      k_poll_event_init(&events[0],
        K_POLL_TYPE_SEM_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_sem);

      k_poll_event_init(&events[1],
        K_POLL_TYPE_FIFO_DATA_AVAILABLE,
        K_POLL_MODE_NOTIFY_ONLY,
        &my_fifo);

      // tags are left uninitialized if unused
    }

After the events are initialized, the array can be passed to \texttt{k_poll()}. A timeout can be specified to wait only for a specified amount of time, or the special values \texttt{K_NO_WAIT} and \texttt{K_FOREVER} to either not wait or wait until an event condition is satisfied and not sooner.

A list of pollers is offered on each semaphore or FIFO and as many events can wait in it as the app wants. Notice that the waiters will be served in first-come-first-serve order, not in priority order.

In case of success, \texttt{k_poll()} returns 0. If it times out, it returns \texttt{-EAGAIN}.

// assume there is no contention on this semaphore and FIFO
// -EADDRINUSE will not occur; the semaphore and/or data will be available

    void do_stuff(void)
    {
      rc = k_poll(events, 2, 1000);
      if (rc == 0) {
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
          k_sem_take(events[0].sem, 0);
        } else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
          data = k_fifo_get(events[1].fifo, 0);
          // handle data
        }
      } else {
        // handle timeout
      }
    }

When \texttt{k_poll()} is called in a loop, the events state must be reset to \texttt{K_POLL_STATE_NOT_READY} by the user.

    void do_stuff(void)
    {
      for(;;) {
        rc = k_poll(events, 2, K_FOREVER);
    }
if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
  k_sem_take(events[0].sem, 0);
} else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
  data = k_fifo_get(events[1].fifo, 0);
  // handle data
}
events[0].state = K_POLL_STATE_NOT_READY;
events[1].state = K_POLL_STATE_NOT_READY;

Using `k_poll_signal_raise()`  One of the types of events is `K_POLL_TYPE_SIGNAL`: this is a “direct” signal to a poll event. This can be seen as a lightweight binary semaphore only one thread can wait for.

A poll signal is a separate object of type `k_poll_signal` that must be attached to a `k_poll_event`, similar to a semaphore or FIFO. It must first be initialized either via `K_POLL_SIGNAL_INITIALIZER()` or `k_poll_signal_init()`.

```c
struct k_poll_signal signal;
void do_stuff(void)
{
  k_poll_signal_init(&signal);
}
```

It is signaled via the `k_poll_signal_raise()` function. This function takes a user result parameter that is opaque to the API and can be used to pass extra information to the thread waiting on the event.

```c
struct k_poll_signal signal;

// thread A
void do_stuff(void)
{
  k_poll_signal_init(&signal);
  struct k_poll_event events[1] = {
    K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
                           K_POLL_MODE_NOTIFY_ONLY,
                           &signal),
  };
  k_poll(events, 1, K_FOREVER);
  if (events.signal->result == 0x1337) { // A-OK!
  } else { // weird error
  }
}

// thread B
void signal_do_stuff(void)
{
  k_poll_signal_raise(&signal, 0x1337);
}
```

If the signal is to be polled in a loop, both its event state and its signaled field must be reset on each iteration if it has been signaled.
struct k_poll_signal signal;
void do_stuff(void)
{
    k_poll_signal_init(&signal);

    struct k_poll_event events[1] = {
        K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
            K_POLL_MODE_NOTIFY_ONLY,
            &signal),
    };

    for (;;) {
        k_poll(events, 1, K_FOREVER);

        if (events[0].signal->result == 0x1337) {
            // A-OK!
        } else {
            // weird error
        }

        events[0].signal->signaled = 0;
        events[0].state = K_POLL_STATE_NOT_READY;
    }
}

Note that poll signals are not internally synchronized. A `k_poll()` call that is passed a signal will return after any code in the system calls `k_poll_signal_raise()`. But if the signal is being externally managed and reset via `k_poll_signal_init()`, it is possible that by the time the application checks, the event state may no longer be equal to `K_POLL_STATE_SIGNALED`, and a (naive) application will miss events. Best practice is always to reset the signal only from within the thread invoking the `k_poll()` loop, or else to use some other event type which tracks event counts: semaphores and FIFOs are more error-proof in this sense because they can’t “miss” events, architecturally.

**Suggested Uses** Use `k_poll()` to consolidate multiple threads that would be pending on one object each, saving possibly large amounts of stack space.

Use a poll signal as a lightweight binary semaphore if only one thread pends on it.

**Note:** Because objects are only signaled if no other thread is waiting for them to become available and only one thread can poll on a specific object, polling is best used when objects are not subject of contention between multiple threads, basically when a single thread operates as a main “server” or “dispatcher” for multiple objects and is the only one trying to acquire these objects.

3.1. Kernel Services
Functions

```c
void k_poll_event_init(struct k_poll_event *event, uint32_t type, int mode, void *obj)
```

Initialize one struct `k_poll_event` instance.

After this routine is called on a poll event, the event it ready to be placed in an event array to be passed to `k_poll()`.

**Parameters**

- `event` – The event to initialize.
- `type` – A bitfield of the types of event, from the K_POLL_TYPE_xxx values. Only values that apply to the same object being polled can be used together. Choosing K_POLL_TYPE_IGNORE disables the event.
- `mode` – Future. Use K_POLL_MODE_NOTIFY_ONLY.
- `obj` – Kernel object or poll signal.

```c
int k_poll(struct k_poll_event *events, int num_events, k_timeout_t timeout)
```

Wait for one or many of multiple poll events to occur.

This routine allows a thread to wait concurrently for one or many of multiple poll events to have occurred. Such events can be a kernel object being available, like a semaphore, or a poll signal event.

When an event notifies that a kernel object is available, the kernel object is not “given” to the thread calling `k_poll()`: it merely signals the fact that the object was available when the `k_poll()` call was in effect. Also, all threads trying to acquire an object the regular way, i.e. by pending on the object, have precedence over the thread polling on the object. This means that the polling thread will never get the poll event on an object until the object becomes available and its pend queue is empty. For this reason, the `k_poll()` call is more effective when the objects being polled only have one thread, the polling thread, trying to acquire them.

When `k_poll()` returns 0, the caller should loop on all the events that were passed to `k_poll()` and check the state field for the values that were expected and take the associated actions.

Before being reused for another call to `k_poll()`, the user has to reset the state field to K_POLL_STATE_NOT_READY.

When called from user mode, a temporary memory allocation is required from the caller’s resource pool.

**Parameters**

- `events` – An array of events to be polled for.
- `num_events` – The number of events in the array.
- `timeout` – Waiting period for an event to be ready, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**

- 0 – One or more events are ready.
- -EAGAIN – Waiting period timed out.
- -EINTR – Polling has been interrupted, e.g. with `k_queue_cancel_wait()`. All output events are still set and valid, cancelled event(s) will be set to K_POLL_STATE_CANCELLED. In other words, -EINTR status means that at least one of output events is K_POLL_STATE_CANCELLED.
- -ENOMEM – Thread resource pool insufficient memory (user mode only)
- -EINVAL – Bad parameters (user mode only)
void k_poll_signal_init(struct k_poll_signal *sig)

Initialize a poll signal object.

Ready a poll signal object to be signaled via k_poll_signal_raise().

Parameters
  • sig – A poll signal.

void k_poll_signal_reset(struct k_poll_signal *sig)

void k_poll_signal_check(struct k_poll_signal *sig, unsigned int *signaled, int *result)

Fetch the signaled state and result value of a poll signal.

Parameters
  • sig – A poll signal object
  • signaled – An integer buffer which will be written nonzero if the object was signaled
  • result – An integer destination buffer which will be written with the result value if the object was signaled, or an undefined value if it was not.

int k_poll_signal_raise(struct k_poll_signal *sig, int result)

Signal a poll signal object.

This routine makes ready a poll signal, which is basically a poll event of type K_POLL_TYPE_SIGNAL. If a thread was polling on that event, it will be made ready to run. A result value can be specified.

The poll signal contains a 'signaled' field that, when set by k_poll_signal_raise(), stays set until the user sets it back to 0 with k_poll_signal_reset(). It thus has to be reset by the user before being passed again to k_poll() or k_poll() will consider it being signaled, and will return immediately.

Note: The result is stored and the 'signaled' field is set even if this function returns an error indicating that an expiring poll was not notified. The next k_poll() will detect the missed raise.

Parameters
  • sig – A poll signal.
  • result – The value to store in the result field of the signal.

Return values
  • 0 – The signal was delivered successfully.
  • -EAGAIN – The polling thread’s timeout is in the process of expiring.

struct k_poll_signal

#include <kernel.h>

Public Members

sys_dlist_t poll_events

PRIVATE - DO NOT TOUCH.
```c
unsigned int signaled
    1 if the event has been signaled, 0 otherwise.
    Stays set to 1 until user resets it to 0.

int result
    custom result value passed to k_poll_signal_raise() if needed

struct k_poll_event
    #include <kernel.h> Poll Event.

Public Members

struct z_poller *poller
    PRIVATE - DO NOT TOUCH.

union k_poll_event
    private data

Per-type data

uint32_t tag
    optional user-specified tag, opaque, untouched by the API

uint32_t type
    bitfield of event types (bitwise-ORed K_POLL_TYPE_xxx values)

uint32_t state
    bitfield of event states (bitwise-ORed K_POLL_STATE_xxx values)

uint32_t mode
    mode of operation, from enum k_poll_modes

uint32_t unused
    unused bits in 32-bit word

union k_poll_event [anonymous]
    per-type data

Semaphores

A semaphore is a kernel object that implements a traditional counting semaphore.

- Concepts
- Implementation
  - Defining a Semaphore
  - Giving a Semaphore
  - Taking a Semaphore
- Suggested Uses
- Configuration Options
- API Reference
```
Concepts  Any number of semaphores can be defined (limited only by available RAM). Each semaphore is referenced by its memory address. A semaphore has the following key properties:

- A count that indicates the number of times the semaphore can be taken. A count of zero indicates that the semaphore is unavailable.
- A limit that indicates the maximum value the semaphore’s count can reach.

A semaphore must be initialized before it can be used. Its count must be set to a non-negative value that is less than or equal to its limit.

A semaphore may be given by a thread or an ISR. Giving the semaphore increments its count, unless the count is already equal to the limit.

A semaphore may be taken by a thread. Taking the semaphore decrements its count, unless the semaphore is unavailable (i.e. at zero). When a semaphore is unavailable a thread may choose to wait for it to be given. Any number of threads may wait on an unavailable semaphore simultaneously. When the semaphore is given, it is taken by the highest priority thread that has waited longest.

Note: You may initialize a “full” semaphore (count equal to limit) to limit the number of threads able to execute the critical section at the same time. You may also initialize an empty semaphore (count equal to 0, with a limit greater than 0) to create a gate through which no waiting thread may pass until the semaphore is incremented. All standard use cases of the common semaphore are supported.

Note: The kernel does allow an ISR to take a semaphore, however the ISR must not attempt to wait if the semaphore is unavailable.

Implementation

Defining a Semaphore  A semaphore is defined using a variable of type k_sem. It must then be initialized by calling k_sem_init().

The following code defines a semaphore, then configures it as a binary semaphore by setting its count to 0 and its limit to 1.

```c
struct k_sem my_sem;
k_sem_init(&my_sem, 0, 1);
```

Alternatively, a semaphore can be defined and initialized at compile time by calling K_SEM_DEFINE.

The following code has the same effect as the code segment above.

```c
K_SEM_DEFINE(my_sem, 0, 1);
```

Giving a Semaphore  A semaphore is given by calling k_sem_give().

The following code builds on the example above, and gives the semaphore to indicate that a unit of data is available for processing by a consumer thread.
void input_data_interrupt_handler(void *arg)
{
/* notify thread that data is available */
k_sem_give(&my_sem);
...
}

Taking a Semaphore  A semaphore is taken by calling `k_sem.take()`.
The following code builds on the example above, and waits up to 50 milliseconds for the semaphore to be given. A warning is issued if the semaphore is not obtained in time.

void consumer_thread(void)
{
...
if (k_sem_take(&my_sem, K_MSEC(50)) != 0) {
   printk("Input data not available!");
} else {
   /* fetch available data */
   ...
}
...
}

Suggested Uses  Use a semaphore to control access to a set of resources by multiple threads.
Use a semaphore to synchronize processing between a producing and consuming threads or ISRs.

Configuration Options  Related configuration options:
   • None.

API Reference  Related code samples
   • Basic Synchronization - Manipulate basic kernel synchronization primitives.

defines

K_SEM_MAX_LIMIT
   Maximum limit value allowed for a semaphore.
   This is intended for use when a semaphore does not have an explicit maximum limit, and instead is just used for counting purposes.

K_SEMDEFINE(name, initial_count, count_limit)
   Statically define and initialize a semaphore.
   The semaphore can be accessed outside the module where it is defined using:
extern struct k_sem <name>;

Parameters
• name – Name of the semaphore.
• initial_count – Initial semaphore count.
• count_limit – Maximum permitted semaphore count.

Functions

int k_sem_init(struct k_sem *sem, unsigned int initial_count, unsigned int limit)
Initialize a semaphore.
This routine initializes a semaphore object, prior to its first use.

See also:
K_SEM_MAX_LIMIT

Parameters
• sem – Address of the semaphore.
• initial_count – Initial semaphore count.
• limit – Maximum permitted semaphore count.

Return values
• 0 – Semaphore created successfully
• -EINVAL – Invalid values

int k_sem_take(struct k_sem *sem, k_timeout_t timeout)
Take a semaphore.
This routine takes sem.

Function properties (list may not be complete)
isr-ok

Note: timeout must be set to K_NO_WAIT if called from ISR.

Parameters
• sem – Address of the semaphore.
• timeout – Waiting period to take the semaphore, or one of the special values K_NO_WAIT and K_FOREVER.

Return values
• 0 – Semaphore taken.
• -EBUSY – Returned without waiting.
• -EAGAIN – Waiting period timed out, or the semaphore was reset during the waiting period.
void k_sem_give(struct k_sem *sem)
    Give a semaphore.
    This routine gives `sem`, unless the semaphore is already at its maximum permitted count.

**Function properties (list may not be complete)**

*isr-ok*

**Parameters**

- `sem` – Address of the semaphore.

void k_sem_reset(struct k_sem *sem)
    Resets a semaphore's count to zero.
    This routine sets the count of `sem` to zero. Any outstanding semaphore takes will be aborted with -EAGAIN.

**Parameters**

- `sem` – Address of the semaphore.

unsigned int k_sem_count_get(struct k_sem *sem)
    Get a semaphore's count.
    This routine returns the current count of `sem`.

**Parameters**

- `sem` – Address of the semaphore.

**Returns**

Current semaphore count.

**User Mode Semaphore API Reference**

The `sys_sem` exists in user memory working as counter semaphore for user mode thread when user mode enabled. When user mode isn't enabled, `sys_sem` behaves like `k_sem`.

**group user_semaphoreApis**

**Defines**

SYS_SEM_DEFINE(_name, _initial_count, _count_limit)
    Statically define and initialize a `sys_sem`.
    The semaphore can be accessed outside the module where it is defined using:

    ```
    extern struct sys_sem <name>;
    ```

    Route this to memory domains using `K_APP_DMEM()`.

**Parameters**

- `_name` – Name of the semaphore.
- `_initial_count` – Initial semaphore count.
- `_count_limit` – Maximum permitted semaphore count.
Functions

int sys_sem_init(struct sys_sem *sem, unsigned int initial_count, unsigned int limit)
Initialize a semaphore.

This routine initializes a semaphore instance, prior to its first use.

Parameters

• sem – Address of the semaphore.
• initial_count – Initial semaphore count.
• limit – Maximum permitted semaphore count.

Return values

• 0 – Initial success.
• -EINVAL – Bad parameters, the value of limit should be located in (0, INT_MAX] and initial_count shouldn't be greater than limit.

int sys_sem_give(struct sys_sem *sem)
Give a semaphore.

This routine gives sem, unless the semaphore is already at its maximum permitted count.

Parameters

• sem – Address of the semaphore.

Return values

• 0 – Semaphore given.
• -EINVAL – Parameter address not recognized.
• -EACCES – Caller does not have enough access.
• -EAGAIN – Count reached Maximum permitted count and try again.

int sys_sem_take(struct sys_sem *sem, k_timeout_t timeout)
Take a sys_sem.

This routine takes sem.

Parameters

• sem – Address of the sys_sem.
• timeout – Waiting period to take the sys_sem, or one of the special values K_NO_WAIT and K_FOREVER.

Return values

• 0 – sys_sem taken.
• -EINVAL – Parameter address not recognized.
• -ETIMEDOUT – Waiting period timed out.
• -EACCES – Caller does not have enough access.

unsigned int sys_sem_count_get(struct sys_sem *sem)
Get sys_sem’s value.

This routine returns the current value of sem.

Parameters

• sem – Address of the sys_sem.
Returns
Current value of sys_sem.

Mutexes

A mutex is a kernel object that implements a traditional reentrant mutex. A mutex allows multiple threads to safely share an associated hardware or software resource by ensuring mutually exclusive access to the resource.

- Concepts
  - Reentrant Locking
  - Priority Inheritance
- Implementation
  - Defining a Mutex
  - Locking a Mutex
  - Unlocking a Mutex
- Suggested Uses
- Configuration Options
- API Reference
- Futex API Reference
- User Mode Mutex API Reference

Concepts  Any number of mutexes can be defined (limited only by available RAM). Each mutex is referenced by its memory address.

A mutex has the following key properties:

- A lock count that indicates the number of times the mutex has been locked by the thread that has locked it. A count of zero indicates that the mutex is unlocked.
- An owning thread that identifies the thread that has locked the mutex, when it is locked.

A mutex must be initialized before it can be used. This sets its lock count to zero.

A thread that needs to use a shared resource must first gain exclusive rights to access it by locking the associated mutex. If the mutex is already locked by another thread, the requesting thread may choose to wait for the mutex to be unlocked.

After locking a mutex, the thread may safely use the associated resource for as long as needed; however, it is considered good practice to hold the lock for as short a time as possible to avoid negatively impacting other threads that want to use the resource. When the thread no longer needs the resource it must unlock the mutex to allow other threads to use the resource.

Any number of threads may wait on a locked mutex simultaneously. When the mutex becomes unlocked it is then locked by the highest-priority thread that has waited the longest.

Note: Mutex objects are not designed for use by ISRs.

Reentrant Locking  A thread is permitted to lock a mutex it has already locked. This allows the thread to access the associated resource at a point in its execution when the mutex may or may not already be locked.
A mutex that is repeatedly locked by a thread must be unlocked an equal number of times before the mutex becomes fully unlocked so it can be claimed by another thread.

**Priority Inheritance**  The thread that has locked a mutex is eligible for *priority inheritance*. This means the kernel will temporarily elevate the thread's priority if a higher priority thread begins waiting on the mutex. This allows the owning thread to complete its work and release the mutex more rapidly by executing at the same priority as the waiting thread. Once the mutex has been unlocked, the unlocking thread resets its priority to the level it had before locking that mutex.

**Note:** The `CONFIG_PRIORITY_CEILING` configuration option limits how high the kernel can raise a thread's priority due to priority inheritance. The default value of 0 permits unlimited elevation.

The owning thread's base priority is saved in the mutex when it obtains the lock. Each time a higher priority thread waits on a mutex, the kernel adjusts the owning thread's priority. When the owning thread releases the lock (or if the high priority waiting thread times out), the kernel restores the thread's base priority from the value saved in the mutex.

This works well for priority inheritance as long as only one locked mutex is involved. However, if multiple mutexes are involved, sub-optimal behavior will be observed if the mutexes are not unlocked in the reverse order to which the owning thread's priority was previously raised. Consequently it is recommended that a thread lock only a single mutex at a time when multiple mutexes are shared between threads of different priorities.

**Implementation**

**Defining a Mutex**  A mutex is defined using a variable of type `k_mutex`. It must then be initialized by calling `k_mutex_init()`.

The following code defines and initializes a mutex.

```c
struct k_mutex my_mutex;
k_mutex_init(&my_mutex);
```

Alternatively, a mutex can be defined and initialized at compile time by calling `K_MUTEX_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_MUTEX_DEFINE(my_mutex);
```

**Locking a Mutex**  A mutex is locked by calling `k_mutex_lock()`.

The following code builds on the example above, and waits indefinitely for the mutex to become available if it is already locked by another thread.

```c
k_mutex_lock(&my_mutex, K_FOREVER);
```

The following code waits up to 100 milliseconds for the mutex to become available, and gives a warning if the mutex does not become available.

```c
if (k_mutex_lock(&my_mutex, K_MSEC(100)) == 0) {
   /* mutex successfully locked */
} else {
   printf("Cannot lock XYZ display\n");
}
Unlocking a Mutex  A mutex is unlocked by calling \texttt{k_mutex_unlock()}.

The following code builds on the example above, and unlocks the mutex that was previously locked by the thread.

\begin{verbatim}
    k_mutex_unlock(&my_mutex);
\end{verbatim}

Suggested Uses  Use a mutex to provide exclusive access to a resource, such as a physical device.

Configuration Options  Related configuration options:

\begin{itemize}
    \item CONFIG_PRIORITY_CEILING
\end{itemize}

API Reference

\texttt{group mutex\_apis}

\textbf{Defines}

\begin{verbatim}
    K_MUTEX_DEFINE(name)
\end{verbatim}

Synchronously define and initialize a mutex.

The mutex can be accessed outside the module where it is defined using:

\begin{verbatim}
    extern struct k_mutex <name>;
\end{verbatim}

\textbf{Parameters}

\begin{itemize}
    \item name – Name of the mutex.
\end{itemize}

\textbf{Functions}

\begin{verbatim}
    int k_mutex_init(struct k_mutex *mutex)
\end{verbatim}

Initialize a mutex.

This routine initializes a mutex object, prior to its first use.

Upon completion, the mutex is available and does not have an owner.

\textbf{Parameters}

\begin{itemize}
    \item mutex – Address of the mutex.
\end{itemize}

\textbf{Return values}

0 – Mutex object created

\begin{verbatim}
    int k_mutex_lock(struct k_mutex *mutex, k_timeout_t timeout)
\end{verbatim}

Lock a mutex.

This routine locks \texttt{mutex}. If the mutex is locked by another thread, the calling thread waits until the mutex becomes available or until a timeout occurs.

A thread is permitted to lock a mutex it has already locked. The operation completes immediately and the lock count is increased by 1.

Mutexes may not be locked in ISRs.

\textbf{Parameters}

\begin{itemize}
    \item mutex – Address of the mutex.
\end{itemize}
timeout – Waiting period to lock the mutex, or one of the special values K_NO_WAIT and K_FOREVER.

Return values
• 0 – Mutex locked.
• -EBUSY – Returned without waiting.
• -EAGAIN – Waiting period timed out.

int k_mutex_unlock(struct k_mutex *mutex)
Unlock a mutex.
This routine unlocks mutex. The mutex must already be locked by the calling thread.
The mutex cannot be claimed by another thread until it has been unlocked by the calling thread as many times as it was previously locked by that thread.
Mutexes may not be unlocked in ISRs, as mutexes must only be manipulated in thread context due to ownership and priority inheritance semantics.

Parameters
• mutex – Address of the mutex.

Return values
• 0 – Mutex unlocked.
• -EPERM – The current thread does not own the mutex
• -EINVAL – The mutex is not locked

Futex API Reference  k_futex is a lightweight mutual exclusion primitive designed to minimize kernel involvement. Uncontended operation relies only on atomic access to shared memory. k_futex are tracked as kernel objects and can live in user memory so that any access bypasses the kernel object permission management mechanism.
Functions

```c
int k_futex_wait(struct k_futex *futex, int expected, k_timeout_t timeout)
```
Pend the current thread on a futex. Tests that the supplied futex contains the expected value, and if so, goes to sleep until some other thread calls `k_futex_wait()` on it.

**Parameters**
- `futex` – Address of the futex.
- `expected` – Expected value of the futex, if it is different the caller will not wait on it.
- `timeout` – Non-negative waiting period on the futex, or one of the special values `K_NO_WAIT` or `K_FOREVER`.

**Return values**
- `EACCES` – Caller does not have read access to futex address.
- `EAGAIN` – If the futex value did not match the expected parameter.
- `EINVAL` – Futex parameter address not recognized by the kernel.
- `ETIMEDOUT` – Thread woke up due to timeout and not a futex wakeup.
- `0` – if the caller went to sleep and was woken up. The caller should check the futex's value on wakeup to determine if it needs to block again.

```c
int k_futex_wake(struct k_futex *futex, bool wake_all)
```
Wake one/all threads pending on a futex.

**Parameters**
- `futex` – Futex to wake up pending threads.
- `wake_all` – If true, wake up all pending threads; If false, wakeup the highest priority thread.

**Return values**
- `EACCES` – Caller does not have access to the futex address.
- `EINVAL` – Futex parameter address not recognized by the kernel.
- `Number` – of threads that were woken up.

User Mode Mutex API Reference

`sys_mutex` behaves almost exactly like `k_mutex`, with the added advantage that a `sys_mutex` instance can reside in user memory. When user mode isn't enabled, `sys_mutex` behaves like `k_mutex`.

**group user_mutex_apis**

**Defines**

```c
SYS_MUTEX_DEFINE(name)
```
Statically define and initialize a `sys_mutex`.

The mutex can be accessed outside the module where it is defined using:
extern struct sys_mutex <name>;

Route this to memory domains using K_APP_DMEM().

**Parameters**

- **name** – Name of the mutex.

**Functions**

static inline void sys_mutex_init(struct sys_mutex *mutex)

Initialize a mutex.

This routine initializes a mutex object, prior to its first use.
Upon completion, the mutex is available and does not have an owner.

This routine is only necessary to call when userspace is disabled and the mutex was not created with `SYS_MUTEX_DEFINE()`.

**Parameters**

- **mutex** – Address of the mutex.

static inline int sys_mutex_lock(struct sys_mutex *mutex, k_timeout_t timeout)

Lock a mutex.

This routine locks `mutex`. If the mutex is locked by another thread, the calling thread waits until the mutex becomes available or until a timeout occurs.

A thread is permitted to lock a mutex it has already locked. The operation completes immediately and the lock count is increased by 1.

**Parameters**

- **mutex** – Address of the mutex, which may reside in user memory
- **timeout** – Waiting period to lock the mutex, or one of the special values `K_NO_WAIT` and `K_FOREVER`.

**Return values**

- **0** – Mutex locked.
- **-EBUSY** – Returned without waiting.
- **-EAGAIN** – Waiting period timed out.
- **-EACCES** – Caller has no access to provided mutex address
- **-EINVAL** – Provided mutex not recognized by the kernel

static inline int sys_mutex_unlock(struct sys_mutex *mutex)

Unlock a mutex.

This routine unlocks `mutex`. The mutex must already be locked by the calling thread.

The mutex cannot be claimed by another thread until it has been unlocked by the calling thread as many times as it was previously locked by that thread.

**Parameters**

- **mutex** – Address of the mutex, which may reside in user memory

**Return values**

- **0** – Mutex unlocked
- **-EACCES** – Caller has no access to provided mutex address
• -EINVAL – Provided mutex not recognized by the kernel or mutex wasn’t locked
• -EPERM – Caller does not own the mutex

Condition Variables

A condition variable is a synchronization primitive that enables threads to wait until a particular condition occurs.

• Concepts
• Implementation
  – Defining a Condition Variable
  – Waiting on a Condition Variable
  – Signaling a Condition Variable
• Suggested Uses
• Configuration Options
• API Reference

Concepts  Any number of condition variables can be defined (limited only by available RAM). Each condition variable is referenced by its memory address.

To wait for a condition to become true, a thread can make use of a condition variable.

A condition variable is basically a queue of threads that threads can put themselves on when some state of execution (i.e., some condition) is not as desired (by waiting on the condition). The function \( k\text{-}condvar\text{-}wait() \) performs atomically the following steps;

1. Releases the last acquired mutex.
2. Puts the current thread in the condition variable queue.

Some other thread, when it changes said state, can then wake one (or more) of those waiting threads and thus allow them to continue by signaling on the condition using \( k\text{-}condvar\text{-}signal() \) or \( k\text{-}condvar\text{-}broadcast() \) then it:

1. Re-acquires the mutex previously released.
2. Returns from \( k\text{-}condvar\text{-}wait() \).

A condition variable must be initialized before it can be used.

Implementation

Defining a Condition Variable  A condition variable is defined using a variable of type \( k\_condvar \). It must then be initialized by calling \( k\_condvar\_init() \).

The following code defines a condition variable:

```c
struct k_condvar my_condvar;
k_condvar_init(&my_condvar);
```

Alternatively, a condition variable can be defined and initialized at compile time by calling \( K\_CONDVAR\_DEFINE \).

The following code has the same effect as the code segment above.
K_CONDVAR_DEFINE(my_condvar);

Waiting on a Condition Variable A thread can wait on a condition by calling `k_condvar_wait()`. The following code waits on the condition variable.

K_MUTEX_DEFINE(mutex);
K_CONDVAR_DEFINE(condvar)

int main(void)
{
    k_mutex_lock(&mutex, K_FOREVER);
    /* block this thread until another thread signals cond. While
     * blocked, the mutex is released, then re-acquired before this
     * thread is woken up and the call returns.
     */
    k_condvar_wait(&condvar, &mutex, K_FOREVER);
    ...
    k_mutex_unlock(&mutex);
}

Signaling a Condition Variable A condition variable is signaled on by calling `k_condvar_signal()` for one thread or by calling `k_condvar_broadcast()` for multiple threads.

The following code builds on the example above.

void worker_thread(void)
{
    k_mutex_lock(&mutex, K_FOREVER);
    /*
     * Do some work and fulfill the condition
     */
    ...
    k_condvar_signal(&condvar);
    ...
    k_mutex_unlock(&mutex);
}

Suggested Uses Use condition variables with a mutex to signal changing states (conditions) from one thread to another thread. Condition variables are not the condition itself and they are not events. The condition is contained in the surrounding programming logic.

Mutexes alone are not designed for use as a notification/synchronization mechanism. They are meant to provide mutually exclusive access to a shared resource only.

Configuration Options Related configuration options:

- None.

API Reference Related code samples

- Condition Variables - Manipulate condition variables in a multithreaded application.
group condvar_apis

Defines

K_CONDVAR_DEFINE(name)

Statically define and initialize a condition variable.
The condition variable can be accessed outside the module where it is defined using:

extern struct k_condvar <name>;

Parameters

• name – Name of the condition variable.

Functions

int k_condvar_init(struct k_condvar *condvar)

Initialize a condition variable.

Parameters

• condvar – Pointer to a k_condvar structure

Return values

0 – Condition variable created successfully

int k_condvar_signal(struct k_condvar *condvar)

Signals one thread that is pending on the condition variable.

Parameters

• condvar – Pointer to a k_condvar structure

Return values

0 – On success

int k_condvar_broadcast(struct k_condvar *condvar)

Unblock all threads that are pending on the condition variable.

Parameters

• condvar – Pointer to a k_condvar structure

Returns

An integer with number of woken threads on success

int k_condvar_wait(struct k_condvar *condvar, struct k_mutex *mutex, k_timeout_t timeout)

Waits on the condition variable releasing the mutex lock.

Atomically releases the currently owned mutex, blocks the current thread waiting on the condition variable specified by condvar, and finally acquires the mutex again.

The waiting thread unblocks only after another thread calls k_condvar_signal, or k_condvar_broadcast with the same condition variable.

Parameters

• condvar – Pointer to a k_condvar structure

• mutex – Address of the mutex.
timeout – Waiting period for the condition variable or one of the special values
K_NO_WAIT and K_FOREVER.

Return values

• 0 – On success
• -EAGAIN – Waiting period timed out.

Events

An event object is a kernel object that implements traditional events.

Concepts

Any number of event objects can be defined (limited only by available RAM). Each event
object is referenced by its memory address. One or more threads may wait on an event object until the
desired set of events has been delivered to the event object. When new events are delivered to the event
object, all threads whose wait conditions have been satisfied become ready simultaneously.

An event object has the following key properties:

• A 32-bit value that tracks which events have been delivered to it.

An event object must be initialized before it can be used.

Events may be delivered by a thread or an ISR. When delivering events, the events may either overwrite
the existing set of events or add to them in a bitwise fashion. When overwriting the existing set of events,
this is referred to as setting. When adding to them in a bitwise fashion, this is referred to as posting.
Both posting and setting events have the potential to fulfill match conditions of multiple threads waiting
on the event object. All threads whose match conditions have been met are made active at the same
time.

Threads may wait on one or more events. They may either wait for all of the requested events, or for
any of them. Furthermore, threads making a wait request have the option of resetting the current set of
events tracked by the event object prior to waiting. Care must be taken with this option when multiple
threads wait on the same event object.

Note: The kernel does allow an ISR to query an event object, however the ISR must not attempt to wait
for the events.

Implementation
Defining an Event Object  
An event object is defined using a variable of type `k_event`. It must then be initialized by calling `k_event_init()`.

The following code defines an event object.

```c
struct k_event my_event;
k_event_init(&my_event);
```

Alternatively, an event object can be defined and initialized at compile time by calling `K_EVENT_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_EVENT_DEFINE(my_event);
```

Setting Events  
Events in an event object are set by calling `k_event_set()`.

The following code builds on the example above, and sets the events tracked by the event object to 0x001.

```c
void input_available_interrupt_handler(void *arg)
{
    /* notify threads that data is available */
    k_event_set(&my_event, 0x001);
    ...
}
```

Posting Events  
Events are posted to an event object by calling `k_event_post()`.

The following code builds on the example above, and posts a set of events to the event object.

```c
void input_available_interrupt_handler(void *arg)
{
    ...
    /* notify threads that more data is available */
    k_event_post(&my_event, 0x120);
    ...
}
```

Waiting for Events  
Threads wait for events by calling `k_event_wait()`.

The following code builds on the example above, and waits up to 50 milliseconds for any of the specified events to be posted. A warning is issued if none of the events are posted in time.

```c
void consumer_thread(void)
{
    uint32_t events;
    
    events = k_event_wait(&my_event, 0xFFF, false, K_MSEC(50));
    if (events == 0) {
        printk("No input devices are available!");
    } else {
        ...
    }
}
```
Alternatively, the consumer thread may desire to wait for all the events before continuing.

```c
void consumer_thread(void)
{
    uint32_t events;

    events = k_event_wait_all(&my_event, 0x121, false, K_MSEC(50));
    if (events == 0) {
        printk("At least one input device is not available!");
    } else {
        /* Access the desired input devices */
    ... } ... 
}
```

**Suggested Uses**  Use events to indicate that a set of conditions have occurred.
Use events to pass small amounts of data to multiple threads at once.

**Configuration Options**  Related configuration options:
- CONFIG_EVENTS

**API Reference**

*group event_apis*

**Defines**

`K_EVENT_DEFINE(name)`

Statically define and initialize an event object.
The event can be accessed outside the module where it is defined using:

```c
extern struct k_event <name>;
```

**Parameters**

- `name` – Name of the event object.

**Functions**

`void k_event_init(struct k_event *event)`

Initialize an event object.
This routine initializes an event object, prior to its first use.

**Parameters**
• **event** – Address of the event object.

```c
uint32_t k_event_post(struct k_event *event, uint32_t events)
```

Post one or more events to an event object.

This routine posts one or more events to an event object. All tasks waiting on the event object `event` whose waiting conditions become met by this posting immediately unpend.

Posting differs from setting in that posted events are merged together with the current set of events tracked by the event object.

**Parameters**

• **event** – Address of the event object

• **events** – Set of events to post to `event`

**Return values**

- Previous – value of the events in `event`

```c
uint32_t k_event_set(struct k_event *event, uint32_t events)
```

Set the events in an event object.

This routine sets the events stored in event object to the specified value. All tasks waiting on the event object `event` whose waiting conditions become met by this immediately unpend.

Setting differs from posting in that set events replace the current set of events tracked by the event object.

**Parameters**

• **event** – Address of the event object

• **events** – Set of events to set in `event`

**Return values**

- Previous – value of the events in `event`

```c
uint32_t k_event_set_masked(struct k_event *event, uint32_t events, uint32_t events_mask)
```

Set or clear the events in an event object.

This routine sets the events stored in event object to the specified value. All tasks waiting on the event object `event` whose waiting conditions become met by this immediately unpend. Unlike `k_event_set`, this routine allows specific event bits to be set and cleared as determined by the mask.

**Parameters**

• **event** – Address of the event object

• **events** – Set of events to set/clear in `event`

• **events_mask** – Mask to be applied to `events`

**Return values**

- Previous – value of the events in `events_mask`

```c
uint32_t k_event_clear(struct k_event *event, uint32_t events)
```

Clear the events in an event object.

This routine clears (resets) the specified events stored in an event object.

**Parameters**

• **event** – Address of the event object

• **events** – Set of events to clear in `event`

**Return values**

- Previous – value of the events in `event`
uint32_t k_event_wait(struct k_event *event, uint32_t events, bool reset, k_timeout_t timeout)
    Wait for any of the specified events.

This routine waits on event object *event until any of the specified events have been delivered to the event object, or the maximum wait time *timeout has expired. A thread may wait on up to 32 distinctly numbered events that are expressed as bits in a single 32-bit word.

**Note:** The caller must be careful when resetting if there are multiple threads waiting for the event object *event.*

**Parameters**
- *event* – Address of the event object
- *events* – Set of desired events on which to wait
- *reset* – If true, clear the set of events tracked by the event object before waiting. If false, do not clear the events.
- *timeout* – Waiting period for the desired set of events or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**
- *set* – of matching events upon success
- 0 – if matching events were not received within the specified time

uint32_t k_event_wait_all(struct k_event *event, uint32_t events, bool reset, k_timeout_t timeout)
    Wait for all of the specified events.

This routine waits on event object *event until all of the specified events have been delivered to the event object, or the maximum wait time *timeout has expired. A thread may wait on up to 32 distinctly numbered events that are expressed as bits in a single 32-bit word.

**Note:** The caller must be careful when resetting if there are multiple threads waiting for the event object *event.*

**Parameters**
- *event* – Address of the event object
- *events* – Set of desired events on which to wait
- *reset* – If true, clear the set of events tracked by the event object before waiting. If false, do not clear the events.
- *timeout* – Waiting period for the desired set of events or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**
- *set* – of matching events upon success
- 0 – if matching events were not received within the specified time

static inline uint32_t k_event_test(struct k_event *event, uint32_t events_mask)
    Test the events currently tracked in the event object.

**Parameters**
- *event* – Address of the event object
events_mask – Set of desired events to test

Return values
Current – value of events in events_mask

struct k_event
#include <kernel.h> Event Structure.

Symmetric Multiprocessing

On multiprocessor architectures, Zephyr supports the use of multiple physical CPUs running Zephyr application code. This support is "symmetric" in the sense that no specific CPU is treated specially by default. Any processor is capable of running any Zephyr thread, with access to all standard Zephyr APIs supported.

No special application code needs to be written to take advantage of this feature. If there are two Zephyr application threads runnable on a supported dual processor device, they will both run simultaneously.

SMP configuration is controlled under the CONFIG_SMP kconfig variable. This must be set to "y" to enable SMP features, otherwise a uniprocessor kernel will be built. In general the platform default will have enabled this anywhere it's supported. When enabled, the number of physical CPUs available is visible at build time as CONFIG_MP_MAX_NUM_CPUS. Likewise, the default for this will be the number of available CPUs on the platform and it is not expected that typical apps will change it. But it is legal and supported to set this to a smaller (but obviously not larger) number for special purposes (e.g. for testing, or to reserve a physical CPU for running non-Zephyr code).

Synchronization

At the application level, core Zephyr IPC and synchronization primitives all behave identically under an SMP kernel. For example semaphores used to implement blocking mutual exclusion continue to be a proper application choice.

At the lowest level, however, Zephyr code has often used the irq_lock()/irq_unlock() primitives to implement fine grained critical sections using interrupt masking. These APIs continue to work via an emulation layer (see below), but the masking technique does not: the fact that your CPU will not be interrupted while you are in your critical section says nothing about whether a different CPU will be running simultaneously and be inspecting or modifying the same data!

Spinlocks

SMP systems provide a more constrained k_spin_lock() primitive that not only masks interrupts locally, as done by irq_lock(), but also atomically validates that a shared lock variable has been modified before returning to the caller, “spinning” on the check if needed to wait for the other CPU to exit the lock. The default Zephyr implementation of k_spin_lock() and k_spin_unlock() is built on top of the pre-existing atomic_layer (itself usually implemented using compiler intrinsics), though facilities exist for architectures to define their own for performance reasons.

One important difference between IRQ locks and spinlocks is that the earlier API was naturally recursive: the lock was global, so it was legal to acquire a nested lock inside of a critical section. Spinlocks are separable: you can have many locks for separate subsystems or data structures, preventing CPUs from contending on a single global resource. But that means that spinlocks must not be used recursively. Code that holds a specific lock must not try to re-acquire it or it will deadlock (it is perfectly legal to nest distinct spinlocks, however). A validation layer is available to detect and report bugs like this.

When used on a uniprocessor system, the data component of the spinlock (the atomic lock variable) is unnecessary and elided. Except for the recursive semantics above, spinlocks in single-CPU contexts produce identical code to legacy IRQ locks. In fact the entirety of the Zephyr core kernel has now been ported to use spinlocks exclusively.
Legacy irq_lock() emulation  For the benefit of applications written to the uniprocessor locking API, irq_lock() and irq_unlock() continue to work compatibly on SMP systems with identical semantics to their legacy versions. They are implemented as a single global spinlock, with a nesting count and the ability to be atomically reacquired on context switch into locked threads. The kernel will ensure that only one thread across all CPUs can hold the lock at any time, that it is released on context switch, and that it is re-acquired when necessary to restore the lock state when a thread is switched in. Other CPUs will spin waiting for the release to happen.

The overhead involved in this process has measurable performance impact, however. Unlike uniprocessor apps, SMP apps using irq_lock() are not simply invoking a very short (often ~1 instruction) interrupt masking operation. That, and the fact that the IRQ lock is global, means that code expecting to be run in an SMP context should be using the spinlock API wherever possible.

CPU Mask  It is often desirable for real time applications to deliberately partition work across physical CPUs instead of relying solely on the kernel scheduler to decide on which threads to execute. Zephyr provides an API, controlled by the CONFIG_SCHED_CPU_MASK kconfig variable, which can associate a specific set of CPUs with each thread, indicating on which CPUs it can run.

By default, new threads can run on any CPU. Calling k_thread_cpu_mask_disable() with a particular CPU ID will prevent that thread from running on that CPU in the future. Likewise k_thread_cpu_mask_enable() will re-enable execution. There are also k_thread_cpu_mask_clear() and k_thread_cpu_mask_enable_all() APIs available for convenience. For obvious reasons, these APIs are illegal if called on a runnable thread. The thread must be blocked or suspended, otherwise an -EINVAL will be returned.

Note that when this feature is enabled, the scheduler algorithm involved in doing the per-CPU mask test requires that the list be traversed in full. The kernel does not keep a per-CPU run queue. That means that the performance benefits from the CONFIG_SCHED_SCALABLE and CONFIG_SCHED_MULTIQ scheduler backends cannot be realized. CPU mask processing is available only when CONFIG_SCHED_DUMB is the selected backend. This requirement is enforced in the configuration layer.

SMP Boot Process  A Zephyr SMP kernel begins boot identically to a uniprocessor kernel. Auxiliary CPUs begin in a disabled state in the architecture layer. All standard kernel initialization, including device initialization, happens on a single CPU before other CPUs are brought online.

Just before entering the application main() function, the kernel calls z_smp_init() to launch the SMP initialization process. This enumerates over the configured CPUs, calling into the architecture layer using arch_start_cpu() for each one. This function is passed a memory region to use as a stack on the foreign CPU (in practice it uses the area that will become that CPU's interrupt stack), the address of a local smp_init_top() callback function to run on that CPU, and a pointer to a "start flag" address which will be used as an atomic signal.

The local SMP initialization (smp_init_top()) on each CPU is then invoked by the architecture layer. Note that interrupts are still masked at this point. This routine is responsible for calling smp_timer_init() to set up any needed stat in the timer driver. On many architectures the timer is a per-CPU device and needs to be configured specially on auxiliary CPUs. Then it waits (spinning) for the atomic "start flag" to be released in the main thread, to guarantee that all SMP initialization is complete before any Zephyr application code runs, and finally calls z_swap() to transfer control to the appropriate runnable thread via the standard scheduler API.

Interprocessor Interrupts  When running in multiprocessor environments, it is occasionally the case that state modified on the local CPU needs to be synchronously handled on a different processor.

One example is the Zephyr k_thread_abort() API, which cannot return until the thread that had been aborted is no longer runnable. If it is currently running on another CPU, that becomes difficult to implement.

Another is low power idle. It is a firm requirement on many devices that system idle be implemented using a low-power mode with as many interrupts (including periodic timer interrupts) disabled or deferred.
Fig. 1: Example SMP initialization process, showing a configuration with two CPUs and two app threads which begin operating simultaneously.
as is possible. If a CPU is in such a state, and on another CPU a thread becomes runnable, the idle CPU has no way to "wake up" to handle the newly-runnable load.

So where possible, Zephyr SMP architectures should implement an interprocessor interrupt. The current framework is very simple: the architecture provides a `arch_sched_ipi()` call, which when invoked will flag an interrupt on all CPUs (except the current one, though that is allowed behavior) which will then invoke the `z_sched_ipi()` function implemented in the scheduler. The expectation is that these APIs will evolve over time to encompass more functionality (e.g. cross-CPU calls), and that the scheduler-specific calls here will be implemented in terms of a more general framework.

Note that not all SMP architectures will have a usable IPI mechanism (either missing, or just undocumented/unimplemented). In those cases Zephyr provides fallback behavior that is correct, but perhaps suboptimal.

Using this, `k_thread_abort()` becomes only slightly more complicated in SMP: for the case where a thread is actually running on another CPU (we can detect this atomically inside the scheduler), we broadcast an IPI and spin, waiting for the thread to either become "DEAD" or for it to re-enter the queue (in which case we terminate it the same way we would have in uniprocessor mode). Note that the "aborted" check happens on any interrupt exit, so there is no special handling needed in the IPI per se. This allows us to implement a reasonable fallback when IPI is not available: we can simply spin, waiting until the foreign CPU receives any interrupt, though this may be a much longer time!

Likewise idle wakeups are trivially implementable with an empty IPI handler. If a thread is added to an empty run queue (i.e. there may have been idle CPUs), we broadcast an IPI. A foreign CPU will then be able to see the new thread when exiting from the interrupt and will switch to it if available.

Without an IPI, however, a low power idle that requires an interrupt will not work to synchronously run new threads. The workaround in that case is more invasive: Zephyr will not enter the system idle handler and will instead spin in its idle loop, testing the scheduler state at high frequency (not spinning on it though, as that would involve severe lock contention) for new threads. The expectation is that power constrained SMP applications are always going to provide an IPI, and this code will only be used for testing purposes or on systems without power consumption requirements.

**SMP Kernel Internals**  In general, Zephyr kernel code is SMP-agnostic and, like application code, will work correctly regardless of the number of CPUs available. But in a few areas there are notable changes in structure or behavior.

**Per-CPU data**  Many elements of the core kernel data need to be implemented for each CPU in SMP mode. For example, the `_current` thread pointer obviously needs to reflect what is running locally, there are many threads running concurrently. Likewise a kernel-provided interrupt stack needs to be created and assigned for each physical CPU, as does the interrupt nesting count used to detect ISR state.

These fields are now moved into a separate struct `_cpu` instance within the `_kernel` struct, which has a `cpus[]` array indexed by ID. Compatibility fields are provided for legacy uniprocessor code trying to access the fields of `cpus[0]` using the older syntax and assembly offsets.

Note that an important requirement on the architecture layer is that the pointer to this CPU struct be available rapidly when in kernel context. The expectation is that `arch_curr_cpu()` will be implemented using a CPU-provided register or addressing mode that can store this value across arbitrary context switches or interrupts and make it available to any kernel-mode code.

Similarly, where on a uniprocessor system Zephyr could simply create a global "idle thread" at the lowest priority, in SMP we may need one for each CPU. This makes the internal predicate test for "is_idle()" in the scheduler, which is a hot path performance environment, more complicated than simply testing the thread pointer for equality with a known static variable. In SMP mode, idle threads are distinguished by a separate field in the thread struct.

**Switch-based context switching**  The traditional Zephyr context switch primitive has been `z_swap()`. Unfortunately, this function takes no argument specifying a thread to switch to. The expectation has always been that the scheduler has already made its preemption decision when its state was last modified
and cached the resulting “next thread” pointer in a location where architecture context switch primitives can find it via a simple struct offset. That technique will not work in SMP, because the other CPU may have modified scheduler state since the current CPU last exited the scheduler (for example: it might already be running that cached thread!).

Instead, the SMP “switch to” decision needs to be made synchronously with the swap call, and as we don’t want per-architecture assembly code to be handling scheduler internal state, Zephyr requires a somewhat lower-level context switch primitives for SMP systems: arch_switch() is always called with interrupts masked, and takes exactly two arguments. The first is an opaque (architecture defined) handle to the context to which it should switch, and the second is a pointer to such a handle into which it should store the handle resulting from the thread that is being switched out. The kernel then implements a portable z_swap() implementation on top of this primitive which includes the relevant scheduler logic in a location where the architecture doesn’t need to understand it.

Similarly, on interrupt exit, switch-based architectures are expected to call z_get_next_switch_handle() to retrieve the next thread to run from the scheduler. The argument to z_get_next_switch_handle() is either the interrupted thread’s “handle” reflecting the same opaque type used by arch_switch(), or NULL if that thread cannot be released to the scheduler just yet. The choice between a handle value or NULL depends on the way CPU interrupt mode is implemented.

Architectures with a large CPU register file would typically preserve only the caller-saved registers on the current thread’s stack when interrupted in order to minimize interrupt latency, and preserve the callee-saved registers only when arch_switch() is called to minimize context switching latency. Such architectures must use NULL as the argument to z_get_next_switch_handle() to determine if there is a new thread to schedule, and follow through with their own arch_switch() or derivative if so, or directly leave interrupt mode otherwise. In the former case it is up to that switch code to store the handle resulting from the thread that is being switched out in that thread’s “switch_handle” field after its context has fully been saved.

Architectures whose entry in interrupt mode already preserves the entire thread state may pass that thread’s handle directly to z_get_next_switch_handle() and be done in one step.

Note that while SMP requires CONFIG_USE_SWITCH, the reverse is not true. A uniprocessor architecture built with CONFIG_SMP set to No might still decide to implement its context switching using arch_switch().

API Reference

group spinlock_apis
   Spinlock APIs.

Defines

K_SPINLOCK_BREAK
   Leaves a code block guarded with K_SPINLOCK after releasing the lock.
   See K_SPINLOCK for details.

K_SPINLOCK(lck)
   Guards a code block with the given spinlock, automatically acquiring the lock before executing the code block.
   The lock will be released either when reaching the end of the code block or when leaving the block with K_SPINLOCK_BREAK.
   Example usage:

   K_SPINLOCK(&mylock) {
   
   }
...execute statements with the lock held...

if (some_condition) {
    ...release the lock and leave the guarded section prematurely:
    K_SPINLOCK_BREAK;
}

...execute statements with the lock held...
}

Behind the scenes this pattern expands to a for-loop whose body is executed exactly once:

for (k_spinlock_key_t key = k_spin_lock(&mylock); ...; k_spin_unlock(&mylock, ...
    key)) {
    ...
}

**Note:** In user mode the spinlock must be placed in memory accessible to the application, see K_APP_DMEM and K_APP_BMEM macros for details.

**Warning:** The code block must execute to its end or be left by calling K_SPINLOCK_BREAK. Otherwise, e.g. if exiting the block with a break, goto or return statement, the spinlock will not be released on exit.

**Parameters**

- `lck` – Spinlock used to guard the enclosed code block.

**Typedefs**

typedef struct z_spinlock_key k_spinlock_key_t
Spinlock key type.

This type defines a “key” value used by a spinlock implementation to store the system interrupt state at the time of a call to `k_spin_lock()`. It is expected to be passed to a matching `k_spin_unlock()`.

This type is opaque and should not be inspected by application code.

**Functions**

**ALWAYS_INLINE static** k_spinlock_key_t k_spin_lock(struct k_spinlock *l)
Lock a spinlock.

This routine locks the specified spinlock, returning a key handle representing interrupt state needed at unlock time. Upon returning, the calling thread is guaranteed not to be suspended or interrupted on its current CPU until it calls `k_spin_unlock()`. The implementation guarantees mutual exclusion: exactly one thread on one CPU will return from `k_spin_lock()` at a time. Other CPUs trying to acquire a lock already held by another CPU will enter an implementation-defined busy loop (“spinning”) until the lock is released.
Separate spin locks may be nested. It is legal to lock an (unlocked) spin lock while holding a different lock. Spin locks are not recursive, however: an attempt to acquire a spin lock that the CPU already holds will deadlock.

In circumstances where only one CPU exists, the behavior of \texttt{k\_spin\_lock()} remains as specified above, though obviously no spinning will take place. Implementations may be free to optimize in uniprocessor contexts such that the locking reduces to an interrupt mask operation.

**Parameters**

- \(l\) – A pointer to the spinlock to lock

**Returns**

A key value that must be passed to \texttt{k\_spin\_unlock()} when the lock is released.

```c
ALWAYS_INLINE static int k_spin_trylock(struct k_spinlock *l, k_spinlock_key_t *k)
```

Attempt to lock a spinlock.

This routine makes one attempt to lock \(l\). If it is successful, then it will store the key into \(k\).

**See also:**

- \texttt{k\_spin\_lock}
- \texttt{k\_spin\_unlock}

**Parameters**

- \(l\) – [in] A pointer to the spinlock to lock
- \(k\) – [out] A pointer to the spinlock key

**Return values**

- 0 – on success
- -EBUSY – if another thread holds the lock

```c
ALWAYS_INLINE static void k_unlock(struct k_spinlock *l, k_spinlock_key_t key)
```

Unlock a spin lock.

This releases a lock acquired by \texttt{k\_spin\_lock()}. After this function is called, any CPU will be able to acquire the lock. If other CPUs are currently spinning inside \texttt{k\_spin\_lock()} waiting for this lock, exactly one of them will return synchronously with the lock held.

Spin locks must be properly nested. A call to \texttt{k\_spin\_unlock()} must be made on the lock object most recently locked using \texttt{k\_spin\_lock()}, using the key value that it returned. Attempts to unlock mis-nested locks, or to unlock locks that are not held, or to passing a key parameter other than the one returned from \texttt{k\_spin\_lock()}, are illegal. When CONFIG\_SPIN\_VALIDATE is set, some of these errors can be detected by the framework.

**Parameters**

- \(l\) – A pointer to the spinlock to release
- \(key\) – The value returned from \texttt{k\_spin\_lock()} when this lock was acquired

```c
struct k_spinlock
#include <spinlock.h> Kernel Spin Lock.
```

This struct defines a spin lock record on which CPUs can wait with \texttt{k\_spin\_lock()}. Any number of spinlocks may be defined in application code.
### 3.1.2 Data Passing

These pages cover kernel objects which can be used to pass data between threads and ISRs. The following table summarizes their high-level features.

<table>
<thead>
<tr>
<th>Object</th>
<th>Bidirectional?</th>
<th>Data structure</th>
<th>Data item size</th>
<th>Data Alignment</th>
<th>ISRs can receive?</th>
<th>ISRs can send?</th>
<th>Overrun handling</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stack</td>
<td>No</td>
<td>Array</td>
<td>Word</td>
<td>Word</td>
<td>Yes [3]</td>
<td>Yes</td>
<td>Undefined behavior</td>
</tr>
<tr>
<td>Mailbox</td>
<td>Yes</td>
<td>Queue</td>
<td>Arbitrary [1]</td>
<td>Arbitrary</td>
<td>No</td>
<td>No</td>
<td>N/A</td>
</tr>
</tbody>
</table>

[1] Callers allocate space for queue overhead in the data elements themselves.

[2] Objects added with k_fifo_alloc_put() and k_lifo_alloc_put() do not have alignment constraints, but use temporary memory from the calling thread’s resource pool.

[3] ISRs can receive only when passing K_NO_WAIT as the timeout argument.

[5] ISRs can send and/or receive only when passing K_NO_WAIT as the timeout argument.

[6] Data item size must be a multiple of the data alignment.

---

## Queues

A Queue in Zephyr is a kernel object that implements a traditional queue, allowing threads and ISRs to add and remove data items of any size. The queue is similar to a FIFO and serves as the underlying implementation for both `k_fifo` and `k_lifo`. For more information on usage see `k_fifo`.

### Configuration Options

Related configuration options:

- None

### API Reference

`group queue_apis`

**Defines**

`K_QUEUE_DEFINE(name)`

Statically define and initialize a queue.

The queue can be accessed outside the module where it is defined using:
extern struct k_queue <name>;

Parameters

- name – Name of the queue.

Functions

void k_queue_init(struct k_queue *queue)
Initialize a queue.
This routine initializes a queue object, prior to its first use.

Parameters

- queue – Address of the queue.

void k_queue_cancel_wait(struct k_queue *queue)
Cancel waiting on a queue.
This routine causes first thread pending on queue, if any, to return from k_queue_get() call with NULL value (as if timeout expired). If the queue is being waited on by k_poll(), it will return with -EINTR and K_POLL_STATE_CANCELLED state (and per above, subsequent k_queue_get() will return NULL).

Function properties (list may not be complete)

isr-ok

Parameters

- queue – Address of the queue.

void k_queue_append(struct k_queue *queue, void *data)
Append an element to the end of a queue.
This routine appends a data item to queue. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

Function properties (list may not be complete)

isr-ok

Parameters

- queue – Address of the queue.
- data – Address of the data item.

int32_t k_queue_alloc_append(struct k_queue *queue, void *data)
Append an element to a queue.
This routine appends a data item to queue. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete)

isr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

Return values
• 0 – on success
• -ENOMEM – if there isn’t sufficient RAM in the caller’s resource pool

void k_queue_prepend(struct k_queue *queue, void *data)
Prepend an element to a queue.

This routine prepends a data item to queue. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel’s use.

Function properties (list may not be complete)

isr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

int32_t k_queue_alloc_prepend(struct k_queue *queue, void *data)
Prepend an element to a queue.

This routine prepends a data item to queue. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread’s resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete)

isr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

Return values
• 0 – on success
• -ENOMEM – if there isn’t sufficient RAM in the caller’s resource pool

void k_queue_insert(struct k_queue *queue, void *prev, void *data)
Inserts an element to a queue.

This routine inserts a data item to queue after previous item. A queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel’s use.

Function properties (list may not be complete)

isr-ok

Parameters
• queue – Address of the queue.
• prev – Address of the previous data item.
• data – Address of the data item.
int k_queue_append_list(struct k_queue *queue, void *head, void *tail)
Atomically append a list of elements to a queue.
This routine adds a list of data items to queue in one operation. The data items must be in a singly-linked list, with the first word in each data item pointing to the next data item; the list must be NULL-terminated.

**Function properties (list may not be complete)**
*isr-ok*

**Parameters**
- queue – Address of the queue.
- head – Pointer to first node in singly-linked list.
- tail – Pointer to last node in singly-linked list.

**Return values**
- 0 – on success
- -EINVAL – on invalid supplied data

int k_queue_merge_slist(struct k_queue *queue, sys_slist_t *list)
Atomically add a list of elements to a queue.
This routine adds a list of data items to queue in one operation. The data items must be in a singly-linked list implemented using a sys_slist_t object. Upon completion, the original list is empty.

**Function properties (list may not be complete)**
*isr-ok*

**Parameters**
- queue – Address of the queue.
- list – Pointer to sys_slist_t object.

**Return values**
- 0 – on success
- -EINVAL – on invalid data

void *k_queue_get(struct k_queue *queue, k_timeout_t timeout)
Get an element from a queue.
This routine removes first data item from queue. The first word of the data item is reserved for the kernel's use.

**Function properties (list may not be complete)**
*isr-ok*

**Note:** timeout must be set to K_NO_WAIT if called from ISR.

**Parameters**
- queue – Address of the queue.
• timeout – Non-negative waiting period to obtain a data item or one of the special values K_NO_WAIT and K_FOREVER.

Returns
Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

bool k_queue_remove(struct k_queue *queue, void *data)
Remove an element from a queue.

This routine removes data item from queue. The first word of the data item is reserved for the kernel's use. Removing elements from k_queue rely on sys_slist_find_and_remove which is not a constant time operation.

Function properties (list may not be complete)
isr-ok

Note: timeout must be set to K_NO_WAIT if called from ISR.

Parameters
• queue – Address of the queue.
• data – Address of the data item.

Returns
true if data item was removed

bool k_queue_unique_append(struct k_queue *queue, void *data)
Append an element to a queue only if it's not present already.

This routine appends data item to queue. The first word of the data item is reserved for the kernel's use. Appending elements to k_queue relies on sys_slist_is_node_in_list which is not a constant time operation.

Function properties (list may not be complete)
isr-ok

Parameters
• queue – Address of the queue.
• data – Address of the data item.

Returns
true if data item was added, false if not

int k_queue_is_empty(struct k_queue *queue)
Query a queue to see if it has data available.

Note that the data might be already gone by the time this function returns if other threads are also trying to read from the queue.

Function properties (list may not be complete)
isr-ok

Parameters
• *queue – Address of the queue.

**Returns**

Non-zero if the queue is empty.

**Returns**

0 if data is available.

```c
void *k_queue_peek_head(struct k_queue *queue)
```

Peek element at the head of queue.

Return element from the head of queue without removing it.

**Parameters**

• *queue – Address of the queue.

**Returns**

Head element, or NULL if queue is empty.

```c
void *k_queue_peek_tail(struct k_queue *queue)
```

Peek element at the tail of queue.

Return element from the tail of queue without removing it.

**Parameters**

• *queue – Address of the queue.

**Returns**

Tail element, or NULL if queue is empty.

### FIFOs

A **FIFO** is a kernel object that implements a traditional first in, first out (FIFO) queue, allowing threads and ISRs to add and remove data items of any size.

- **Concepts**
- **Implementation**
  - Defining a FIFO
  - Writing to a FIFO
  - Reading from a FIFO
- **Suggested Uses**
- **Configuration Options**
- **API Reference**

**Concepts** Any number of FIFOs can be defined (limited only by available RAM). Each FIFO is referenced by its memory address.

A FIFO has the following key properties:

- A **queue** of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A FIFO must be initialized before it can be used. This sets its queue to empty.

FIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes
of application data requires $N+4$ (or $N+8$) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_fifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread's resource pool.

**Note:** FIFO data items are restricted to single active instance across all FIFO data queues. Any attempt to re-add a FIFO data item to a queue before it has been removed from the queue to which it was previously added will result in undefined behavior.

A data item may be **added** to a FIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the FIFO's queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a FIFO by a thread. If the FIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty FIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

**Note:** The kernel does allow an ISR to remove an item from a FIFO, however the ISR must not attempt to wait if the FIFO is empty.

If desired, **multiple data items** can be added to a FIFO in a single operation if they are chained together into a singly-linked list. This capability can be useful if multiple writers are adding sets of related data items to the FIFO, as it ensures the data items in each set are not interleaved with other data items. Adding multiple data items to a FIFO is also more efficient than adding them one at a time, and can be used to guarantee that anyone who removes the first data item in a set will be able to remove the remaining data items without waiting.

**Implementation**

**Defining a FIFO** A FIFO is defined using a variable of type `k_fifo`. It must then be initialized by calling `k_fifo_init()`.

The following code defines and initializes an empty FIFO.

```c
struct k_fifo my_fifo;
k_fifo_init(&my_fifo);
```

Alternatively, an empty FIFO can be defined and initialized at compile time by calling `K_FIFO_DEFINE`. The following code has the same effect as the code segment above.

```c
K_FIFO_DEFINE(my_fifo);
```

**Writing to a FIFO** A data item is added to a FIFO by calling `k_fifo_put()`.

The following code builds on the example above, and uses the FIFO to send data to one or more consumer threads.

```c
struct data_item_t {
    void *fifo_reserved; /* 1st word reserved for use by FIFO */
    ...
};

struct data_item_t tx_data;
```

(continues on next page)
void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...

        /* send data to consumers */
        k_fifo_put(&my_fifo, &tx_data);

        ...
    }
}

Additionally, a singly-linked list of data items can be added to a FIFO by calling \texttt{k_fifo_put_list()} or \texttt{k_fifo_put_slist()}.

Finally, a data item can be added to a FIFO with \texttt{k_fifo_alloc_put()}. With this API, there is no need to reserve space for the kernel's use in the data item, instead additional memory will be allocated from the calling thread's resource pool until the item is read.

Reading from a FIFO A data item is removed from a FIFO by calling \texttt{k_fifo_get()}. The following code builds on the example above, and uses the FIFO to obtain data items from a producer thread, which are then processed in some manner.

void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t *rx_data;

    while (1) {
        rx_data = k_fifo_get(&my_fifo, K_FOREVER);

        /* process FIFO data item */
        ...
    }
}

Suggested Uses Use a FIFO to asynchronously transfer data items of arbitrary size in a “first in, first out” manner.

Configuration Options Related configuration options:

- None

API Reference

group fifo_apis

Defines

\texttt{k_fifo_init(fifo)}

Initialize a FIFO queue.

This routine initializes a FIFO queue, prior to its first use.
Parameters

- `fifo` – Address of the FIFO queue.

```c
k_fifo_cancel_wait(fifo)
```

Cancel waiting on a FIFO queue.

This routine causes first thread pending on `fifo`, if any, to return from `k_fifo_get()` call with NULL value (as if timeout expired).

**Function properties (list may not be complete)**

* `isr-ok`

Parameters

- `fifo` – Address of the FIFO queue.

```c
k_fifo_put(fifo, data)
```

Add an element to a FIFO queue.

This routine adds a data item to `fifo`. A FIFO data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel’s use.

**Function properties (list may not be complete)**

* `isr-ok`

Parameters

- `fifo` – Address of the FIFO.
- `data` – Address of the data item.

```c
k_fifo_alloc_put(fifo, data)
```

Add an element to a FIFO queue.

This routine adds a data item to `fifo`. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread’s resource pool, which is automatically freed when the item is removed. The data itself is not copied.

**Function properties (list may not be complete)**

* `isr-ok`

Parameters

- `fifo` – Address of the FIFO.
- `data` – Address of the data item.

Return values

- `0` – on success
- `-ENOMEM` – if there isn’t sufficient RAM in the caller’s resource pool

```c
k_fifo_put_list(fifo, head, tail)
```

Atomically add a list of elements to a FIFO.

This routine adds a list of data items to `fifo` in one operation. The data items must be in a singly-linked list, with the first word of each data item pointing to the next data item; the list must be NULL-terminated.
Function properties (list may not be complete)
  \textit{isr-ok}

Parameters
  \begin{itemize}
  \item \texttt{fifo} – Address of the FIFO queue.
  \item \texttt{head} – Pointer to first node in singly-linked list.
  \item \texttt{tail} – Pointer to last node in singly-linked list.
  \end{itemize}

\texttt{k_fifo_put_slist(fifo, list)}

Atomically add a list of elements to a FIFO queue.

This routine adds a list of data items to \texttt{fifo} in one operation. The data items must be in a singly-linked list implemented using a \texttt{sys\_slist\_t} object. Upon completion, the \texttt{sys\_slist\_t} object is invalid and must be re-initialized via \texttt{sys\_slist\_init()}. 

Function properties (list may not be complete)
  \textit{isr-ok}

Parameters
  \begin{itemize}
  \item \texttt{fifo} – Address of the FIFO queue.
  \item \texttt{list} – Pointer to \texttt{sys\_slist\_t} object.
  \end{itemize}

\texttt{k_fifo_get(fifo, timeout)}

Get an element from a FIFO queue.

This routine removes a data item from \texttt{fifo} in a “first in, first out” manner. The first word of the data item is reserved for the kernel’s use.

Function properties (list may not be complete)
  \textit{isr-ok}

\underline{Note:} \texttt{timeout} must be set to \texttt{K\_NO\_WAIT} if called from ISR.

Parameters
  \begin{itemize}
  \item \texttt{fifo} – Address of the FIFO queue.
  \item \texttt{timeout} – Waiting period to obtain a data item, or one of the special values \texttt{K\_NO\_WAIT} and \texttt{K\_FOREVER}.
  \end{itemize}

Returns
  Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

\texttt{k_fifo_is_empty(fifo)}

Query a FIFO queue to see if it has data available.

Note that the data might be already gone by the time this function returns if other threads is also trying to read from the FIFO.
Parameters

- fifo – Address of the FIFO queue.

Returns
Non-zero if the FIFO queue is empty.

Returns
0 if data is available.

k_fifo_peek_head(fifo)

Peek element at the head of a FIFO queue.
Return element from the head of FIFO queue without removing it. A use case for this is if elements of the FIFO object are themselves containers. Then on each iteration of processing, a head container will be peeked, and some data processed out of it, and only if the container is empty, it will be completely remove from the FIFO queue.

Parameters

- fifo – Address of the FIFO queue.

Returns
Head element, or NULL if the FIFO queue is empty.

k_fifo_peek_tail(fifo)

Peek element at the tail of FIFO queue.
Return element from the tail of FIFO queue (without removing it). A use case for this is if elements of the FIFO queue are themselves containers. Then it may be useful to add more data to the last container in a FIFO queue.

Parameters

- fifo – Address of the FIFO queue.

Returns
Tail element, or NULL if a FIFO queue is empty.

K_FIFO_DEFINE(name)

Statically define and initialize a FIFO queue.
The FIFO queue can be accessed outside the module where it is defined using:

```
extern struct k_fifo <name>;
```

Parameters

- name – Name of the FIFO queue.

LIFOs

A LIFO is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove data items of any size.
Concepts  Any number of LIFOs can be defined (limited only by available RAM). Each LIFO is referenced by its memory address.

A LIFO has the following key properties:

- A **queue** of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A LIFO must be initialized before it can be used. This sets its queue to empty.

LIFO data items must be aligned on a word boundary, as the kernel reserves the first word of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_lifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread’s resource pool.

**Note:** LIFO data items are restricted to single active instance across all LIFO data queues. Any attempt to re-add a LIFO data item to a queue before it has been removed from the queue to which it was previously added will result in undefined behavior.

A data item may be **added** to a LIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the LIFO’s queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a LIFO by a thread. If the LIFO’s queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty LIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

**Note:** The kernel does allow an ISR to remove an item from a LIFO, however the ISR must not attempt to wait if the LIFO is empty.

Implementation

**Defining a LIFO**

A LIFO is defined using a variable of type `k_lifo`. It must then be initialized by calling `k_lifo_init()`.

The following defines and initializes an empty LIFO.

```c
struct k_lifo my_lifo;

k_lifo_init(&my_lifo);
```

Alternatively, an empty LIFO can be defined and initialized at compile time by calling `K_LIFO_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_LIFO_DEFINE(my_lifo);
```
Writing to a LIFO  A data item is added to a LIFO by calling `k_lifo_put()`. The following code builds on the example above, and uses the LIFO to send data to one or more consumer threads.

```c
struct data_item_t {
    void *LIFO_reserved; /* 1st word reserved for use by LIFO */
    ...
};

struct data_item_t tx_data;

void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...

        /* send data to consumers */
        k_lifo_put(&my_lifo, &tx_data);

        ...
    }
}
```

A data item can be added to a LIFO with `k_lifo_alloc_put()`. With this API, there is no need to reserve space for the kernel's use in the data item, instead additional memory will be allocated from the calling thread's resource pool until the item is read.

Reading from a LIFO  A data item is removed from a LIFO by calling `k_lifo_get()`. The following code builds on the example above, and uses the LIFO to obtain data items from a producer thread, which are then processed in some manner.

```c
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t *rx_data;

    while (1) {
        /* process LIFO data item */
        rx_data = k_lifo_get(&my_lifo, K_FOREVER);

        /* process LIFO data item */
        ...
    }
}
```

Suggested Uses  Use a LIFO to asynchronously transfer data items of arbitrary size in a “last in, first out” manner.

Configuration Options  Related configuration options:

- None.

API Reference

group lifo_apis
Defines

k_lifo_init(lifo)
Initialize a LIFO queue.
This routine initializes a LIFO queue object, prior to its first use.

Parameters
• lifo – Address of the LIFO queue.

k_lifo_put(lifo, data)
Add an element to a LIFO queue.
This routine adds a data item to lifo. A LIFO queue data item must be aligned on a word boundary, and the first word of the item is reserved for the kernel's use.

Function properties (list may not be complete)
isr-ok

Parameters
• lifo – Address of the LIFO queue.
• data – Address of the data item.

k_lifo_alloc_put(lifo, data)
Add an element to a LIFO queue.
This routine adds a data item to lifo. There is an implicit memory allocation to create an additional temporary bookkeeping data structure from the calling thread's resource pool, which is automatically freed when the item is removed. The data itself is not copied.

Function properties (list may not be complete)
isr-ok

Parameters
• lifo – Address of the LIFO.
• data – Address of the data item.

Return values
• 0 – on success
• -ENOMEM – if there isn't sufficient RAM in the caller's resource pool

k_lifo_get(lifo, timeout)
Get an element from a LIFO queue.
This routine removes a data item from LIFO in a “last in, first out” manner. The first word of the data item is reserved for the kernel's use.

Function properties (list may not be complete)
isr-ok

Note: timeout must be set to K_NO_WAIT if called from ISR.
• \texttt{lifo} – Address of the LIFO queue.
• \texttt{timeout} – Waiting period to obtain a data item, or one of the special values \texttt{K\_NO\_WAIT} and \texttt{K\_FOREVER}.

\textbf{Returns}
Address of the data item if successful; NULL if returned without waiting, or waiting period timed out.

\texttt{K\_LIFO\_DEFINE(name)}
Statically define and initialize a LIFO queue.
The LIFO queue can be accessed outside the module where it is defined using:

\begin{verbatim}
extern struct k_lifo <name>;
\end{verbatim}

\textbf{Parameters}
• \texttt{name} – Name of the fifo.

\textbf{Stacks}
A stack is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove a limited number of integer data values.

\begin{itemize}
\item \textbf{Concepts}
\item \textbf{Implementation}
\begin{itemize}
\item \textit{Defining a Stack}
\item \textit{Pushing to a Stack}
\item \textit{Popping from a Stack}
\end{itemize}
\item \textbf{Suggested Uses}
\item \textbf{Configuration Options}
\item \textbf{API Reference}
\end{itemize}

\textbf{Concepts} Any number of stacks can be defined (limited only by available RAM). Each stack is referenced by its memory address.

A stack has the following key properties:

• A \textbf{queue} of integer data values that have been added but not yet removed. The queue is implemented using an array of stack\_data\_t values and must be aligned on a native word boundary. The stack\_data\_t type corresponds to the native word size i.e. 32 bits or 64 bits depending on the CPU architecture and compilation mode.

• A \textbf{maximum quantity} of data values that can be queued in the array.

A stack must be initialized before it can be used. This sets its queue to empty.

A data value can be \texttt{added} to a stack by a thread or an ISR. The value is given directly to a waiting thread, if one exists; otherwise the value is added to the LIFO’s queue.

\textbf{Note}: If \texttt{CONFIG\_NO\_RUNTIME\_CHECKS} is enabled, the kernel will \textit{not} detect and prevent attempts to add a data value to a stack that has already reached its maximum quantity of queued values. Adding a data value to a stack that is already full will result in array overflow, and lead to unpredictable behavior.
A data value may be **removed** from a stack by a thread. If the stack’s queue is empty a thread may choose to wait for it to be given. Any number of threads may wait on an empty stack simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

**Note:** The kernel does allow an ISR to remove an item from a stack, however the ISR must not attempt to wait if the stack is empty.

### Implementation

**Defining a Stack**  A stack is defined using a variable of type `k_stack`. It must then be initialized by calling `k_stack_init()` or `k_stack_alloc_init()`. In the latter case, a buffer is not provided and it is instead allocated from the calling thread’s resource pool.

The following code defines and initializes an empty stack capable of holding up to ten word-sized data values.

```c
#define MAX_ITEMS 10
stack_data_t my_stack_array[MAX_ITEMS];
struct k_stack my_stack;
k_stack_init(&my_stack, my_stack_array, MAX_ITEMS);
```

Alternatively, a stack can be defined and initialized at compile time by calling `K_STACK_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the stack and its array of data values.

```c
K_STACK_DEFINE(my_stack, MAX_ITEMS);
```

**Pushing to a Stack**  A data item is added to a stack by calling `k_stack_push()`.

The following code builds on the example above, and shows how a thread can create a pool of data structures by saving their memory addresses in a stack.

```c
/* define array of data structures */
struct my_buffer_type {
    int field1;
    ...
};
struct my_buffer_type my_buffers[MAX_ITEMS];

/* save address of each data structure in a stack */
for (int i = 0; i < MAX_ITEMS; i++) {
    k_stack_push(&my_stack, (stack_data_t)&my_buffers[i]);
}
```

**Popping from a Stack**  A data item is taken from a stack by calling `k_stack_pop()`.

The following code builds on the example above, and shows how a thread can dynamically allocate an unused data structure. When the data structure is no longer required, the thread must push its address back on the stack to allow the data structure to be reused.
```c
struct my_buffer_type *new_buffer;
k_stack_pop(&buffer_stack, (stack_data_t *)&new_buffer, K_FOREVER);
new_buffer->field1 = ...;
```

**Suggested Uses**  Use a stack to store and retrieve integer data values in a “last in, first out” manner, when the maximum number of stored items is known.

**Configuration Options**  Related configuration options:

- None.

**API Reference**

group stack_apis

**Defines**

K_STACK_DEFINE(name, stack_num_entries)

Statically define and initialize a stack.

The stack can be accessed outside the module where it is defined using:

```c
extern struct k_stack <name>;
```

**Parameters**

- name – Name of the stack.
- stack_num_entries – Maximum number of values that can be stacked.

**Functions**

void k_stack_init(struct k_stack *stack, stack_data_t *buffer, uint32_t num_entries)

Initialize a stack.

This routine initializes a stack object, prior to its first use.

**Parameters**

- stack – Address of the stack.
- buffer – Address of array used to hold stacked values.
- num_entries – Maximum number of values that can be stacked.

int32_t k_stack_alloc_init(struct k_stack *stack, uint32_t num_entries)

Initialize a stack.

This routine initializes a stack object, prior to its first use. Internal buffers will be allocated from the calling thread's resource pool. This memory will be released if k_stack_cleanup() is called, or userspace is enabled and the stack object loses all references to it.

**Parameters**

- stack – Address of the stack.
- num_entries – Maximum number of values that can be stacked.
Returns
-ENOMEM if memory couldn’t be allocated

int k_stack_cleanup(struct k_stack *stack)
Release a stack’s allocated buffer.
If a stack object was given a dynamically allocated buffer via \texttt{k_stack_alloc_init()}, this will free it. This function does nothing if the buffer wasn’t dynamically allocated.

Parameters
• \texttt{stack} – Address of the stack.

Return values
• 0 – on success
• -EAGAIN – when object is still in use

int k_stack_push(struct k_stack *stack, stack_data_t data)
Push an element onto a stack.
This routine adds a stack\_data\_t value \texttt{data} to \texttt{stack}.

Function properties (list may not be complete)
isr-ok

Parameters
• \texttt{stack} – Address of the stack.
• \texttt{data} – Value to push onto the stack.

Return values
• 0 – on success
• -ENOMEM – if stack is full

int k_stack_pop(struct k_stack *stack, stack_data_t *data, k_timeout_t timeout)
Pop an element from a stack.
This routine removes a stack\_data\_t value from \texttt{stack} in a “last in, first out” manner and stores the value in \texttt{data}.

Function properties (list may not be complete)
isr-ok

Note: \texttt{timeout} must be set to K\_NO\_WAIT if called from ISR.

Parameters
• \texttt{stack} – Address of the stack.
• \texttt{data} – Address of area to hold the value popped from the stack.
• \texttt{timeout} – Waiting period to obtain a value, or one of the special values K\_NO\_WAIT and K\_FOREVER.

Return values
• 0 – Element popped from stack.
• EBUSY – Returned without waiting.
Message Queues

A message queue is a kernel object that implements a simple message queue, allowing threads and ISRs to asynchronously send and receive fixed-size data items.

- **Concepts**
- **Implementation**
  - Defining a Message Queue
  - Writing to a Message Queue
  - Reading from a Message Queue
  - Peeking into a Message Queue
- **Suggested Uses**
- **Configuration Options**
- **API Reference**

**Concepts**  Any number of message queues can be defined (limited only by available RAM). Each message queue is referenced by its memory address.

A message queue has the following key properties:

- A **ring buffer** of data items that have been sent but not yet received.
- A **data item size**, measured in bytes.
- A **maximum quantity** of data items that can be queued in the ring buffer.

A message queue must be initialized before it can be used. This sets its ring buffer to empty.

A data item can be **sent** to a message queue by a thread or an ISR. The data item pointed at by the sending thread is copied to a waiting thread, if one exists; otherwise the item is copied to the message queue's ring buffer, if space is available. In either case, the size of the data area being sent **must** equal the message queue's data item size.

If a thread attempts to send a data item when the ring buffer is full, the sending thread may choose to wait for space to become available. Any number of sending threads may wait simultaneously when the ring buffer is full; when space becomes available it is given to the highest priority sending thread that has waited the longest.

A data item can be **received** from a message queue by a thread. The data item is copied to the area specified by the receiving thread; the size of the receiving area **must** equal the message queue's data item size.

If a thread attempts to receive a data item when the ring buffer is empty, the receiving thread may choose to wait for a data item to be sent. Any number of receiving threads may wait simultaneously when the ring buffer is empty; when a data item becomes available it is given to the highest priority receiving thread that has waited the longest.

A thread can also **peek** at the message on the head of a message queue without removing it from the queue. The data item is copied to the area specified by the receiving thread; the size of the receiving area **must** equal the message queue's data item size.

---

**Note:** The kernel does allow an ISR to receive an item from a message queue, however the ISR must not attempt to wait if the message queue is empty.
Note: Alignment of the message queue's ring buffer is not necessary. The underlying implementation uses `memcpy()` (which is alignment-agnostic) and does not expose any internal pointers.

Implementation

Defining a Message Queue  A message queue is defined using a variable of type `k_msgq`. It must then be initialized by calling `k_msgq_init()`.

The following code defines and initializes an empty message queue that is capable of holding 10 items, each of which is 12 bytes long.

```c
struct data_item_type {
    uint32_t field1;
    uint32_t field2;
    uint32_t field3;
};
char my_msgq_buffer[10 * sizeof(struct data_item_type)];
struct k_msgq my_msgq;
k_msgq_init(&my_msgq, my_msgq_buffer, sizeof(struct data_item_type), 10);
```

Alternatively, a message queue can be defined and initialized at compile time by calling `K_MSGQ_DEFINE`. The following code has the same effect as the code segment above. Observe that the macro defines both the message queue and its buffer.

```c
K_MSGQ_DEFINE(my_msgq, sizeof(struct data_item_type), 10, 1);
```

Writing to a Message Queue  A data item is added to a message queue by calling `k_msgq_put()`.

The following code builds on the example above, and uses the message queue to pass data items from a producing thread to one or more consuming threads. If the message queue fills up because the consumers can't keep up, the producing thread throws away all existing data so the newer data can be saved.

```c
void producer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* create data item to send (e.g. measurement, timestamp, ...) */
        data = ...;

        /* send data to consumers */
        while (k_msgq_put(&my_msgq, &data, K_NO_WAIT) != 0) {
            /* message queue is full: purge old data & try again */
            k_msgq_purge(&my_msgq);
        }

        /* data item was successfully added to message queue */
    }
}
```
Reading from a Message Queue  A data item is taken from a message queue by calling `k_msgq_get()`. The following code builds on the example above, and uses the message queue to process data items generated by one or more producing threads. Note that the return value of `k_msgq_get()` should be tested as `-ENOMSG` can be returned due to `k_msgq_purge()`.

```c
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* get a data item */
        k_msgq_get(&my_msgq, &data, K_FOREVER);

        /* process data item */
        ...
    }
}
```

Peeking into a Message Queue  A data item is read from a message queue by calling `k_msgq_peek()`. The following code peeks into the message queue to read the data item at the head of the queue that is generated by one or more producing threads.

```c
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* read a data item by peeking into the queue */
        k_msgq_peek(&my_msgq, &data);

        /* process data item */
        ...
    }
}
```

Suggested Uses  Use a message queue to transfer small data items between threads in an asynchronous manner.

Note: A message queue can be used to transfer large data items, if desired. However, this can increase interrupt latency as interrupts are locked while a data item is written or read. The time to write or read a data item increases linearly with its size since the item is copied in its entirety to or from the buffer in memory. For this reason, it is usually preferable to transfer large data items by exchanging a pointer to the data item, rather than the data item itself.

A synchronous transfer can be achieved by using the kernel's mailbox object type.

Configuration Options  Related configuration options:

- None.

3.1. Kernel Services 387
Defines

K_MSGQ_FLAG_ALLOC

K_MSGQ_DEFINE(q_name, q_msg_size, q_max_msgs, q_align)

Statically define and initialize a message queue.

The message queue’s ring buffer contains space for \( q_{\text{max}}_{\text{msgs}} \) messages, each of which is \( q_{\text{msg}}_{\text{size}} \) bytes long. Alignment of the message queue’s ring buffer is not necessary, setting \( q_{\text{align}} \) to 1 is sufficient.

The message queue can be accessed outside the module where it is defined using:

```
extern struct k_msgq <name>;
```

Parameters

- \( q_{\text{name}} \) – Name of the message queue.
- \( q_{\text{msg}}_{\text{size}} \) – Message size (in bytes).
- \( q_{\text{max}}_{\text{msgs}} \) – Maximum number of messages that can be queued.
- \( q_{\text{align}} \) – Alignment of the message queue’s ring buffer (power of 2).

Functions

void k_msgq_init(struct k_msgq *msgq, char *buffer, size_t msg_size, uint32_t max_msgs)

Initialize a message queue.

This routine initializes a message queue object, prior to its first use.

The message queue’s ring buffer must contain space for \( \text{max}_\text{msgs} \) messages, each of which is \( \text{msg}_\text{size} \) bytes long. Alignment of the message queue’s ring buffer is not necessary.

Parameters

- \( \text{msgq} \) – Address of the message queue.
- \( \text{buffer} \) – Pointer to ring buffer that holds queued messages.
- \( \text{msg}_\text{size} \) – Message size (in bytes).
- \( \text{max}_\text{msgs} \) – Maximum number of messages that can be queued.

int k_msgq_alloc_init(struct k_msgq *msgq, size_t msg_size, uint32_t max_msgs)

Initialize a message queue.

This routine initializes a message queue object, prior to its first use, allocating its internal ring buffer from the calling thread’s resource pool.

Memory allocated for the ring buffer can be released by calling \( \text{k}_\text{msgq}_\text{cleanup}() \), or if userspace is enabled and the \( \text{msgq} \) object loses all of its references.

Parameters

- \( \text{msgq} \) – Address of the message queue.
- \( \text{msg}_\text{size} \) – Message size (in bytes).
- \( \text{max}_\text{msgs} \) – Maximum number of messages that can be queued.

Returns

0 on success, -ENOMEM if there was insufficient memory in the thread’s resource pool, or -EINVAL if the size parameters cause an integer overflow.
int k_msgq_cleanup(struct k_msgq *msgq)
    Release allocated buffer for a queue.

    Releases memory allocated for the ring buffer.

Parameters
• msgq – message queue to cleanup

Return values
• 0 – on success
• -EBUSY – Queue not empty

int k_msgq_put(struct k_msgq *msgq, const void *data, k_timeout_t timeout)
    Send a message to a message queue.

This routine sends a message to message queue q.

Function properties (list may not be complete)
    isr-ok

Note: The message content is copied from data into msgq and the data pointer is not retained, so the message content will not be modified by this function.

Parameters
• msgq – Address of the message queue.
• data – Pointer to the message.
• timeout – Non-negative waiting period to add the message, or one of the special values K_NO_WAIT and K_FOREVER.

Return values
• 0 – Message sent.
• -ENOMSG – Returned without waiting or queue purged.
• -EAGAIN – Waiting period timed out.

int k_msgq_get(struct k_msgq *msgq, void *data, k_timeout_t timeout)
    Receive a message from a message queue.

This routine receives a message from message queue q in a “first in, first out” manner.

Function properties (list may not be complete)
    isr-ok

Note: timeout must be set to K_NO_WAIT if called from ISR.

Parameters
• msgq – Address of the message queue.
• data – Address of area to hold the received message.
• `timeout` – Waiting period to receive the message, or one of the special values `K_NO_WAIT` and `K_FOREVER`.

**Return values**

- 0 – Message received.
- -ENOMSG – Returned without waiting.
- -EAGAIN – Waiting period timed out.

```c
int k_msgq_peek(struct k_msgq *msgq, void *data)
```

*Peek/read a message from a message queue.*

This routine reads a message from message queue `q` in a “first in, first out” manner and leaves the message in the queue.

**Function properties (list may not be complete)**

- `isr-ok`

**Parameters**

- `msgq` – Address of the message queue.
- `data` – Address of area to hold the message read from the queue.

**Return values**

- 0 – Message read.
- -ENOMSG – Returned when the queue has no message.

```c
int k_msgq_peek_at(struct k_msgq *msgq, void *data, uint32_t idx)
```

*Peek/read a message from a message queue at the specified index.*

This routine reads a message from message queue at the specified index and leaves the message in the queue. `k_msgq_peek_at(msgq, data, 0)` is equivalent to `k_msgq_peek(msgq, data)`.

**Function properties (list may not be complete)**

- `isr-ok`

**Parameters**

- `msgq` – Address of the message queue.
- `data` – Address of area to hold the message read from the queue.
- `idx` – Message queue index at which to peek

**Return values**

- 0 – Message read.
- -ENOMSG – Returned when the queue has no message at index.

```c
void k_msgq_purge(struct k_msgq *msgq)
```

*Purge a message queue.*

This routine discards all unreceived messages in a message queue's ring buffer. Any threads that are blocked waiting to send a message to the message queue are unblocked and see an -ENOMSG error code.

**Parameters**

- `msgq` – Address of the message queue.
uint32_t k_msgq_num_free_get(struct k_msgq *msgq)
Get the amount of free space in a message queue.

This routine returns the number of unused entries in a message queue's ring buffer.

**Parameters**

- `msgq` – Address of the message queue.

**Returns**

Number of unused ring buffer entries.

```c
void k_msgq_get_attrs(struct k_msgq *msgq, struct k_msgq_attrs *attrs)
```

Get basic attributes of a message queue.

This routine fetches basic attributes of message queue into `attrs` argument.

**Parameters**

- `msgq` – Address of the message queue.
- `attrs` – pointer to message queue attribute structure.

```c
uint32_t k_msgq_num_used_get(struct k_msgq *msgq)
```

Get the number of messages in a message queue.

This routine returns the number of messages in a message queue's ring buffer.

**Parameters**

- `msgq` – Address of the message queue.

**Returns**

Number of messages.

```c
#include <kernel.h> Message Queue Structure.
```

### Public Members

```c
_wait_q_t wait_q
Message queue wait queue.
```

```c
struct k_spinlock lock
Lock.
```

```c
size_t msg_size
Message size.
```

```c
uint32_t max_msgs
Maximal number of messages.
```

```c
char *buffer_start
Start of message buffer.
```

```c
char *buffer_end
End of message buffer.
```
char *read_ptr
   Read pointer.

char *write_ptr
   Write pointer.

uint32_t used_msgs
   Number of used messages.

uint8_t flags
   Message queue.

struct k_msgqAttrs
   #include <kernel.h> Message Queue Attributes.

Public Members

size_t msg_size
   Message Size.

uint32_t max_msgs
   Maximal number of messages.

uint32_t used_msgs
   Used messages.

Mailboxes

A mailbox is a kernel object that provides enhanced message queue capabilities that go beyond the capabilities of a message queue object. A mailbox allows threads to send and receive messages of any size synchronously or asynchronously.

- Concepts
  - Message Format
  - Message Lifecycle
  - Thread Compatibility
  - Message Flow Control
- Implementation
  - Defining a Mailbox
  - Message Descriptors
  - Sending a Message
  - Receiving a Message
- Suggested Uses
- Configuration Options
Any number of mailboxes can be defined (limited only by available RAM). Each mailbox is referenced by its memory address.

A mailbox has the following key properties:

- A **send queue** of messages that have been sent but not yet received.
- A **receive queue** of threads that are waiting to receive a message.

A mailbox must be initialized before it can be used. This sets both of its queues to empty.

A mailbox allows threads, but not ISRs, to exchange messages. A thread that sends a message is known as the **sending thread**, while a thread that receives the message is known as the **receiving thread**. Each message may be received by only one thread (i.e. point-to-multipoint and broadcast messaging is not supported).

Messages exchanged using a mailbox are handled non-anonymously, allowing both threads participating in an exchange to know (and even specify) the identity of the other thread.

**Message Format** A **message descriptor** is a data structure that specifies where a message's data is located, and how the message is to be handled by the mailbox. Both the sending thread and the receiving thread supply a message descriptor when accessing a mailbox. The mailbox uses the message descriptors to perform a message exchange between compatible sending and receiving threads. The mailbox also updates certain message descriptor fields during the exchange, allowing both threads to know what has occurred.

A mailbox message contains zero or more bytes of **message data**. The size and format of the message data is application-defined, and can vary from one message to the next.

A **message buffer** is an area of memory provided by the thread that sends or receives the message data. An array or structure variable can often be used for this purpose.

A message that has neither form of message data is called an **empty message**.

**Note**: A message whose message buffer exists, but contains zero bytes of actual data, is not an empty message.

**Message Lifecycle** The life cycle of a message is straightforward. A message is created when it is given to a mailbox by the sending thread. The message is then owned by the mailbox until it is given to a receiving thread. The receiving thread may retrieve the message data when it receives the message from the mailbox, or it may perform data retrieval during a second, subsequent mailbox operation. Only when data retrieval has occurred is the message deleted by the mailbox.

**Thread Compatibility** A sending thread can specify the address of the thread to which the message is sent, or send it to any thread by specifying `K_ANY`. Likewise, a receiving thread can specify the address of the thread from which it wishes to receive a message, or it can receive a message from any thread by specifying `K_ANY`. A message is exchanged only when the requirements of both the sending thread and receiving thread are satisfied; such threads are said to be **compatible**.

For example, if thread A sends a message to thread B (and only thread B) it will be received by thread B if thread B tries to receive a message from thread A or if thread B tries to receive from any thread. The exchange will not occur if thread B tries to receive a message from thread C. The message can never be received by thread C, even if it tries to receive a message from thread A (or from any thread).
**Message Flow Control**  Mailbox messages can be exchanged *synchronously* or *asynchronously*. In a synchronous exchange, the sending thread blocks until the message has been fully processed by the receiving thread. In an asynchronous exchange, the sending thread does not wait until the message has been received by another thread before continuing; this allows the sending thread to do other work (such as gather data that will be used in the next message) before the message is given to a receiving thread and fully processed. The technique used for a given message exchange is determined by the sending thread.

The synchronous exchange technique provides an implicit form of flow control, preventing a sending thread from generating messages faster than they can be consumed by receiving threads. The asynchronous exchange technique provides an explicit form of flow control, which allows a sending thread to determine if a previously sent message still exists before sending a subsequent message.

**Implementation**

**Defining a Mailbox**  A mailbox is defined using a variable of type `k_mbox`. It must then be initialized by calling `k_mbox_init()`.

The following code defines and initializes an empty mailbox.

```c
struct k_mbox my_mailbox;
k_mbox_init(&my_mailbox);
```

Alternatively, a mailbox can be defined and initialized at compile time by calling `K_MBOX_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_MBOX_DEFINE(my_mailbox);
```

**Message Descriptors**  A message descriptor is a structure of type `k_mbox_msg`. Only the fields listed below should be used; any other fields are for internal mailbox use only.

- **info**  A 32-bit value that is exchanged by the message sender and receiver, and whose meaning is defined by the application. This exchange is bi-directional, allowing the sender to pass a value to the receiver during any message exchange, and allowing the receiver to pass a value to the sender during a synchronous message exchange.

- **size**  The message data size, in bytes. Set it to zero when sending an empty message, or when sending a message buffer with no actual data. When receiving a message, set it to the maximum amount of data desired, or to zero if the message data is not wanted. The mailbox updates this field with the actual number of data bytes exchanged once the message is received.

- **tx_data**  A pointer to the sending thread's message buffer. Set it to `NULL` when sending an empty message. Leave this field uninitialized when receiving a message.

- **tx_target_thread**  The address of the desired receiving thread. Set it to `K_ANY` to allow any thread to receive the message. Leave this field uninitialized when receiving a message. The mailbox updates this field with the actual receiver's address once the message is received.

- **rx_source_thread**  The address of the desired sending thread. Set it to `K_ANY` to receive a message sent by any thread. Leave this field uninitialized when sending a message. The mailbox updates this field with the actual sender's address when the message is put into the mailbox.
Sending a Message  A thread sends a message by first creating its message data, if any.

Next, the sending thread creates a message descriptor that characterizes the message to be sent, as described in the previous section.

Finally, the sending thread calls a mailbox send API to initiate the message exchange. The message is immediately given to a compatible receiving thread, if one is currently waiting. Otherwise, the message is added to the mailbox's send queue.

Any number of messages may exist simultaneously on a send queue. The messages in the send queue are sorted according to the priority of the sending thread. Messages of equal priority are sorted so that the oldest message can be received first.

For a synchronous send operation, the operation normally completes when a receiving thread has both received the message and retrieved the message data. If the message is not received before the waiting period specified by the sending thread is reached, the message is removed from the mailbox's send queue and the send operation fails. When a send operation completes successfully the sending thread can examine the message descriptor to determine which thread received the message, how much data was exchanged, and the application-defined info value supplied by the receiving thread.

Note:  A synchronous send operation may block the sending thread indefinitely, even when the thread specifies a maximum waiting period. The waiting period only limits how long the mailbox waits before the message is received by another thread. Once a message is received there is no limit to the time the receiving thread may take to retrieve the message data and unblock the sending thread.

For an asynchronous send operation, the operation always completes immediately. This allows the sending thread to continue processing regardless of whether the message is given to a receiving thread immediately or added to the send queue. The sending thread may optionally specify a semaphore that the mailbox gives when the message is deleted by the mailbox, for example, when the message has been received and its data retrieved by a receiving thread. The use of a semaphore allows the sending thread to easily implement a flow control mechanism that ensures that the mailbox holds no more than an application-specified number of messages from a sending thread (or set of sending threads) at any point in time.

Note:  A thread that sends a message asynchronously has no way to determine which thread received the message, how much data was exchanged, or the application-defined info value supplied by the receiving thread.

Sending an Empty Message  This code uses a mailbox to synchronously pass 4 byte random values to any consuming thread that wants one. The message “info” field is large enough to carry the information being exchanged, so the data portion of the message isn’t used.

```c
void producer_thread(void)
{
    struct k_mbox_msg send_msg;

    while (1) {
        /* generate random value to send */
        uint32_t random_value = sys_rand32_get();

        /* prepare to send empty message */
        send_msg.info = random_value;
        send_msg.size = 0;
        send_msg.tx_data = NULL;
        send_msg.tx_block.data = NULL;
    }
}
```

(continues on next page)
send_msg.tx_target_thread = K_ANY;

/* send message and wait until a consumer receives it */
k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);
}
}

Sending Data Using a Message Buffer  This code uses a mailbox to synchronously pass variable-sized requests from a producing thread to any consuming thread that wants it. The message “info” field is used to exchange information about the maximum size message buffer that each thread can handle.

```c
void producer_thread(void)
{
    char buffer[100];
    int buffer_bytes_used;

    struct k_mbox_msg send_msg;

    while (1) {
        /* generate data to send */
        ...
        buffer_bytes_used = ... ;
        memcpy(buffer, source, buffer_bytes_used);

        /* prepare to send message */
        send_msg.info = buffer_bytes_used;
        send_msg.size = buffer_bytes_used;
        send_msg.tx_data = buffer;
        send_msg.tx_block.data = NULL;
        send_msg.tx_target_thread = K_ANY;

        /* send message and wait until a consumer receives it */
        k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);

        /* info, size, and tx_target_thread fields have been updated */

        /* verify that message data was fully received */
        if (send_msg.size < buffer_bytes_used) {
            printf("some message data dropped during transfer!");
            printf("receiver only had room for %d bytes", send_msg.info);
        }
    }
}
```

Receiving a Message  A thread receives a message by first creating a message descriptor that characterizes the message it wants to receive. It then calls one of the mailbox receive APIs. The mailbox searches its send queue and takes the message from the first compatible thread it finds. If no compatible thread exists, the receiving thread may choose to wait for one. If no compatible thread appears before the waiting period specified by the receiving thread is reached, the receive operation fails. Once a receive operation completes successfully the receiving thread can examine the message descriptor to determine which thread sent the message, how much data was exchanged, and the application-defined info value supplied by the sending thread.

Any number of receiving threads may wait simultaneously on a mailboxes' receive queue. The threads
are sorted according to their priority; threads of equal priority are sorted so that the one that started waiting first can receive a message first.

**Note:** Receiving threads do not always receive messages in a first in, first out (FIFO) order, due to the thread compatibility constraints specified by the message descriptors. For example, if thread A waits to receive a message only from thread X and then thread B waits to receive a message from thread Y, an incoming message from thread Y to any thread will be given to thread B and thread A will continue to wait.

The receiving thread controls both the quantity of data it retrieves from an incoming message and where the data ends up. The thread may choose to take all of the data in the message, to take only the initial part of the data, or to take no data at all. Similarly, the thread may choose to have the data copied into a message buffer of its choice.

The following sections outline various approaches a receiving thread may use when retrieving message data.

**Retrieving Data at Receive Time** The most straightforward way for a thread to retrieve message data is to specify a message buffer when the message is received. The thread indicates both the location of the message buffer (which must not be NULL) and its size.

The mailbox copies the message’s data to the message buffer as part of the receive operation. If the message buffer is not big enough to contain all of the message’s data, any uncopied data is lost. If the message is not big enough to fill all of the buffer with data, the unused portion of the message buffer is left unchanged. In all cases the mailbox updates the receiving thread’s message descriptor to indicate how many data bytes were copied (if any).

The immediate data retrieval technique is best suited for small messages where the maximum size of a message is known in advance.

The following code uses a mailbox to process variable-sized requests from any producing thread, using the immediate data retrieval technique. The message “info” field is used to exchange information about the maximum size message buffer that each thread can handle.

```c
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[100];
    int i;
    int total;

    while (1) {
        /* prepare to receive message */
        recv_msg.info = 100;
        recv_msg.size = 100;
        recv_msg.rx_source_thread = K_ANY;

        /* get a data item, waiting as long as needed */
        k_mbox_get(&my_mailbox, &recv_msg, buffer, K_FOREVER);

        /* info, size, and rx_source_thread fields have been updated */

        /* verify that message data was fully received */
        if (recv_msg.info != recv_msg.size) {
            printf("some message data dropped during transfer!\n");
            printf("sender tried to send %d bytes", recv_msg.info);
        }
    }
}
```

(continues on next page)
Retrieving Data Later Using a Message Buffer  A receiving thread may choose to defer message data retrieval at the time the message is received, so that it can retrieve the data into a message buffer at a later time. The thread does this by specifying a message buffer location of NULL and a size indicating the maximum amount of data it is willing to retrieve later.

The mailbox does not copy any message data as part of the receive operation. However, the mailbox still updates the receiving thread’s message descriptor to indicate how many data bytes are available for retrieval.

The receiving thread must then respond as follows:

- If the message descriptor size is zero, then either the sender’s message contained no data or the receiving thread did not want to receive any data. The receiving thread does not need to take any further action, since the mailbox has already completed data retrieval and deleted the message.

- If the message descriptor size is non-zero and the receiving thread still wants to retrieve the data, the thread must call `k_mbox_data_get()` and supply a message buffer large enough to hold the data. The mailbox copies the data into the message buffer and deletes the message.

- If the message descriptor size is non-zero and the receiving thread does not want to retrieve the data, the thread must call `k_mbox_data_get()` and specify a message buffer of NULL. The mailbox deletes the message without copying the data.

The subsequent data retrieval technique is suitable for applications where immediate retrieval of message data is undesirable. For example, it can be used when memory limitations make it impractical for the receiving thread to always supply a message buffer capable of holding the largest possible incoming message.

The following code uses a mailbox's deferred data retrieval mechanism to get message data from a producing thread only if the message meets certain criteria, thereby eliminating unneeded data copying. The message “info” field supplied by the sender is used to classify the message.

```c
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[10000];

    while (1) {
        /* prepare to receive message */
        recv_msg.size = 10000;
        recv_msg.rx_source_thread = K_ANY;

        /* get message, but not its data */
        k_mbox_get(&my_mailbox, &recv_msg, NULL, K_FOREVER);

        /* get message data for only certain types of messages */
        if (is_message_type_ok(recv_msg.info)) {
            /* retrieve message data and delete the message */
            k_mbox_data_get(&recv_msg, buffer);
        }
    }
}
```
Suggested Uses  Use a mailbox to transfer data items between threads whenever the capabilities of a message queue are insufficient.

Configuration Options  Related configuration options:

API Reference

**group** mailbox_apis

### Defines

**K_MBOX_DEFINE(name)**
Statically define and initialize a mailbox.

The mailbox is to be accessed outside the module where it is defined using:

```c
extern struct k_mbox <name>;
```

**Parameters**

- name – Name of the mailbox.

### Functions

**void k_mbox_init(struct k_mbox *mbox)**
Initialize a mailbox.

This routine initializes a mailbox object, prior to its first use.

**Parameters**

- mbox – Address of the mailbox.

**int k_mbox_put(struct k_mbox *mbox, struct k_mbox_msg *tx_msg, k_timeout_t timeout)**
Send a mailbox message in a synchronous manner.

This routine sends a message to mbox and waits for a receiver to both receive and process it. The message data may be in a buffer, in a memory pool block, or non-existent (i.e. an empty message).

**Parameters**

- mbox – Address of the mailbox.
- tx_msg – Address of the transmit message descriptor.
timeout – Waiting period for the message to be received, or one of the special values K_NO_WAIT and K_FOREVER. Once the message has been received, this routine waits as long as necessary for the message to be completely processed.

**Return values**

- 0 – Message sent.
- -ENOMSG – Returned without waiting.
- -EAGAIN – Waiting period timed out.

```c
void k_mbox_async_put(struct k_mbox *mbox, struct k_mbox_msg *tx_msg, struct k_sem *sem)
```

Send a mailbox message in an asynchronous manner.

This routine sends a message to `mbox` without waiting for a receiver to process it. The message data may be in a buffer, in a memory pool block, or non-existent (i.e. an empty message). Optionally, the semaphore `sem` will be given when the message has been both received and completely processed by the receiver.

**Parameters**

- `mbox` – Address of the mailbox.
- `tx_msg` – Address of the transmit message descriptor.
- `sem` – Address of a semaphore, or NULL if none is needed.

```c
int k_mbox_get(struct k_mbox *mbox, struct k_mbox_msg *rx_msg, void *buffer, k_timeout_t timeout)
```

Receive a mailbox message.

This routine receives a message from `mbox`, then optionally retrieves its data and disposes of the message.

**Parameters**

- `mbox` – Address of the mailbox.
- `rx_msg` – Address of the receive message descriptor.
- `buffer` – Address of the buffer to receive data, or NULL to defer data retrieval and message disposal until later.
- `timeout` – Waiting period for a message to be received, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**

- 0 – Message received.
- -ENOMSG – Returned without waiting.
- -EAGAIN – Waiting period timed out.

```c
void k_mbox_data_get(struct k_mbox_msg *rx_msg, void *buffer)
```

Retrieve mailbox message data into a buffer.

This routine completes the processing of a received message by retrieving its data into a buffer, then disposing of the message.

Alternatively, this routine can be used to dispose of a received message without retrieving its data.

**Parameters**

- `rx_msg` – Address of the receive message descriptor.
- `buffer` – Address of the buffer to receive data, or NULL to discard the data.
struct k_mbox_msg
   #include <kernel.h> Mailbox Message Structure.

Public Members

size_t size
   size of message (in bytes)

uint32_t info
   application-defined information value

void *tx_data
   sender's message data buffer

struct k_mem_block tx_block
   message data block descriptor

k_tid_t rx_source_thread
   source thread id

k_tid_t tx_target_thread
   target thread id

struct k_mbox
   #include <kernel.h> Mailbox Structure.

Public Members

_wait_q_t tx_msg_queue
   Transmit messages queue.

_wait_q_t rx_msg_queue
   Receive message queue.

Pipes

A pipe is a kernel object that allows a thread to send a byte stream to another thread. Pipes can be used to synchronously transfer chunks of data in whole or in part.

- Concepts
- Implementation
   - Writing to a Pipe
   - Reading from a Pipe
   - Flushing a Pipe's Buffer
   - Flushing a Pipe
Concepts  The pipe can be configured with a ring buffer which holds data that has been sent but not
yet received; alternatively, the pipe may have no ring buffer.

Any number of pipes can be defined (limited only by available RAM). Each pipe is referenced by its
memory address.

A pipe has the following key property:

- A **size** that indicates the size of the pipe's ring buffer. Note that a size of zero defines a pipe with
  no ring buffer.

A pipe must be initialized before it can be used. The pipe is initially empty.

Data is synchronously **sent** either in whole or in part to a pipe by a thread. If the specified minimum
number of bytes can not be immediately satisfied, then the operation will either fail immediately or
attempt to send as many bytes as possible and then pend in the hope that the send can be completed
later. Accepted data is either copied to the pipe's ring buffer or directly to the waiting reader(s).

Data is synchronously **received** from a pipe by a thread. If the specified minimum number of bytes can
not be immediately satisfied, then the operation will either fail immediately or attempt to receive as
many bytes as possible and then pend in the hope that the receive can be completed later. Accepted data
is either copied from the pipe's ring buffer or directly from the waiting sender(s).

Data may also be **flushed** from a pipe by a thread. Flushing can be performed either on the entire pipe
or on only its ring buffer. Flushing the entire pipe is equivalent to reading all the information in the ring
buffer and waiting to be written into a giant temporary buffer which is then discarded. Flushing the
ring buffer is equivalent to reading only the data in the ring buffer into a temporary buffer which is then
discarded. Flushing the ring buffer does not guarantee that the ring buffer will stay empty; flushing it
may allow a pended writer to fill the ring buffer.

**Note:** Flushing does not in practice allocate or use additional buffers.

**Note:** The kernel does allow for an ISR to flush a pipe from an ISR. It also allows it to send/receive data
to/from one provided it does not attempt to wait for space/data.

**Implementation**  A pipe is defined using a variable of type *k_pipe* and an optional character buffer of
type *unsigned char*. It must then be initialized by calling *k_pipe_init()*.

The following code defines and initializes an empty pipe that has a ring buffer capable of holding 100
bytes and is aligned to a 4-byte boundary.

```
unsigned char __aligned(4) my_ring_buffer[100];
struct k_pipe my_pipe;

k_pipe_init(&my_pipe, my_ring_buffer, sizeof(my_ring_buffer));
```

Alternatively, a pipe can be defined and initialized at compile time by calling *K_PIPE_DEFINE*.

The following code has the same effect as the code segment above. Observe that that macro defines both
the pipe and its ring buffer.
Writing to a Pipe  Data is added to a pipe by calling `k_pipe_put()`. The following code builds on the example above, and uses the pipe to pass data from a producing thread to one or more consuming threads. If the pipe's ring buffer fills up because the consumers can't keep up, the producing thread waits for a specified amount of time.

```c
struct message_header {
    ...
};

void producer_thread(void)
{
    unsigned char *data;
    size_t total_size;
    size_t bytes_written;
    int    rc;
    ...

    while (1) {
        /* Craft message to send in the pipe */
        data = ...;
        total_size = ...;

        /* send data to the consumers */
        rc = k_pipe_put(&my_pipe, data, total_size, &bytes_written,
                        sizeof(struct message_header), K_NO_WAIT);

        if (rc < 0) {
            /* Incomplete message header sent */
            ...
        } else if (bytes_written < total_size) {
            /* Some of the data was sent */
            ...
        } else {
            /* All data sent */
            ...
        }
    }
}
```

Reading from a Pipe  Data is read from the pipe by calling `k_pipe_get()`. The following code builds on the example above, and uses the pipe to process data items generated by one or more producing threads.

```c
void consumer_thread(void)
{
    unsigned char buffer[120];
    size_t bytes_read;
    struct message_header *header = (struct message_header *)buffer;

    while (1) {
        rc = k_pipe_get(&my_pipe, buffer, sizeof(buffer), &bytes_read,
                        sizeof(header), K_MSEC(100));
    }
}
```
if ((rc < 0) || (bytes_read < sizeof (header))) {
    /* Incomplete message header received */
    ...
} else if (header->num_data_bytes + sizeof(header) > bytes_read) {
    /* Only some data was received */
    ...
} else {
    /* All data was received */
    ...
}
}

Use a pipe to send streams of data between threads.

**Note:** A pipe can be used to transfer long streams of data if desired. However it is often preferable to send pointers to large data items to avoid copying the data.

**Flushing a Pipe's Buffer** Data is flushed from the pipe's ring buffer by calling `k_pipe_buffer_flush()`.

The following code builds on the examples above, and flushes the pipe's buffer.

```c
void monitor_thread(void)
{
    while (1) {
        /* Pipe buffer contains stale data. Flush it. */
        k_pipe_buffer_flush(&my_pipe);
        ...
    }
}
```

**Flushing a Pipe** All data in the pipe is flushed by calling `k_pipe_flush()`.

The following code builds on the examples above, and flushes all the data in the pipe.

```c
void monitor_thread(void)
{
    while (1) {
        /* Critical error detected. Flush the entire pipe to reset it. */
        k_pipe_flush(&my_pipe);
        ...
    }
}
```

**Suggested uses** Use a pipe to send streams of data between threads.

**Note:** A pipe can be used to transfer long streams of data if desired. However it is often preferable to send pointers to large data items to avoid copying the data. Copying large data items will negatively
impact interrupt latency as a spinlock is held while copying that data.

**Configuration Options**  Related configuration options:

- **CONFIG_PIPES**

**API Reference**

`group pipe_apis`

**Defines**

```c
K_PIPE_DEFINE(name, pipe_buffer_size, pipe_align)
```

Statically define and initialize a pipe.

The pipe can be accessed outside the module where it is defined using:

```c
extern struct k_pipe <name>;
```

**Parameters**

- **name** – Name of the pipe.
- **pipe_buffer_size** – Size of the pipe's ring buffer (in bytes), or zero if no ring buffer is used.
- **pipe_align** – Alignment of the pipe's ring buffer (power of 2).

**Functions**

```c
void k_pipe_init(struct k_pipe *pipe, unsigned char *buffer, size_t size)
```

Initialize a pipe.

This routine initializes a pipe object, prior to its first use.

**Parameters**

- **pipe** – Address of the pipe.
- **buffer** – Address of the pipe's ring buffer, or NULL if no ring buffer is used.
- **size** – Size of the pipe's ring buffer (in bytes), or zero if no ring buffer is used.

```c
int k_pipe_cleanup(struct k_pipe *pipe)
```

Release a pipe's allocated buffer.

If a pipe object was given a dynamically allocated buffer via `k_pipe_alloc_init()`, this will free it. This function does nothing if the buffer wasn't dynamically allocated.

**Parameters**

- **pipe** – Address of the pipe.

**Return values**

- **0** – on success
- **-EAGAIN** – nothing to cleanup
int k_pipe_alloc_init(struct k_pipe *pipe, size_t size)
Initialize a pipe and allocate a buffer for it.

Storage for the buffer region will be allocated from the calling thread's resource pool. This memory will be released if k_pipeCleanup() is called, or userspace is enabled and the pipe object loses all references to it.

This function should only be called on uninitialized pipe objects.

**Parameters**

- **pipe** – Address of the pipe.
- **size** – Size of the pipe's ring buffer (in bytes), or zero if no ring buffer is used.

**Return values**

- **0** – on success
- **-ENOMEM** – if memory couldn't be allocated

int k_pipe_put(struct k_pipe *pipe, void *data, size_t bytes_to_write, size_t *bytes_written, size_t min_xfer, k_timeout_t timeout)
Write data to a pipe.

This routine writes up to bytes_to_write bytes of data to pipe.

**Parameters**

- **pipe** – Address of the pipe.
- **data** – Address of data to write.
- **bytes_to_write** – Size of data (in bytes).
- **bytes_written** – Address of area to hold the number of bytes written.
- **min_xfer** – Minimum number of bytes to write.
- **timeout** – Waiting period to wait for the data to be written, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**

- **0** – At least min_xfer bytes of data were written.
- **-EINVAL** – Returned without waiting; zero data bytes were written.
- **-EAGAIN** – Waiting period timed out; between zero and min_xfer minus one data bytes were written.

int k_pipe_get(struct k_pipe *pipe, void *data, size_t bytes_to_read, size_t *bytes_read, size_t min_xfer, k_timeout_t timeout)
Read data from a pipe.

This routine reads up to bytes_to_read bytes of data from pipe.

**Parameters**

- **pipe** – Address of the pipe.
- **data** – Address to place the data read from pipe.
- **bytes_to_read** – Maximum number of data bytes to read.
- **bytes_read** – Address of area to hold the number of bytes read.
- **min_xfer** – Minimum number of data bytes to read.
- **timeout** – Waiting period to wait for the data to be read, or one of the special values K_NO_WAIT and K_FOREVER.

**Return values**
0 – At least min_xfer bytes of data were read.
• -EINVAL – invalid parameters supplied
• -EIO – Returned without waiting; zero data bytes were read.
• -EAGAIN – Waiting period timed out; between zero and min_xfer minus one
data bytes were read.

size_t k_pipe_read_avail(struct k_pipe *pipe)
Query the number of bytes that may be read from pipe.

Parameters
• pipe – Address of the pipe.

Return values
a – number n such that 0 <= n <= k_pipe::size; the result is zero for unbuffered
pipes.

size_t k_pipe_write_avail(struct k_pipe *pipe)
Query the number of bytes that may be written to pipe.

Parameters
• pipe – Address of the pipe.

Return values
a – number n such that 0 <= n <= k_pipe::size; the result is zero for unbuffered
pipes.

void k_pipe_flush(struct k_pipe *pipe)
Flush the pipe of write data.
This routine flushes the pipe. Flushing the pipe is equivalent to reading both all the data in
the pipe's buffer and all the data waiting to go into that pipe into a large temporary buffer
and discarding the buffer. Any writers that were previously pended become unpended.

Parameters
• pipe – Address of the pipe.

void k_pipe_buffer_flush(struct k_pipe *pipe)
Flush the pipe’s internal buffer.
This routine flushes the pipe’s internal buffer. This is equivalent to reading up to N bytes from
the pipe (where N is the size of the pipe's buffer) into a temporary buffer and then discarding
that buffer. If there were writers previously pending, then some may unpend as they try to fill
up the pipe's emptied buffer.

Parameters
• pipe – Address of the pipe.

struct k_pipe

#include <kernel.h> Pipe Structure.

Public Members

unsigned char *buffer
Pipe buffer: may be NULL.
size_t size
   Buffer size.

size_t bytes_used

size_t read_index
   Where in buffer to read from.

size_t write_index
   Where in buffer to write.

struct k_spinlock lock
   Synchronization lock.

_wait_q_t readers
   Reader wait queue.

_wait_q_t writers
   Writer wait queue.

uint8_t flags
   Wait queue.
   Flags

3.1.3 Memory Management

See Memory Management.

3.1.4 Timing

These pages cover timing related services.

Kernel Timing

Zephyr provides a robust and scalable timing framework to enable reporting and tracking of timed events from hardware timing sources of arbitrary precision.
Time Units

Kernel time is tracked in several units which are used for different purposes.

Real time values, typically specified in milliseconds or microseconds, are the default presentation of time to application code. They have the advantages of being universally portable and pervasively understood, though they may not match the precision of the underlying hardware perfectly.

The kernel presents a “cycle” count via the `k_cycle_get_32()` and `k_cycle_get_64()` APIs. The intent is that this counter represents the fastest cycle counter that the operating system is able to present to the user (for example, a CPU cycle counter) and that the read operation is very fast. The expectation is that very sensitive application code might use this in a polling manner to achieve maximal precision. The frequency of this counter is required to be steady over time, and is available from `sys_clock_hw_cycles_per_sec()` (which on almost all platforms is a runtime constant that evaluates to `CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC`).

For asynchronous timekeeping, the kernel defines a “ticks” concept. A “tick” is the internal count in which the kernel does all its internal uptime and timeout bookkeeping. Interrupts are expected to be delivered on tick boundaries to the extent practical, and no fractional ticks are tracked. The choice of tick rate is configurable via `CONFIG_SYS_CLOCK_TICKS_PER_SEC`. Defaults on most hardware platforms (ones that support setting arbitrary interrupt timeouts) are expected to be in the range of 10 kHz, with software emulation platforms and legacy drivers using a more traditional 100 Hz value.

Conversion

Zephyr provides an extensively enumerated conversion library with rounding control for all time units. Any unit of “ms” (milliseconds), “us” (microseconds), “tick”, or “cyc” can be converted to any other. Control of rounding is provided, and each conversion is available in “floor” (round down to nearest output unit), “ceil” (round up) and “near” (round to nearest). Finally the output precision can be specified as either 32 or 64 bits.

For example: `k_ms_to_ticks ceil32()` will convert a millisecond input value to the next higher number of ticks, returning a result truncated to 32 bits of precision; and `k_cyc_to_us_floor64()` will convert a measured cycle count to an elapsed number of microseconds in a full 64 bits of precision. See the reference documentation for the full enumeration of conversion routines.

On most platforms, where the various counter rates are integral multiples of each other and where the output fits within a single word, these conversions expand to a 2-4 operation sequence, requiring full precision only where actually required and requested.

Uptime

The kernel tracks a system uptime count on behalf of the application. This is available at all times via `k_uptime_get()`, which provides an uptime value in milliseconds since system boot. This is expected to be the utility used by most portable application code.

The internal tracking, however, is as a 64 bit integer count of ticks. Apps with precise timing requirements (that are willing to do their own conversions to portable real time units) may access this with `k_uptime_ticks()`.

Timeouts

The Zephyr kernel provides many APIs with a “timeout” parameter. Conceptually, this indicates the time at which an event will occur. For example:

- Kernel blocking operations like `k_sem_take()` or `k_queue_get()` may provide a timeout after which the routine will return with an error code if no data is available.
- Kernel `k_timer` objects must specify delays for their duration and period.
- The kernel `k_work_delayable` API provides a timeout parameter indicating when a work queue item will be added to the system queue.

All these values are specified using a `k_timeout_t` value. This is an opaque struct type that must be initialized using one of a family of kernel timeout macros. The most common, `K_MSEC`, defines a time in milliseconds after the current time.

What is meant by “current time” for relative timeouts depends on the context:
• When scheduling a relative timeout from within a timeout callback (e.g. from within the expiry function passed to `k_timer_init()` or the work handler passed to `k_work_init_delayable()`), “current time” is the exact time at which thecurrently firing timeout was originally scheduled even if the “real time” will already have advanced. This is to ensure that timers scheduled from within another timer’s callback will always be calculated with a precise offset to the firing timer. It is thereby possible to fire at regular intervals without introducing systematic clock drift over time.

• When scheduling a timeout from application context, “current time” means the value returned by `k_uptime_ticks()` at the time at which the kernel receives the timeout value.

Other options for timeout initialization follow the unit conventions described above: `K_NSEC()`, `K_USEC`, `K_TICKS` and `K_CYC()` specify timeout values that will expire after specified numbers of nanoseconds, microseconds, ticks and cycles, respectively.

Precision of `k_timeout_t` values is configurable, with the default being 32 bits. Large uptime counts in non-tick units will experience complicated rollover semantics, so it is expected that timing-sensitive applications with long uptimes will be configured to use a 64 bit timeout type.

Finally, it is possible to specify timeouts as absolute times since system boot. A timeout initialized with `K_TIMEOUT_ABS_MS` indicates a timeout that will expire after the system uptime reaches the specified value. There are likewise nanosecond, microsecond, cycles and ticks variants of this API.

Timing Internals

Timeout Queue  All Zephyr `k_timeout_t` events specified using the API above are managed in a single, global queue of events. Each event is stored in a double-linked list, with an attendant delta count in ticks from the previous event. The action to take on an event is specified as a callback function pointer provided by the subsystem requesting the event, along with a _timeout tracking struct that is expected to be embedded within subsystem-defined data structures (for example: a wait_q struct, or a `k_tid_t` thread struct).

Note that all variant units passed via a `k_timeout_t` are converted to ticks once on insertion into the list. There no multiple-converson steps internal to the kernel, so precision is guaranteed at the tick level no matter how many events exist or how long a timeout might be.

Note that the list structure means that the CPU work involved in managing large numbers of timeouts is quadratic in the number of active timeouts. The API design of the timeout queue was intended to permit a more scalable backend data structure, but no such implementation exists currently.

Timer Drivers  Kernel timing at the tick level is driven by a timer driver with a comparatively simple API.

• The driver is expected to be able to “announce” new ticks to the kernel via the `sys_clock_announce()` call, which passes an integer number of ticks that have elapsed since the last announce call (or system boot). These calls can occur at any time, but the driver is expected to attempt to ensure (to the extent practical given interrupt latency interactions) that they occur near tick boundaries (i.e. not “halfway through” a tick), and most importantly that they be correct over time and subject to minimal skew vs. other counters and real world time.

• The driver is expected to provide a `sys_clock_set_timeout()` call to the kernel which indicates how many ticks may elapse before the kernel must receive an announce call to trigger registered timeouts. It is legal to announce new ticks before that moment (though they must be correct) but delay after that will cause events to be missed. Note that the timeout value passed here is in a delta from current time, but that does not absolve the driver of the requirement to provide ticks at a steady rate over time. Naive implementations of this function are subject to bugs where the fractional tick gets “reset” incorrectly and causes clock skew.

• The driver is expected to provide a `sys_clock_elapsed()` call which provides a current indication of how many ticks have elapsed (as compared to a real world clock) since the last call to `sys_clock_announce()`, which the kernel needs to test newly arriving timeouts for expiration.
Note that a natural implementation of this API results in a “tickless” kernel, which receives and processes timer interrupts only for registered events, relying on programmable hardware counters to provide irregular interrupts. But a traditional, “ticked” or “dumb” counter driver can be trivially implemented also:

- The driver can receive interrupts at a regular rate corresponding to the OS tick rate, calling `sys_clock_announce()` with an argument of one each time.
- The driver can ignore calls to `sys_clock_set_timeout()`, as every tick will be announced regardless of timeout status.
- The driver can return zero for every call to `sys_clock_elapsed()` as no more than one tick can be detected as having elapsed (because otherwise an interrupt would have been received).

**SMP Details** In general, the timer API described above does not change when run in a multiprocessor context. The kernel will internally synchronize all access appropriately, and ensure that all critical sections are small and minimal. But some notes are important to detail:

- Zephyr is agnostic about which CPU services timer interrupts. It is not illegal (though probably undesirable in some circumstances) to have every timer interrupt handled on a single processor. Existing SMP architectures implement symmetric timer drivers.
- The `sys_clock_announce()` call is expected to be globally synchronized at the driver level. The kernel does not do any per-CPU tracking, and expects that if two timer interrupts fire simultaneously, that only one will provide the current tick count to the timing subsystem. The other may legally provide a tick count of zero if no ticks have elapsed. It should not “skip” the announce call because of timeslicing requirements (see below).
- Some SMP hardware uses a single, global timer device, others use a per-CPU counter. The complexity here (for example: ensuring counter synchronization between CPUs) is expected to be managed by the driver, not the kernel.
- The next timeout value passed back to the driver via `sys_clock_set_timeout()` is done identically for every CPU. So by default, every CPU will see simultaneous timer interrupts for every event, even though by definition only one of them should see a non-zero ticks argument to `sys_clock_announce()`. This is probably a correct default for timing sensitive applications (because it minimizes the chance that an errant ISR or interrupt lock will delay a timeout), but may be a performance problem in some cases. The current design expects that any such optimization is the responsibility of the timer driver.

**Time Slicing** An auxiliary job of the timing subsystem is to provide tick counters to the scheduler that allow implementation of time slicing of threads. A thread time-slice cannot be a timeout value, as it does not reflect a global expiration but instead a per-CPU value that needs to be tracked independently on each CPU in an SMP context.

Because there may be no other hardware available to drive timeslicing, Zephyr multiplexes the existing timer driver. This means that the value passed to `sys_clock_set_timeout()` may be clamped to a smaller value than the current next timeout when a time sliced thread is currently scheduled.

**Subsystems that keep millisecond APIs** In general, code like this will port just like applications code will. Millisecond values from the user may be treated any way the subsystem likes, and then converted into kernel timeouts using `K_MSEC()` at the point where they are presented to the kernel.

Obviously this comes at the cost of not being able to use new features, like the higher precision timeout constructors or absolute timeouts. But for many subsystems with simple needs, this may be acceptable.

One complexity is `K_FOREVER`. Subsystems that might have been able to accept this value to their millisecond API in the past no longer can, because it is no longer an integral type. Such code will need to use a different, integer-valued token to represent “forever”. `K_NO_WAIT` has the same typesafety concern too, of course, but as it is (and has always been) simply a numerical zero, it has a natural porting path.
Subsystems using `k_timeout_t`  Ideally, code that takes a “timeout” parameter specifying a time to wait should be using the kernel native abstraction where possible. But `k_timeout_t` is opaque, and needs to be converted before it can be inspected by an application.

Some conversions are simple. Code that needs to test for `K_FOREVER` can simply use the `K_TIMEOUT_EQ()` macro to test the opaque struct for equality and take special action.

The more complicated case is when the subsystem needs to take a timeout and loop, waiting for it to finish while doing some processing that may require multiple blocking operations on underlying kernel code. For example, consider this design:

```c
void my_wait_for_event(struct my_subsys *obj, int32_t timeout_in_ms)
{
    while (true) {
        uint32_t start = k_uptime_get_32();
        if (is_event_complete(obj)) {
            return;
        }
        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout_in_ms);
        /* Subtract elapsed time */
        timeout_in_ms -= (k_uptime_get_32() - start);
    }
}
```

This code requires that the timeout value be inspected, which is no longer possible. For situations like this, the new API provides the internal `sys_timepoint_calc()` and `sys_timepoint_timeout()` routines that converts an arbitrary timeout to and from a timepoint value based on an uptime tick at which it will expire. So such a loop might look like:

```c
void my_wait_for_event(struct my_subsys *obj, k_timeout_t timeout)
{
    /* Compute the end time from the timeout */
    k_timepoint_t end = sys_timepoint_calc(timeout);
    do {
        if (is_event_complete(obj)) {
            return;
        }
        /* Update timeout with remaining time */
        timeout = sys_timepoint_timeout(end);
        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout);
    } while (!K_TIMEOUT_EQ(timeout, K_NO_WAIT));
}
```

Note that `sys_timepoint_calc()` accepts special values `K_FOREVER` and `K_NO_WAIT`, and works identically for absolute timeouts as well as conventional ones. Conversely, `sys_timepoint_timeout()` may return `K_FOREVER` or `K_NO_WAIT` if those were used to create the timepoint, the later also being returned if the timepoint is now in the past. For simple cases, `sys_timepoint_expired()` can be used as well.

But some care is still required for subsystems that use those. Note that delta timeouts need to be interpreted relative to a “current time”, and obviously that time is the time of the call to `sys_timepoint_calc()`. But the user expects that the time is the time they passed the timeout to you. Care must be taken to call this function just once, as synchronously as possible to the timeout creation.
in user code. It should not be used on a “stored” timeout value, and should never be called iteratively in a loop.

API Reference

group clock_apis

System Clock APIs.

Defines

K_NO_WAIT

Generate null timeout delay.

This macro generates a timeout delay that instructs a kernel API not to wait if the requested operation cannot be performed immediately.

Returns

Timeout delay value.

K_nsec(t)

Generate timeout delay from nanoseconds.

This macro generates a timeout delay that instructs a kernel API to wait up to t nanoseconds to perform the requested operation. Note that timer precision is limited to the tick rate, not the requested value.

Parameters

• t – Duration in nanoseconds.

Returns

Timeout delay value.

K_usec(t)

Generate timeout delay from microseconds.

This macro generates a timeout delay that instructs a kernel API to wait up to t microseconds to perform the requested operation. Note that timer precision is limited to the tick rate, not the requested value.

Parameters

• t – Duration in microseconds.

Returns

Timeout delay value.

K_cyc(t)

Generate timeout delay from cycles.

This macro generates a timeout delay that instructs a kernel API to wait up to t cycles to perform the requested operation.

Parameters

• t – Duration in cycles.

Returns

Timeout delay value.
K_TICKS(t)
Generate timeout delay from system ticks.
This macro generates a timeout delay that instructs a kernel API to wait up to t ticks to perform the requested operation.

Parameters
• t – Duration in system ticks.

Returns
Timeout delay value.

K_MSEC(ms)
Generate timeout delay from milliseconds.
This macro generates a timeout delay that instructs a kernel API to wait up to ms milliseconds to perform the requested operation.

Parameters
• ms – Duration in milliseconds.

Returns
Timeout delay value.

K.SECONDS(s)
Generate timeout delay from seconds.
This macro generates a timeout delay that instructs a kernel API to wait up to s seconds to perform the requested operation.

Parameters
• s – Duration in seconds.

Returns
Timeout delay value.

K_MINUTES(m)
Generate timeout delay from minutes.
This macro generates a timeout delay that instructs a kernel API to wait up to m minutes to perform the requested operation.

Parameters
• m – Duration in minutes.

Returns
Timeout delay value.

K.HOURS(h)
Generate timeout delay from hours.
This macro generates a timeout delay that instructs a kernel API to wait up to h hours to perform the requested operation.

Parameters
• h – Duration in hours.

Returns
Timeout delay value.
K_FOREVER
Generate infinite timeout delay.
This macro generates a timeout delay that instructs a kernel API to wait as long as necessary
to perform the requested operation.

Returns
Timeout delay value.

K_TICKS_FOREVER
K_TIMEOUT_EQ(a, b)
Compare timeouts for equality.
The k_timeout_t object is an opaque struct that should not be inspected by application code.
This macro exists so that users can test timeout objects for equality with known constants
(e.g. K_NO_WAIT and K_FOREVER) when implementing their own APIs in terms of Zephyr
timeout constants.

Returns
True if the timeout objects are identical

NSEC_PER_USEC
number of nanoseconds per microsecond

NSEC_PER_MSEC
number of nanoseconds per millisecond

USEC_PER_MSEC
number of microseconds per millisecond

MSEC_PER_SEC
number of milliseconds per second

SEC_PER_MIN
number of seconds per minute

MIN_PER_HOUR
number of minutes per hour

HOUR_PER_DAY
number of hours per day

USEC_PER_SEC
number of microseconds per second

NSEC_PER_SEC
number of nanoseconds per second

SYS_CLOCK_HW_CYCLES_TO_NS_AVG(X, NCYCLES)
SYS_CLOCK_HW_CYCLES_TO_NS_AVG converts CPU clock cycles to nanoseconds and calculates the average cycle time.
**Typedefs**

typedef uint32_t k_ticks_t

Tick precision used in timeout APIs.

This type defines the word size of the timeout values used in `k_timeout_t` objects, and thus defines an upper bound on maximum timeout length (or equivalently minimum tick duration). Note that this does not affect the size of the system uptime counter, which is always a 64 bit count of ticks.

**Functions**

void `sys_clock_set_timeout`(int32_t ticks, bool idle)

Set system clock timeout.

Informs the system clock driver that the next needed call to `sys_clock_announce()` will not be until the specified number of ticks from the the current time have elapsed. Note that spurious calls to `sys_clock_announce()` are allowed (i.e. it's legal to announce every tick and implement this function as a noop), the requirement is that one tick announcement should occur within one tick BEFORE the specified expiration (that is, passing ticks==1 means "announce the next tick", this convention was chosen to match legacy usage). Similarly a ticks value of zero (or even negative) is legal and treated identically: it simply indicates the kernel would like the next tick announcement as soon as possible.

Note that ticks can also be passed the special value K_TICKS_FOREVER, indicating that no future timer interrupts are expected or required and that the system is permitted to enter an indefinite sleep even if this could cause rollover of the internal counter (i.e. the system uptime counter is allowed to be wrong).

Note also that it is conventional for the kernel to pass INT_MAX for ticks if it wants to preserve the uptime tick count but doesn't have a specific event to await. The intent here is that the driver will schedule any needed timeout as far into the future as possible. For the specific case of INT_MAX, the next call to `sys_clock_announce()` may occur at any point in the future, not just at INT_MAX ticks. But the correspondence between the announced ticks and real-world time must be correct.

A final note about SMP: note that the call to `sys_clock_set_timeout()` is made on any CPU, and reflects the next timeout desired globally. The resulting calls(s) to `sys_clock_announce()` must be properly serialized by the driver such that a given tick is announced exactly once across the system. The kernel does not (cannot, really) attempt to serialize things by "assigning" timeouts to specific CPUs.

**Parameters**

- ticks – Timeout in tick units
- idle – Hint to the driver that the system is about to enter the idle state immediately after setting the timeout

void `sys_clock_idle_exit`(void)

Timer idle exit notification.

This notifies the timer driver that the system is exiting the idle and allows it to do whatever bookkeeping is needed to restore timer operation and compute elapsed ticks.

**Note:** Legacy timer drivers also use this opportunity to call back into `sys_clock_announce()` to notify the kernel of expired ticks. This is allowed for compatibility, but not recommended. The kernel will figure that out on its own.
void sys_clock_announce(int32_t ticks)
  Announce time progress to the kernel.
  Informs the kernel that the specified number of ticks have elapsed since the last call to
  *sys_clock_announce* (or system startup for the first call). The timer driver is expected to
delivery these announcements as close as practical (subject to hardware and latency limitations) to tick boundaries.

**Parameters**

- **ticks** – Elapsed time, in ticks

```c
uint32_t sys_clock_elapsed(void)
```

Ticks elapsed since last *sys_clock_announce* call.

Queries the clock driver for the current time elapsed since the last call to *sys_clock_announce* was made. The kernel will call this with appropriate locking, the driver needs only provide an
 instantaneous answer.

```c
void sys_clock_disable(void)
```

Disable system timer.

---

**Note:** Not all system timer drivers has the capability of being disabled. The config
CONFIG_SYSTEM_TIMER_HAS_DISABLE_SUPPORT can be used to check if the system timer has
the capability of being disabled.

```c
uint32_t sys_clock_cycle_get_32(void)
```

Hardware cycle counter.

Timer drivers are generally responsible for the system cycle counter as well as the tick an-
nouncements. This function is generally called out of the architecture layer (See also: arch_k_cycle_get_32()) to implement the cycle counter, though the user-facing API is owned by the architecture, not the driver. The rate must match CON-
FIG_SYS_CLOCK_HW_CYCLES_PER_SEC.

**Note:** If the counter clock is large enough for this to wrap its full range within a few seconds (i.e. CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC is greater than 50Mhz) then it is recom-
mended to also implement *sys_clock_cycle_get_64*.

**Returns**

The current cycle time. This should count up monotonically through the full 32
bit space, wrapping at 0xffffffff. Hardware with fewer bits of precision in the
timer is expected to synthesize a 32 bit count.

```c
uint64_t sys_clock_cycle_get_64(void)
```

64 bit hardware cycle counter

As for *sys_clock_cycle_get_32*, but with a 64 bit return value. Not all hard-
ware has 64 bit counters. This function need be implemented only if CON-
FIG_TIMER_HAS_64BIT_CYCLE_COUNTER is set.

**Note:** If the counter clock is large enough for *sys_clock_cycle_get_32* to wrap its full
range within a few seconds (i.e. CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC is greater than
50Mhz) then it is recommended to implement this API.
Returns
The current cycle time. This should count up monotonically through the full 64
bit space, wrapping at $2^{64}-1$. Hardware with fewer bits of precision in the
timer is generally not expected to implement this API.

```c
int64_t k_uptime_ticks(void)
Get system uptime, in system ticks.
```

This routine returns the elapsed time since the system booted, in ticks (c.f. `CONFIG_SYS_CLOCK_TICKS_PER_SEC`), which is the fundamental unit of resolution of kernel timekeeping.

Returns
Current uptime in ticks.

```c
static inline int64_t k_uptime_get(void)
Get system uptime.
```

This routine returns the elapsed time since the system booted, in milliseconds.

Note: While this function returns time in milliseconds, it does not mean it has millisecond resolution. The actual resolution depends on `CONFIG_SYS_CLOCK_TICKS_PER_SEC` config option.

Returns
Current uptime in milliseconds.

```c
static inline uint32_t k_uptime_get_32(void)
Get system uptime (32-bit version).
```

This routine returns the lower 32 bits of the system uptime in milliseconds.

Because correct conversion requires full precision of the system clock there is no benefit to using this over `k_uptime_get()` unless you know the application will never run long enough for the system clock to approach $2^{32}$ ticks. Calls to this function may involve interrupt blocking and 64-bit math.

Note: While this function returns time in milliseconds, it does not mean it has millisecond resolution. The actual resolution depends on `CONFIG_SYS_CLOCK_TICKS_PER_SEC` config option.

Returns
The low 32 bits of the current uptime, in milliseconds.

```c
static inline int64_t k_uptime_delta(int64_t *reftime)
Get elapsed time.
```

This routine computes the elapsed time between the current system uptime and an earlier reference time, in milliseconds.

Parameters
- `reftime` – Pointer to a reference time, which is updated to the current uptime upon return.

Returns
Elapsed time.
static inline uint32_t k_cycle_get_32(void)
    Read the hardware clock.
    This routine returns the current time, as measured by the system’s hardware clock.

    Returns
    Current hardware clock up-counter (in cycles).

static inline uint64_t k_cycle_get_64(void)
    Read the 64-bit hardware clock.
    This routine returns the current time in 64-bits, as measured by the system’s hardware clock, if available.

    See also:
    CONFIG_TIMER_HAS_64BIT_CYCLE_COUNTER

    Returns
    Current hardware clock up-counter (in cycles).

uint32_t sys_clock_tick_get_32(void)
    Return the lower part of the current system tick count.

    Returns
    the current system tick count

int64_t sys_clock_tick_get(void)
    Return the current system tick count.

    Returns
    the current system tick count

k_timepoint_t sys_timepoint_calc(k_timeout_t timeout)
    Calculate a timepoint value.
    Returns a timepoint corresponding to the expiration (relative to an unlocked “now”) of a timeout object. When used correctly, this should be called once, synchronously with the user passing a new timeout value. It should not be used iteratively to adjust a timeout (see sys_timepoint_timeout() for that purpose).

    See also:
    sys_timepoint_timeout()

    See also:
    sys_timepoint_expired()

    Parameters
    • timeout – Timeout value relative to current time (may also be K_FOREVER or K_NO_WAIT).

    Return values
    Timepoint – value corresponding to given timeout

k_timeout_t sys_timepoint_timeout(k_timepoint_t timepoint)
    Remaining time to given timepoint.
    Returns the timeout interval between current time and provided timepoint. If the timepoint is now in the past or if it was created with K_NO_WAIT then K_NO_WAIT is returned. If it was created with K_FOREVER then K_FOREVER is returned.
See also:

`sys_timepoint_calc()`

Parameters

• `timepoint` – Timepoint for which a timeout value is wanted.

Return values

Corresponding – timeout value.

static inline uint64_t sys_clock_timeout_end_calc(k_timeout_t timeout)

Provided for backward compatibility.

This is deprecated. Consider `sys_timepoint_calc()` instead.

See also:

`sys_timepoint_calc()`

static inline int sys_timepoint_cmp(k_timepoint_t a, k_timepoint_t b)

Compare two timepoint values.

This function is used to compare two timepoint values.

Parameters

• `a` – Timepoint to compare

• `b` – Timepoint to compare against.

Returns

zero if both timepoints are the same. Negative value if timepoint `a` is before timepoint `b`, positive otherwise.

static inline bool sys_timepoint_expired(k_timepoint_t timepoint)

Indicates if timepoint is expired.

See also:

`sys_timepoint_calc()`

Parameters

• `timepoint` – Timepoint to evaluate

Return values

true – if the timepoint is in the past, false otherwise

struct k_timeout_t

#include <sys_clock.h> Kernel timeout type.

Timeout arguments presented to kernel APIs are stored in this opaque type, which is capable of representing times in various formats and units. It should be constructed from application data using one of the macros defined for this purpose (e.g. `K_MSEC()`, `K_TIMEOUT_ABS_TICKS()`, etc...), or be one of the two constants `K_NO_WAIT` or `K_FOREVER`. Applications should not inspect the internal data once constructed. Timeout values may be compared for equality with the `K_TIMEOUT_EQ()` macro.
struct k_timepoint_t
    #include <sys_clock.h> Kernel timepoint type.
    Absolute timepoints are stored in this opaque type. It is best not to inspect its content directly.

    sys_timepoint_timeout()
See also:
    sys_timepoint_expired()

Timers

A timer is a kernel object that measures the passage of time using the kernel's system clock. When a timer's specified time limit is reached it can perform an application-defined action, or it can simply record the expiration and wait for the application to read its status.

- Concepts
- Implementation
  - Defining a Timer
  - Using a Timer Expiry Function
  - Reading Timer Status
  - Using Timer Status Synchronization
- Suggested Uses
- Configuration Options
- API Reference

Concepts  Any number of timers can be defined (limited only by available RAM). Each timer is referenced by its memory address.

A timer has the following key properties:

- A **duration** specifying the time interval before the timer expires for the first time. This is a k_timeout_t value that may be initialized via different units.

- A **period** specifying the time interval between all timer expirations after the first one, also a k_timeout_t. It must be non-negative. A period of K_NO_WAIT (i.e. zero) or K_FOREVER means that the timer is a one shot timer that stops after a single expiration. (For example then, if a timer is started with a duration of 200 and a period of 75, it will first expire after 200ms and then every 75ms after that.)

- An **expiry function** that is executed each time the timer expires. The function is executed by the system clock interrupt handler. If no expiry function is required a NULL function can be specified.

- A **stop function** that is executed if the timer is stopped prematurely while running. The function is executed by the thread that stops the timer. If no stop function is required a NULL function can be specified.
• A **status** value that indicates how many times the timer has expired since the status value was last read.

A timer must be initialized before it can be used. This specifies its expiry function and stop function values, sets the timer's status to zero, and puts the timer into the **stopped** state.

A timer is **started** by specifying a duration and a period. The timer's status is reset to zero, then the timer enters the **running** state and begins counting down towards expiry.

Note that the timer's duration and period parameters specify **minimum** delays that will elapse. Because of internal system timer precision (and potentially runtime interactions like interrupt delay) it is possible that more time may have passed as measured by reads from the relevant system time APIs. But at least this much time is guaranteed to have elapsed.

When a running timer expires its status is incremented and the timer executes its expiry function, if one exists; If a thread is waiting on the timer, it is unblocked. If the timer's period is zero the timer enters the stopped state; otherwise the timer restarts with a new duration equal to its period.

A running timer can be stopped in mid-countdown, if desired. The timer's status is left unchanged, then the timer enters the stopped state and executes its stop function, if one exists. If a thread is waiting on the timer, it is unblocked. Attempting to stop a non-running timer is permitted, but has no effect on the timer since it is already stopped.

A running timer can be restarted in mid-countdown, if desired. The timer's status is reset to zero, then the timer begins counting down using the new duration and period values specified by the caller. If a thread is waiting on the timer, it continues waiting.

A timer's status can be read directly at any time to determine how many times the timer has expired since its status was last read. Reading a timer's status resets its value to zero. The amount of time remaining before the timer expires can also be read; a value of zero indicates that the timer is stopped.

A thread may read a timer's status indirectly by **synchronizing** with the timer. This blocks the thread until the timer's status is non-zero (indicating that it has expired at least once) or the timer is stopped; if the timer status is already non-zero or the timer is already stopped the thread continues without waiting. The synchronization operation returns the timer's status and resets it to zero.

**Note:** Only a single user should examine the status of any given timer, since reading the status (directly or indirectly) changes its value. Similarly, only a single thread at a time should synchronize with a given timer. ISRs are not permitted to synchronize with timers, since ISRs are not allowed to block.

**Implementation**

**Defining a Timer**  A timer is defined using a variable of type `k_timer`. It must then be initialized by calling `k_timer_init()`.

The following code defines and initializes a timer.

```c
struct k_timer my_timer;
extern void my_expiry_function(struct k_timer *timer_id);
k_timer_init(&my_timer, my_expiry_function, NULL);
```

Alternatively, a timer can be defined and initialized at compile time by calling `K_TIMER_DEFINE`.

The following code has the same effect as the code segment above.

```c
K_TIMER_DEFINE(my_timer, my_expiry_function, NULL);
```
Using a Timer Expiry Function  The following code uses a timer to perform a non-trivial action on a periodic basis. Since the required work cannot be done at interrupt level, the timer’s expiry function submits a work item to the `system workqueue`, whose thread performs the work.

```c
void my_work_handler(struct k_work *work)
{
    /* do the processing that needs to be done periodically */
    ...
}

K_WORK_DEFINE(my_work, my_work_handler);

void my_timer_handler(struct k_timer *dummy)
{
    k_work_submit(&my_work);
}

K_TIMER_DEFINE(my_timer, my_timer_handler, NULL);
...

// start periodic timer that expires once every second */
k_timer_start(&my_timer, K_SECONDS(1), K_SECONDS(1));
```

Reading Timer Status  The following code reads a timer's status directly to determine if the timer has expired or not.

```c
K_TIMER_DEFINE(my_status_timer, NULL, NULL);
...

// start one shot timer that expires after 200 ms */
k_timer_start(&my_status_timer, K_MSEC(200), K_NO_WAIT);

// do work */
...

// check timer status */
if (k_timer_status_get(&my_status_timer) > 0) {
    /* timer has expired */
} else if (k_timer_remaining_get(&my_status_timer) == 0) {
    /* timer was stopped (by someone else) before expiring */
} else {
    /* timer is still running */
}
```

Using Timer Status Synchronization  The following code performs timer status synchronization to allow a thread to do useful work while ensuring that a pair of protocol operations are separated by the specified time interval.

```c
K_TIMER_DEFINE(my_sync_timer, NULL, NULL);
...

// do first protocol operation */
...
/* start one shot timer that expires after 500 ms */
k_timer_start(&my_sync_timer, K_MSEC(500), K_NO_WAIT);

/* do other work */
...

/* ensure timer has expired (waiting for expiry, if necessary) */
k_timer_status_sync(&my_sync_timer);

/* do second protocol operation */
...

Note: If the thread had no other work to do it could simply sleep between the two protocol operations, without using a timer.

Suggested Uses  Use a timer to initiate an asynchronous operation after a specified amount of time.
Use a timer to determine whether or not a specified amount of time has elapsed. In particular, timers should be used when higher precision and/or unit control is required than that afforded by the simpler k_sleep() and k_usleep() calls.
Use a timer to perform other work while carrying out operations involving time limits.

Note: If a thread needs to measure the time required to perform an operation it can read the system clock or the hardware clock directly, rather than using a timer.

Configuration Options  Related configuration options:
  • None

  • KSCAN - Use the KSCAN API to read key presses and releases on a keyboard matrix.

group timer_apis

Defines

K_TIMER_DEFINE(name, expiry_fn, stop_fn)
  Statically define and initialize a timer.
The timer can be accessed outside the module where it is defined using:

extern struct k_timer <name>;

Parameters
  • name – Name of the timer variable.
  • expiry_fn – Function to invoke each time the timer expires.
• stop_fn – Function to invoke if the timer is stopped while running.

Typedefs

typedef void (*k_timer_expiry_t)(struct k_timer *timer)

Timer expiry function type.

A timer's expiry function is executed by the system clock interrupt handler each time the timer expires. The expiry function is optional, and is only invoked if the timer has been initialized with one.

Param timer
Address of timer.

typedef void (*k_timer_stop_t)(struct k_timer *timer)

Timer stop function type.

A timer's stop function is executed if the timer is stopped prematurely. The function runs in the context of call that stops the timer. As k_timer_stop() can be invoked from an ISR, the stop function must be callable from interrupt context (isr-ok).

The stop function is optional, and is only invoked if the timer has been initialized with one.

Param timer
Address of timer.

Functions

void k_timer_init(struct k_timer *timer, k_timer_expiry_t expiry_fn, k_timer_stop_t stop_fn)

Initialize a timer.

This routine initializes a timer, prior to its first use.

Parameters

• timer – Address of timer.
• expiry_fn – Function to invoke each time the timer expires.
• stop_fn – Function to invoke if the timer is stopped while running.

void k_timer_start(struct k_timer *timer, k_timeout_t duration, k_timeout_t period)

Start a timer.

This routine starts a timer, and resets its status to zero. The timer begins counting down using the specified duration and period values.

Attempting to start a timer that is already running is permitted. The timer's status is reset to zero and the timer begins counting down using the new duration and period values.

Parameters

• timer – Address of timer.
• duration – Initial timer duration.
• period – Timer period.

void k_timer_stop(struct k_timer *timer)

Stop a timer.

This routine stops a running timer prematurely. The timer's stop function, if one exists, is invoked by the caller.
Attempting to stop a timer that is not running is permitted, but has no effect on the timer.

**Function properties (list may not be complete)**

`isr-ok`

**Note:** The stop handler has to be callable from ISRs if `k_timer_stop` is to be called from ISRs.

**Parameters**

- `timer` – Address of timer.

```c
uint32_t k_timer_status_get(struct k_timer *timer)
```

Read timer status.

This routine reads the timer’s status, which indicates the number of times it has expired since its status was last read.

Calling this routine resets the timer’s status to zero.

**Parameters**

- `timer` – Address of timer.

**Returns**

Timer status.

```c
uint32_t k_timer_status_sync(struct k_timer *timer)
```

Synchronize thread to timer expiration.

This routine blocks the calling thread until the timer’s status is non-zero (indicating that it has expired at least once since it was last examined) or the timer is stopped. If the timer status is already non-zero, or the timer is already stopped, the caller continues without waiting.

Calling this routine resets the timer’s status to zero.

This routine must not be used by interrupt handlers, since they are not allowed to block.

**Parameters**

- `timer` – Address of timer.

**Returns**

Timer status.

```c
k_ticks_t k_timer_expires_ticks(const struct k_timer *timer)
```

Get next expiration time of a timer, in system ticks.

This routine returns the future system uptime reached at the next time of expiration of the timer, in units of system ticks. If the timer is not running, current system time is returned.

**Parameters**

- `timer` – The timer object

**Returns**

Uptime of expiration, in ticks

```c
k_ticks_t k_timer_remaining_ticks(const struct k_timer *timer)
```

Get time remaining before a timer next expires, in system ticks.

This routine computes the time remaining before a running timer next expires, in units of system ticks. If the timer is not running, it returns zero.
static inline uint32_t k_timer_remaining_get(struct k_timer *timer)
    Get time remaining before a timer next expires.
    
    This routine computes the (approximate) time remaining before a running timer next expires. 
    If the timer is not running, it returns zero.

    Parameters
    • timer – Address of timer.

    Returns
    Remaining time (in milliseconds).

void k_timer_user_data_set(struct k_timer *timer, void *user_data)
    Associate user-specific data with a timer.
    
    This routine records the user_data with the timer, to be retrieved later.
    It can be used e.g. in a timer handler shared across multiple subsystems to retrieve data
    specific to the subsystem this timer is associated with.

    Parameters
    • timer – Address of timer.
    • user_data – User data to associate with the timer.

void *k_timer_user_data_get(const struct k_timer *timer)
    Retrieve the user-specific data from a timer.

    Parameters
    • timer – Address of timer.

    Returns
    The user data.

These pages cover other kernel services.

Atomic Services
An atomic variable is one that can be read and modified by threads and ISRs in an uninterruptible manner. 
It 32-bit on 32-bit machines and 64-bit on 64-bit machines.

- Concepts
- Implementation
  - Defining an Atomic Variable
  - Manipulating an Atomic Variable
  - Manipulating an Array of Atomic Variables
  - Memory Ordering
- Suggested Uses
- Configuration Options
- API Reference
Concepts

Any number of atomic variables can be defined (limited only by available RAM).

Using the kernel's atomic APIs to manipulate an atomic variable guarantees that the desired operation occurs correctly, even if higher priority contexts also manipulate the same variable.

The kernel also supports the atomic manipulation of a single bit in an array of atomic variables.

Implementation

Defining an Atomic Variable

An atomic variable is defined using a variable of type `atomic_t`.

By default an atomic variable is initialized to zero. However, it can be given a different value using `ATOMIC_INIT`:

```c
atomic_t flags = ATOMIC_INIT(0xFF);
```

Manipulating an Atomic Variable

An atomic variable is manipulated using the APIs listed at the end of this section.

The following code shows how an atomic variable can be used to keep track of the number of times a function has been invoked. Since the count is incremented atomically, there is no risk that it will become corrupted in mid-increment if a thread calling the function is interrupted if by a higher priority context that also calls the routine.

```c
atomic_t call_count;

int call_counting_routine(void)
{
    /* increment invocation counter */
    atomic_inc(&call_count);

    /* do rest of routine's processing */
    ...
}
```

Manipulating an Array of Atomic Variables

An array of 32-bit atomic variables can be defined in the conventional manner. However, you can also define an N-bit array of atomic variables using `ATOMIC_DEFINE`.

A single bit in array of atomic variables can be manipulated using the APIs listed at the end of this section that end with `_bit()`.

The following code shows how a set of 200 flag bits can be implemented using an array of atomic variables.

```c
#define NUM_FLAG_BITS 200

ATOMIC_DEFINE(flag_bits, NUM_FLAG_BITS);

/* set specified flag bit & return its previous value */
int set_flag_bit(int bit_position)
{
    return (int)atomic_set_bit(flag_bits, bit_position);
}
```
**Memory Ordering**  For consistency and correctness, all Zephyr atomic APIs are expected to include a full memory barrier (in the sense of e.g. “serializing” instructions on x86, “DMB” on ARM, or a “sequentially consistent” operation as defined by the C++ memory model) where needed by hardware to guarantee a reliable picture across contexts. Any architecture-specific implementations are responsible for ensuring this behavior.

**Suggested Uses**  Use an atomic variable to implement critical section processing that only requires the manipulation of a single 32-bit value.

Use multiple atomic variables to implement critical section processing on a set of flag bits in a bit array longer than 32 bits.

**Note:**  Using atomic variables is typically far more efficient than using other techniques to implement critical sections such as using a mutex or locking interrupts.

**Configuration Options**  Related configuration options:

- `CONFIG_ATOMIC_OPERATIONS_BUILTIN`
- `CONFIG_ATOMIC_OPERATIONS_ARCH`
- `CONFIG_ATOMIC_OPERATIONS_C`

**API Reference**

**Important:**  All atomic services APIs can be used by both threads and ISRs.

---

`group atomic_apis`

**Defines**

**ATOMIC_INIT(i)**

Initialize an atomic variable.

This macro can be used to initialize an atomic variable. For example,

```
atomic_t my_var = ATOMIC_INIT(75);
```

**Parameters**

- `i` – Value to assign to atomic variable.

**ATOMIC_PTR_INIT(p)**

Initialize an atomic pointer variable.

This macro can be used to initialize an atomic pointer variable. For example,

```
atomic_ptr_t my_ptr = ATOMIC_PTR_INIT(&data);
```

**Parameters**

- `p` – Pointer value to assign to atomic pointer variable.
ATOMIC_BITMAP_SIZE(num_bits)
This macro computes the number of atomic variables necessary to represent a bitmap with num_bits.

Parameters
- num_bits – Number of bits.

ATOMIC_DEFINE(name, num_bits)
Define an array of atomic variables.
This macro defines an array of atomic variables containing at least num_bits bits.

Note: If used from file scope, the bits of the array are initialized to zero; if used from within a function, the bits are left uninitialized.

Parameters
- name – Name of array of atomic variables.
- num_bits – Number of bits needed.

Functions

static inline bool atomic_test_bit(const atomic_t *target, int bit)
Atomically test a bit.
This routine tests whether bit number bit of target is set or not. The target may be a single atomic variable or an array of them.

Note: As for all atomic APIs, includes a full/sequentially-consistant memory barrier (where applicable).

Parameters
- target – Address of atomic variable or array.
- bit – Bit number (starting from 0).

Returns
true if the bit was set, false if it wasn’t.

static inline bool atomic_test_and_clear_bit(atomic_t *target, int bit)
Atomically test and clear a bit.
Atomically clear bit number bit of target and return its old value. The target may be a single atomic variable or an array of them.

Note: As for all atomic APIs, includes a full/sequentially-consistant memory barrier (where applicable).

Parameters
- target – Address of atomic variable or array.
- bit – Bit number (starting from 0).

Returns
false if the bit was already cleared, true if it wasn’t.
static inline bool atomic_test_and_set_bit(atomic_t *target, int bit)
    Atomically set a bit.
    Atomically set bit number bit of target and return its old value. The target may be a single
    atomic variable or an array of them.

    **Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where
    applicable).

    **Parameters**
    
    • target – Address of atomic variable or array.
    • bit – Bit number (starting from 0).

    **Returns**
    true if the bit was already set, false if it wasn’t.

static inline void atomic_clear_bit(atomic_t *target, int bit)
    Atomically clear a bit.
    Atomically clear bit number bit of target. The target may be a single atomic variable or an
    array of them.

    **Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where
    applicable).

    **Parameters**
    
    • target – Address of atomic variable or array.
    • bit – Bit number (starting from 0).

static inline void atomic_set_bit(atomic_t *target, int bit)
    Atomically set a bit.
    Atomically set bit number bit of target. The target may be a single atomic variable or an array
    of them.

    **Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where
    applicable).

    **Parameters**
    
    • target – Address of atomic variable or array.
    • bit – Bit number (starting from 0).

static inline void atomic_set_bit_to(atomic_t *target, int bit, bool val)
    Atomically set a bit to a given value.
    Atomically set bit number bit of target to value val. The target may be a single atomic variable
    or an array of them.

    **Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where
    applicable).
Parameters

- **target** – Address of atomic variable or array.
- **bit** – Bit number (starting from 0).
- **val** – true for 1, false for 0.

static inline bool atomic_cas(atomic_t *target, atomic_val_t old_value, atomic_val_t new_value)

Atomic compare-and-set.

This routine performs an atomic compare-and-set on `target`. If the current value of `target` equals `old_value`, `target` is set to `new_value`. If the current value of `target` does not equal `old_value`, `target` is left unchanged.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.
- **old_value** – Original value to compare against.
- **new_value** – New value to store.

Returns

true if `new_value` is written, false otherwise.

static inline bool atomic_ptr_cas(atomic_ptr_t *target, atomic_ptr_val_t old_value, atomic_ptr_val_t new_value)

Atomic compare-and-set with pointer values.

This routine performs an atomic compare-and-set on `target`. If the current value of `target` equals `old_value`, `target` is set to `new_value`. If the current value of `target` does not equal `old_value`, `target` is left unchanged.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters

- **target** – Address of atomic variable.
- **old_value** – Original value to compare against.
- **new_value** – New value to store.

Returns

true if `new_value` is written, false otherwise.

static inline atomic_val_t atomic_add(atomic_t *target, atomic_val_t value)

Atomic addition.

This routine performs an atomic addition on `target`.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).
• target – Address of atomic variable.
• value – Value to add.

**Returns**
Previous value of target.

static inline atomic_val_t atomic_sub(atomic_t *target, atomic_val_t value)
Atomic subtraction.
This routine performs an atomic subtraction on target.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

**Parameters**
• target – Address of atomic variable.
• value – Value to subtract.

**Returns**
Previous value of target.

static inline atomic_val_t atomic_inc(atomic_t *target)
Atomic increment.
This routine performs an atomic increment by 1 on target.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

**Parameters**
• target – Address of atomic variable.

**Returns**
Previous value of target.

static inline atomic_val_t atomic_dec(atomic_t *target)
Atomic decrement.
This routine performs an atomic decrement by 1 on target.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

**Parameters**
• target – Address of atomic variable.

**Returns**
Previous value of target.

static inline atomic_val_t atomic_get(const atomic_t *target)
Atomic get.
This routine performs an atomic read on target.
### atomic_val_t atomic_set(atomic_t *target, atomic_val_t value)

**Atomic get-and-set.** This routine atomically sets `target` to `value` and returns the previous value of `target`.

**Parameters**
- `target` – Address of atomic variable.
- `value` – Value to write to `target`.

**Returns**
Previous value of `target`.

### atomic_ptr_val_t atomic_ptr_set(atomic_ptr_t *target, atomic_ptr_val_t value)

**Atomic get-and-set for pointer values.** This routine atomically sets `target` to `value` and returns the previous value of `target`.

**Parameters**
- `target` – Address of atomic variable.
- `value` – Value to write to `target`.

**Returns**
Previous value of `target`.
static inline atomic_val_t atomic_clear(atomic_t *target)
Atomic clear.
This routine atomically sets target to zero and returns its previous value. (Hence, it is equivalent to atomic_set(target, 0).)

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.

static inline atomic_ptr_val_t atomic_ptr_clear(atomic_ptr_t *target)
Atomic clear of a pointer value.
This routine atomically sets target to zero and returns its previous value. (Hence, it is equivalent to atomic_set(target, 0).)

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.

static inline atomic_val_t atomic_or(atomic_t *target, atomic_val_t value)
Atomic bitwise inclusive OR.
This routine atomically sets target to the bitwise inclusive OR of target and value.

Note: As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

Parameters
• target – Address of atomic variable.
• value – Value to OR.

static inline atomic_val_t atomic_xor(atomic_t *target, atomic_val_t value)
Atomic bitwise exclusive OR (XOR).
This routine atomically sets target to the bitwise exclusive OR (XOR) of target and value.

3.1. Kernel Services 435
**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

**Parameters**

- `target` – Address of atomic variable.
- `value` – Value to XOR

**Returns**

Previous value of `target`.

```c
static inline atomic_val_t atomic_and(atomic_t *target, atomic_val_t value)
```

Atomic bitwise AND.

This routine atomically sets `target` to the bitwise AND of `target` and `value`.

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

**Parameters**

- `target` – Address of atomic variable.
- `value` – Value to AND.

**Returns**

Previous value of `target`.

```c
static inline atomic_val_t atomic_nand(atomic_t *target, atomic_val_t value)
```

Atomic bitwise NAND.

This routine atomically sets `target` to the bitwise NAND of `target` and `value`. (This operation is equivalent to `target = ~(target & value)`.)

**Note:** As for all atomic APIs, includes a full/sequentially-consistent memory barrier (where applicable).

**Parameters**

- `target` – Address of atomic variable.
- `value` – Value to NAND.

**Returns**

Previous value of `target`.

**Floating Point Services**

The kernel allows threads to use floating point registers on board configurations that support these registers.

**Note:** Floating point services are currently available only for boards based on ARM Cortex-M SoCs supporting the Floating Point Extension, the Intel x86 architecture, the SPARC architecture and ARCv2 SoCs supporting the Floating Point Extension. The services provided are architecture specific.
The kernel does not support the use of floating point registers by ISRs.

- **Concepts**
  - No FP registers mode
  - Unshared FP registers mode
  - Shared FP registers mode
- **Implementation**
  - Performing Floating Point Arithmetic
- **Suggested Uses**
- **Configuration Options**
- **API Reference**

**Concepts**  The kernel can be configured to provide only the floating point services required by an application. Three modes of operation are supported, which are described below. In addition, the kernel's support for the SSE registers can be included or omitted, as desired.

**No FP registers mode**  This mode is used when the application has no threads that use floating point registers. It is the kernel's default floating point services mode. If a thread uses any floating point register, the kernel generates a fatal error condition and aborts the thread.

**Unshared FP registers mode**  This mode is used when the application has only a single thread that uses floating point registers. On x86 platforms, the kernel initializes the floating point registers so they can be used by any thread (initialization in skipped on ARM Cortex-M platforms and ARCv2 platforms). The floating point registers are left unchanged whenever a context switch occurs.

**Note:**  The behavior is undefined, if two or more threads attempt to use the floating point registers, as the kernel does not attempt to detect (or prevent) multiple threads from using these registers.

**Shared FP registers mode**  This mode is used when the application has two or more threads that use floating point registers. Depending upon the underlying CPU architecture, the kernel supports one or more of the following thread sub-classes:

- non-user: A thread that cannot use any floating point registers
- FPU user: A thread that can use the standard floating point registers
- SSE user: A thread that can use both the standard floating point registers and SSE registers

The kernel initializes and enables access to the floating point registers, so they can be used by any thread, then saves and restores these registers during context switches to ensure the computations performed by each FPU user or SSE user are not impacted by the computations performed by the other users.
On the ARM Cortex-M architecture with the Floating Point Extension, the kernel treats all threads as FPU users when shared FP registers mode is enabled. This means that any thread is allowed to access the floating point registers. The ARM kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them.

Pretag a thread that intends to use the FP registers by using one of the techniques listed below.

- A statically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created ARM thread can be pretagged by passing the `K_FP_REGS` option to `k_thread_create()`.

Pretagging a thread with the `K_FP_REGS` option instructs the MPU-based stack protection mechanism to properly configure the size of the thread’s guard region to always guarantee stack overflow detection, and enable lazy stacking for the given thread upon thread creation.

During thread context switching the ARM kernel saves the callee-saved floating point registers, if the switched-out thread has been using them. Additionally, the caller-saved floating point registers are saved on the thread’s stack. If the switched-in thread has been using the floating point registers, the kernel restores the callee-saved FP registers of the switched-in thread and the caller-saved FP context is restored from the thread’s stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers.

Each thread that intends to use the floating point registers must provide an extra 72 bytes of stack space where the callee-saved FP context can be saved.

Lazy Stacking is currently enabled in Zephyr applications on ARM Cortex-M architecture, minimizing interrupt latency, when the floating point context is active.

When the MPU-based stack protection mechanism is not enabled, lazy stacking is always active in the Zephyr application. When the MPU-based stack protection is enabled, the following rules apply with respect to lazy stacking:

- Lazy stacking is activated by default on threads that are pretagged with `K_FP_REGS`.
- Lazy stacking is activated dynamically on threads that are not pretagged with `K_FP_REGS`, as soon as the kernel detects that they are using the floating point registers.

If an ARM thread does not require use of the floating point registers any more, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching.

On the ARM64 (Aarch64) architecture the kernel treats each thread as a FPU user on a case-by-case basis. A “lazy save” algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are not saved when switching from an FPU user to a non-user thread, and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don’t have a persistent register context, there are no provision for saving an ISR’s FPU context either, hence the IRQ disabling.
Each thread object becomes 512 bytes larger when Shared FP registers mode is enabled.

**ARCv2 architecture**  On the ARCv2 architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques:

- A statically-created ARC thread can be tagged by passing the `K_FP_REGS` option to `k_thread_define`.
- A dynamically-created ARC thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

If an ARC thread does not require use of the floating point registers any more, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching.

During thread context switching the ARC kernel saves the *callee-saved* floating point registers, if the switched-out thread has been using them. Additionally, the *caller-saved* floating point registers are saved on the thread's stack. If the switched-in thread has been using the floating point registers, the kernel restores the *callee-saved* FP registers of the switched-in thread and the *caller-saved* FP context is restored from the thread's stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers. An extra 16 bytes (single floating point hardware) or 32 bytes (double floating point hardware) of stack space is required to load and store floating point registers.

**RISC-V architecture**  On the RISC-V architecture the kernel treats each thread as an FPU user on a case-by-case basis with the FPU access allocated on demand. A “lazy save” algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the FPU registers are *not* saved when switching from an FPU user to a non-user thread (or an FPU user that doesn’t touch the FPU during its scheduling slot), and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don’t have a persistent register context, there are no provision for saving an ISR’s FPU context either, hence the IRQ disabling.

As an optimization, the FPU context is preemptively restored upon scheduling back an “active FPU user” thread that had its FPU context saved away due to FPU usage by another thread. Active FPU users are so designated when they make the FPU state “dirty” during their most recent scheduling slot before being scheduled out. So if a thread doesn’t modify the FPU state within its scheduling slot and another thread claims the FPU for itself afterwards then that first thread will be subjected to the on-demand regime and won’t have its FPU context restored until it attempts to access it again. But if that thread does modify the FPU before being scheduled out then it is likely to continue using it when scheduled back in and preemptively restoring its FPU context saves on the exception trap overhead that would occur otherwise.

Each thread object becomes 136 bytes (single-precision floating point hardware) or 264 bytes (double-precision floating point hardware) larger when Shared FP registers mode is enabled.

**SPARC architecture**  On the SPARC architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques:

- A statically-created thread can be tagged by passing the `K_FP_REGS` option to `k_thread_define`.
- A dynamically-created thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

During thread context switch at exit from interrupt handler, the SPARC kernel saves *all* floating point registers, if the FPU was enabled in the switched-out thread. Floating point registers are saved on the thread’s stack. Floating point registers are restored when a thread context is restored if they were saved at the context save. Saving and restoring of the floating point registers is synchronous and thus not lazy.

The FPU is always disabled when an ISR is called (independent of `CONFIG_FPU_SHARING`).

Floating point disabling with `k_float_disable()` is not implemented.
When `CONFIG_FPU_SHARING` is used, then 136 bytes of stack space is required for each FPU user thread to load and store floating point registers. No extra stack is required if `CONFIG_FPU_SHARING` is not used.

**x86 architecture**  On the x86 architecture the kernel treats each thread as a non-user, FPU user or SSE user on a case-by-case basis. A “lazy save” algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are not saved when switching from an FPU user to a non-user thread, and then back to the original FPU user. The following table indicates the amount of additional stack space a thread must provide so the registers can be saved properly.

<table>
<thead>
<tr>
<th>Thread type</th>
<th>FP register use</th>
<th>Extra stack space required</th>
</tr>
</thead>
<tbody>
<tr>
<td>cooperative</td>
<td>any</td>
<td>0 bytes</td>
</tr>
<tr>
<td>preemptive</td>
<td>none</td>
<td>0 bytes</td>
</tr>
<tr>
<td>preemptive</td>
<td>FPU</td>
<td>108 bytes</td>
</tr>
<tr>
<td>preemptive</td>
<td>SSE</td>
<td>464 bytes</td>
</tr>
</tbody>
</table>

The x86 kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them. The thread is tagged as an SSE user if the kernel has been configured to support the SSE registers, or as an FPU user if the SSE registers are not supported. If this would result in a thread that is an FPU user being tagged as an SSE user, or if the application wants to avoid the exception handling overhead involved in auto-tagging threads, it is possible to pretag a thread using one of the techniques listed below.

- A statically-created x86 thread can be pretagged by passing the `K_FP_REGS` or `K_SSE_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created x86 thread can be pretagged by passing the `K_FP_REGS` or `K_SSE_REGS` option to `k_thread_create()`.
- An already-created x86 thread can pretag itself once it has started by passing the `K_FP_REGS` or `K_SSE_REGS` option to `k_float_enable()`.

If an x86 thread uses the floating point registers infrequently it can call `k_float_disable()` to remove its tagging as an FPU user or SSE user. This eliminates the need for the kernel to take steps to preserve the contents of the floating point registers during context switches when there is no need to do so. When the thread again needs to use the floating point registers it can re-tag itself as an FPU user or SSE user by calling `k_float_enable()`.

**Implementation**

**Performing Floating Point Arithmetic**  No special coding is required for a thread to use floating point arithmetic if the kernel is properly configured.

The following code shows how a routine can use floating point arithmetic to avoid overflow issues when computing the average of a series of integer values.

```c
int average(int *values, int num_values)
{
    double sum;
    int i;
    sum = 0.0;
    for (i = 0; i < num_values; i++) {
        sum += *values;
        values++;
    }
    return sum / num_values;
}
```
Suggested Uses  Use the kernel floating point services when an application needs to perform floating point operations.

Configuration Options  To configure unshared FP registers mode, enable the CONFIG_FPU configuration option and leave the CONFIG_FPU_SHARING configuration option disabled.

To configure shared FP registers mode, enable both the CONFIG_FPU configuration option and the CONFIG_FPU_SHARING configuration option. Also, ensure that any thread that uses the floating point registers has sufficient added stack space for saving floating point register values during context switches, as described above.

For x86, use the CONFIG_X86_SSE configuration option to enable support for SSEx instructions.

API Reference

group float APIs

Version

Kernel version handling and APIs related to kernel version being used.

API Reference

uint32_t sys_kernel_version_get(void)

Return the kernel version of the present build.

The kernel version is a four-byte value, whose format is described in the file “kernel_version.h”.

Returns

kernel version

SYS_KERNEL_VER_MAJOR(ver)

SYS_KERNEL_VER_MINOR(ver)

SYS_KERNEL_VER_PATCHLEVEL(ver)

Fatal Errors

Software Errors Triggered in Source Code  Zephyr provides several methods for inducing fatal error conditions through either build-time checks, conditionally compiled assertions, or deliberately invoked panic or oops conditions.

Runtime Assertions  Zephyr provides some macros to perform runtime assertions which may be conditionally compiled. Their definitions may be found in include/zephyr/sys/__assert.h.

Assertions are enabled by setting the __ASSERT_ON preprocessor symbol to a non-zero value. There are two ways to do this:

• Use the CONFIG_ASSERT and CONFIG_ASSERT_LEVEL kconfig options.
• Add `-D__ASSERT_ON=<level>` to the project’s `CFLAGS`, either on the build command line or in a `CMakeLists.txt`.

The `__ASSERT_ON` method takes precedence over the `kconfig` option if both are used.

Specifying an assertion level of 1 causes the compiler to issue warnings that the kernel contains debug-type `__ASSERT()` statements; this reminder is issued since assertion code is not normally present in a final product. Specifying assertion level 2 suppresses these warnings.

Assertions are enabled by default when running Zephyr test cases, as configured by the `CONFIG_TEST` option.

The policy for what to do when encountering a failed assertion is controlled by the implementation of `assert_post_action()`. Zephyr provides a default implementation with weak linkage which invokes a kernel oops if the thread that failed the assertion was running in user mode, and a kernel panic otherwise.

`__ASSERT()` The `__ASSERT()` macro can be used inside kernel and application code to perform optional runtime checks which will induce a fatal error if the check does not pass. The macro takes a string message which will be printed to provide context to the assertion. In addition, the kernel will print a text representation of the expression code that was evaluated, and the file and line number where the assertion can be found.

For example:

```
__ASSERT(foo == 0xF0CACC1A, "Invalid value of foo, got 0x%x", foo);
```

If at runtime `foo` had some unexpected value, the error produced may look like the following:

```
ASSERTION FAIL [foo == 0xF0CACC1A] @ ZEPHYR_BASE/tests/kernel/fatal/src/main.c:367
    Invalid value of foo, got 0xdeadbeef
[00:00:00.000,000] <err> os: r0/a1: 0x00000004 r1/a2: 0x0000016f r2/a3: 0x00000000
[00:00:00.000,000] <err> os: r3/a4: 0x00000000 r12/ip: 0x00000000 r14/lr: 0x00000a6d
[00:00:00.000,000] <err> os: xpsr: 0x61000000
[00:00:00.000,000] <err> os: Faulting instruction address (r15/pc): 0x00009fe4
[00:00:00.000,000] <err> os: >>> ZEPHYR FATAL ERROR 4: Kernel panic
[00:00:00.000,000] <err> os: Current thread: 0x20000414 (main)
[00:00:00.000,000] <err> os: Halting system
```

`__ASSERT_EVAL()` The `__ASSERT_EVAL()` macro can also be used inside kernel and application code, with special semantics for the evaluation of its arguments.

It makes use of the `__ASSERT()` macro, but has some extra flexibility. It allows the developer to specify different actions depending whether the `__ASSERT()` macro is enabled or not. This can be particularly useful to prevent the compiler from generating comments (errors, warnings or remarks) about variables that are only used with `__ASSERT()` being assigned a value, but otherwise unused when the `__ASSERT()` macro is disabled.

Consider the following example:

```
int x;
x = foo();
__ASSERT(x != 0, "foo() returned zero!");
```

If `__ASSERT()` is disabled, then ‘x’ is assigned a value, but never used. This type of situation can be resolved using the `__ASSERT_EVAL()` macro.
__ASSERT_EVAL ((void) foo(),
int x = foo(),
x != 0,
"foo() returned zero!");

The first parameter tells __ASSERT_EVAL() what to do if __ASSERT() is disabled. The second parameter tells __ASSERT_EVAL() what to do if __ASSERT() is enabled. The third and fourth parameters are the parameters it passes to __ASSERT().

__ASSERT_NO_MSG() The __ASSERT_NO_MSG() macro can be used to perform an assertion that reports the failed test and its location, but lacks additional debugging information provided to assist the user in diagnosing the problem; its use is discouraged.

Build Assertions Zephyr provides two macros for performing build-time assertion checks. These are evaluated completely at compile-time, and are always checked.

BUILD_ASSERT() This has the same semantics as C's _Static_assert or C++'s static_assert. If the evaluation fails, a build error will be generated by the compiler. If the compiler supports it, the provided message will be printed to provide further context.

Unlike __ASSERT(), the message must be a static string, without printf()-like format codes or extra arguments.

For example, suppose this check fails:

BUILD_ASSERT(FOO == 2000, "Invalid value of FOO");

With GCC, the output resembles:

```
tests/kernel/fatal/src/main.c: In function 'test_main':
include/toolchain/gcc.h:28:37: error: static assertion failed: "Invalid value of FOO"
#define BUILD_ASSERT(EXPR, MSG) _Static_assert(EXPR, "" MSG)
^~~~~~~~~~~~~~
tests/kernel/fatal/src/main.c:370:2: note: in expansion of macro 'BUILD_ASSERT'
BUILD_ASSERT(FOO == 2000,
^~~~~~~~~~~~~~~
```

Kernel Oops A kernel oops is a software triggered fatal error invoked by k_oops(). This should be used to indicate an unrecoverable condition in application logic.

The fatal error reason code generated will be K_ERR_KERNEL_OOPS.

Kernel Panic A kernel error is a software triggered fatal error invoked by k_panic(). This should be used to indicate that the Zephyr kernel is in an unrecoverable state. Implementations of k_sys_fatal_error_handler() should not return if the kernel encounters a panic condition, as the entire system needs to be reset.

Threads running in user mode are not permitted to invoke k_panic(), and doing so will generate a kernel oops instead. Otherwise, the fatal error reason code generated will be K_ERR_KERNEL_PANIC.

Exceptions

Spurious Interrupts If the CPU receives a hardware interrupt on an interrupt line that has not had a handler installed with IRQ_CONNECT() or irq_connect_dynamic(), then the kernel will generate a fatal error with the reason code K_ERR_SPURIOUS_IRQ().
Stack Overflows  In the event that a thread pushes more data onto its execution stack than its stack buffer provides, the kernel may be able to detect this situation and generate a fatal error with a reason code of K_ERR_STACK_CHK_FAIL.

If a thread is running in user mode, then stack overflows are always caught, as the thread will simply not have permission to write to adjacent memory addresses outside of the stack buffer. Because this is enforced by the memory protection hardware, there is no risk of data corruption to memory that the thread would not otherwise be able to write to.

If a thread is running in supervisor mode, or if CONFIG_USERSPACE is not enabled, depending on configuration stack overflows may or may not be caught. CONFIG_HW_STACK_PROTECTION is supported on some architectures and will catch stack overflows in supervisor mode, including when handling a system call on behalf of a user thread. Typically this is implemented via dedicated CPU features, or read-only MMU/MPU guard regions placed immediately adjacent to the stack buffer. Stack overflows caught in this way can detect the overflow, but cannot guarantee against data corruption and should be treated as a very serious condition impacting the health of the entire system.

If a platform lacks memory management hardware support, CONFIG_STACK_SENTINEL is a software-only stack overflow detection feature which periodically checks if a sentinel value at the end of the stack buffer has been corrupted. It does not require hardware support, but provides no protection against data corruption. Since the checks are typically done at interrupt exit, the overflow may be detected a nontrivial amount of time after the stack actually overflowed.

Finally, Zephyr supports GCC compiler stack canaries via CONFIG_STACK_CANARIES. If enabled, the compiler will insert a canary value randomly generated at boot into function stack frames, checking that the canary has not been overwriten at function exit. If the check fails, the compiler invokes __stack_chk_fail(), whose Zephyr implementation invokes a fatal stack overflow error. An error in this case does not indicate that the entire stack buffer has overflowed, but instead that the current function stack frame has been corrupted. See the compiler documentation for more details.

Other Exceptions  Any other type of unhandled CPU exception will generate an error code of K_ERR_CPU_EXCEPTION.

Fatal Error Handling  The policy for what to do when encountering a fatal error is determined by the implementation of the k_sys_fatal_error_handler() function. This function has a default implementation with weak linkage that calls LOG_PANIC() to dump all pending logging messages and then unconditionally halts the system with k_fatal_halt().

Applications are free to implement their own error handling policy by overriding the implementation of k_sys_fatal_error_handler(). If the implementation returns, the faulting thread will be aborted and the system will otherwise continue to function. See the documentation for this function for additional details and constraints.

API Reference

group fatal_apis

Functions

FUNC_NORETURN void k_fatal_halt(unsigned int reason)
  Halt the system on a fatal error.
  Invokes architecture-specific code to power off or halt the system in a low power state. Lacking that, lock interrupts and sit in an idle loop.

Parameters

  • reason – Fatal exception reason code
void k_sys_fatal_error_handler(unsigned int reason, const z_arch_esf_t *esf)

Fatal error policy handler.

This function is not invoked by application code, but is declared as a weak symbol so that applications may introduce their own policy.

The default implementation of this function halts the system unconditionally. Depending on architecture support, this may be a simple infinite loop, power off the hardware, or exit an emulator.

If this function returns, then the currently executing thread will be aborted.

A few notes for custom implementations:

- If the error is determined to be unrecoverable, \texttt{LOG_PANIC()} should be invoked to flush any pending logging buffers.
- \texttt{K_ERR_KERNEL_PANIC} indicates a severe unrecoverable error in the kernel itself, and should not be considered recoverable. There is an assertion in \texttt{z_fatal_error()} to enforce this.
- Even outside of a kernel panic, unless the fault occurred in user mode, the kernel itself may be in an inconsistent state, with API calls to kernel objects possibly exhibiting undefined behavior or triggering another exception.

**Parameters**

- \texttt{reason} – The reason for the fatal error
- \texttt{esf} – Exception context, with details and partial or full register state when the error occurred. May in some cases be \texttt{NULL}.

**Thread Local Storage (TLS)**

Thread Local Storage (TLS) allows variables to be allocated on a per-thread basis. These variables are stored in the thread stack which means every thread has its own copy of these variables.

Zephyr currently requires toolchain support for TLS.

**Configuration** To enable thread local storage in Zephyr, \texttt{CONFIG_THREAD_LOCAL_STORAGE} needs to be enabled. Note that this option may not be available if the architecture or the SoC does not have the hidden option \texttt{CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE} enabled, which means the architecture or the SoC does not have the necessary code to support thread local storage and/or the toolchain does not support TLS.

\texttt{CONFIG_ERRNO_IN_TLS} can be enabled together with \texttt{CONFIG_ERRNO} to let the variable \texttt{errno} be a thread local variable. This allows user threads to access the value of \texttt{errno} without making a system call.

**Declaring and Using Thread Local Variables** The keyword \texttt{__thread} can be used to declare thread local variables.

For example, to declare a thread local variable in header files:

```c
extern __thread int i;
```

And to declare the actual variable in source files:

```c
__thread int i;
```

Keyword \texttt{static} can also be used to limit the variable within a source file:
Using the thread local variable is the same as using other variable, for example:

```c
void testing(void) {
    i = 10;
}
```

## 3.2 Device Driver Model

### 3.2.1 Introduction

The Zephyr kernel supports a variety of device drivers. Whether a driver is available depends on the board and the driver.

The Zephyr device model provides a consistent device model for configuring the drivers that are part of a system. The device model is responsible for initializing all the drivers configured into the system.

Each type of driver (e.g. UART, SPI, I2C) is supported by a generic type API.

In this model the driver fills in the pointer to the structure containing the function pointers to its API functions during driver initialization. These structures are placed into the RAM section in initialization level order.

### 3.2.2 Standard Drivers

Device drivers which are present on all supported board configurations are listed below.

- **Interrupt controller**: This device driver is used by the kernel's interrupt management subsystem.
- **Timer**: This device driver is used by the kernel's system clock and hardware clock subsystem.
- **Serial communication**: This device driver is used by the kernel's system console subsystem.
- **Entropy**: This device driver provides a source of entropy numbers for the random number generator subsystem.
3.2.3 Synchronous Calls

Zephyr provides a set of device drivers for multiple boards. Each driver should support an interrupt-based implementation, rather than polling, unless the specific hardware does not provide any interrupt.

High-level calls accessed through device-specific APIs, such as i2c.h or spi.h, are usually intended as synchronous. Thus, these calls should be blocking.

3.2.4 Driver APIs

The following APIs for device drivers are provided by device.h. The APIs are intended for use in device drivers only and should not be used in applications.

DEVICE_DEFINE()
Create device object and related data structures including setting it up for boot-time initialization.

DEVICE_NAME_GET()
Converts a device identifier to the global identifier for a device object.

DEVICE_GET()
Obtain a pointer to a device object by name.

DEVICE_DECLARE()
Declare a device object. Use this when you need a forward reference to a device that has not yet been defined.

3.2.5 Driver Data Structures

The device initialization macros populate some data structures at build time which are split into read-only and runtime-mutable parts. At a high level we have:

```c
struct device {
    const char *name;
    const void *config;
    const void *api;
    void * const data;
};
```

The config member is for read-only configuration data set at build time. For example, base memory mapped IO addresses, IRQ line numbers, or other fixed physical characteristics of the device. This is the config pointer passed to DEVICE_DEFINE() and related macros.

The data struct is kept in RAM, and is used by the driver for per-instance runtime housekeeping. For example, it may contain reference counts, semaphores, scratch buffers, etc.

The api struct maps generic subsystem APIs to the device-specific implementations in the driver. It is typically read-only and populated at build time. The next section describes this in more detail.
3.2.6 Subsystems and API Structures

Most drivers will be implementing a device-independent subsystem API. Applications can simply program to that generic API, and application code is not specific to any particular driver implementation.

A subsystem API definition typically looks like this:

```c
typedef int (*subsystem_do_this_t)(const struct device *dev, int foo, int bar);
typedef void (*subsystem_do_that_t)(const struct device *dev, void *baz);

struct subsystem_api {
    subsystem_do_this_t do_this;
    subsystem_do_that_t do_that;
};
```

```c
static inline int subsystem_do_this(const struct device *dev, int foo, int bar)
{
    struct subsystem_api *api;
    api = (struct subsystem_api *)dev->api;
    return api->do_this(dev, foo, bar);
}
```

```c
static inline void subsystem_do_that(const struct device *dev, void *baz)
{
    struct subsystem_api *api;
    api = (struct subsystem_api *)dev->api;
    api->do_that(dev, baz);
}
```

A driver implementing a particular subsystem will define the real implementation of these APIs, and populate an instance of subsystem_api structure:

```c
static int my_driver_do_this(const struct device *dev, int foo, int bar)
{
    ...
}

static void my_driver_do_that(const struct device *dev, void *baz)
{
    ...
}

static struct subsystem_api my_driver_api_funcs = {
    .do_this = my_driver_do_this,
    .do_that = my_driver_do_that
};
```

The driver would then pass `my_driver_api_funcs` as the `api` argument to `DEVICE_DEFINE()`.

**Note:** Since pointers to the API functions are referenced in the `api` struct, they will always be included in the binary even if unused; `gc-sections` linker option will always see at least one reference to them. Providing for link-time size optimizations with driver APIs in most cases requires that the optional feature be controlled by a Kconfig option.
3.2.7 Device-Specific API Extensions

Some devices can be cast as an instance of a driver subsystem such as GPIO, but provide additional functionality that cannot be exposed through the standard API. These devices combine subsystem operations with device-specific APIs, described in a device-specific header.

A device-specific API definition typically looks like this:

```c
#include <zephyr/drivers/subsystem.h>

/* When extensions need not be invoked from user mode threads */
int specific_do_that(const struct device *dev, int foo);

/* When extensions must be invokable from user mode threads */
__syscall int specific_from_user(const struct device *dev, int bar);

/* Only needed when extensions include syscalls */
#include <syscalls/specific.h>
```

A driver implementing extensions to the subsystem will define the real implementation of both the subsystem API and the specific APIs:

```c
static int generic_do_this(const struct device *dev, void *arg)
{
    ...
}

static struct generic_api api {
    ...
    .do_this = generic_do_this,
    ...
};

/* supervisor-only API is globally visible */
int specific_do_that(const struct device *dev, int foo)
{
    ...
}

/* syscall API passes through a translation */
int z_impl_specific_from_user(const struct device *dev, int bar)
{
    ...
}

#define CONFIG_USERSPACE

#include <zephyr/syscall_handler.h>

int z_vrfy_specific_from_user(const struct device *dev, int bar)
{
    Z_OOPS(Z_SYSCALL_SPECIFIC_DRIVER(dev, K_OBJ_DRIVER_GENERIC, &api));
    return z_impl_specific_do_that(dev, bar)
}

#include <syscalls/specific_from_user_mrsh.c>

#endif /* CONFIG_USERSPACE */
```
Applications use the device through both the subsystem and specific APIs.

**Note:** Public API for device-specific extensions should be prefixed with the compatible for the device to which it applies. For example, if adding special functions to support the Maxim DS3231 the identifier fragment `specific` in the examples above would be `maxim_ds3231`.

### 3.2.8 Single Driver, Multiple Instances

Some drivers may be instantiated multiple times in a given system. For example there can be multiple GPIO banks, or multiple UARTS. Each instance of the driver will have a different `config` struct and `data` struct.

Configuring interrupts for multiple drivers instances is a special case. If each instance needs to configure a different interrupt line, this can be accomplished through the use of per-instance configuration functions, since the parameters to `IRQ_CONNECT()` need to be resolvable at build time.

For example, let's say we need to configure two instances of `my_driver`, each with a different interrupt line. In `drivers/subsystem/subsystem_my_driver.h`:

```c
typedef void (*my_driver_config_irq_t)(const struct device *dev);

struct my_driver_config {
    DEVICE_MMIO_ROM;
    my_driver_config_irq_t config_func;
};
```

In the implementation of the common init function:

```c
void my_driver_isr(const struct device *dev)
{
    /* Handle interrupt */
    ...
}

int my_driver_init(const struct device *dev)
{
    const struct my_driver_config *config = dev->config;

    DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);

    /* Do other initialization stuff */
    ...

    config->config_func(dev);

    return 0;
}
```

Then when the particular instance is declared:

```c
#if CONFIG_MY_DRIVER_0

DEVICE_DECLARE(my_driver_0);

static void my_driver_config_irq_0(const struct device *dev)
{
    IRQ_CONNECT(MY_DRIVER_0_IRQ, MY_DRIVER_0_PRI, my_driver_isr,
(continues on next page)
Note the use of `DEVICE_DECLARE()` to avoid a circular dependency on providing the IRQ handler argument and the definition of the device itself.

### 3.2.9 Initialization Levels

Drivers may depend on other drivers being initialized first, or require the use of kernel services. `DEVICE_DEFINE()` and related APIs allow the user to specify at what time during the boot sequence the init function will be executed. Any driver will specify one of four initialization levels:

**EARLY**
Used very early in the boot process, right after entering the C domain (\_cstart()). This can be used in architectures and SoCs that extend or implement architecture code and use drivers or system services that have to be initialized before the Kernel calls any architecture specific initialization code.

**PRE_KERNEL_1**
Used for devices that have no dependencies, such as those that rely solely on hardware present in the processor/SOC. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. The interrupt subsystem will be configured however so it’s OK to set up interrupts. Init functions at this level run on the interrupt stack.

**PRE_KERNEL_2**
Used for devices that rely on the initialization of devices initialized as part of the PRE_KERNEL_1 level. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. Init functions at this level run on the interrupt stack.

**POST_KERNEL**
Used for devices that require kernel services during configuration. Init functions at this level run in context of the kernel main task.

**APPLICATION**
Used for application components (i.e. non-kernel components) that need automatic configuration. These devices can use all services provided by the kernel during configuration. Init functions at this level run on the kernel main task.

Within each initialization level you may specify a priority level, relative to other devices in the same initialization level. The priority level is specified as an integer value in the range 0 to 99; lower values indicate earlier initialization. The priority level must be a decimal integer literal without leading zeroes or sign (e.g. 32), or an equivalent symbolic name (e.g. `\#define MY_INIT_PRIO 32`); symbolic expressions are not permitted (e.g. `\#define CONFIG_KERNEL_INIT_PRIORITY_DEFAULT + 5`).

Drivers and other system utilities can determine whether startup is still in pre-kernel states by using the `k_is_pre_kernel()` function.
3.2.10 System Drivers

In some cases you may just need to run a function at boot. For such cases, the SYS_INIT can be used. This macro does not take any config or runtime data structures and there isn’t a way to later get a device pointer by name. The same device policies for initialization level and priority apply.

3.2.11 Error handling

In general, it’s best to use __ASSERT() macros instead of propagating return values unless the failure is expected to occur during the normal course of operation (such as a storage device full). Bad parameters, programming errors, consistency checks, pathological/unrecoverable failures, etc., should be handled by assertions.

When it is appropriate to return error conditions for the caller to check, 0 should be returned on success and a POSIX errno.h code returned on failure. See https://github.com/zephyrproject-rtos/zephyr/wiki/Naming-Conventions#return-codes for details about this.

3.2.12 Memory Mapping

On some systems, the linear address of peripheral memory-mapped I/O (MMIO) regions cannot be known at build time:

• The I/O ranges must be probed at runtime from the bus, such as with PCI express
• A memory management unit (MMU) is active, and the physical address of the MMIO range must be mapped into the page tables at some virtual memory location determined by the kernel.

These systems must maintain storage for the MMIO range within RAM and establish the mapping within the driver’s init function. Other systems do not care about this and can use MMIO physical addresses directly from DTS and do not need any RAM-based storage for it.

For drivers that may need to deal with this situation, a set of APIs under the DEVICE_MMIO scope are defined, along with a mapping function device_map().

Device Model Drivers with one MMIO region

The simplest case is for drivers which need to maintain one MMIO region. These drivers will need to use the DEVICE_MMIO_ROM and DEVICE_MMIO_RAM macros in the definitions for their config_info and driver_data structures, with initialization of the config_info from DTS using DEVICE_MMIO_ROM_INIT. A call to DEVICE_MMIO_MAP() is made within the init function:

```c
struct my_driver_config {
    DEVICE_MMIO_ROM; /* Must be first */
    ...
}

struct my_driver_dev_data {
    DEVICE_MMIO_RAM; /* Must be first */
    ...
}

const static struct my_driver_config my_driver_config_0 = {
    DEVICE_MMIO_ROM_INIT(DT_DRV_INST(...)),
    ...
}

int my_driver_init(const struct device *dev)
```
The particular expansion of these macros depends on configuration. On a device with no MMU or PCI-e, `DEVICE_MMIO_MAP` and `DEVICE_MMIO_RAM` expand to nothing.

Device Model Drivers with multiple MMIO regions

Some drivers may have multiple MMIO regions. In addition, some drivers may already be implementing a form of inheritance which requires some other data to be placed first in the `config_info` and `driver_data` structures.

This can be managed with the `DEVICE_MMIO_NAMED` variant macros. These require that `DEV_CFG()` and `DEV_DATA()` macros be defined to obtain a properly typed pointer to the driver's `config_info` or `dev_data` structs. For example:

```c
struct my_driver_config {
    ...
    DEVICE_MMIO_NAMED_ROM(corge);
    DEVICE_MMIO_NAMED_ROM(grault);
    ...
}

struct my_driver_dev_data {
    ...
    DEVICE_MMIO_NAMED_RAM(corge);
    DEVICE_MMIO_NAMED_RAM(grault);
    ...
}

#define DEV_CFG(_dev) \
    ((const struct my_driver_config *)((_dev)->config))

#define DEV_DATA(_dev) \
    ((struct my_driver_dev_data *)((_dev)->data))

const static struct my_driver_config my_driver_config_0 = {
    ...
    DEVICE_MMIO_NAMED_ROM_INIT(corge, DT_DRV_INST(...)),
    DEVICE_MMIO_NAMED_ROM_INIT(grault, DT_DRV_INST(...)),
    ...
}

int my_driver_init(const struct device *dev)
{
    (continues on next page)
Device Model Drivers with multiple MMIO regions in the same DT node

Some drivers may have multiple MMIO regions defined into the same DT device node using the reg-names property to differentiate them, for example:

```dts-v1/
/
{
    a-driver@40000000 {
        reg = <0x40000000 0x1000>,
              <0x40001000 0x1000>;
        reg-names = "corge", "grault";
    }
};
```

This can be managed as seen in the previous section but this time using the DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME macro instead. So the only difference would be in the driver config struct:

```c
const static struct my_driver_config my_driver_config_0 = {
    ...
    DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(corge, DT_DRV_INST(...)),
    DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(grault, DT_DRV_INST(...)),
    ...
};
```

Drivers that do not use Zephyr Device Model

Some drivers or driver-like code may not use Zephyr’s device model, and alternative storage must be arranged for the MMIO data. An example of this are timer drivers, or interrupt controller code.

This can be managed with the DEVICE_MMIO_TOPOLEVEL set of macros, for example:

```c
DEVICE_MMIO_TOPOLEVEL_STATIC(my_regs, DT_DRV_INST(...));

void some_init_code(...) {
    ...
    DEVICE_MMIO_TOPOLEVEL_MAP(my_regs, K_MEM_CACHE_NONE);
    ...
}  
(continues on next page)
Drivers that do not use DTS

Some drivers may not obtain the MMIO physical address from DTS, such as is the case with PCI-E. In this case the device_map() function may be used directly:

```c
void some_init_code(...) {
    ...
    struct pcie_bar mbar;
    bool bar_found = pcie_get_mbar(bdf, index, &mbar);
    
    device_map(DEVICE_MMIO_RAM_PTR(dev), mbar.phys_addr, mbar.size, K_MEM_CACHE_NONE);
    ...
}
```

For these cases, DEVICE_MMIO_ROM directives may be omitted.

### 3.2.13 API Reference

#### group device_model

Device Model.

**Defines**

**DEVICE_HANDLE_NULL**

Flag value used to identify an unknown device.

**DEVICE_NAME_GET(dev_id)**

Expands to the name of a global device object.

Return the full name of a device object symbol created by `DEVICE_DEFINE()`, using the `dev_id` provided to `DEVICE_DEFINE()`. This is the name of the global variable storing the device structure, not a pointer to the string in the `device::name` field.

It is meant to be used for declaring extern symbols pointing to device objects before using the `DEVICE_GET` macro to get the device object.

This macro is normally only useful within device driver source code. In other situations, you are probably looking for `device_get_binding()`.

**Parameters**

- dev_id – Device identifier.

**Returns**

The full name of the device object defined by device definition macros.
DEVICE_DEFINE(dev_id, name, init_fn, pm, data, config, level, prio, api)
Create a device object and set it up for boot time initialization.

This macro defines a device that is automatically configured by the kernel during system initialization. This macro should only be used when the device is not being allocated from a devicetree node. If you are allocating a device from a devicetree node, use DEVICE_DT_DEFINE() or DEVICE_DT_INST_DEFINE() instead.

Parameters
- dev_id – A unique token which is used in the name of the global device structure as a C identifier.
- name – A string name for the device, which will be stored in device::name. This name can be used to look up the device with device_get_binding(). This must be less than Z_DEVICE_MAX_NAME_LEN characters (including terminating NULL) in order to be looked up from user mode.
- init_fn – Pointer to the device's initialization function, which will be run by the kernel during system initialization. Can be NULL.
- pm – Pointer to the device's power management resources, a pm_device, which will be stored in device::pm field. Use NULL if the device does not use PM.
- data – Pointer to the device's private mutable data, which will be stored in device::data.
- config – Pointer to the device's private constant data, which will be stored in device::config.
- level – The device's initialization level (PRE_KERNEL_1, PRE_KERNEL_2 or POST_KERNEL).
- prio – The device's priority within its initialization level. See SYS_INIT() for details.
- api – Pointer to the device's API structure. Can be NULL.

DEVICE_DT_NAME(node_id)
Return a string name for a devicetree node.

This macro returns a string literal usable as a device's name from a devicetree node identifier.

Parameters
- node_id – The devicetree node identifier.

Returns
The value of the node's label property, if it has one. Otherwise, the node's full name in node-name@unit-address form.

DEVICE_DT_DEFINE(node_id, init_fn, pm, data, config, level, prio, api, ...)
Create a device object from a devicetree node identifier and set it up for boot time initialization.

This macro defines a device that is automatically configured by the kernel during system initialization. The global device object's name as a C identifier is derived from the node's dependency ordinal. device::name is set to DEVICE_DT_NAME(node_id).

The device is declared with extern visibility, so a pointer to a global device object can be obtained with DEVICE_DT_GET(node_id) from any source file that includes <zephyr/device.h>. Before using the pointer, the referenced object should be checked using device_is_ready().

Parameters
- node_id – The devicetree node identifier.
• `init_fn` – Pointer to the device's initialization function, which will be run by the kernel during system initialization. Can be `NULL`.

• `pm` – Pointer to the device's power management resources, a `pm_device`, which will be stored in `device::pm`. Use `NULL` if the device does not use PM.

• `data` – Pointer to the device's private mutable data, which will be stored in `device::data`.

• `config` – Pointer to the device's private constant data, which will be stored in `device::config` field.

• `level` – The device's initialization level (PRE_KERNEL_1, PRE_KERNEL_2 or POST_KERNEL).

• `prio` – The device's priority within its initialization level. See SYS_INIT() for details.

• `api` – Pointer to the device's API structure. Can be `NULL`.

`DEVICE_DT_INST_DEFINE(inst, ...)`

Like `DEVICE_DT_DEFINE()`, but uses an instance of a DT_DRV_COMPAT compatible instead of a node identifier.

**Parameters**

- `inst` – Instance number. The `node_id` argument to `DEVICE_DT_DEFINE()` is set to `DT_DRV_INST(inst)`.

- `...` – Other parameters as expected by `DEVICE_DT_DEFINE()`.

`DEVICE_DT_NAME_GET(node_id)`

The name of the global device object for `node_id`.

Returns the name of the global device structure as a C identifier. The device must be allocated using `DEVICE_DT_DEFINE()` or `DEVICE_DT_INST_DEFINE()` for this to work.

This macro is normally only useful within device driver source code. In other situations, you are probably looking for `DEVICE_DT_GET()`.

**Parameters**

- `node_id` – Devicetree node identifier

**Returns**

The name of the device object as a C identifier

`DEVICE_DT_GET(node_id)`

Get a `device` reference from a devicetree node identifier.

Returns a pointer to a device object created from a devicetree node, if any device was allocated by a driver.

If no such device was allocated, this will fail at linker time. If you get an error that looks like `undefined reference to __device_dts_ord_<N>`, that is what happened. Check to make sure your device driver is being compiled, usually by enabling the Kconfig options it requires.

**Parameters**

- `node_id` – A devicetree node identifier

**Returns**

A pointer to the device object created for that node

`DEVICE_DT_INST_GET(inst)`

Get a `device` reference for an instance of a DT_DRV_COMPAT compatible.

This is equivalent to `DEVICE_DT_GET(DT_DRV_INST(inst))`.

**Parameters**
• inst – DT_DRV_COMPAT instance number

Returns
A pointer to the device object created for that instance

DEVICE_DT_GET_ANY(compat)
Get a device reference from a devicetree compatible.
If an enabled devicetree node has the given compatible and a device object was created from it, this returns a pointer to that device.
If there no such devices, this returns NULL.
If there are multiple, this returns an arbitrary one.
If this returns non-NULL, the device must be checked for readiness before use, e.g. with device_is_ready().

Parameters
• compat – lowercase-and-underscores devicetree compatible

Returns
da pointer to a device, or NULL

DEVICE_DT_GET_ONE(compat)
Get a device reference from a devicetree compatible.
If an enabled devicetree node has the given compatible and a device object was created from it, this returns a pointer to that device.
If there are no such devices, this will fail at compile time.
If there are multiple, this returns an arbitrary one.
If this returns non-NULL, the device must be checked for readiness before use, e.g. with device_is_ready().

Parameters
• compat – lowercase-and-underscores devicetree compatible

Returns
da pointer to a device

DEVICE_DT_GET_OR_NULL(node_id)
Utility macro to obtain an optional reference to a device.
If the node identifier refers to a node with status okay, this returns DEVICE_DT_GET(node_id).
Otherwise, it returns NULL.

Parameters
• node_id – devicetree node identifier

Returns
da device reference for the node identifier, which may be NULL.

DEVICE_GET(dev_id)
Obtain a pointer to a device object by name.
Return the address of a device object created by DEVICE_DEFINE(), using the dev_id provided to DEVICE_DEFINE().

Parameters
• dev_id – Device identifier.

Returns
A pointer to the device object created by DEVICE_DEFINE()
DEVICE_DECLARE(dev_id)
Declare a static device object.

This macro can be used at the top-level to declare a device, such that DEVICE_GET() may be used before the full declaration in DEVICE_DEFINE().

This is often useful when configuring interrupts statically in a device's init or per-instance config function, as the init function itself is required by DEVICE_DEFINE() and use of DEVICE_GET() inside it creates a circular dependency.

Parameters
- dev_id – Device identifier.

DEVICE_INIT_DT_GET(node_id)
Get a init_entry reference from a devicetree node.

Parameters
- node_id – A devicetree node identifier

Returns
A pointer to the init_entry object created for that node

DEVICE_INIT_GET(dev_id)
Get a init_entry reference from a device identifier.

Parameters
- dev_id – Device identifier.

Returns
A pointer to the init_entry object created for that device

Typedefs

typedef int16_t device_handle_t
Type used to represent a “handle” for a device.

Every device has an associated handle. You can get a pointer to a device from its handle and vice versa, but the handle uses less space than a pointer. The device.h API mainly uses handles to store lists of multiple devices in a compact way.

The extreme values and zero have special significance. Negative values identify functionality that does not correspond to a Zephyr device, such as the system clock or a SYS_INIT() function.

See also:
device_handle_get()

See also:
device_from_handle()

typedef int (*device_visitor_callback_t)(const struct device *dev, void *context)
Prototype for functions used when iterating over a set of devices.

Such a function may be used in API that identifies a set of devices and provides a visitor API supporting caller-specific interaction with each device in the set.

The visit is said to succeed if the visitor returns a non-negative value.
See also:

device_required_foreach()

See also:

device_supported_foreach()

Param dev
a device in the set being iterated

Param context
state used to support the visitor function

Return
A non-negative number to allow walking to continue, and a negative error code
to case the iteration to stop.

Functions

static inline device_handle_t device_handle_get(const struct device *dev)
Get the handle for a given device.

Parameters
• dev – the device for which a handle is desired.

Returns
the handle for the device, or DEVICE_HANDLE_NULL if the device does not have
an associated handle.

static inline const struct device *device_from_handle(device_handle_t dev_handle)
Get the device corresponding to a handle.

Parameters
• dev_handle – the device handle

Returns
the device that has that handle, or a null pointer if dev_handle does not identify
a device.

static inline const device_handle_t *device_required_handles_get(const struct device *dev,
size_t *count)
Get the device handles for devicetree dependencies of this device.
This function returns a pointer to an array of device handles. The length of the array is stored
in the count parameter.
The array contains a handle for each device that dev requires directly, as determined from the
devicetree. This does not include transitive dependencies; you must recursively determine
those.

Parameters
• dev – the device for which dependencies are desired.
• count – pointer to where this function should store the length of the returned
array. No value is stored if the call returns a null pointer. The value may be set
to zero if the device has no devicetree dependencies.

Returns
a pointer to a sequence of count device handles, or a null pointer if dev does not
have any dependency data.
static inline const device_handle_t *device_injected_handles_get(const struct device *dev, size_t *count)

Get the device handles for injected dependencies of this device.

This function returns a pointer to an array of device handles. The length of the array is stored in the count parameter.

The array contains a handle for each device that dev manually injected as a dependency, via providing extra arguments to Z_DEVICE_DEFINE. This does not include transitive dependencies; you must recursively determine those.

**Parameters**
- `dev` – the device for which injected dependencies are desired.
- `count` – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if the device has no devicetree dependencies.

**Returns**
- a pointer to a sequence of *count device handles, or a null pointer if dev does not have any dependency data.

static inline const device_handle_t *device_supported_handles_get(const struct device *dev, size_t *count)

Get the set of handles that this device supports.

This function returns a pointer to an array of device handles. The length of the array is stored in the count parameter.

The array contains a handle for each device that dev “supports” — that is, devices that require dev directly – as determined from the devicetree. This does not include transitive dependencies; you must recursively determine those.

**Parameters**
- `dev` – the device for which supports are desired.
- `count` – pointer to where this function should store the length of the returned array. No value is stored if the call returns a null pointer. The value may be set to zero if nothing in the devicetree depends on dev.

**Returns**
- a pointer to a sequence of *count device handles, or a null pointer if dev does not have any dependency data.

int device_required_foreach(const struct device *dev, device_visitor_callback_t visitor_cb, void *context)

Visit every device that dev directly requires.

Zephyr maintains information about which devices are directly required by another device; for example an I2C-based sensor driver will require an I2C controller for communication. Required devices can derive from statically-defined devicetree relationships or dependencies registered at runtime.

This API supports operating on the set of required devices. Example uses include making sure required devices are ready before the requiring device is used, and releasing them when the requiring device is no longer needed.

There is no guarantee on the order in which required devices are visited.

If the visitor_cb function returns a negative value iteration is halted, and the returned value from the visitor is returned from this function.

**Note:** This API is not available to unprivileged threads.
Parameters

- **dev** – a device of interest. The devices that this device depends on will be used as the set of devices to visit. This parameter must not be null.
- **visitor_cb** – the function that should be invoked on each device in the dependency set. This parameter must not be null.
- **context** – state that is passed through to the visitor function. This parameter may be null if visitor_cb tolerates a null context.

Returns

The number of devices that were visited if all visits succeed, or the negative value returned from the first visit that did not succeed.

```c
int device_supported_foreach(const struct device *dev, device_visitor_callback_t visitor_cb, void *context)
```

Visit every device that `dev` directly supports.

Zephyr maintains information about which devices are directly supported by another device; for example an I2C controller will support an I2C-based sensor driver. Supported devices can derive from statically-defined devicetree relationships.

This API supports operating on the set of supported devices. Example uses include iterating over the devices connected to a regulator when it is powered on.

There is no guarantee on the order in which required devices are visited.

If the `visitor_cb` function returns a negative value iteration is halted, and the returned value from the visitor is returned from this function.

**Note:** This API is not available to unprivileged threads.

Parameters

- **dev** – a device of interest. The devices that this device supports will be used as the set of devices to visit. This parameter must not be null.
- **visitor_cb** – the function that should be invoked on each device in the support set. This parameter must not be null.
- **context** – state that is passed through to the visitor function. This parameter may be null if visitor_cb tolerates a null context.

Returns

The number of devices that were visited if all visits succeed, or the negative value returned from the first visit that did not succeed.

```c
const struct device *device_get_binding(const char *name)
```

Get a device reference from its `device::name` field.

This function iterates through the devices on the system. If a device with the given `name` field is found, and that device initialized successfully at boot time, this function returns a pointer to the device.

If no device has the given `name`, this function returns NULL.

This function also returns NULL when a device is found, but it failed to initialize successfully at boot time. (To troubleshoot this case, set a breakpoint on your device driver's initialization function.)

**Parameters**

- **name** – device name to search for. A null pointer, or a pointer to an empty string, will cause NULL to be returned.
Returns

pointer to device structure with the given name; NULL if the device is not found or if the device with that name's initialization function failed.

bool device_is_ready(const struct device *dev)

Verify that a device is ready for use.

Indicates whether the provided device pointer is for a device known to be in a state where it can be used with its standard API.

This can be used with device pointers captured from DEVICE_DT_GET(), which does not include the readiness checks of device_get_binding(). At minimum this means that the device has been successfully initialized.

Parameters

• dev – pointer to the device in question.

Return values

• true – If the device is ready for use.
• false – If the device is not ready for use or if a NULL device pointer is passed as argument.

struct device_state

#include <device.h> Runtime device dynamic structure (in RAM) per driver instance.

Fields in this are expected to be default-initialized to zero. The kernel driver infrastructure and driver access functions are responsible for ensuring that any non-zero initialization is done before they are accessed.

Public Members

uint8_t init_res

Device initialization return code (positive errno value).

Device initialization functions return a negative errno code if they fail. In Zephyr, errno values do not exceed 255, so we can store the positive result value in a uint8_t type.

bool initialized

Indicates the device initialization function has been invoked.

struct device

#include <device.h> Runtime device structure (in ROM) per driver instance.

Public Members

const char *name

Name of the device instance.

const void *config

Address of device instance config information.

const void *api

Address of the API structure exposed by the device instance.
struct device_state *state
    Address of the common device state.

void *data
    Address of the device instance private data.

const device_handle_t *deps
    Optional pointer to dependencies associated with the device.
    This encodes a sequence of sets of device handles that have some relationship
to this node. The individual sets are extracted with dedicated API, such as device_required_handles_get(). Only available if CONFIG_DEVICE_DEPS is enabled.

struct pm_device *pm
    Reference to the device PM resources (only available if CONFIG_PM_DEVICE is enabled).

3.3 User Mode

Zephyr offers the capability to run threads at a reduced privilege level which we call user mode. The current implementation is designed for devices with MPU hardware.

For details on creating threads that run in user mode, please see Lifecycle.

3.3.1 Overview

Threat Model

User mode threads are considered to be untrusted by Zephyr and are therefore isolated from other user mode threads and from the kernel. A flawed or malicious user mode thread cannot leak or modify the private data/resources of another thread or the kernel, and cannot interfere with or control another user mode thread or the kernel.

Example use-cases of Zephyr's user mode features:

- The kernel can protect against many unintentional programming errors which could otherwise silently or spectacularly corrupt the system.
- The kernel can sandbox complex data parsers such as interpreters, network protocols, and filesystems such that malicious third-party code or data cannot compromise the kernel or other threads.
- The kernel can support the notion of multiple logical "applications", each with their own group of threads and private data structures, which are isolated from each other if one crashes or is otherwise compromised.

Design Goals   For threads running in a non-privileged CPU state (hereafter referred to as 'user mode') we aim to protect against the following:

- We prevent access to memory not specifically granted, or incorrect access to memory that has an incompatible policy, such as attempting to write to a read-only area.
  - Access to thread stack buffers will be controlled with a policy which partially depends on the underlying memory protection hardware.
    - A user thread will by default have read/write access to its own stack buffer.
    - A user thread will never by default have access to user thread stacks that are not members of the same memory domain.
* A user thread will never by default have access to thread stacks owned by a supervisor thread, or thread stacks used to handle system call privilege elevations, interrupts, or CPU exceptions.

* A user thread may have read/write access to the stacks of other user threads in the same memory domain, depending on hardware.

  · On MPU systems, threads may only access their own stack buffer.
  · On MMU systems, threads may access any user thread stack in the same memory domain. Portable code should not assume this.

  – By default, program text and read-only data are accessible to all threads on read-only basis, kernel-wide. This policy may be adjusted.
  – User threads by default are not granted default access to any memory except what is noted above.

• We prevent use of device drivers or kernel objects not specifically granted, with the permission granularity on a per object or per driver instance basis.

• We validate kernel or driver API calls with incorrect parameters that would otherwise cause a crash or corruption of data structures private to the kernel. This includes:

  – Using the wrong kernel object type.
  – Using parameters outside of proper bounds or with nonsensical values.
  – Passing memory buffers that the calling thread does not have sufficient access to read or write, depending on the semantics of the API.
  – Use of kernel objects that are not in a proper initialization state.

• We ensure the detection and safe handling of user mode stack overflows.

• We prevent invoking system calls to functions excluded by the kernel configuration.

• We prevent disabling of or tampering with kernel-defined and hardware-enforced memory protections.

• We prevent re-entry from user to supervisor mode except through the kernel-defined system calls and interrupt handlers.

• We prevent the introduction of new executable code by user mode threads, except to the extent to which this is supported by kernel system calls.

We are specifically not protecting against the following attacks:

• The kernel itself, and any threads that are executing in supervisor mode, are assumed to be trusted.

• The toolchain and any supplemental programs used by the build system are assumed to be trusted.

• The kernel build is assumed to be trusted. There is considerable build-time logic for creating the tables of valid kernel objects, defining system calls, and configuring interrupts. The .elf binary files that are worked with during this process are all assumed to be trusted code.

• We can’t protect against mistakes made in memory domain configuration done in kernel mode that exposes private kernel data structures to a user thread. RAM for kernel objects should always be configured as supervisor-only.

• It is possible to make top-level declarations of user mode threads and assign them permissions to kernel objects. In general, all C and header files that are part of the kernel build producing zephyr.elf are assumed to be trusted.

• We do not protect against denial of service attacks through thread CPU starvation. Zephyr has no thread priority aging and a user thread of a particular priority can starve all threads of lower priority, and also other threads of the same priority if time-slicing is not enabled.

• There are build-time defined limits on how many threads can be active simultaneously, after which creation of new user threads will fail.
Stack overflows for threads running in supervisor mode may be caught, but the integrity of the system cannot be guaranteed.

High-level Policy Details

Broadly speaking, we accomplish these thread-level memory protection goals through the following mechanisms:

- Any user thread will only have access to a subset of memory: typically its stack, program text, read-only data, and any partitions configured in the Memory Protection Design it belongs to. Access to any other RAM must be done on the thread’s behalf through system calls, or specifically granted by a supervisor thread using the memory domain APIs. Newly created threads inherit the memory domain configuration of the parent. Threads may communicate with each other by having shared membership of the same memory domains, or via kernel objects such as semaphores and pipes.

- User threads cannot directly access memory belonging to kernel objects. Although pointers to kernel objects are used to reference them, actual manipulation of kernel objects is done through system call interfaces. Device drivers and threads stacks are also considered kernel objects. This ensures that any data inside a kernel object that is private to the kernel cannot be tampered with.

- User threads by default have no permission to access any kernel object or driver other than their own thread object. Such access must be granted by another thread that is either in supervisor mode or has permission on both the receiving thread object and the kernel object being granted access to. The creation of new threads has an option to automatically inherit permissions of all kernel objects granted to the parent, except the parent thread itself.

- For performance and footprint reasons Zephyr normally does little or no parameter error checking for kernel object or device driver APIs. Access from user mode through system calls involves an extra layer of handler functions, which are expected to rigorously validate access permissions and type of the object, check the validity of other parameters through bounds checking or other means, and verify proper read/write access to any memory buffers involved.

- Thread stacks are defined in such a way that exceeding the specified stack space will generate a hardware fault. The way this is done specifically varies per architecture.

Constraints

All kernel objects, thread stacks, and device driver instances must be defined at build time if they are to be used from user mode. Dynamic use-cases for kernel objects will need to go through pre-defined pools of available objects.

There are some constraints if additional application binary data is loaded for execution after the kernel starts:

- Loaded object code will not be able to define any kernel objects that will be recognized by the kernel. This code will instead need to use APIs for requesting kernel objects from pools.

- Similarly, since the loaded object code will not be part of the kernel build process, this code will not be able to install interrupt handlers, instantiate device drivers, or define system calls, regardless of what mode it runs in.

- Loaded object code that does not come from a verified source should always be entered with the CPU already in user mode.

3.3.2 Memory Protection Design

Zephyr’s memory protection design is geared towards microcontrollers with MPU (Memory Protection Unit) hardware. We do support some architectures, such as x86, which have a paged MMU (Memory Management Unit), but in that case the MMU is used like an MPU with an identity page table.
All of the discussion below will be using MPU terminology; systems with MMUs can be considered to have an MPU with an unlimited number of programmable regions.

There are a few different levels on how memory access is configured when Zephyr memory protection features are enabled, which we will describe here:

**Boot Time Memory Configuration**

This is the configuration of the MPU after the kernel has started up. It should contain the following:

- Any configuration of memory regions which need to have special caching or write-back policies for basic hardware and driver function. Note that most MPUs have the concept of a default memory access policy map, which can be enabled as a “background” mapping for any area of memory that doesn’t have an MPU region configuring it. It is strongly recommended to use this to maximize the number of available MPU regions for the end user. On ARMv7-M/ARMv8-M this is called the System Address Map, other CPUs may have similar capabilities.
- A read-only, executable region or regions for program text and ro-data, that is accessible to user mode. This could be further sub-divided into a read-only region for ro-data, and a read-only, executable region for text, but this will require an additional MPU region. This is required so that threads running in user mode can read ro-data and fetch instructions.
- Depending on configuration, user-accessible read-write regions to support extra features like GCOV, HEP, etc.

Assuming there is a background map which allows supervisor mode to access any memory it needs, and regions are defined which grant user mode access to text/ro-data, this is sufficient for the boot time configuration.

**Hardware Stack Overflow**

`CONFIG_HW_STACK_PROTECTION` is an optional feature which detects stack buffer overflows when the system is running in supervisor mode. This catches issues when the entire stack buffer has overflowed, and not individual stack frames, use compiler-assisted `CONFIG_STACK_CANARIES` for that.

Like any crash in supervisor mode, no guarantees can be made about the overall health of the system after a supervisor mode stack overflow, and any instances of this should be treated as a serious error. However it’s still very useful to know when these overflows happen, as without robust detection logic the system will either crash in mysterious ways or behave in an undefined manner when the stack buffer overflows.

Some systems implement this feature by creating at runtime a ‘guard’ MPU region which is set to be read-only and is at either the beginning or immediately preceding the supervisor mode stack buffer. If the stack overflows an exception will be generated.

This feature is optional and is not required to catch stack overflows in user mode; disabling this may free 1-2 MPU regions depending on the MPU design.

Other systems may have dedicated CPU support for catching stack overflows and no extra MPU regions will be required.

**Thread Stack**

Any thread running in user mode will need access to its own stack buffer. On context switch into a user mode thread, a dedicated MPU region will be programmed with the bounds of the stack buffer. A thread exceeding its stack buffer will start pushing data onto memory it doesn’t have access to and a memory access violation exception will be generated.
Thread Resource Pools

A small subset of kernel APIs, invoked as system calls, require heap memory allocations. This memory is used only by the kernel and is not accessible directly by user mode. In order to use these system calls, invoking threads must assign themselves to a resource pool, which is a \texttt{k_heap} object. Memory is drawn from a thread's resource pool using \texttt{z_thread_malloc()} and freed with \texttt{k_free()}.

The APIs which use resource pools are as follows, with any alternatives noted for users who do not want heap allocations within their application:

- \texttt{k_stack_alloc_init()} sets up a \texttt{k_stack} with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare \texttt{k_stacks} that are automatically initialized at boot with \texttt{K_STACK_DEFINE()}, or to initialize the \texttt{k_stack} in supervisor mode with \texttt{k_stack_init()}.
- \texttt{k_pipe_alloc_init()} sets up a \texttt{k_pipe} object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare \texttt{k_pipes} that are automatically initialized at boot with \texttt{K_PIPE_DEFINE()}, or to initialize the \texttt{k_pipe} in supervisor mode with \texttt{k_pipe_init()}.
- \texttt{k_msgq_alloc_init()} sets up a \texttt{k_msgq} object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare a \texttt{k_msgq} that is automatically initialized at boot with \texttt{K_MSGQ_DEFINE()}, or to initialize the \texttt{k_msgq} in supervisor mode with \texttt{k_msgq_init()}.
- \texttt{k_poll()} when invoked from user mode, needs to make a kernel-side copy of the provided events array while waiting for an event. This copy is freed when \texttt{k_poll()} returns for any reason.
- \texttt{k_queue_alloc_prepend()} and \texttt{k_queue_alloc_append()} allocate a container structure to place the data in, since the internal bookkeeping information that defines the queue cannot be placed in the memory provided by the user.
- \texttt{k_object_alloc()} allows for entire kernel objects to be dynamically allocated at runtime and a usable pointer to them returned to the caller.

The relevant API is \texttt{k_thread_heap_assign()} which assigns a \texttt{k_heap} to draw these allocations from for the target thread.

If the system heap is enabled, then the system heap may be used with \texttt{k_thread_system_pool_assign()}, but it is preferable for different logical applications running on the system to have their own pools.

Memory Domains

The kernel ensures that any user thread will have access to its own stack buffer, plus program text and read-only data. The memory domain APIs are the way to grant access to additional blocks of memory to a user thread.

Conceptually, a memory domain is a collection of some number of memory partitions. The maximum number of memory partitions in a domain is limited by the number of available MPU regions. This is why it is important to minimize the number of boot-time MPU regions.

Memory domains are not intended to control access to memory from supervisor mode. In some cases this may be unavoidable; for example some architectures do not allow for the definition of regions which are read-only to user mode but read-write to supervisor mode. A great deal of care must be taken when working with such regions to not unintentionally cause the kernel to crash when accessing such a region. Any attempt to use memory domain APIs to control supervisor mode access is at best undefined behavior; supervisor mode access policy is only intended to be controlled by boot-time memory regions.

Memory domain APIs are only available to supervisor mode. The only control user mode has over memory domains is that any user thread's child threads will automatically become members of the parent's domain.
All threads are members of a memory domain, including supervisor threads (even though this has no implications on their memory access). There is a default domain k_mem_domain_default which will be assigned to threads if they have not been specifically assigned to a domain, or inherited a memory domain membership from their parent thread. The main thread starts as a member of the default domain.

Memory Partitions Each memory partition consists of a memory address, a size, and access attributes. It is intended that memory partitions are used to control access to system memory. Defining memory partitions are subject to the following constraints:

- The partition must represent a memory region that can be programmed by the underlying memory management hardware, and needs to conform to any underlying hardware constraints. For example, many MPU-based systems require that partitions be sized to some power of two, and aligned to their own size. For MMU-based systems, the partition must be aligned to a page and the size some multiple of the page size.
- Partitions within the same memory domain may not overlap each other. There is no notion of precedence among partitions within a memory domain. Partitions within a memory domain are assumed to have a higher precedence than any boot-time memory regions, however whether a memory domain partition can overlap a boot-time memory region is architecture specific.
- The same partition may be specified in multiple memory domains. For example there may be a shared memory area that multiple domains grant access to.
- Care must be taken in determining what memory to expose in a partition. It is not appropriate to provide direct user mode access to any memory containing private kernel data.
- Memory domain partitions are intended to control access to system RAM. Configuration of memory partitions which do not correspond to RAM may not be supported by the architecture; this is true for MMU-based systems.

There are two ways to define memory partitions: either manually or automatically.

Manual Memory Partitions The following code declares a global array buf, and then declares a read-write partition for it which may be added to a domain:

```c
uint8_t __aligned(32) buf[32];
K_MEM_PARTITION_DEFINE(my_partition, buf, sizeof(buf), K_MEM_PARTITION_P_RW_U_RW);
```

This does not scale particularly well when we are trying to contain multiple objects spread out across several C files into a single partition.

Automatic Memory Partitions Automatic memory partitions are created by the build system. All globals which need to be placed inside a partition are tagged with their destination partition. The build system will then coalesce all of these into a single contiguous block of memory, zero any BSS variables at boot, and define a memory partition of appropriate base address and size which contains all the tagged data.

Automatic memory partitions are only configured as read-write regions. They are defined with K_APPMEM_PARTITION_DEFINE(). Global variables are then routed to this partition using K_APP_DMEM() for initialized data and K_APP_BMEM() for BSS.

```
#include <zephyr/app_memory/app_memdomain.h>

/* Declare a k_mem_partition "my_partition" that is read-write to * user mode. Note that we do not specify a base address or size. */
K_APPMEM_PARTITION_DEFINE(my_partition);
```

(continues on next page)
/* The global variable var1 will be inside the bounds of my_partition and be initialized with 37 at boot. */
K_APP_DMEM(my_partition) int var1 = 37;

/* The global variable var2 will be inside the bounds of my_partition and be zeroed at boot size K_APP_BMEM() was used, indicating a BSS variable. */
K_APP_BMEM(my_partition) int var2;

The build system will ensure that the base address of my_partition will be properly aligned, and the total size of the region conforms to the memory management hardware requirements, adding padding if necessary.

If multiple partitions are being created, a variadic preprocessor macro can be used as provided in app_macro_support.h:

FOR_EACH(K_APPMEM_PARTITION_DEFINE, part0, part1, part2);

Automatic Partitions for Static LibraryGlobals The build-time logic for setting up automatic memory partitions is in scripts/build/gen_app_partitions.py. If a static library is linked into Zephyr, it is possible to route all the globals in that library to a specific memory partition with the --library argument.

For example, if the Newlib C library is enabled, the Newlib globals all need to be placed in z_libc_partition. The invocation of the script in the top-level CMakeLists.txt adds the following:

gen_app_partitions.py ... --library libc.a z_libc_partition ...

For pre-compiled libraries there is no support for expressing this in the project-level configuration or build files; the toplevel CMakeLists.txt must be edited.

For Zephyr libraries created using zephyr_library or zephyr_library_named the zephyr_library_app_memory function can be used to specify the memory partition where all
globals in the library should be placed.

**Pre-defined Memory Partitions** There are a few memory partitions which are pre-defined by the system:

- **z_malloc_partition** - This partition contains the system-wide pool of memory used by libc malloc(). Due to possible starvation issues, it is not recommended to draw heap memory from a global pool, instead it is better to define various sys_heap objects and assign them to specific memory domains.

- **z_libc_partition** - Contains globals required by the C library and runtime. Required when using either the Minimal C library or the Newlib C Library. Required when CONFIG_STACK_CANARIES is enabled.

Library-specific partitions are listed in `include/app_memory/partitions.h`. For example, to use the MBEDTLS library from user mode, the `k_mbedtls_partition` must be added to the domain.

**Memory Domain Usage**

**Create a Memory Domain** A memory domain is defined using a variable of type `k_mem_domain`. It must then be initialized by calling `k_mem_domain_init()`.

The following code defines and initializes an empty memory domain.

```c
struct k_mem_domain app0_domain;

k_mem_domain_init(&app0_domain, 0, NULL);
```

**Add Memory Partitions into a Memory Domain** There are two ways to add memory partitions into a memory domain.

This first code sample shows how to add memory partitions while creating a memory domain.

```c
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                        K_MEM_PARTITION_P_RW_U_RW);
K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                        K_MEM_PARTITION_P_RW_U_RO);

struct k_mem_partition *app0_parts[] = {
  app0_part0,
  app0_part1
};

k_mem_domain_init(&app0_domain, ARRAY_SIZE(app0_parts), app0_parts);
```

This second code sample shows how to add memory partitions into an initialized memory domain one by one.

```c
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];
```

(continues on next page)
K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
    K_MEM_PARTITION_P_RW_U_RW);
K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
    K_MEM_PARTITION_P_RW_U_RO);
k_mem_domain_add_partition(&app0_domain, &app0_part0);
k_mem_domain_add_partition(&app0_domain, &app0_part1);

**Note:** The maximum number of memory partitions is limited by the maximum number of MPU regions or the maximum number of MMU tables.

### Memory Domain Assignment
Any thread may join a memory domain, and any memory domain may have multiple threads assigned to it. Threads are assigned to memory domains with an API call:

```c
k_mem_domain_add_thread(&app0_domain, app_thread_id);
```

If the thread was already a member of some other domain (including the default domain), it will be removed from it in favor of the new one.

In addition, if a thread is a member of a memory domain, and it creates a child thread, that thread will belong to the domain as well.

### Remove a Memory Partition from a Memory Domain
The following code shows how to remove a memory partition from a memory domain.

```c
k_mem_domain_remove_partition(&app0_domain, &app0_part1);
```

The `k_mem_domain_remove_partition()` API finds the memory partition that matches the given parameter and removes that partition from the memory domain.

### Available Partition Attributes
When defining a partition, we need to set access permission attributes to the partition. Since the access control of memory partitions relies on either an MPU or MMU, the available partition attributes would be architecture dependent.

The complete list of available partition attributes for a specific architecture is found in the architecture-specific include file `include/zephyr/arch/<arch name>/arch.h`, (for example, `include/zephyr/arch/arm/arch.h`). Some examples of partition attributes are:

```c
/* Denote partition is privileged read/write, unprivileged read/write */
K_MEM_PARTITION_P_RW_U_RW

/* Denote partition is privileged read/write, unprivileged read-only */
K_MEM_PARTITION_P_RW_U_RO
```

In almost all cases `K_MEM_PARTITION_P_RW_U_RW` is the right choice.

### Configuration Options

Related configuration options:

- `CONFIG_MAX_DOMAIN_PARTITIONS`
API Reference

The following memory domain APIs are provided by include/zephyr/kernel.h:

group mem_domain_apis

Defines

K_MEM_PARTITION_DEFINE(name, start, size, attr)
    Statically declare a memory partition.

Functions

int k_mem_domain_init(struct k_mem_domain *domain, uint8_t num_parts, struct k_mem_partition *parts[])
Initialization a memory domain.

Initialize a memory domain with given name and memory partitions.
See documentation for k_mem_domain_add_partition() for details about partition constraints.
Do not call k_mem_domain_init() on the same memory domain more than once, doing so is undefined behavior.

Parameters

• domain – The memory domain to be initialized.
• num_parts – The number of array items of “parts” parameter.
• parts – An array of pointers to the memory partitions. Can be NULL if num_parts is zero.

Return values

• 0 – if successful
• -EINVAL – if invalid parameters supplied
• -ENOMEM – if insufficient memory

int k_mem_domain_add_partition(struct k_mem_domain *domain, struct k_mem_partition *part)
Add a memory partition into a memory domain.

Add a memory partition into a memory domain. Partitions must conform to the following constraints:

• Partitions in the same memory domain may not overlap each other.
• Partitions must not be defined which expose private kernel data structures or kernel objects.
• The starting address alignment, and the partition size must conform to the constraints of the underlying memory management hardware, which varies per architecture.
• Memory domain partitions are only intended to control access to memory from user mode threads.
• If CONFIG_EXECUTE_XOR_WRITE is enabled, the partition must not allow both writes and execution.

Violating these constraints may lead to CPU exceptions or undefined behavior.

3.3. User Mode
Parameters
- **domain** – The memory domain to be added a memory partition.
- **part** – The memory partition to be added

Return values
- 0 – if successful
- -EINVAL – if invalid parameters supplied
- -ENOSPC – if no free partition slots available

```c
int k_mem_domain_remove_partition(struct k_mem_domain *domain, struct k_mem_partition *part)
```

Remove a memory partition from a memory domain.

Parameters
- **domain** – The memory domain to be removed a memory partition.
- **part** – The memory partition to be removed

Return values
- 0 – if successful
- -EINVAL – if invalid parameters supplied
- -ENOENT – if no matching partition found

```c
int k_mem_domain_add_thread(struct k_mem_domain *domain, k_tid_t thread)
```

Add a thread into a memory domain.

Parameters
- **domain** – The memory domain that the thread is going to be added into.
- **thread** – ID of thread going to be added into the memory domain.

Returns
0 if successful, fails otherwise.

Variables

```c
struct k_mem_domain k_mem_domain_default
```

Default memory domain.

All threads are a member of some memory domain, even if running in supervisor mode. Threads belong to this default memory domain if they haven't been added to or inherited membership from some other domain.

This memory domain has the z_libc_partition partition for the C library added to it if exists.

```c
struct k_mem_partition
```

`<mem_domain.h>` Memory Partition.

A memory partition is a region of memory in the linear address space with a specific access policy.
The alignment of the starting address, and the alignment of the size value may have varying requirements based on the capabilities of the underlying memory management hardware; arbitrary values are unlikely to work.

**Public Members**

```c
uintptr_t start
    start address of memory partition
size_t size
    size of memory partition
k_mem_partition_attr_t attr
    attribute of memory partition
```

```c
struct k_mem_domain
#include <mem_domain.h> Memory Domain.
A memory domain is a collection of memory partitions, used to represent a user thread's access policy for the linear address space. A thread may be a member of only one memory domain, but any memory domain may have multiple threads that are members.
Supervisor threads may also be a member of a memory domain; this has no implications on their memory access but can be useful as any child threads inherit the memory domain membership of the parent.
A user thread belonging to a memory domain with no active partitions will have guaranteed access to its own stack buffer, program text, and read-only data.

**Public Members**

```c
struct k_mem_partition partitions[CONFIG_MAX_DOMAIN_partitions]
    partitions in the domain
sys_dlist_t mem_domain_q
    Doubly linked list of member threads.
uint8_t num_partitions
    number of active partitions in the domain
```

### 3.3.3 Kernel Objects

A kernel object can be one of three classes of data:

- A core kernel object, such as a semaphore, thread, pipe, etc.
- A thread stack, which is an array of z_thread_stack_element and declared with `K_THREAD_STACK_DEFINE()`
- A device driver instance (const struct device) that belongs to one of a defined set of subsystems
The set of known kernel objects and driver subsystems is defined in include/kernel.h as k_objects.

Kernel objects are completely opaque to user threads. User threads work with addresses to kernel objects when making API calls, but may never dereference these addresses, doing so will cause a memory protection fault. All kernel objects must be placed in memory that is not accessible by user threads.

Since user threads may not directly manipulate kernel objects, all use of them must go through system calls. In order to perform a system call on a kernel object, checks are performed by system call handler functions that the kernel object address is valid and that the calling thread has sufficient permissions to work with it.

Permission on an object also has the semantics of a reference to an object. This is significant for certain object APIs which do temporary allocations, or objects which themselves have been allocated from a runtime memory pool.

If an object loses all references, two events may happen:

- If the object has an associated cleanup function, the cleanup function may be called to release any runtime-allocated buffers the object was using.
- If the object itself was dynamically allocated, the memory for the object will be freed.

### Object Placement

Kernel objects that are only used by supervisor threads have no restrictions and can be located anywhere in the binary, or even declared on stacks. However, to prevent accidental or intentional corruption by user threads, they must not be located in any memory that user threads have direct access to.

In order for a static kernel object to be usable by a user thread via system call APIs, several conditions must be met on how the kernel object is declared:

- The object must be declared as a top-level global at build time, such that it appears in the ELF symbol table. It is permitted to declare kernel objects with static scope. The post-build script scripts/build/gen_kobject_list.py scans the generated ELF file to find kernel objects and places their memory addresses in a special table of kernel object metadata. Kernel objects may be members of arrays or embedded within other data structures.
- Kernel objects must be located in memory reserved for the kernel. They must not be located in any memory partitions that are user-accessible.
- Any memory reserved for a kernel object must be used exclusively for that object. Kernel objects may not be members of a union data type.

Kernel objects that are found but do not meet the above conditions will not be included in the generated table that is used to validate kernel object pointers passed in from user mode.

The debug output of the scripts/build/gen_kobject_list.py script may be useful when debugging why some object was unexpectedly not being tracked. This information will be printed if the script is run with the --verbose flag, or if the build system is invoked with verbose output.

### Dynamic Objects

Kernel objects may also be allocated at runtime if CONFIG_DYNAMIC_OBJECTS is enabled. In this case, the k_object_alloc() API may be used to instantiate an object from the calling thread's resource pool. Such allocations may be freed in two ways:

- Supervisor threads may call k_object_free() to force a dynamic object to be released.
- If an object's references drop to zero (which happens when no threads have permissions on it) the object will be automatically freed. User threads may drop their own permission on an object with k_object_release(), and their permissions are automatically cleared when a thread terminates. Supervisor threads may additionally revoke references for another thread using k_object_access_revoke().
Because permissions are also used for reference counting, it is important for supervisor threads to acquire permissions on objects they are using even though the access control aspects of the permission system are not enforced.

Implementation Details  The scripts/build/gen_kobject_list.py script is a post-build step which finds all the valid kernel object instances in the binary. It accomplishes this by parsing the DWARF debug information present in the generated ELF file for the kernel.

Any instances of structs or arrays corresponding to kernel objects that meet the object placement criteria will have their memory addresses placed in a special perfect hash table of kernel objects generated by the ‘gperf’ tool. When a system call is made and the kernel is presented with a memory address of what may or may not be a valid kernel object, the address can be validated with a constant-time lookup in this table.

Drivers are a special case. All drivers are instances of device, but it is important to know what subsystem a driver belongs to so that incorrect operations, such as calling a UART API on a sensor driver object, can be prevented. When a device struct is found, its API pointer is examined to determine what subsystem the driver belongs to.

The table itself maps kernel object memory addresses to instances of z_object, which has all the metadata for that object. This includes:

- A bitfield indicating permissions on that object. All threads have a numerical ID assigned to them at build time, used to index the permission bitfield for an object to see if that thread has permission on it. The size of this bitfield is controlled by the CONFIG_MAX_THREAD_BYTES option and the build system will generate an error if this value is too low.
- A type field indicating what kind of object this is, which is some instance of k_objects.
- A set of flags for that object. This is currently used to track initialization state and whether an object is public or not.
- An extra data field. The semantics of this field vary by object type, see the definition of z_object_data.

Dynamic objects allocated at runtime are tracked in a runtime red/black tree which is used in parallel to the gperf table when validating object pointers.

Supervisor Thread Access Permission

Supervisor threads can access any kernel object. However, permissions for supervisor threads are still tracked for two reasons:

- If a supervisor thread calls k_thread_user_mode_enter(), the thread will then run in user mode with any permissions it had been granted (in many cases, by itself) when it was a supervisor thread.
- If a supervisor thread creates a user thread with the K_INHERIT_PERMS option, the child thread will be granted the same permissions as the parent thread, except the parent thread object.

User Thread Access Permission

By default, when a user thread is created, it will only have access permissions on its own thread object. Other kernel objects by default are not usable. Access to them needs to be explicitly or implicitly granted. There are several ways to do this.

- If a thread is created with the K_INHERIT_PERMS, that thread will inherit all the permissions of the parent thread, except the parent thread object.
- A thread that has permission on an object, or is running in supervisor mode, may grant permission on that object to another thread via the k_object_access_grant() API. The convenience pseudo-function k_thread_access_grant() may also be used, which accepts an arbitrary number of objects.
of pointers to kernel objects and calls `k_object_access_grant()` on each of them. The thread
being granted permission, or the object whose access is being granted, do not need to be in an ini-
tialized state. If the caller is from user mode, the caller must have permissions on both the kernel
object and the target thread object.

- Supervisor threads may declare a particular kernel object to be a public object, usable by all cur-
rent and future threads with the `k_object_access_all_grant()` API. You must assume that any
untrusted or exploited code will then be able to access the object. Use this API with caution!
- If a thread was declared statically with `K_THREAD_DEFINE()`, then the `K_THREAD_ACCESS_GRANT()`
may be used to grant that thread access to a set of kernel objects at boot time.

Once a thread has been granted access to an object, such access may be removed with the
`k_object_access_revoke()` API. This API is not available to user threads, however user threads may
use `k_object_release()` to relinquish their own permissions on an object.

API calls from supervisor mode to set permissions on kernel objects that are not being tracked by the
kernel will be no-ops. Doing the same from user mode will result in a fatal error for the calling thread.

Objects allocated with `k_object_alloc()` implicitly grant permission on the allocated object to the
calling thread.

**Initialization State**

Most operations on kernel objects will fail if the object is considered to be in an uninitialized state. The
appropriate init function for the object must be performed first.

Some objects will be implicitly initialized at boot:

- Kernel objects that were declared with static initialization macros (such as `K_SEM_DEFINE`
for semaphores) will be in an initialized state at build time.
- Device driver objects are considered initialized after their init function is run by the kernel early in
the boot process.

If a kernel object is initialized with a private static initializer, the object must have `z_object_init()`
called on it at some point by a supervisor thread, otherwise the kernel will consider the object unin-
itialized if accessed by a user thread. This is very uncommon, typically only for kernel objects that are
embedded within some larger struct and initialized statically.

```c
struct foo {
    struct k_sem sem;
    ...
};

struct foo my_foo = {
    .sem = Z_SEM_INITIALIZER(my_foo.sem, 0, 1),
    ...
};
...
z_object_init(&my_foo.sem);
...
```

**Creating New Kernel Object Types**

When implementing new kernel features or driver subsystems, it may be necessary to define some new
kernel object types. There are different steps needed for creating core kernel objects and new driver
subsystems.
Creating New Core Kernel Objects

- In scripts/build/gen_kobject_list.py, add the name of the struct to the kobjects list.

Instances of the new struct should now be tracked.

Creating New Driver Subsystem Kernel Objects

All driver instances are device. They are differentiated by what API struct they are set to.

- In scripts/build/gen_kobject_list.py, add the name of the API struct for the new subsystem to the subsystems list.

Driver instances of the new subsystem should now be tracked.

Configuration Options

Related configuration options:

- CONFIG_USERSPACE
- CONFIG_MAX_THREAD_BYTES

API Reference

group usermode_apis

Defines

K_THREAD_ACCESS_GRANT(name_, ...)

Grant a static thread access to a list of kernel objects.

For threads declared with K_THREAD_DEFINE(), grant the thread access to a set of kernel objects. These objects do not need to be in an initialized state. The permissions will be granted when the threads are initialized in the early boot sequence.

All arguments beyond the first must be pointers to kernel objects.

Parameters

- name_ – Name of the thread, as passed to K_THREAD_DEFINE()

K_OBJ_FLAG_INITIALIZED

Object initialized.

K_OBJ_FLAG_PUBLIC

Object is Public.

K_OBJ_FLAG_ALLOC

Object allocated.

K_OBJ_FLAG_DRIVER

Driver Object.
Functions

void k_object_access_grant(const void *object, struct k_thread *thread)
Grant a thread access to a kernel object.

The thread will be granted access to the object if the caller is from supervisor mode, or the
caller is from user mode AND has permissions on both the object and the thread whose access
is being granted.

Parameters
• object – Address of kernel object
• thread – Thread to grant access to the object

void k_object_access_revoke(const void *object, struct k_thread *thread)
Revoke a thread's access to a kernel object.

The thread will lose access to the object if the caller is from supervisor mode, or the caller is
from user mode AND has permissions on both the object and the thread whose access is being
revoked.

Parameters
• object – Address of kernel object
• thread – Thread to remove access to the object

void k_object_release(const void *object)
Release an object.

Allows user threads to drop their own permission on an object Their permissions are automat-
cally cleared when a thread terminates.

Parameters
• object – The object to be released

void k_object_access_all_grant(const void *object)
Grant all present and future threads access to an object.

If the caller is from supervisor mode, or the caller is from user mode and have sufficient
permissions on the object, then that object will have permissions granted to it for all current
and future threads running in the system, effectively becoming a public kernel object.

Use of this API should be avoided on systems that are running untrusted code as it is possible
for such code to derive the addresses of kernel objects and perform unwanted operations on
them.

It is not possible to revoke permissions on public objects; once public, any thread may use it.

Parameters
• object – Address of kernel object

bool k_object_is_valid(const void *obj, enum k_objects otype)
Check if a kernel object is of certain type and is valid.

This checks if the kernel object exists, of certain type, and has been initialized.

Parameters
• obj – Address of the kernel object
• otype – Object type (use K_OBJ_ANY for ignoring type checking)

Returns
True if kernel object (obj) exists, of certain type, and has been initialized. False
otherwise.
static inline void k_object_free(void *obj)
    Free an object.

Parameters
    • obj –

3.3.4 System Calls

User threads run with a reduced set of privileges than supervisor threads: certain CPU instructions may not be used, and they have access to only a limited part of the memory map. System calls (may) allow user threads to perform operations not directly available to them.

When defining system calls, it is very important to ensure that access to the API's private data is done exclusively through system call interfaces. Private kernel data should never be made available to user mode threads directly. For example, the k_queue APIs were intentionally not made available as they store bookkeeping information about the queue directly in the queue buffers which are visible from user mode.

APIs that allow the user to register callback functions that run in supervisor mode should never be exposed as system calls. Reserve these for supervisor-mode access only.

This section describes how to declare new system calls and discusses a few implementation details relevant to them.

Components

All system calls have the following components:

• A C prototype prefixed with __syscall for the API. It will be declared in some header under include/ or in another SYSCALL_INCLUDE_DIRS directory. This prototype is never implemented manually, instead it gets created by the scripts/build/gen_syscalls.py script. What gets generated is an inline function which either calls the implementation function directly (if called from supervisor mode) or goes through privilege elevation and validation steps (if called from user mode).

• An implementation function, which is the real implementation of the system call. The implementation function may assume that all parameters passed in have been validated if it was invoked from user mode.

• A verification function, which wraps the implementation function and does validation of all the arguments passed in.

• An unmarshalling function, which is an automatically generated handler that must be included by user source code.

C Prototype

The C prototype represents how the API is invoked from either user or supervisor mode. For example, to initialize a semaphore:

```c
__syscall void k_sem_init(struct k_sem *sem, unsigned int initial_count,
                          unsigned int limit);
```

The __syscall attribute is very special. To the C compiler, it simply expands to 'static inline'. However to the post-build scripts/build/parse_syscalls.py script, it indicates that this API is a system call. The scripts/build/parse_syscalls.py script does some parsing of the function prototype, to determine the data types of its return value and arguments, and has some limitations:

• Array arguments must be passed in as pointers, not arrays. For example, int foo[] or int foo[12] is not allowed, but should instead be expressed as int *foo.

3.3. User Mode
• Function pointers horribly confuse the limited parser. The workaround is to typedef them first, and then express in the argument list in terms of that typedef.

• __syscall must be the first thing in the prototype.

The preprocessor is intentionally not used when determining the set of system calls to generate. However, any generated system calls that don’t actually have a verification function defined (because the related feature is not enabled in the kernel configuration) will instead point to a special verification for unimplemented system calls. Data type definitions for APIs should not have conditional visibility to the compiler.

Any header file that declares system calls must include a special generated header at the very bottom of the header file. This header follows the naming convention syscalls/<name of header file>. For example, at the bottom of include/sensor.h:

```c
#include <syscalls/sensor.h>
```

C prototype functions must be declared in one of the directories listed in the CMake variable SYSCALL_INCLUDE_DIRS. This list always contains APPLICATION_SOURCE_DIR when CONFIG_APPLICATION_DEFINED_SYSCALL is set, or ${ZEPHYR_BASE}/subsys/tesstsuite/ztest/include when CONFIG_ZTEST is set. Additional paths can be added to the list through the CMake command line or in CMake code that is run before find_package(Zephyr ...) is run. ${ZEPHYR_BASE}/include is always scanned for potential syscall prototypes.

Note that not all syscalls will be included in the final binaries. CMake functions zephyr_syscall_header and zephyr_syscall_header_ifdef are used to specify which header files contain syscall prototypes where those syscalls must be present in the final binaries. Note that header files inside directories listed in CMake variable SYSCALL_INCLUDE_DIRS will always have their syscalls present in final binaries. To force all syscalls to be included in the final binaries, turn on CONFIG_EMIT_ALL_SYSCALLS.

Invocation Context Source code that uses system call APIs can be made more efficient if it is known that all the code inside a particular C file runs exclusively in user mode, or exclusively in supervisor mode. The system will look for the definition of macros __ZEPHYR_SUPERVISOR__ or __ZEPHYR_USER__, typically these will be added to the compiler flags in the build system for the related files.

• If CONFIG_USERSPACE is not enabled, all APIs just directly call the implementation function.

• Otherwise, the default case is to make a runtime check to see if the processor is currently running in user mode, and either make the system call or directly call the implementation function as appropriate.

• If __ZEPHYR_SUPERVISOR__ is defined, then it is assumed that all the code runs in supervisor mode and all APIs just directly call the implementation function. If the code was actually running in user mode, there will be a CPU exception as soon as it tries to do something it isn’t allowed to do.

• If __ZEPHYR_USER__ is defined, then it is assumed that all the code runs in user mode and system calls are unconditionally made.

Implementation Details Declaring an API with __syscall causes some code to be generated in C and header files by the scripts/build/gen_syscalls.py script, all of which can be found in the project out directory under include/generated/:

• The system call is added to the enumerated type of system call IDs, which is expressed in include/generated/syscall_list.h. It is the name of the API in uppercase, prefixed with K_SYSCALL_.

• An entry for the system call is created in the dispatch table _k_syscall_table, expressed in include/generated/syscall_dispatch.c
  
  – This table only contains syscalls where their corresponding prototypes are declared in header files when CONFIG_EMIT_ALL_SYSCALLS is enabled:

    * Indicated by CMake functions zephyr_syscall_header and zephyr_syscall_header_ifdef, or
* Under directories specified in CMake variable `SYSCALL_INCLUDE_DIRS`.

- A weak verification function is declared, which is just an alias of the 'unimplemented system call' verifier. This is necessary since the real verification function may or may not be built depending on the kernel configuration. For example, if a user thread makes a sensor subsystem API call, but the sensor subsystem is not enabled, the weak verifier will be invoked instead.

- An unmarshalling function is defined in `include/generated/<name>_mrsh.c`

The body of the API is created in the generated system header. Using the example of `k_sem_init()`, this API is declared in `include/kernel.h`. At the bottom of `include/kernel.h` is:

```
#include <syscalls/kernel.h>
```

Inside this header is the body of `k_sem_init()`:

```c
static inline void k_sem_init(struct k_sem * sem, unsigned int initial_count, unsigned int limit)
{
    #ifdef CONFIG_USERSPACE
    if (z_syscall_trap()) {
        arch_syscall_invoke3(*(uintptr_t *)&sem, *(uintptr_t *)&initial_count,
            *(uintptr_t *)&limit, K_SYSCALL_K_SEM_INIT);
        return;
    }
    compiler_barrier();
    #endif
    z_impl_k_sem_init(sem, initial_count, limit);
}
```

This generates an inline function that takes three arguments with void return value. Depending on context it will either directly call the implementation function or go through a system call elevation. A prototype for the implementation function is also automatically generated.

The final layer is the invocation of the system call itself. All architectures implementing system calls must implement the seven inline functions `_arch_syscall_invoke0()` through `_arch_syscall_invoke6()`. These functions marshal arguments into designated CPU registers and perform the necessary privilege elevation. Parameters of API inline function, before being passed as arguments to system call, are C casted to `uintptr_t` which matches size of register. Exception to above is passing 64-bit parameters on 32-bit systems, in which case 64-bit parameters are split into lower and higher part and passed as two consecutive arguments. There is always a `uintptr_t` type return value, which may be neglected if not needed.

![System Call execution flow](image)

**Fig. 3: System Call execution flow**

Some system calls may have more than six arguments, but number of arguments passed via registers is
limited to six for all architectures. Additional arguments will need to be passed in an array in the source memory space, which needs to be treated as untrusted memory in the verification function. This code (packing, unpacking and validation) is generated automatically as needed in the stub above and in the unmarshalling function.

System calls return `uintptr_t` type value that is C casted, by wrapper, to a return type of API prototype declaration. This means that 64-bit value may not be directly returned, from a system call to its wrapper, on 32-bit systems. To solve the problem the automatically generated wrapper function defines 64-bit intermediate variable, which is considered untrusted buffer, on its stack and passes pointer to that variable to the system call, as a final argument. Upon return from the system call the value written to that buffer will be returned by the wrapper function. The problem does not exist on 64-bit systems which are able to return 64-bit values directly.

**Implementation Function**

The implementation function is what actually does the work for the API. Zephyr normally does little to no error checking of arguments, or does this kind of checking with assertions. When writing the implementation function, validation of any parameters is optional and should be done with assertions.

All implementation functions must follow the naming convention, which is the name of the API prefixed with `z_impl_`. Implementation functions may be declared in the same header as the API as a static inline function or declared in some C file. There is no prototype needed for implementation functions, these are automatically generated.

**Verification Function**

The verification function runs on the kernel side when a user thread makes a system call. When the user thread makes a software interrupt to elevate to supervisor mode, the common system call entry point uses the system call ID provided by the user to look up the appropriate unmarshalling function for that system call and jump into it. This in turn calls the verification function.

Verification and unmarshalling functions only run when system call APIs are invoked from user mode. If an API is invoked from supervisor mode, the implementation is simply called and there is no software trap.

The purpose of the verification function is to validate all the arguments passed in. This includes:

- Any kernel object pointers provided. For example, the semaphore APIs must ensure that the semaphore object passed in is a valid semaphore and that the calling thread has permission on it.
- Any memory buffers passed in from user mode. Checks must be made that the calling thread has read or write permissions on the provided buffer.
- Any other arguments that have a limited range of valid values.

Verification functions involve a great deal of boilerplate code which has been made simpler by some macros in `include/zephyr/syscall_handler.h`. Verification functions should be declared using these macros.

**Argument Validation** Several macros exist to validate arguments:

- `Z_SYSCALL_OBJ()` Checks a memory address to assert that it is a valid kernel object of the expected type, that the calling thread has permissions on it, and that the object is initialized.
- `Z_SYSCALL_OBJ_INIT()` is the same as `Z_SYSCALL_OBJ()`, except that the provided object may be uninitialized. This is useful for verifiers of object init functions.
- `Z_SYSCALL_OBJ_NEVER_INIT()` is the same as `Z_SYSCALL_OBJ()`, except that the provided object must be uninitialized. This is not used very often, currently only for `k_thread_create()`.
• Z_SYSCALL_MEMORY_READ() validates a memory buffer of a particular size. The calling thread must have read permissions on the entire buffer.

• Z_SYSCALL_MEMORY_WRITE() is the same as Z_SYSCALL_MEMORY_READ() but the calling thread must additionally have write permissions.

• Z_SYSCALL_MEMORY_ARRAY_READ() validates an array whose total size is expressed as separate arguments for the number of elements and the element size. This macro correctly accounts for multiplication overflow when computing the total size. The calling thread must have read permissions on the total size.

• Z_SYSCALL_MEMORY_ARRAY_WRITE() is the same as Z_SYSCALL_MEMORY_ARRAY_READ() but the calling thread must additionally have write permissions.

• Z_SYSCALL_VERIFY_MSG() does a runtime check of some boolean expression which must evaluate to true otherwise the check will fail. A variant Z_SYSCALL_VERIFY exists which does not take a message parameter, instead printing the expression tested if it fails. The latter should only be used for the most obvious of tests.

• Z_SYSCALL_DRIVER_OP() checks at runtime if a driver instance is capable of performing a particular operation. While this macro can be used by itself, it's mostly a building block for macros that are automatically generated for every driver subsystem. For instance, to validate the GPIO driver, one could use the Z_SYSCALL_DRIVER_GPIO() macro.

• Z_SYSCALL_SPECIFIC_DRIVER() is a runtime check to verify that a provided pointer is a valid instance of a specific device driver, that the calling thread has permissions on it, and that the driver has been initialized. It does this by checking the API structure pointer that is stored within the driver instance and ensuring that it matches the provided value, which should be the address of the specific driver's API structure.

If any check fails, the macros will return a nonzero value. The macro Z_OOPS() can be used to induce a kernel oops which will kill the calling thread. This is done instead of returning some error condition to keep the APIs the same when calling from supervisor mode.

Verifier Definition All system calls are dispatched to a verifier function with a prefixed z_vrfy_ name based on the system call. They have exactly the same return type and argument types as the wrapped system call. Their job is to execute the system call (generally by calling the implementation function) after having validated all arguments.

The verifier is itself invoked by an automatically generated unmarshaller function which takes care of unpacking the register arguments from the architecture layer and casting them to the correct type. This is defined in a header file that must be included from user code, generally somewhere after the definition of the verifier in a translation unit (so that it can be inlined).

For example:

```c
static int z_vrfy_k_sem_take(struct k_sem *sem, int32_t timeout)
{
    Z_OOPS(Z_SYSCALL_OBJ(sem, K_OBJ_SEM));
    return z_impl_k_sem_take(sem, timeout);
}
#include <syscalls/k_sem_take_mrsh.c>
```

Verification Memory Access Policies Parameters passed to system calls by reference require special handling, because the value of these parameters can be changed at any time by any user thread that has access to the memory that parameter points to. If the kernel makes any logical decisions based on the contents of this memory, this can open up the kernel to attacks even if checking is done. This is a class of exploits known as TOCTOU (Time Of Check to Time Of Use).

The proper procedure to mitigate these attacks is to make a copies in the verification function, and only perform parameter checks on the copies, which user threads will never have access to. The implemen-
tation functions get passed the copy and not the original data sent by the user. The \texttt{z_user_to_copy()} and \texttt{z_user_from_copy()} APIs exist for this purpose.

There is one exception in place, with respect to large data buffers which are only used to provide a memory area that is either only written to, or whose contents are never used for any validation or control flow. Further discussion of this later in this section.

As a first example, consider a parameter which is used as an output parameter for some integral value:

```c
int z_vrfy_some_syscall(int *out_param)
{
    int local_out_param;
    int ret;

    ret = z_impl_some_syscall(&local_out_param);
    Z_OOPS(z_user_to_copy(out_param, &local_out_param, sizeof(*out_param)));
    return ret;
}
```

Here we have allocated \texttt{local_out_param} on the stack, passed its address to the implementation function, and then used \texttt{z_user_to_copy()} to fill in the memory passed in by the caller.

It might be tempting to do something more concise:

```c
int z_vrfy_some_syscall(int *out_param)
{
    Z_OOPS(Z_SYSCALL_MEMORY_WRITE(out_param, sizeof(*out_param)));
    return z_impl_some_syscall(out_param);
}
```

However, this is unsafe if the implementation ever does any reads to this memory as part of its logic. For example, it could be used to store some counter value, and this could be meddled with by user threads that have access to its memory. It is by far safest for small integral values to do the copying as shown in the first example.

Some parameters may be input/output. For instance, it's not uncommon to see APIs which pass in a pointer to some size\_t which is a maximum allowable size, which is then updated by the implementation to reflect the actual number of bytes processed. This too should use a stack copy:

```c
int z_vrfy_in_out_syscall(size_t *size_ptr)
{
    size_t size;
    int ret;

    Z_OOPS(z_user_from_copy(&size, size_ptr, sizeof(size)));
    ret = z_impl_in_out_syscall(&size);
    Z_OOPS(z_user_to_copy(size_ptr, &size, sizeof(size)));
    return ret;
}
```

Many system calls pass in structures or even linked data structures. All should be copied. Typically this is done by allocating copies on the stack:

```c
struct bar {
    ...
};

struct foo {
    ...
    struct bar *bar_left;
```

(continues on next page)
struct bar *bar_right;

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar bar_right_copy;
    struct bar bar_left_copy;

    Z_OOPS(z_user_from_copy(&foo_copy, foo, sizeof(*foo)));
    Z_OOPS(z_user_from_copy(&bar_right_copy, foo_copy.bar_right,
                           sizeof(struct bar)));
    foo_copy.bar_right = &bar_right_copy;
    Z_OOPS(z_user_from_copy(&bar_left_copy, foo_copy.bar_left,
                            sizeof(struct bar)));
    foo_copy.bar_left = &bar_left_copy;

    return z_impl_must_alloc(&foo_copy);
}

In some cases the amount of data isn't known at compile time or may be too large to allocate on
the stack. In this scenario, it may be necessary to draw memory from the caller's resource pool via
z_thread_malloc(). This should always be considered last resort. Functional safety programming
guidelines heavily discourage usage of heap and the fact that a resource pool is used must be clearly
documented. Any issues with allocation must be reported, to a caller, with returning the -ENOMEM . The
Z_OOPS() should never be used to verify if resource allocation has been successful.

struct bar {
    ...
};

struct foo {
    size_t count;
    struct bar *bar_list; /* array of struct bar of size count */
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar *bar_list_copy;
    size_t bar_list_bytes;

    /* Safely copy foo into foo_copy */
    Z_OOPS(z_user_from_copy(&foo_copy, foo, sizeof(*foo)));

    /* Bounds check the count member, in the copy we made */
    if (foo_copy.count > 32) {
        return -EINVAL;
    }

    /* Allocate RAM for the bar_list, replace the pointer in
    * foo_copy */
    bar_list_bytes = foo_copy.count * sizeof(struct bar);
    bar_list_copy = z_thread_malloc(bar_list_bytes);

    (continues on next page)
if (bar_list_copy == NULL) {
    return -ENOMEM;
}
Z_OOPS(z_user_from_copy(bar_list_copy, foo_copy.bar_list,
    bar_list_bytes));
foo_copy.bar_list = bar_list_copy;
ret = z_impl_must_alloc(&foo_copy);
/* All done with the memory, free it and return */
k_free(foo_copy.bar_list_copy);
return ret;
}

Finally, we must consider large data buffers. These represent areas of user memory which either have data copied out of, or copied into. It is permitted to pass these pointers to the implementation function directly. The caller's access to the buffer still must be validated with Z_SYSCALL_MEMORY APIs. The following constraints need to be met:

- If the buffer is used by the implementation function to write data, such as data captured from some MMIO region, the implementation function must only write this data, and never read it.
- If the buffer is used by the implementation function to read data, such as a block of memory to write to some hardware destination, this data must be read without any processing. No conditional logic can be implemented due to the data buffer's contents. If such logic is required a copy must be made.
- The buffer must only be used synchronously with the call. The implementation must not ever save the buffer address and use it asynchronously, such as when an interrupt fires.

int z_vrfy_get_data_from_kernel(void *buf, size_t size)
{
    Z_OOPS(Z_SYSCALL_MEMORY_WRITE(buf, size));
    return z_impl_get_data_from_kernel(buf, size);
}

Verification Return Value Policies When verifying system calls, it's important to note which kinds of verification failures should propagate a return value to the caller, and which should simply invoke Z_OOPS() which kills the calling thread. The current conventions are as follows:

1. For system calls that are defined but not compiled, invocations of these missing system calls are routed to handler_no_syscall() which invokes Z_OOPS().
2. Any invalid access to memory found by the set of Z_SYSCALL_MEMORY APIs, z_user_from_copy(), z_user_to_copy() should trigger a Z_OOPS. This happens when the caller doesn't have appropriate permissions on the memory buffer or some size calculation overflowed.
3. Most system calls take kernel object pointers as an argument, checked either with one of the Z_SYSCALL_OBJ functions, Z_SYSCALL_DRIVER_nnnnn, or manually using z_object_validate(). These can fail for a variety of reasons: missing driver API, bad kernel object pointer, wrong kernel object type, or improper initialization state. These issues should always invoke Z_OOPS().
4. Any error resulting from a failed memory heap allocation, often from invoking z_thread_malloc(), should propagate -ENOMEM to the caller.
5. General parameter checks should be done in the implementation function, in most cases using CHECKIF().
   - The behavior of CHECKIF() depends on the kernel configuration, but if user mode is enabled, CONFIG_RUNTIME_ERROR_CHECKS is enforced, which guarantees that these checks will be made
and a return value propagated.

6. It is totally forbidden for any kind of kernel mode callback function to be registered from user mode. APIs which simply install callbacks shall not be exposed as system calls. Some driver subsystem APIs may take optional function callback pointers. User mode verification functions for these APIs must enforce that these are NULL and should invoke Z_OOPS() if not.

7. Some parameter checks are enforced only from user mode. These should be checked in the verification function and propagate a return value to the caller if possible.

There are some known exceptions to these policies currently in Zephyr:

- `k_thread_join()` and `k_thread_abort()` are no-ops if the thread object isn’t initialized. This is because for threads, the initialization bit pulls double-duty to indicate whether a thread is running, cleared upon exit. See #23030.
- `k_thread_create()` invokes `Z_OOPS()` for parameter checks, due to a great deal of existing code ignoring the return value. This will also be addressed by #23030.
- `k_thread_abort()` invokes `Z_OOPS()` if an essential thread is aborted, as the function has no return value.
- Various system calls related to logging invoke `Z_OOPS()` when bad parameters are passed in as they do not propagate errors.

**Configuration Options**

Related configuration options:

- `CONFIG_USERSPACE`
- `CONFIG_EMIT_ALL_SYSCALLS`

**APIs**

Helper macros for creating system call verification functions are provided in `include/zephyr/syscall_handler.h`:

- `Z_SYSCALL_OBJ()`
- `Z_SYSCALL_OBJ_INIT()`  
- `Z_SYSCALL_OBJ_NEVER_INIT()`  
- `Z_OOPS()`  
- `Z_SYSCALL_MEMORY_READ()`  
- `Z_SYSCALL_MEMORY_WRITE()`  
- `Z_SYSCALL_MEMORY_ARRAY_READ()`  
- `Z_SYSCALL_MEMORY_ARRAY_WRITE()`  
- `Z_SYSCALL_VERIFY_MSG()`  
- `Z_SYSCALL_VERIFY`

Functions for invoking system calls are defined in `include/zephyr/syscall.h`:

- `_arch_syscall_invoke0()`  
- `_arch_syscall_invoke1()`  
- `_arch_syscall_invoke2()`  
- `_arch_syscall_invoke3()`  
- `_arch_syscall_invoke4()`
• _arch_syscall_invoke5()
• _arch_syscall_invoke6()

### 3.3.5 MPU Stack Objects

#### Thread Stack Creation

Thread stacks are declared statically with `K_THREAD_STACK_DEFINE()` or embedded within structures using `K_THREAD_STACK_MEMBER()`.

For architectures which utilize memory protection unit (MPU) hardware, stacks are physically contiguous allocations. This contiguous allocation has implications for the placement of stacks in memory, as well as the implementation of other features such as stack protection and userspace. The implications for placement are directly attributed to the alignment requirements for MPU regions. This is discussed in the memory placement section below.

#### Stack Guards

Stack protection mechanisms require hardware support that can restrict access to memory. Memory protection units can provide this kind of support. The MPU provides a fixed number of regions. Each region contains information about the start, end, size, and access attributes to be enforced on that particular region.

Stack guards are implemented by using a single MPU region and setting the attributes for that region to not allow write access. If invalid accesses occur, a fault ensues. The stack guard is defined at the bottom (the lowest address) of the stack.

#### Memory Placement

During stack creation, a set of constraints are enforced on the allocation of memory. These constraints include determining the alignment of the stack and the correct sizing of the stack. During linking of the binary, these constraints are used to place the stacks properly.

The main source of the memory constraints is the MPU design for the SoC. The MPU design may require specific constraints on the region definition. These can include alignment of beginning and end addresses, sizes of allocations, or even interactions between overlapping regions.

Some MPUs require that each region be aligned to a power of two. These SoCs will have `CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT` defined. This means that a 1500 byte stack should be aligned to a 2kB boundary and the stack size should also be adjusted to 2kB to ensure that nothing else is placed in the remainder of the region. SoCs which include the unmodified ARM v7m MPU will have these constraints.

Some ARM MPUs use start and end addresses to define MPU regions and both the start and end addresses require 32 byte alignment. An example of this kind of MPU is found in the NXP FRDM K64F.

MPUs may have a region priority mechanisms that use the highest priority region that covers the memory access to determine the enforcement policy. Others may logically OR regions to determine enforcement policy.

Size and alignment constraints may result in stack allocations being larger than the requested size. Region priority mechanisms may result in some added complexity when implementing stack guards.
3.3.6 MPU Backed Userspace

The MPU backed userspace implementation requires the creation of a secondary set of stacks. These stacks exist in a 1:1 relationship with each thread stack defined in the system. The privileged stacks are created as a part of the build process.

A post-build script `scripts/build/gen_kobject_list.py` scans the generated ELF file and finds all of the thread stack objects. A set of privileged stacks, a lookup table, and a set of helper functions are created and added to the image.

During the process of dropping a thread to user mode, the privileged stack information is filled in and later used by the swap and system call infrastructure to configure the MPU regions properly for the thread stack and guard (if applicable).

During system calls, the user mode thread's access to the system call and the passed-in parameters are all validated. The user mode thread is then elevated to privileged mode, the stack is switched to use the privileged stack, and the call is made to the specified kernel API. On return from the kernel API, the thread is set back to user mode and the stack is restored to the user stack.

3.4 Memory Management

The following contains various topics regarding memory management.

3.4.1 Memory Heaps

Zephyr provides a collection of utilities that allow threads to dynamically allocate memory.

Synchronized Heap Allocator

Creating a Heap The simplest way to define a heap is statically, with the `K_HEAP_DEFINE` macro. This creates a static `k_heap` variable with a given name that manages a memory region of the specified size.

Heaps can also be created to manage arbitrary regions of application-controlled memory using `k_heap_init()`.

Allocating Memory Memory can be allocated from a heap using `k_heap_alloc()`, passing it the address of the heap object and the number of bytes desired. This functions similarly to standard C `malloc()`, returning a NULL pointer on an allocation failure.

The heap supports blocking operation, allowing threads to go to sleep until memory is available. The final argument is a `k_timeout_t` timeout value indicating how long the thread may sleep before returning, or else one of the constant timeout values `K_NO_WAIT` or `K_FOREVER`.

Releasing Memory Memory allocated with `k_heap_alloc()` must be released using `k_heap_free()`.

Similar to standard C `free()`, the pointer provided must be either a NULL value or a pointer previously returned by `k_heap_alloc()` for the same heap. Freeing a NULL value is defined to have no effect.

Low Level Heap Allocator

The underlying implementation of the `k_heap` abstraction is provided a data structure named `sys_heap`. This implements exactly the same allocation semantics, but provides no kernel synchronization tools. It is available for applications that want to manage their own blocks of memory in contexts (for example, userspace) where synchronization is unavailable or more complicated. Unlike `k_heap`, all calls to any `sys_heap` functions on a single heap must be serialized by the caller. Simultaneous use from separate threads is disallowed.
Implementation Internally, the `sys_heap` memory block is partitioned into “chunks” of 8 bytes. All allocations are made out of a contiguous region of chunks. The first chunk of every allocation or unused block is prefixed by a chunk header that stores the length of the chunk, the length of the next lower (“left”) chunk in physical memory, a bit indicating whether the chunk is in use, and chunk-indexed link pointers to the previous and next chunk in a “free list” to which unused chunks are added.

The heap code takes reasonable care to avoid fragmentation. Free block lists are stored in “buckets” by their size, each bucket storing blocks within one power of two (i.e. a bucket for blocks of 3-4 chunks, another for 5-8, 9-16, etc...) this allows new allocations to be made from the smallest/most-fragmented blocks available. Also, as allocations are freed and added to the heap, they are automatically combined with adjacent free blocks to prevent fragmentation.

All metadata is stored at the beginning of the contiguous block of heap memory, including the variable-length list of bucket list heads (which depend on heap size). The only external memory required is the `sys_heap` structure itself.

The `sys_heap` functions are unsynchronized. Care must be taken by any users to prevent concurrent access. Only one context may be inside one of the API functions at a time.

The heap code takes care to present high performance and reliable latency. All `sys_heap` API functions are guaranteed to complete within constant time. On typical architectures, they will all complete within 1-200 cycles. One complexity is that the search of the minimum bucket size for an allocation (the set of free blocks that “might fit”) has a compile-time upper bound of iterations to prevent unbounded list searches, at the expense of some fragmentation resistance. This `CONFIG_SYS_HEAP_ALLOC_LOOPS` value may be chosen by the user at build time, and defaults to a value of 3.

Multi-Heap Wrapper Utility

The `sys_heap` utility requires that all managed memory be in a single contiguous block. It is common for complicated microcontroller applications to have more complicated memory setups that they still want to manage dynamically as a "heap". For example, the memory might exist as separate discontiguous regions, different areas may have different cache, performance or power behavior, peripheral devices may only be able to perform DMA to certain regions, etc...

For those situations, Zephyr provides a `sys_multi_heap` utility. Effectively this is a simple wrapper around a set of one or more `sys_heap` objects. It should be initialized after its child heaps via `sys_multi_heap_init()`, after which each heap can be added to the managed set via `sys_multi_heap_add_heap()`. No destruction utility is provided; just as for `sys_heap`, applications that want to destroy a multi heap should simply ensure all allocated blocks are freed (or at least will never be used again) and repurpose the underlying memory for another usage.

It has a single pair of allocation entry points, `sys_multi_heap_alloc()` and `sys_multi_heap_aligned_alloc()`. These behave identically to the `sys_heap` functions with similar names, except that they also accept an opaque “configuration” parameter. This pointer is uninspected by the multi heap code itself; instead it is passed to a callback function provided at initialization time. This application-provided callback is responsible for doing the underlying allocation from one of the managed heaps, and may use the configuration parameter in any way it likes to make that decision.

When unused, a multi heap may be freed via `sys_multi_heap_free()`. The application does not need to pass a configuration parameter. Memory allocated from any of the managed `sys_heap` objects may be freed with in the same way.

System Heap

The `system heap` is a predefined memory allocator that allows threads to dynamically allocate memory from a common memory region in a `malloc()`-like manner.

Only a single system heap is defined. Unlike other heaps or memory pools, the system heap cannot be directly referenced using its memory address.

The size of the system heap is configurable to arbitrary sizes, subject to space availability.
A thread can dynamically allocate a chunk of heap memory by calling `k_malloc()`. The address of the allocated chunk is guaranteed to be aligned on a multiple of pointer sizes. If a suitable chunk of heap memory cannot be found `NULL` is returned.

When the thread is finished with a chunk of heap memory it can release the chunk back to the system heap by calling `k_free()`.

**Defining the Heap Memory Pool** The size of the heap memory pool is specified using the `CONFIG_HEAP_MEM_POOL_SIZE` configuration option.

By default, the heap memory pool size is zero bytes. This value instructs the kernel not to define the heap memory pool object. The maximum size is limited by the amount of available memory in the system. The project build will fail in the link stage if the size specified can not be supported.

**Allocating Memory** A chunk of heap memory is allocated by calling `k_malloc()`.

The following code allocates a 200 byte chunk of heap memory, then fills it with zeros. A warning is issued if a suitable chunk is not obtained.

```c
char *mem_ptr;

mem_ptr = k_malloc(200);
if (mem_ptr != NULL)) {
    memset(mem_ptr, 0, 200);
    ...
} else {
    printf("Memory not allocated");
}
```

**Releasing Memory** A chunk of heap memory is released by calling `k_free()`.

The following code allocates a 75 byte chunk of memory, then releases it once it is no longer needed.

```c
char *mem_ptr;

mem_ptr = k_malloc(75);
... /* use memory block */
k_free(mem_ptr);
```

**Suggested Uses** Use the heap memory pool to dynamically allocate memory in a `malloc()`-like manner.

**Configuration Options** Related configuration options:

- `CONFIG_HEAP_MEM_POOL_SIZE`

**API Reference**

`group heap_apis`

`Defines`
K_HEAP_DEFINE(name, bytes)
Define a static k_heap.

This macro defines and initializes a static memory region and k_heap of the requested size. After kernel start, &name can be used as if k_heap_init() had been called.

Note that this macro enforces a minimum size on the memory region to accommodate metadata requirements. Very small heaps will be padded to fit.

Parameters
• name – Symbol name for the struct k_heap object
• bytes – Size of memory region, in bytes

K_HEAP_DEFINE_NOCACHE(name, bytes)
Define a static k_heap in uncached memory.

This macro defines and initializes a static memory region and k_heap of the requested size in uncached memory. After kernel start, &name can be used as if k_heap_init() had been called.

Note that this macro enforces a minimum size on the memory region to accommodate metadata requirements. Very small heaps will be padded to fit.

Parameters
• name – Symbol name for the struct k_heap object
• bytes – Size of memory region, in bytes

Functions

void k_heap_init(struct k_heap *h, void *mem, size_t bytes)
Initialize a k_heap.

This constructs a synchronized k_heap object over a memory region specified by the user. Note that while any alignment and size can be passed as valid parameters, internal alignment restrictions inside the inner sys_heap mean that not all bytes may be usable as allocated memory.

Parameters
• h – Heap struct to initialize
• mem – Pointer to memory.
• bytes – Size of memory region, in bytes

void *k_heap_aligned_alloc(struct k_heap *h, size_t align, size_t bytes, k_timeout_t timeout)
Allocate aligned memory from a k_heap.

Behaves in all ways like k_heap_alloc(), except that the returned memory (if available) will have a starting address in memory which is a multiple of the specified power-of-two alignment value in bytes. The resulting memory can be returned to the heap using k_heap_free().

Function properties (list may not be complete)
isr-ok

Note: timeout must be set to K_NO_WAIT if called from ISR.

Note: When CONFIG_MULTITHREADING=n any timeout is treated as K_NO_WAIT.
Parameters

- h – Heap from which to allocate
- align – Alignment in bytes, must be a power of two
- bytes – Number of bytes requested
- timeout – How long to wait, or K_NO_WAIT

Returns

Pointer to memory the caller can now use

```c
void *k_heap_alloc(struct k_heap *h, size_t bytes, k_timeout_t timeout)
```
Allocate memory from a `k_heap`.

Allocates and returns a memory buffer from the memory region owned by the heap. If no memory is available immediately, the call will block for the specified timeout (constructed via the standard timeout API, or K_NO_WAIT or K_FOREVER) waiting for memory to be freed. If the allocation cannot be performed by the expiration of the timeout, NULL will be returned. Allocated memory is aligned on a multiple of pointer sizes.

Function properties (list may not be complete)

`isr-ok`

Note: `timeout` must be set to K_NO_WAIT if called from ISR.

Note: When CONFIG_MULTITHREADING=n any `timeout` is treated as K_NO_WAIT.

Parameters

- h – Heap from which to allocate
- bytes – Desired size of block to allocate
- timeout – How long to wait, or K_NO_WAIT

Returns

A pointer to valid heap memory, or NULL

```c
void k_heap_free(struct k_heap *h, void *mem)
```
Free memory allocated by `k_heap_alloc()`

Returns the specified memory block, which must have been returned from `k_heap_alloc()`, to the heap for use by other callers. Passing a NULL block is legal, and has no effect.

Parameters

- h – Heap to which to return the memory
- mem – A valid memory block, or NULL

```c
void *k_aligned_alloc(size_t align, size_t size)
```
Allocate memory from the heap with a specified alignment.

This routine provides semantics similar to aligned_alloc(); memory is allocated from the heap with a specified alignment. However, one minor difference is that `k_aligned_alloc()` accepts any non-zero `size`, whereas aligned_alloc() only accepts a `size` that is an integral multiple of `align`.

Above, aligned_alloc() refers to: C11 standard (ISO/IEC 9899:2011): 7.22.3.1 The aligned_alloc function (p: 347-348)
Parameters

- **align** – Alignment of memory requested (in bytes).
- **size** – Amount of memory requested (in bytes).

Returns

Address of the allocated memory if successful; otherwise NULL.

```c
void *k_malloc(size_t size)
```

Allocate memory from the heap.

This routine provides traditional malloc() semantics. Memory is allocated from the heap memory pool. Allocated memory is aligned on a multiple of pointer sizes.

Parameters

- **size** – Amount of memory requested (in bytes).

Returns

Address of the allocated memory if successful; otherwise NULL.

```c
void k_free(void *ptr)
```

Free memory allocated from heap.

This routine provides traditional free() semantics. The memory being returned must have been allocated from the heap memory pool.

If `ptr` is NULL, no operation is performed.

Parameters

- **ptr** – Pointer to previously allocated memory.

```c
void *k_calloc(size_t nmemb, size_t size)
```

Allocate memory from heap, array style.

This routine provides traditional calloc() semantics. Memory is allocated from the heap memory pool and zeroed.

Parameters

- **nmemb** – Number of elements in the requested array
- **size** – Size of each array element (in bytes).

Returns

Address of the allocated memory if successful; otherwise NULL.

```c
struct k_heap
```

# include `<kernel.h>`

Heap listener

```c
#include <kernel.h>
```

Heap listener

```c
group heap_listener_apis
```

Defines

```c
HEAP_ID_FROM_POINTER(heap_pointer)
```

Construct heap identifier from heap pointer.

Construct a heap identifier from a pointer to the heap object, such as `sys_heap`.

Parameters
• heap_pointer – Pointer to the heap object

**HEAP_ID_LIBC**

Libc heap identifier.
Identifier of the global libc heap.

**HEAP_LISTENER_ALLOC_DEFINE(name, _heap_id, _alloc_cb)**

Define heap event listener node for allocation event.

Sample usage:

```c
void on_heap_alloc(uintptr_t heap_id, void *mem, size_t bytes)
{
    LOG_INF("Memory allocated at %p, size %ld", heap_id, mem, bytes);
}

HEAP_LISTENER_ALLOC_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_alloc);
```

**Parameters**

- **name** – Name of the heap event listener object
- **_heap_id** – Identifier of the heap to be listened
- **_alloc_cb** – Function to be called for allocation event

**HEAP_LISTENER_FREE_DEFINE(name, _heap_id, _free_cb)**

Define heap event listener node for free event.

Sample usage:

```c
void on_heap_free(uintptr_t heap_id, void *mem, size_t bytes)
{
    LOG_INF("Memory freed at %p, size %ld", heap_id, mem, bytes);
}

HEAP_LISTENER_FREE_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_free);
```

**Parameters**

- **name** – Name of the heap event listener object
- **_heap_id** – Identifier of the heap to be listened
- **_free_cb** – Function to be called for free event

**HEAP_LISTENER_RESIZE_DEFINE(name, _heap_id, _resize_cb)**

Define heap event listener node for resize event.

Sample usage:

```c
void on_heap_resized(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)
{
    LOG_INF("Libc heap end moved from %p to %p", old_heap_end, new_heap_end);
}

HEAP_LISTENER_RESIZE_DEFINE(my_listener, HEAP_ID_LIBC, on_heap_resized);
```

**Parameters**
• name – Name of the heap event listener object
• _heap_id – Identifier of the heap to be listened
• _resize_cb – Function to be called when the listened heap is resized

**Typedefs**

typedef void (*heap_listener_resize_cb_t)(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)

Callback used when heap is resized.

**Note:** Minimal C library does not emit this event.

**Param heap_id**
  Identifier of heap being resized

**Param old_heap_end**
  Pointer to end of heap before resize

**Param new_heap_end**
  Pointer to end of heap after resize

typedef void (*heap_listener_alloc_cb_t)(uintptr_t heap_id, void *mem, size_t bytes)

Callback used when there is heap allocation.

**Note:** Heaps managed by libraries outside of code in Zephyr main code repository may not emit this event.

**Note:** The number of bytes allocated may not match exactly to the request to the allocation function. Internal mechanism of the heap may allocate more than requested.

**Param heap_id**
  Heap identifier

**Param mem**
  Pointer to the allocated memory

**Param bytes**
  Size of allocated memory

typedef void (*heap_listener_free_cb_t)(uintptr_t heap_id, void *mem, size_t bytes)

Callback used when memory is freed from heap.

**Note:** Heaps managed by libraries outside of code in Zephyr main code repository may not emit this event.

**Note:** The number of bytes freed may not match exactly to the request to the allocation function. Internal mechanism of the heap dictates how memory is allocated or freed.
**Param heap_id**
Heap identifier

**Param mem**
Pointer to the freed memory

**Param bytes**
Size of freed memory

** Enums**

```c
enum heap_event_types
{
    enumerator HEAP_EVT_UNKNOWN = 0,
    enumerator HEAP_RESIZE,
    enumerator HEAP_ALLOC,
    enumerator HEAP_FREE,
    enumerator HEAP_REALLOC,
    enumerator HEAP_MAX_EVENTS,
};
```

** Functions**

```c
void heap_listener_register(struct heap_listener *listener)
{
    Register heap event listener.
    Add the listener to the global list of heap listeners that can be notified by different heap implementations upon certain events related to the heap usage.
}

Parameters
- listener – Pointer to the heap_listener object

void heap_listener_unregister(struct heap_listener *listener)
{
    Unregister heap event listener.
    Remove the listener from the global list of heap listeners that can be notified by different heap implementations upon certain events related to the heap usage.
}

Parameters
- listener – Pointer to the heap_listener object

void heap_listener_notify_alloc(uintptr_t heap_id, void *mem, size_t bytes)
{
    Notify listeners of heap allocation event.
    Notify registered heap event listeners with matching heap identifier that an allocation has been done on heap.
}

Parameters
- heap_id – Heap identifier
• mem – Pointer to the allocated memory
• bytes – Size of allocated memory

void heap_listener_notify_free(uintptr_t heap_id, void *mem, size_t bytes)

Notify listeners of heap free event.
Notify registered heap event listeners with matching heap identifier that memory is freed on heap

Parameters
• heap_id – Heap identifier
• mem – Pointer to the freed memory
• bytes – Size of freed memory

void heap_listener_notify_resize(uintptr_t heap_id, void *old_heap_end, void *new_heap_end)

Notify listeners of heap resize event.
Notify registered heap event listeners with matching heap identifier that the heap has been resized.

Parameters
• heap_id – Heap identifier
• old_heap_end – Address of the heap end before the change
• new_heap_end – Address of the heap end after the change

struct heap_listener
#include <heap_listener.h>

Public Members

sys_snnode_t node
Singly linked list node.

uintptr_t heap_id
Identifier of the heap whose events are listened.
It can be a heap pointer, if the heap is represented as an object, or 0 in the case of the
global libc heap.

typedef enum heap_event_types

enum heap_event_types event
The heap event to be notified.

3.4.2 Shared Multi Heap

The shared multi-heap memory pool manager uses the multi-heap allocator to manage a set of reserved
memory regions with different capabilities / attributes (cacheable, non-cacheable, etc.).

All the different regions can be added at run-time to the shared multi-heap pool providing an opaque
“attribute” value (an integer or enum value) that can be used by drivers or applications to request
memory with certain capabilities.

This framework is commonly used as follow:
1. At boot time some platform code initialize the shared multi-heap framework using `shared_multi_heap_pool_init()` and add the memory regions to the pool with `shared_multi_heap_add()`, possibly gathering the needed information for the regions from the DT.

2. Each memory region encoded in a `shared_multi_heap_region` structure. This structure is also carrying an opaque and user-defined integer value that is used to define the region capabilities (for example: cacheability, cpu affinity, etc...)

// Init the shared multi-heap pool
shared_multi_heap_pool_init()

// Fill the struct with the data for cacheable memory
struct shared_multi_heap_region cacheable_r0 = {
    .addr = addr_r0,
    .size = size_r0,
    .attr = SMH_REG_ATTR_CACHEABLE,
};

// Add the region to the pool
shared_multi_heap_add(&cacheable_r0, NULL);

// Add another cacheable region
struct shared_multi_heap_region cacheable_r1 = {
    .addr = addr_r1,
    .size = size_r1,
    .attr = SMH_REG_ATTR_CACHEABLE,
};

shared_multi_heap_add(&cacheable_r1, NULL);

// Add a non-cacheable region
struct shared_multi_heap_region non_cacheable_r2 = {
    .addr = addr_r2,
    .size = size_r2,
    .attr = SMH_REG_ATTR_NON_CACHEABLE,
};

shared_multi_heap_add(&non_cacheable_r2, NULL);

3. When a driver or application needs some dynamic memory with a certain capability, it can use `shared_multi_heap_alloc()` (or the aligned version) to request the memory by using the opaque parameter to select the correct set of attributes for the needed memory. The framework will take care of selecting the correct heap (thus memory region) to carve memory from, based on the opaque parameter and the runtime state of the heaps (available memory, heap state, etc...)

// Allocate 4K from cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_CACHEABLE, 0x1000);

// Allocate 4K from non-cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_NON_CACHEABLE, 0x1000);

### Adding new attributes

The API does not enforce any attributes, but at least it defines the two most common ones: `SMH_REG_ATTR_CACHEABLE` and `SMH_REG_ATTR_NON_CACHEABLE`
Shared Multi-Heap (SMH) interface.

The shared multi-heap manager uses the multi-heap allocator to manage a set of memory regions with different capabilities / attributes (cacheable, non-cacheable, etc…).

All the different regions can be added at run-time to the shared multi-heap pool providing an opaque “attribute” value (an integer or enum value) that can be used by drivers or applications to request memory with certain capabilities.

This framework is commonly used as follow:

- At boot time some platform code initialize the shared multi-heap framework using `shared_multi_heap_pool_init` and add the memory regions to the pool with `shared_multi_heap_add`, possibly gathering the needed information for the regions from the DT.
- Each memory region encoded in a `shared_multi_heap_region` structure. This structure is also carrying an opaque and user-defined integer value that is used to define the region capabilities (for example: cacheability, cpu affinity, etc…)
- When a driver or application needs some dynamic memory with a certain capability, it can use `shared_multi_heap_alloc` (or the aligned version) to request the memory by using the opaque parameter to select the correct set of attributes for the needed memory. The framework will take care of selecting the correct heap (thus memory region) to carve memory from, based on the opaque parameter and the runtime state of the heaps (available memory, heap state, etc…)

Defines

`MAX_SHARED_MULTI_HEAP_ATTR`
Maximum number of standard attributes.

 Enums

`enum shared_multi_heap_attr`
SMH region attributes enumeration type.
Enumeration type for some common memory region attributes.

`Values`:

`enumerator SMH_REG_ATTR_CACHEABLE`
cacheable

`enumerator SMH_REG_ATTR_NON_CACHEABLE`
on-cacheable

`enumerator SMH_REG_ATTR_NUM`
must be the last item

 Functions
int shared_multi_heap_pool_init(void)
    Init the pool.
    This must be the first function to be called to initialize the shared multi-heap pool. All the
    individual heaps must be added later with \texttt{shared_multi_heap_add}.

\textbf{Note:} As for the generic multi-heap allocator the expectation is that this function will be
called at soc- or board-level.

\textbf{Return values}
\begin{itemize}
  \item 0 – on success.
  \item -EALREADY – when the pool was already initied.
  \item other – errno codes
\end{itemize}

\texttt{void *} \texttt{shared_multi_heap_alloc(enum \texttt{shared_multi_heap_attr} attr, size\_t bytes)}
Allocate memory from the memory shared multi-heap pool.
Allocates a block of memory of the specified size in bytes and with a specified capability /
attribute. The opaque attribute parameter is used by the backend to select the correct heap to
allocate memory from.

\textbf{Parameters}
\begin{itemize}
  \item \texttt{attr} – capability / attribute requested for the memory block.
  \item \texttt{bytes} – requested size of the allocation in bytes.
\end{itemize}

\textbf{Return values}
\begin{itemize}
  \item \texttt{ptr} – a valid pointer to heap memory.
  \item \texttt{err} – NULL if no memory is available.
\end{itemize}

\texttt{void *} \texttt{shared_multi_heap_aligned_alloc(enum \texttt{shared_multi_heap_attr} attr, size\_t align, size\_t bytes)}
Allocate aligned memory from the memory shared multi-heap pool.
Allocates a block of memory of the specified size in bytes and with a specified capability /
attribute. Takes an additional parameter specifying a power of two alignment in bytes.

\textbf{Parameters}
\begin{itemize}
  \item \texttt{attr} – capability / attribute requested for the memory block.
  \item \texttt{align} – power of two alignment for the returned pointer, in bytes.
  \item \texttt{bytes} – requested size of the allocation in bytes.
\end{itemize}

\textbf{Return values}
\begin{itemize}
  \item \texttt{ptr} – a valid pointer to heap memory.
  \item \texttt{err} – NULL if no memory is available.
\end{itemize}

\texttt{void} \texttt{shared_multi_heap_free(void *} \texttt{block})
Free memory from the shared multi-heap pool.
Used to free the passed block of memory that must be the return value of a previously call to
\texttt{shared_multi_heap_alloc} or \texttt{shared_multi_heap_aligned_alloc}.

\textbf{Parameters}
\begin{itemize}
  \item \texttt{block} – block to free, must be a pointer to a block allocated by
  \texttt{shared_multi_heap_alloc} or \texttt{shared_multi_heap_aligned_alloc}.
\end{itemize}
int shared_multi_heap_add(struct shared_multi_heap_region *region, void *user_data)
    Add an heap region to the shared multi-heap pool.
    This adds a shared multi-heap region to the multi-heap pool.

Parameters
- user_data – pointer to any data for the heap.
- region – pointer to the memory region to be added.

Return values
- 0 – on success.
- -EINVAL – when the region attribute is out-of-bound.
- -ENOMEM – when there are no more heaps available.
- other – errno codes

struct shared_multi_heap_region
    #include <shared_multi_heap.h> SMH region struct.
    This struct is carrying information about the memory region to be added in the multi-heap pool.

Public Members

uint32_t attr
    Memory heap attribute.

uintptr_t addr
    Memory heap starting virtual address.

size_t size
    Memory heap size in bytes.

3.4.3 Memory Slabs

A memory slab is a kernel object that allows memory blocks to be dynamically allocated from a designated memory region. All memory blocks in a memory slab have a single fixed size, allowing them to be allocated and released efficiently and avoiding memory fragmentation concerns.
Any number of memory slabs can be defined (limited only by available RAM). Each memory slab is referenced by its memory address.

A memory slab has the following key properties:

- The **block size** of each block, measured in bytes. It must be at least \(4N\) bytes long, where \(N\) is greater than 0.
- The **number of blocks** available for allocation. It must be greater than zero.
- A **buffer** that provides the memory for the memory slab's blocks. It must be at least “block size” times “number of blocks” bytes long.

The memory slab's buffer must be aligned to an \(N\)-byte boundary, where \(N\) is a power of 2 larger than 2 (i.e. 4, 8, 16, ...). To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of \(N\).

A memory slab must be initialized before it can be used. This marks all of its blocks as unused.

A thread that needs to use a memory block simply allocates it from a memory slab. When the thread finishes with a memory block, it must release the block back to the memory slab so the block can be reused.

If all the blocks are currently in use, a thread can optionally wait for one to become available. Any number of threads may wait on an empty memory slab simultaneously; when a memory block becomes available, it is given to the highest-priority thread that has waited the longest.

Unlike a heap, more than one memory slab can be defined, if needed. This allows for a memory slab with smaller blocks and others with larger-sized blocks. Alternatively, a memory pool object may be used.

**Internal Operation** A memory slab's buffer is an array of fixed-size blocks, with no wasted space between the blocks.

The memory slab keeps track of unallocated blocks using a linked list; the first 4 bytes of each unused block provide the necessary linkage.

**Implementation**

**Defining a Memory Slab** A memory slab is defined using a variable of type `k_mem_slab`. It must then be initialized by calling `k_mem_slab_init()`.

The following code defines and initializes a memory slab that has 6 blocks that are 400 bytes long, each of which is aligned to a 4-byte boundary.

```c
struct k_mem_slab my_slab;
char __aligned(4) my_slab_buffer[6 * 400];
k_mem_slab_init(my_slab, my_slab_buffer, 400, 6);
```

Alternatively, a memory slab can be defined and initialized at compile time by calling `K_MEM_SLAB_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the memory slab and its buffer.

```c
K_MEM_SLAB_DEFINE(my_slab, 400, 6, 4);
```

Similarly, you can define a memory slab in private scope:

```c
K_MEM_SLAB_DEFINE_STATIC(my_slab, 400, 6, 4);
```
Allocating a Memory Block  A memory block is allocated by calling \texttt{k\_mem\_slab\_alloc()}. The following code builds on the example above, and waits up to 100 milliseconds for a memory block to become available, then fills it with zeroes. A warning is printed if a suitable block is not obtained.

```c
char *block_ptr;
if (k_mem_slab_alloc(&my_slab, &block_ptr, 100) == 0)) {
    memset(block_ptr, 0, 400);
    ...
} else {
    printf("Memory allocation time-out");
}
```

Releasing a Memory Block  A memory block is released by calling \texttt{k\_mem\_slab\_free()}. The following code builds on the example above, and allocates a memory block, then releases it once it is no longer needed.

```c
char *block_ptr;

k_mem_slab_alloc(&my_slab, &block_ptr, K_FOREVER);
... /* use memory block pointed at by block_ptr */

k_mem_slab_free(&my_slab, block_ptr);
```

Suggested Uses

Use a memory slab to allocate and free memory in fixed-size blocks.

Use memory slab blocks when sending large amounts of data from one thread to another, to avoid unnecessary copying of the data.

Configuration Options

Related configuration options:

- \texttt{CONFIG\_MEM\_SLAB\_TRACE\_MAX\_UTILIZATION}

API Reference

\texttt{group mem\_slab\_apis}

Defines

\texttt{K\_MEM\_SLAB\_DEFINE(name, slab\_block\_size, slab\_num\_blocks, slab\_align)}

Statically define and initialize a memory slab in a public (non-static) scope.

The memory slab’s buffer contains \texttt{slab\_num\_blocks} memory blocks that are \texttt{slab\_block\_size} bytes long. The buffer is aligned to a \texttt{slab\_align} -byte boundary. To ensure that each memory block is similarly aligned to this boundary, \texttt{slab\_block\_size} must also be a multiple of \texttt{slab\_align}.

The memory slab can be accessed outside the module where it is defined using:

```c
extern struct k\_mem\_slab <name>;
```
Note: This macro cannot be used together with a static keyword. If such a use-case is desired, use \texttt{K_MEM_SLAB_DEFINE_STATIC} instead.

**Parameters**

- \texttt{name} – Name of the memory slab.
- \texttt{slab\_block\_size} – Size of each memory block (in bytes).
- \texttt{slab\_num\_blocks} – Number memory blocks.
- \texttt{slab\_align} – Alignment of the memory slab's buffer (power of 2).

\texttt{K_MEM_SLAB_DEFINE_STATIC(name, slab\_block\_size, slab\_num\_blocks, slab\_align)}

Statically define and initialize a memory slab in a private (static) scope.

The memory slab's buffer contains \texttt{slab\_num\_blocks} memory blocks that are \texttt{slab\_block\_size} bytes long. The buffer is aligned to a \texttt{slab\_align}-byte boundary. To ensure that each memory block is similarly aligned to this boundary, \texttt{slab\_block\_size} must also be a multiple of \texttt{slab\_align}.

**Parameters**

- \texttt{name} – Name of the memory slab.
- \texttt{slab\_block\_size} – Size of each memory block (in bytes).
- \texttt{slab\_num\_blocks} – Number memory blocks.
- \texttt{slab\_align} – Alignment of the memory slab's buffer (power of 2).

**Functions**

\begin{verbatim}
int k_mem_slab_init(struct k_mem_slab *slab, void *buffer, size_t block_size, uint32_t num_blocks)

Initialize a memory slab.

Initializes a memory slab, prior to its first use.

The memory slab's buffer contains \texttt{slab\_num\_blocks} memory blocks that are \texttt{slab\_block\_size} bytes long. The buffer must be aligned to an N-byte boundary matching a word boundary, where N is a power of 2 (i.e. 4 on 32-bit systems, 8, 16, ...). To ensure that each memory block is similarly aligned to this boundary, \texttt{slab\_block\_size} must also be a multiple of N.

**Parameters**

- \texttt{slab} – Address of the memory slab.
- \texttt{buffer} – Pointer to buffer used for the memory blocks.
- \texttt{block\_size} – Size of each memory block (in bytes).
- \texttt{num\_blocks} – Number of memory blocks.

**Return values**

- 0 – on success
- -EINVAL – invalid data supplied
\end{verbatim}

\begin{verbatim}
int k_mem_slab_alloc(struct k_mem_slab *slab, void **mem, k_timeout_t timeout)

Allocate memory from a memory slab.

This routine allocates a memory block from a memory slab.
\end{verbatim}
Function properties (list may not be complete)

**isr-ok**

---

**Note:** *timeout* must be set to K_NO_WAIT if called from ISR.

---

**Note:** When CONFIG_MULTITHREADING=n any *timeout* is treated as K_NO_WAIT.

### Parameters

- `slab` – Address of the memory slab.
- `mem` – Pointer to block address area.
- `timeout` – Non-negative waiting period to wait for operation to complete. Use K_NO_WAIT to return without waiting, or K_FOREVER to wait as long as necessary.

### Return values

- **0** – Memory allocated. The block address area pointed at by `mem` is set to the starting address of the memory block.
- `-ENOMEM` – Returned without waiting.
- `-EAGAIN` – Waiting period timed out.
- `-EINVAL` – Invalid data supplied

```c
void k_mem_slab_free(struct k_mem_slab *slab, void *mem)
```

Free memory allocated from a memory slab.

This routine releases a previously allocated memory block back to its associated memory slab.

### Parameters

- `slab` – Address of the memory slab.
- `mem` – Pointer to the memory block (as returned by `k_mem_slab_alloc()`).

```c
static inline uint32_t k_mem_slab_num_used_get(struct k_mem_slab *slab)
```

Get the number of used blocks in a memory slab.

This routine gets the number of memory blocks that are currently allocated in `slab`.

### Parameters

- `slab` – Address of the memory slab.

### Returns

Number of allocated memory blocks.

```c
static inline uint32_t k_mem_slab_max_used_get(struct k_mem_slab *slab)
```

Get the number of maximum used blocks so far in a memory slab.

This routine gets the maximum number of memory blocks that were allocated in `slab`.

### Parameters

- `slab` – Address of the memory slab.

### Returns

Maximum number of allocated memory blocks.
static inline uint32_t k_mem_slab_num_free_get(struct k_mem_slab *slab)

Get the number of unused blocks in a memory slab.

This routine gets the number of memory blocks that are currently unallocated in `slab`.

**Parameters**

- `slab` – Address of the memory slab.

**Returns**

Number of unallocated memory blocks.

```c
int k_mem_slab_runtime_stats_get(struct k_mem_slab *slab, struct sys_memory_stats *stats)
```

Get the memory stats for a memory slab.

This routine gets the runtime memory usage stats for the slab `slab`.

**Parameters**

- `slab` – Address of the memory slab
- `stats` – Pointer to memory into which to copy memory usage statistics

**Return values**

- 0 – Success
- -EINVAL – Any parameter points to NULL

```c
int k_mem_slab_runtime_stats_reset_max(struct k_mem_slab *slab)
```

Reset the maximum memory usage for a slab.

This routine resets the maximum memory usage for the slab `slab` to its current usage.

**Parameters**

- `slab` – Address of the memory slab

**Return values**

- 0 – Success
- -EINVAL – Memory slab is NULL

### 3.4.4 Memory Blocks Allocator

The Memory Blocks Allocator allows memory blocks to be dynamically allocated from a designated memory region, where:

- All memory blocks have a single fixed size.
- Multiple blocks can be allocated or freed at the same time.
- A group of blocks allocated together may not be contiguous. This is useful for operations such as scatter-gather DMA transfers.
- Bookkeeping of allocated blocks is done outside of the associated buffer (unlike memory slab). This allows the buffer to reside in memory regions where these can be powered down to conserve energy.

- **Concepts**
  - Internal Operation
- **Memory Blocks Allocator**
- **Multi Memory Blocks Allocator Group**
Concepts

Any number of Memory Blocks Allocator can be defined (limited only by available RAM). Each allocator is referenced by its memory address.

A memory blocks allocator has the following key properties:

- The block size of each block, measured in bytes. It must be at least 4N bytes long, where N is greater than 0.
- The number of blocks available for allocation. It must be greater than zero.
- A buffer that provides the memory for the memory slab's blocks. It must be at least “block size” times “number of blocks” bytes long.
- A blocks bitmap to keep track of which block has been allocated.

The buffer must be aligned to an N-byte boundary, where N is a power of 2 larger than 2 (i.e. 4, 8, 16, ...). To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of N.

Due to the use of internal bookkeeping structures and their creation, each memory blocks allocator must be declared and defined at compile time.

Internal Operation  Each buffer associated with an allocator is an array of fixed-size blocks, with no wasted space between the blocks.

The memory blocks allocator keeps track of unallocated blocks using a bitmap.

Memory Blocks Allocator  

Internally, the memory blocks allocator uses a bitmap to keep track of which blocks have been allocated. Each allocator, utilizing the sys_bitarray interface, gets memory blocks one by one from the backing buffer up to the requested number of blocks. All the metadata about an allocator is stored outside of the backing buffer. This allows the memory region of the backing buffer to be powered down to conserve energy, as the allocator code never touches the content of the buffer.

Multi Memory Blocks Allocator Group  

The Multi Memory Blocks Allocator Group utility functions provide a convenient to manage a group of allocators. A custom allocator choosing function is used to choose which allocator to use among this group.

An allocator group should be initialized at runtime via sys_multi_mem_blocks_init(). Each allocator can then be added via sys_multi_mem_blocks_add_allocator().

To allocate memory blocks from group, sys_multi_mem_blocks_alloc() is called with an opaque “configuration” parameter. This parameter is passed directly to the allocator choosing function so that an
appropriate allocator can be chosen. After an allocator is chosen, memory blocks are allocated via `sys_mem_blocks_alloc()`. Allocated memory blocks can be freed via `sys_multi_mem_blocks_free()`. The caller does not need to pass a configuration parameter. The allocator code matches the passed in memory addresses to find the correct allocator and then memory blocks are freed via `sys_mem_blocks_free()`.

Usage

Defining a Memory Blocks Allocator A memory blocks allocator is defined using a variable of type `sys_mem_blocks_t`. It needs to be defined and initialized at compile time by calling `SYS_MEM_BLOCKS_DEFINE`.

The following code defines and initializes a memory blocks allocator which has 4 blocks that are 64 bytes long, each of which is aligned to a 4-byte boundary:

```
SYS_MEM_BLOCKS_DEFINE(allocator, 64, 4, 4);
```

Similarly, you can define a memory slab in private scope:

```
SYS_MEM_BLOCKS_DEFINE_STATIC(static_allocator, 64, 4, 4);
```

A pre-defined buffer can also be provided to the allocator where the buffer can be placed separately. Note that the alignment of the buffer needs to be done at its definition.

```
uint8_t __aligned(4) backing_buffer[64 * 4];
SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(allocator, 64, 4, backing_buffer);
```

Allocating Memory Blocks Memory blocks can be allocated by calling `sys_mem_blocks_alloc()`.

```
int ret;
uintptr_t blocks[2];
ret = sys_mem_blocks_alloc(allocator, 2, blocks);
```

If `ret == 0`, the array `blocks` will contain an array of memory addresses pointing to the allocated blocks.

Releasing a Memory Block Memory blocks are released by calling `sys_mem_blocks_free()`.

The following code builds on the example above which allocates 2 memory blocks, then releases them once they are no longer needed.

```
int ret;
uintptr_t blocks[2];
ret = sys_mem_blocks_alloc(allocator, 2, blocks);
... /* perform some operations on the allocated memory blocks */
ret = sys_mem_blocks_free(allocator, 2, blocks);
```

Using Multi Memory Blocks Allocator Group The following code demonstrates how to initialize an allocator group:

```
sys_mem_blocks_t *choice_fn(struct sys_multi_mem_blocks *group, void *cfg)
{
    ...
}
```

(continues on next page)
SYS_MEM_BLOCKS_DEFINE(allocator0, 64, 4, 4);
SYS_MEM_BLOCKS_DEFINE(allocator1, 64, 4, 4);

static sys_multi_mem_blocks_t alloc_group;

sys_multi_mem_blocks_init(&alloc_group, choice_fn);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator0);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator1);

To allocate and free memory blocks from the group:

```c
int ret;
uintptr_t blocks[1];
size_t blk_size;

ret = sys_multi_mem_blocks_alloc(&alloc_group, UINT_TO_POINTER(0),
                                 1, blocks, &blk_size);

ret = sys_multi_mem_blocks_free(&alloc_group, 1, blocks);
```

### API Reference

**group mem_blocks_apis**

**Defines**

SYS_MEM_BLOCKS_DEFINE(name, blk_sz, num_blks, buf_align)
Create a memory block object with a new backing buffer.

**Parameters**

- `name` – Name of the memory block object.
- `blk_sz` – Size of each memory block (in bytes).
- `num_blks` – Total number of memory blocks.
- `buf_align` – Alignment of the memory block buffer (power of 2).

SYS_MEM_BLOCKS_DEFINE_STATIC(name, blk_sz, num_blks, buf_align)
Create a static memory block object with a new backing buffer.

**Parameters**

- `name` – Name of the memory block object.
- `blk_sz` – Size of each memory block (in bytes).
- `num_blks` – Total number of memory blocks.
- `buf_align` – Alignment of the memory block buffer (power of 2).

SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(name, blk_sz, num_blks, buf)
Create a memory block object with a providing backing buffer.

**Parameters**

- `name` – Name of the memory block object.
- `blk_sz` – Size of each memory block (in bytes).
SYS_MEM_BLOCKS_DEFINE_STATIC_WITH_EXT_BUF(name, blk_sz, num_blks, buf)

Create a static memory block object with a providing backing buffer.

**Parameters**

- **name** – Name of the memory block object.
- **blk_sz** – Size of each memory block (in bytes).
- **num_blks** – Total number of memory blocks.
- **buf** – Backing buffer of type uint8_t.

**Typedefs**

typedef struct sys_mem_blocks sys_mem_blocks_t

Memory Blocks Allocator.

typedef struct sys_multi_mem_blocks sys_multi_mem_blocks_t

Multi Memory Blocks Allocator.

typedef sys_mem_blocks_t *(sys_multi_mem_blocks_choice_fn_t)(struct sys_multi_mem_blocks *group, void *cfg)

Multi memory blocks allocator choice function.

This is a user-provided functions whose responsibility is selecting a specific memory blocks allocator based on the opaque cfg value, which is specified by the user as an argument to sys_multi_mem_blocks_alloc(). The callback returns a pointer to the chosen allocator where the allocation is performed.

NULL may be returned, which will cause the allocation to fail and a -EINVAL reported to the calling code.

**Param group**

Multi memory blocks allocator structure.

**Param cfg**

An opaque user-provided value. It may be interpreted in any way by the application.

**Return**

A pointer to the chosen allocator, or NULL if none is chosen.

**Functions**

int sys_mem_blocks_alloc(sys_mem_blocks_t *mem_block, size_t count, void **out_blocks)

Allocate multiple memory blocks.

Allocate multiple memory blocks, and place their pointers into the output array.

**Parameters**

- **mem_block** – [in] Pointer to memory block object.
- **count** – [in] Number of blocks to allocate.
- **out_blocks** – [out] Output array to be populated by pointers to the memory blocks. It must have at least count elements.
Return values

• 0 – Successful
• -EINVAL – Invalid argument supplied.
• -ENOMEM – Not enough blocks for allocation.

int sys_mem_blocks_alloc_contiguous(sys_mem_blocks_t *mem_block, size_t count, void **out_block)

Allocate a contiguous set of memory blocks.
Allocate multiple memory blocks, and place their pointers into the output array.

Parameters

• mem_block – [in] Pointer to memory block object.
• count – [in] Number of blocks to allocate.
• out_block – [out] Output pointer to the start of the allocated block set

Return values

• 0 – Successful
• -EINVAL – Invalid argument supplied.
• -ENOMEM – Not enough contiguous blocks for allocation.

int sys_mem_blocks_get(sys_mem_blocks_t *mem_block, void *in_block, size_t count)

Force allocation of a specified blocks in a memory block object.
Allocate a specified blocks in a memory block object. Note: use caution when mixing
sys_mem_blocks_get and sys_mem_blocks_alloc, allocation may take any of the free mem-

Parameters

• mem_block – [in] Pointer to memory block object.
• in_block – [in] Address of the first required block to allocate
• count – [in] Number of blocks to allocate.

Return values

• 0 – Successful
• -EINVAL – Invalid argument supplied.
• -ENOMEM – Some of blocks are taken and cannot be allocated

int sys_mem_blocks_is_region_free(sys_mem_blocks_t *mem_block, void *in_block, size_t count)

check if the region is free

Parameters

• mem_block – [in] Pointer to memory block object.
• in_block – [in] Address of the first block to check
• count – [in] Number of blocks to check.

Return values

• 1 – All memory blocks are free
• 0 – At least one of the memory blocks is taken
int sys_mem_blocks_free(sys_mem_blocks_t *mem_block, size_t count, void **in_blocks)

Free multiple memory blocks.

Free multiple memory blocks according to the array of memory block pointers.

Parameters

• mem_block – [in] Pointer to memory block object.
• count – [in] Number of blocks to free.
• in_blocks – [in] Input array of pointers to the memory blocks.

Return values

• 0 – Successful
• -EINVAL – Invalid argument supplied.
• -EFAULT – Invalid pointers supplied.

int sys_mem_blocks_free_contiguous(sys_mem_blocks_t *mem_block, void *block, size_t count)

Free contiguous multiple memory blocks.

Free contiguous multiple memory blocks

Parameters

• mem_block – [in] Pointer to memory block object.
• block – [in] Pointer to the first memory block
• count – [in] Number of blocks to free.

Return values

• 0 – Successful
• -EINVAL – Invalid argument supplied.
• -EFAULT – Invalid pointer supplied.

void sys_multi_mem_blocks_init(sys_multi_mem_blocks_t *group, sys_multi_mem_blocks_choice_fn_t choice_fn)

Initialize multi memory blocks allocator group.

Initialize a sys_multi_mem_block struct with the specified choice function. Note that individual allocator must be added later with sys_multi_mem_blocks_add_allocator.

Parameters

• group – Multi memory blocks allocator structure.
• choice_fn – A sys_multi_mem_blocks_choice_fn_t callback used to select the allocator to be used at allocation time

void sys_multi_mem_blocks_add_allocator(sys_multi_mem_blocks_t *group, sys_mem_blocks_t *alloc)

Add an allocator to an allocator group.

This adds a known allocator to an existing multi memory blocks allocator group.

Parameters

• group – Multi memory blocks allocator structure.
• alloc – Allocator to add
int sys_multi_mem_blocks_alloc(sys_multi_mem_blocks_t *group, void *cfg, size_t count, void **out_blocks, size_t *blk_size)

Allocate memory from multi memory blocks allocator group.

Just as for sys_mem_blocks_alloc(), allocates multiple blocks of memory. Takes an opaque configuration pointer passed to the choice function, which is used by integration code to choose an allocator.

Parameters

- **group** - [in] Multi memory blocks allocator structure.
- **cfg** - [in] Opaque configuration parameter, as for sys_multi_mem_blocks_choice_fn_t
- **count** - [in] Number of blocks to allocate
- **out_blocks** - [out] Output array to be populated by pointers to the memory blocks. It must have at least count elements.
- **blk_size** - [out] If not NULL, output the block size of the chosen allocator.

Return values

- 0 – Successful
- -EINVAL – Invalid argument supplied, or no allocator chosen.
- -ENOMEM – Not enough blocks for allocation.

int sys_multi_mem_blocks_free(sys_multi_mem_blocks_t *group, size_t count, void **in_blocks)

Free memory allocated from multi memory blocks allocator group.

Free previous allocated memory blocks from sys_multi_mem_blocks_alloc().

Note that all blocks in in_blocks must be from the same allocator.

Parameters

- **group** - [in] Multi memory blocks allocator structure.
- **count** - [in] Number of blocks to free.
- **in_blocks** - [in] Input array of pointers to the memory blocks.

Return values

- 0 – Successful
- -EINVAL – Invalid argument supplied, or no allocator chosen.
- -EFAULT – Invalid pointer(s) supplied.

### 3.4.5 Demand Paging

Demand paging provides a mechanism where data is only brought into physical memory as required by current execution context. The physical memory is conceptually divided in page-sized page frames as regions to hold data.

- When the processor tries to access data and the data page exists in one of the page frames, the execution continues without any interruptions.
- When the processor tries to access the data page that does not exist in any page frames, a page fault occurs. The paging code then brings in the corresponding data page from backing store into physical memory if there is a free page frame. If there is no more free page frames, the eviction algorithm is invoked to select a data page to be paged out, thus freeing up a page frame for new data to be paged in. If this data page has been modified after it is first paged in, the data will be
written back into the backing store. If no modifications is done or after written back into backing store, the data page is now considered paged out and the corresponding page frame is now free. The paging code then invokes the backing store to page in the data page corresponding to the location of the requested data. The backing store copies that data page into the free page frame. Now the data page is in physical memory and execution can continue.

There are functions where paging in and out can be invoked manually using `k_mem_page_in()` and `k_mem_page_out()`. `k_mem_page_in()` can be used to page in data pages in anticipation that they are required in the near future. This is used to minimize number of page faults as these data pages are already in physical memory, and thus minimizing latency. `k_mem_page_out()` can be used to page out data pages where they are not going to be accessed for a considerable amount of time. This frees up page frames so that the next page in can be executed faster as the paging code does not need to invoke the eviction algorithm.

**Terminology**

**Data Page**
A data page is a page-sized region of data. It may exist in a page frame, or be paged out to some backing store. Its location can always be looked up in the CPU's page tables (or equivalent) by virtual address. The data type will always be `void *` or in some cases `uint8_t *` when doing pointer arithmetic.

**Page Frame**
A page frame is a page-sized physical memory region in RAM. It is a container where a data page may be placed. It is always referred to by physical address. Zephyr has a convention of using `uintptr_t` for physical addresses. For every page frame, a `struct z_page_frame` is instantiated to store metadata. Flags for each page frame:

- **Z_PAGE_FRAME_PINNED** indicates a page frame is pinned in memory and should never be paged out.
- **Z_PAGE_FRAME_RESERVED** indicates a physical page reserved by hardware and should not be used at all.
- **Z_PAGE_FRAME_MAPPED** is set when a physical page is mapped to virtual memory address.
- **Z_PAGE_FRAME_BUSY** indicates a page frame is currently involved in a page-in/out operation.
- **Z_PAGE_FRAME_BACKED** indicates a page frame has a clean copy in the backing store.

**Z_SCRATCH_PAGE**
The virtual address of a special page provided to the backing store to: * Copy a data page from Z_SCRATCH_PAGE to the specified location; or, * Copy a data page from the provided location to Z_SCRATCH_PAGE. This is used as an intermediate page for page in/out operations. This scratch needs to be mapped read/write for backing store code to access. However the data page itself may only be mapped as read-only in virtual address space. If this page is provided as-is to backing store, the data page must be re-mapped as read/write which has security implications as the data page is no longer read-only to other parts of the application.

**Paging Statistics**
Paging statistics can be obtained via various function calls when `CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS` is enabled:

- Overall statistics via `k_mem_paging_stats_get()`
- Per-thread statistics via `k_mem_paging_thread_stats_get()` if `CONFIG_DEMAND_PAGING_THREAD_STATS` is enabled
- Execution time histogram can be obtained when `CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM` is enabled, and `CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS` is defined. Note that the timing is highly dependent on the architecture, SoC or board.
is highly recommended that \texttt{k_mem_paging_eviction_histogram_bounds[]} and
\texttt{k_mem_paging_backing_store_histogram_bounds[]} be defined for a particular application.

- Execution time histogram of eviction algorithm via \texttt{k_mem_paging_histogram_eviction_get()}
- Execution time histogram of backing store doing page-in via \texttt{k_mem_paging_histogram_backing_store_page_in_get()}
- Execution time histogram of backing store doing page-out via \texttt{k_mem_paging_histogram_backing_store_page_out_get()}

Eviction Algorithm

The eviction algorithm is used to determine which data page and its corresponding page frame can be
paged out to free up a page frame for the next page in operation. There are two functions which are
called from the kernel paging code:

- \texttt{k_mem_paging_eviction_init()} is called to initialize the eviction algorithm. This is called at
  \texttt{POST_KERNEL}.
- \texttt{k_mem_paging_eviction_select()} is called to select a data page to evict. A function argument
  \texttt{dirty} is written to signal the caller whether the selected data page has been modified since it is
  first paged in. If the \texttt{dirty} bit is returned as set, the paging code signals to the backing store to
  write the data page back into storage (thus updating its content). The function returns a pointer
  to the page frame corresponding to the selected data page.

Currently, a NRU (Not-Recently-Used) eviction algorithm has been implemented as a sample. This is a
very simple algorithm which ranks each data page on whether they have been accessed and modified.
The selection is based on this ranking.

To implement a new eviction algorithm, the two functions mentioned above must be implemented.

Backing Store

Backing store is responsible for paging in/out data page between their corresponding page frames and
storage. These are the functions which must be implemented:

- \texttt{k_mem_paging_backing_store_init()} is called to initialized the backing store at \texttt{POST_KERNEL}.
- \texttt{k_mem_paging_backing_store_location_get()} is called to reserve a backing store location so a data page can be paged out. This location token is passed to \texttt{k_mem_paging_backing_store_page_out()} to perform actual page out operation.
- \texttt{k_mem_paging_backing_store_location_free()} is called to free a backing store location (the location token) which can then be used for subsequent page out operation.
- \texttt{k_mem_paging_backing_store_page_in()} copies a data page from the backing store location associated with the provided location token to the page pointed by \texttt{Z_SCRATCH_PAGE}.
- \texttt{k_mem_paging_backing_store_page_out()} copies a data page from \texttt{Z_SCRATCH_PAGE} to the backing store location associated with the provided location token.
- \texttt{k_mem_paging_backing_store_page_finalize()} is invoked after \texttt{k_mem_paging_backing_store_page_in()} so that the page frame struct may be updated for internal accounting. This can be a no-op.

To implement a new backing store, the functions mentioned above must be implemented. \texttt{k_mem_paging_backing_store_page_finalize()} can be an empty function if so desired.

API Reference

\texttt{group mem-demand-paging}
Functions

int k_mem_page_out(void *addr, size_t size)
   Evict a page-aligned virtual memory region to the backing store.
   Useful if it is known that a memory region will not be used for some time. All the data pages
   within the specified region will be evicted to the backing store if they weren’t already, with
   their associated page frames marked as available for mappings or page-ins.
   None of the associated page frames mapped to the provided region should be pinned.
   Note that there are no guarantees how long these pages will be evicted, they could take page
   faults immediately.
   If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by
   ISRs as the backing store may be in-use.

   Parameters
   • addr – Base page-aligned virtual address
   • size – Page-aligned data region size

   Return values
   • 0 – Success
   • -ENOMEM – Insufficient space in backing store to satisfy request. The region may
     be partially paged out.

void k_mem_page_in(void *addr, size_t size)
   Load a virtual data region into memory.
   After the function completes, all the page frames associated with this function will be paged
   in. However, they are not guaranteed to stay there. This is useful if the region is known to be
   used soon.
   If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by
   ISRs as the backing store may be in-use.

   Parameters
   • addr – Base page-aligned virtual address
   • size – Page-aligned data region size

void k_mem_pin(void *addr, size_t size)
   Pin an aligned virtual data region, paging in as necessary.
   After the function completes, all the page frames associated with this region will be resi-
   dent in memory and pinned such that they stay that way. This is a stronger version of
   z_mem_page_in().
   If CONFIG_DEMAND_PAGING_ALLOW_IRQ is enabled, this function may not be called by
   ISRs as the backing store may be in-use.

   Parameters
   • addr – Base page-aligned virtual address
   • size – Page-aligned data region size

void k_mem_unpin(void *addr, size_t size)
   Un-pin an aligned virtual data region.
   After the function completes, all the page frames associated with this region will be no longer
   marked as pinned. This does not evict the region, follow this with z_mem_page_out() if you
   need that.

   Parameters
• **addr** – Base page-aligned virtual address
• **size** – Page-aligned data region size

```c
void k_mem_paging_stats_get(struct k_mem_paging_stats_t *stats)
```

Get the paging statistics since system startup.

This populates the paging statistics struct being passed in as argument.

**Parameters**

• **stats** – [inout] Paging statistics struct to be filled.

```c
void k_mem_paging_thread_stats_get(struct k_thread *thread, struct k_mem_paging_stats_t *stats)
```

Get the paging statistics since system startup for a thread.

This populates the paging statistics struct being passed in as argument for a particular thread.

**Parameters**

• **thread** – [in] Thread
• **stats** – [inout] Paging statistics struct to be filled.

```c
void k_mem_paging_histogram_eviction_get(struct k_mem_paging_histogram_t *hist)
```

Get the eviction timing histogram.

This populates the timing histogram struct being passed in as argument.

**Parameters**

• **hist** – [inout] Timing histogram struct to be filled.

```c
void k_mem_paging_histogramBackingStorePageIn_get(struct k_mem_paging_histogram_t *hist)
```

Get the backing store page-in timing histogram.

This populates the timing histogram struct being passed in as argument.

**Parameters**

• **hist** – [inout] Timing histogram struct to be filled.

```c
void k_mem_paging_histogramBackingStorePageOut_get(struct k_mem_paging_histogram_t *hist)
```

Get the backing store page-out timing histogram.

This populates the timing histogram struct being passed in as argument.

**Parameters**

• **hist** – [inout] Timing histogram struct to be filled.

---

**Eviction Algorithm APIs**

*group mem-demand-paging-eviction*

Eviction algorithm APIs.

**Functions**
struct z_page_frame *k_mem_paging_eviction_select(bool *dirty)
    Select a page frame for eviction.

    The kernel will invoke this to choose a page frame to evict if there are no free page frames.
    This function will never be called before the initial k_mem_paging_eviction_init().
    This function is invoked with interrupts locked.

    **Parameters**
    - **dirty** – [out] Whether the page to evict is dirty

    **Returns**
    The page frame to evict

void k_mem_paging_eviction_init(void)
    Initialization function.

    Called at POST_KERNEL to perform any necessary initialization tasks for the eviction algo-
    rithm. k_mem_paging_eviction_select() is guaranteed to never be called until this has returned,
    and this will only be called once.

**Backing Store APIs**

*group* mem-demand-paging-backing-store

Backin store APIs.

**Functions**

int k_mem_paging_backing_store_location_get(struct z_page_frame *pf, uintptr_t *location,
    bool page_fault)

    Reserve or fetch a storage location for a data page loaded into a page frame.

    The returned location token must be unique to the mapped virtual address. This location will
    be used in the backing store to page out data page contents for later retrieval. The location
    value must be page-aligned.

    This function may be called multiple times on the same data page. If its page frame has its
    Z_PAGE_FRAME_BACKED bit set, it is expected to return the previous backing store location
    for the data page containing a cached clean copy. This clean copy may be updated on page-
    out, or used to discard clean pages without needing to write out their contents.

    If the backing store is full, some other backing store location which caches a loaded
    data page may be selected, in which case its associated page frame will have the
    Z_PAGE_FRAME_BACKED bit cleared (as it is no longer cached).

    pf->addr will indicate the virtual address the page is currently mapped to. Large, sparse
    backing stores which can contain the entire address space may simply generate location tokens
    purely as a function of pf->addr with no other management necessary.

    This function distinguishes whether it was called on behalf of a page fault. A free backing
    store location must always be reserved in order for page faults to succeed. If the page_fault
    parameter is not set, this function should return -ENOMEM even if one location is available.

    This function is invoked with interrupts locked.

    **Parameters**
    - **pf** – Virtual address to obtain a storage location
    - **location** – [out] storage location token
    - **page_fault** – Whether this request was for a page fault
Returns
0 Success

Returns
-ENOMEM Backing store is full

void k_mem_paging_backing_store_location_free(uintptr_t location)
Free a backing store location.

Any stored data may be discarded, and the location token associated with this address may
be re-used for some other data page.

This function is invoked with interrupts locked.

Parameters
• location – Location token to free

void k_mem_paging_backing_store_page_out(uintptr_t location)
Copy a data page from Z_SCRATCH_PAGE to the specified location.

Immediately before this is called, Z_SCRATCH_PAGE will be mapped read-write to the in-
tended source page frame for the calling context.

Calls to this and k_mem_paging_backing_store_page_in() will always be serialized, but inter-
rupts may be enabled.

Parameters
• location – Location token for the data page, for later retrieval

void k_mem_paging_backing_store_page_in(uintptr_t location)
Copy a data page from the provided location to Z_SCRATCH_PAGE.

Immediately before this is called, Z_SCRATCH_PAGE will be mapped read-write to the in-
tended destination page frame for the calling context.

Calls to this and k_mem_paging_backing_store_page_out() will always be serialized, but inter-
rupts may be enabled.

Parameters
• location – Location token for the data page

void k_mem_paging_backing_store_page_finalize(struct z_page_frame *pf, uintptr_t location)
Update internal accounting after a page-in.

This is invoked after k_mem_paging_backing_store_page_in() and interrupts have been* re-
locked, making it safe to access the z_page_frame data. The location value will be the same
passed to k_mem_paging_backing_store_page_in().

The primary use-case for this is to update custom fields for the backing store in the page
frame, to reflect where the data should be evicted to if it is paged out again. This may be a
no-op in some implementations.

If the backing store caches paged-in data pages, this is the appropriate time to set the
Z_PAGE_FRAME_BACKED bit. The kernel only skips paging out clean data pages if they
are noted as clean in the page tables and the Z_PAGE_FRAME_BACKED bit is set in their
associated page frame.

Parameters
• pf – Page frame that was loaded in
• location – Location of where the loaded data page was retrieved
void k_mem_paging_backing_store_init(void)
Backging store initialization function.
The implementation may expect to receive page in/out calls as soon as this returns, but not before that. Called at POST_KERNEL.

This function is expected to do two things:
• Initialize any internal data structures and accounting for the backing store.
• If the backing store already contains all or some loaded kernel data pages at boot time, Z_PAGE_FRAME_BACKED should be appropriately set for their associated page frames, and any internal accounting set up appropriately.

3.5  Data Structures

Zephyr provides a library of common general purpose data structures used within the kernel, but useful by application code in general. These include list and balanced tree structures for storing ordered data, and a ring buffer for managing “byte stream” data in a clean way.

Note that in general, the collections are implemented as “intrusive” data structures. The “node” data is the only struct used by the library code, and it does not store a pointer or other metadata to indicate what user data is “owned” by that node. Instead, the expectation is that the node will be itself embedded within a user-defined struct. Macros are provided to retrieve a user struct address from the embedded node pointer in a clean way. The purpose behind this design is to allow the collections to be used in contexts where dynamic allocation is disallowed (i.e. there is no need to allocate node objects because the memory is provided by the user).

Note also that these libraries are uniformly unsynchronized; access to them is not threadsafe by default. These are data structures, not synchronization primitives. The expectation is that any locking needed will be provided by the user.

3.5.1 Single-linked List

Zephyr provides a sys_slist_t type for storing simple singly-linked list data (i.e. data where each list element stores a pointer to the next element, but not the previous one). This supports constant-time access to the first (head) and last (tail) elements of the list, insertion before the head and after the tail of the list and constant time removal of the head. Removal of subsequent nodes requires access to the “previous” pointer and thus can only be performed in linear time by searching the list.

The sys_slist_t struct may be instantiated by the user in any accessible memory. It should be initialized with either sys_slist_init() or by static assignment from SYS_SLIST_STATIC_INIT before use. Its interior fields are opaque and should not be accessed by user code.

The end nodes of a list may be retrieved with sys_slist_peek_head() and sys_slist_peek_tail(), which will return NULL if the list is empty, otherwise a pointer to a sys_snode_t struct.

The sys_snodde_t struct represents the data to be inserted. In general, it is expected to be allocated/controlled by the user, usually embedded within a struct which is to be added to the list. The container struct pointer may be retrieved from a list node using SYS_SLIST_CONTAINER, passing it the struct name of the containing struct and the field name of the node. Internally, the sys_snodde_t struct contains only a next pointer, which may be accessed with sys_slist_peek_next().

Lists may be modified by adding a single node at the head or tail with sys_slist_prepend() and sys_slist_append(). They may also have a node added to an interior point with sys_slist_insert(), which inserts a new node after an existing one. Similarly sys_slist_remove() will remove a node given a pointer to its predecessor. These operations are all constant time.

Convenience routines exist for more complicated modifications to a list. sys_slist_merge_slist() will append an entire list to an existing one. sys_slist_append_list() will append a bounded subset of
an existing list in constant time. And `sys_slist_find_and_remove()` will search a list (in linear time) for a given node and remove it if present.

Finally the slist implementation provides a set of “for each” macros that allows for iterating over a list in a natural way without needing to manually traverse the next pointers. `SYS_SLIST_FOR_EACH_NODE` will enumerate every node in a list given a local variable to store the node pointer. `SYS_SLIST_FOR_EACH_NODE_SAFE` behaves similarly, but has a more complicated implementation that requires an extra scratch variable for storage and allows the user to delete the iterated node during the iteration. Each of those macros also exists in a “container” variant (`SYS_SLIST_FOR_EACH_CONTAINER` and `SYS_SLIST_FOR_EACH_CONTAINER_SAFE`) which assigns a local variable of a type that matches the user’s container struct and not the node struct, performing the required offsets internally. And `SYS_SLIST_ITERATE_FROM_NODE` exists to allow for enumerating a node and all its successors only, without inspecting the earlier part of the list.

### Single-linked List Internals

The slist code is designed to be minimal and conventional. Internally, a `sys_slist_t` struct is nothing more than a pair of “head” and “tail” pointer fields. And a `sys_snnode_t` stores only a single “next” pointer.

![Fig. 4: An slist containing three elements.](image)

![Fig. 5: An empty slist](image)

The specific implementation of the list code, however, is done with an internal “Z_GENLIST” template API which allows for extracting those fields from arbitrary structures and emits an arbitrarily named set of functions. This allows for implementing more complicated single-linked list variants using the same basic primitives. The genlist implementor is responsible for a custom implementation of the primitive operations only: an “init” step for each struct, and a “get” and “set” primitives for each of head, tail and next pointers on their relevant structs. These inline functions are passed as parameters to the genlist macro expansion.

Only one such variant, sflist, exists in Zephyr at the moment.

### Flagged List

The `sys_sflist_t` is implemented using the described genlist template API. With the exception of symbol naming ("sflist" instead of "slist") and the additional API described next, it operates in all ways identically to the slist API.
It adds the ability to associate exactly two bits of user defined “flags” with each list node. These can be accessed and modified with `sys_sfnode_flags_get()` and `sys_sfnode_flags_get()`. Internally, the flags are stored unioned with the bottom bits of the next pointer and incur no SRAM storage overhead when compared with the simpler slist code.

**Single-linked List API Reference**

*group single-linked-list apis*

Single-linked list implementation.

Single-linked list implementation using inline macros/functions. This API is not thread safe, and thus if a list is used across threads, calls to functions must be protected with synchronization primitives.

**Defines**

```c
SYS_SLIST_FOR_EACH_NODE(__sl, __sn)
```

Provide the primitive to iterate on a list Note: the loop is unsafe and thus __sn should not be removed.

User **MUST** add the loop statement curly braces enclosing its own code:

```c
SYS_SLIST_FOR_EACH_NODE(l, n) {
  <user code>
}
```

This and other SYS_SLIST_*() macros are not thread safe.

**Parameters**

- __sl – A pointer on a sys_slist_t to iterate on
- __sn – A sys_snode_t pointer to peek each node of the list

```c
SYS_SLIST_ITERATE_FROM_NODE(__sl, __sn)
```

Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __sn should not be removed.

User **MUST** add the loop statement curly braces enclosing its own code:

```c
SYS_SLIST_ITERATE_FROM_NODE(l, n) {
  <user code>
}
```

Like SYS_SLIST_FOR_EACH_NODE(), but __sn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.

This and other SYS_SLIST_*() macros are not thread safe.

**Parameters**

- __sl – A pointer on a sys_slist_t to iterate on
- __sn – A sys_snode_t pointer to peek each node of the list it contains the starting node, or NULL to start from the head

```c
SYS_SLIST_FOR_EACH_NODE_SAFE(__sl, __sn, __sns)
```

Provide the primitive to safely iterate on a list Note: __sn can be removed, it will not break the loop.

User **MUST** add the loop statement curly braces enclosing its own code:
SYS_SLIST_FOR_EACH_NODE_SAFE(l, n, s) {
    <user code>
}

This and other SYS_SLIST_*() macros are not thread safe.

Parameters

- __sl – A pointer on a sys_slist_t to iterate on
- __sn – A sys_snodo_t pointer to peek each node of the list
- __sns – A sys_snodo_t pointer for the loop to run safely

SYS_SLIST_CONTAINER(__ln, __cn, __n)

Provide the primitive to resolve the container of a list node Note: it is safe to use with NULL pointer nodes.

Parameters

- __ln – A pointer on a sys_node_t to get its container
- __cn – Container struct type pointer
- __n – The field name of sys_node_t within the container struct

SYS_SLIST_PEEK_HEAD_CONTAINER(__sl, __cn, __n)

Provide the primitive to peek container of the list head.

Parameters

- __sl – A pointer on a sys_slist_t to peek
- __cn – Container struct type pointer
- __n – The field name of sys_node_t within the container struct

SYS_SLIST_PEEK_TAIL_CONTAINER(__sl, __cn, __n)

Provide the primitive to peek container of the list tail.

Parameters

- __sl – A pointer on a sys_slist_t to peek
- __cn – Container struct type pointer
- __n – The field name of sys_node_t within the container struct

SYS_SLIST_PEEK_NEXT_CONTAINER(__cn, __n)

Provide the primitive to peek the next container.

Parameters

- __cn – Container struct type pointer
- __n – The field name of sys_node_t within the container struct

SYS_SLIST_FOR_EACH_CONTAINER(__sl, __cn, __n)

Provide the primitive to iterate on a list under a container Note: the loop is unsafe and thus __cn should not be detached.

User MUST add the loop statement curly braces enclosing its own code:

SYS_SLIST_FOR_EACH_CONTAINER(l, c, n) {
    <user code>
}

Parameters
• __sl – A pointer on a sys_slist_t to iterate on
• __cn – A pointer to peek each entry of the list
• __cns – A pointer for the loop to run safely
• __n – The field name of sys_node_t within the container struct

SYS_SLIST_FOR_EACH_CONTAINER_SAFE(__sl, __cn, __cns, __n)

Provide the primitive to safely iterate on a list under a container. Note: __cn can be detached, it will not break the loop.

User MUST add the loop statement curly braces enclosing its own code:

```
SYS_SLIST_FOR_EACH_NODE_SAFE(l, c, cn, n) {
    <user code>
}
```

**Parameters**

• __sl – A pointer on a sys_slist_t to iterate on
• __cn – A pointer to peek each entry of the list
• __cns – A pointer for the loop to run safely
• __n – The field name of sys_node_t within the container struct

SYS_SLIST_STATIC_INIT(ptr_to_list)

Statically initialize a single-linked list.

**Parameters**

• ptr_to_list – A pointer on the list to initialize

**Typedefs**

typedef struct _snode sys_snode_t

Single-linked list node structure.

typedef struct _slist sys_slist_t

Single-linked list structure.

**Functions**

static inline void sys_slist_init(sys_slist_t *list)

Initialize a list.

**Parameters**

• list – A pointer on the list to initialize

static inline sys_snode_t *sys_slist_peek_head(sys_slist_t *list)

Peek the first node from the list.

**Parameters**

• list – A pointer on the list to peek the first node from

**Returns**

A pointer on the first node of the list (or NULL if none)
static inline sys_snode_t *sys_slist_peek_tail(sys_slist_t *list)
    Peek the last node from the list.

    Parameters
    • list – A point on the list to peek the last node from

    Returns
    A pointer on the last node of the list (or NULL if none)

static inline bool sys_slist_is_empty(sys_slist_t *list)
    Test if the given list is empty.

    Parameters
    • list – A pointer on the list to test

    Returns
    a boolean, true if it's empty, false otherwise

static inline sys_snode_t *sys_slist_peek_next_no_check(sys_node_t *node)
    Peek the next node from current node, node is not NULL.
    Faster then sys_slist_peek_next() if node is known not to be NULL.

    Parameters
    • node – A pointer on the node where to peek the next node

    Returns
    a pointer on the next node (or NULL if none)

static inline sys_snode_t *sys_slist_peek_next(sys_node_t *node)
    Peek the next node from current node.

    Parameters
    • node – A pointer on the node where to peek the next node

    Returns
    a pointer on the next node (or NULL if none)

static inline void sys_slist_prepend(sys_slist_t *list, sys_snode_t *node)
    Prepend a node to the given list.
    This and other sys_slist_*() functions are not thread safe.

    Parameters
    • list – A pointer on the list to affect
    • node – A pointer on the node to prepend

static inline void sys_slist_append(sys_slist_t *list, sys_snode_t *node)
    Append a node to the given list.
    This and other sys_slist_*() functions are not thread safe.

    Parameters
    • list – A pointer on the list to affect
    • node – A pointer on the node to append

static inline void sys_slist_append_list(sys_slist_t *list, void *head, void *tail)
    Append a list to the given list.
    Append a singly-linked, NULL-terminated list consisting of nodes containing the pointer to the
    next node as the first element of a node, to list. This and other sys_slist_*() functions are not
    thread safe.
FIXME: Why are the element parameters void *?

Parameters

• list – A pointer on the list to affect
• head – A pointer to the first element of the list to append
• tail – A pointer to the last element of the list to append

static inline void sys_slist_merge_slist(sys_slist_t *list, sys_slist_t *list_to_append)
merge two slists, appending the second one to the first

When the operation is completed, the appending list is empty. This and other sys_slist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• list_to_append – A pointer to the list to append.

static inline void sys_slist_insert(sys_slist_t *list, sys_snodo_t *prev, sys_snodo_t *node)
Insert a node to the given list.

This and other sys_slist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• prev – A pointer on the previous node
• node – A pointer on the node to insert

static inline sys_snodo_t *sys_slist_get_not_empty(sys_slist_t *list)
Fetch and remove the first node of the given list.

List must be known to be non-empty. This and other sys_slist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect

Returns

A pointer to the first node of the list

static inline sys_snodo_t *sys_slist_get(sys_slist_t *list)
Fetch and remove the first node of the given list.

This and other sys_slist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect

Returns

A pointer to the first node of the list (or NULL if empty)

static inline void sys_slist_remove(sys_slist_t *list, sys_snodo_t *prev_node, sys_snodo_t *node)
Remove a node.

This and other sys_slist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• prev_node – A pointer on the previous node (can be NULL, which means the node is the list’s head)
static inline bool sys_slist_find_and_remove(sys_slist_t *list, sys_snnode_t *node)

Find and remove a node from a list.

This and other sys_slist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• node – A pointer on the node to remove from the list

Returns

true if node was removed

static inline size_t sys_slist_len(sys_slist_t *list)

Compute the size of the given list in O(n) time.

Parameters

• list – A pointer on the list

Returns

an integer equal to the size of the list, or 0 if empty

Flagged List API Reference

Flagged single-linked list implementation.

Similar to Single-linked list with the added ability to define two bits of user “flags” for each node. They can be accessed and modified using the sys_sfnode_flags_get() and sys_sfnode_flags_set() APIs.

Flagged single-linked list implementation using inline macros/functions. This API is not thread safe, and thus if a list is used across threads, calls to functions must be protected with synchronization primitives.

Defines

SYS_SFLIST_FOR_EACH_NODE(__sl, __sn)

Provide the primitive to iterate on a list Note: the loop is unsafe and thus __sn should not be removed.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_SFLIST_FOR_EACH_NODE(l, n) {
    <user code>
}
```

This and other SYS_SFLIST_*() macros are not thread safe.

Parameters

• __sl – A pointer on a sys_sflist_t to iterate on
• __sn – A sys_sfnode_t pointer to peek each node of the list

SYS_SFLIST_ITERATE_FROM_NODE(__sl, __sn)

Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __sn should not be removed.

User MUST add the loop statement curly braces enclosing its own code:
SYS_SFLIST_ITERATE_FROM_NODE(l, n) {
   <user code>
}

Like SYS_SFLIST_FOR_EACH_NODE(), but __dn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.

This and other SYS_SFLIST_*() macros are not thread safe.

Parameters
- __sl – A pointer on a sys_sflist_t to iterate on
- __sn – A sys_sfnode_t pointer to peek each node of the list it contains the starting node, or NULL to start from the head

SYS_SFLIST_FOR_EACH_NODE_SAFE(__sl, __sn, __sns)
Provide the primitive to safely iterate on a list Note: __sn can be removed, it will not break the loop.
User MUST add the loop statement curly braces enclosing its own code:

SYS_SFLIST_FOR_EACH_NODE_SAFE(l, n, s) {
   <user code>
}

This and other SYS_SFLIST_*() macros are not thread safe.

Parameters
- __sl – A pointer on a sys_sflist_t to iterate on
- __sn – A sys_sfnode_t pointer to peek each node of the list
- __sns – A sys_sfnode_t pointer for the loop to run safely

SYS_SFLIST_CONTAINER(__ln, __cn, __n)
Provide the primitive to resolve the container of a list node Note: it is safe to use with NULL pointer nodes.

Parameters
- __ln – A pointer on a sys_sfnode_t to get its container
- __cn – Container struct type pointer
- __n – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_PEEK_HEAD_CONTAINER(__sl, __cn, __n)
Provide the primitive to peek container of the list head.

Parameters
- __sl – A pointer on a sys_sflist_t to peek
- __cn – Container struct type pointer
- __n – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_PEEK_TAIL_CONTAINER(__sl, __cn, __n)
Provide the primitive to peek container of the list tail.

Parameters
- __sl – A pointer on a sys_sflist_t to peek
- __cn – Container struct type pointer
- __n – The field name of sys_sfnode_t within the container struct
SYS_SFLIST_PEEK_NEXT_CONTAINER(__cn, __n)

Provide the primitive to peek the next container.

**Parameters**
- __cn – Container struct type pointer
- __n – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_FOR_EACH_CONTAINER(__sl, __cn, __n)

Provide the primitive to iterate on a list under a container Note: the loop is unsafe and thus __cn should not be detached.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_SFLIST_FOR_EACH_CONTAINER(l, c, n) {
    <user code>
}
```

**Parameters**
- __sl – A pointer on a sys_sflist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __n – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_FOR_EACH_CONTAINER_SAFE(__sl, __cn, __cns, __n)

Provide the primitive to safely iterate on a list under a container Note: __cn can be detached, it will not break the loop.

User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_SFLIST_FOR_EACH_NODE_SAFE(l, c, cn, n) {
    <user code>
}
```

**Parameters**
- __sl – A pointer on a sys_sflist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __cns – A pointer for the loop to run safely
- __n – The field name of sys_sfnode_t within the container struct

SYS_SFLIST_STATIC_INIT(ptr_to_list)

Statically initialize a flagged single-linked list.

**Parameters**
- ptr_to_list – A pointer on the list to initialize

SYS_SFLIST_FLAGS_MASK

**Typedefs**

typedef uint32_t unative_t
typedef struct _sfnode sys_sfnode_t
    Flagged single-linked list node structure.

typedef struct _sflist sys_sflist_t
    Flagged single-linked list structure.

Functions

static inline void sys_sflist_init(sys_sflist_t *list)
    Initialize a list.
    Parameters
    • list – A pointer on the list to initialize

static inline uint8_t sys_sfnode_flags_get(sys_sfnode_t *node)
    Fetch flags value for a particular sfnode.
    Parameters
    • node – A pointer to the node to fetch flags from
    Returns
    The value of flags, which will be between 0 and 3

static inline sys_sfnode_t *sys_sflist_peek_head(sys_sflist_t *list)
    Peek the first node from the list.
    Parameters
    • list – A point on the list to peek the first node from
    Returns
    A pointer on the first node of the list (or NULL if none)

static inline sys_sfnode_t *sys_sflist_peek_tail(sys_sflist_t *list)
    Peek the last node from the list.
    Parameters
    • list – A point on the list to peek the last node from
    Returns
    A pointer on the last node of the list (or NULL if none)

static inline void sys_sfnode_init(sys_sfnode_t *node, uint8_t flags)
    Initialize an sflist node.
    Set an initial flags value for this slist node, which can be a value between 0 and 3. These
    flags will persist even if the node is moved around within a list, removed, or transplanted to
    a different slist.
    This is ever so slightly faster than sys_sfnode_flags_set() and should only be used on a node
    that hasn’t been added to any list.
    Parameters
    • node – A pointer to the node to set the flags on
    • flags – A value between 0 and 3 to set the flags value
static inline void sys_sfnode_flags_set(sys_sfnode_t *node, uint8_t flags)
    Set flags value for an sflist node.

Set a flags value for this slist node, which can be a value between 0 and 3. These flags will persist even if the node is moved around within a list, removed, or transplanted to a different slist.

Parameters

• node – A pointer to the node to set the flags on
• flags – A value between 0 and 3 to set the flags value

static inline bool sys_sflist_is_empty(sys_sflist_t *list)
    Test if the given list is empty.

Parameters

• list – A pointer on the list to test

Returns

a boolean, true if it's empty, false otherwise

static inline sys_sfnode_t *sys_sflist_peek_next_no_check(sys_sfnode_t *node)
    Peek the next node from current node, node is not NULL.

Faster then sys_sflist_peek_next() if node is known not to be NULL.

Parameters

• node – A pointer on the node where to peek the next node

Returns

a pointer on the next node (or NULL if none)

static inline sys_sfnode_t *sys_sflist_peek_next(sys_sflist_t *node)
    Peek the next node from current node.

Parameters

• node – A pointer on the node where to peek the next node

Returns

a pointer on the next node (or NULL if none)

static inline void sys_sflist_prepend(sys_sflist_t *list, sys_sfnode_t *node)
    Prepend a node to the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• node – A pointer on the node to prepend

static inline void sys_sflist_append(sys_sflist_t *list, sys_sfnode_t *node)
    Append a node to the given list.

This and other sys_sflist_*() functions are not thread safe.

Parameters

• list – A pointer on the list to affect
• node – A pointer on the node to append
static inline void sys_sflist_append_list(sys_sflist_t *list, void *head, void *tail)
    Append a list to the given list.
    Append a singly-linked, NULL-terminated list consisting of nodes containing the pointer to the next node as the first element of a node, to list. This and other sys_sflist_*() functions are not thread safe.

    FIXME: Why are the element parameters void *?

    Parameters
    • list – A pointer on the list to affect
    • head – A pointer to the first element of the list to append
    • tail – A pointer to the last element of the list to append

static inline void sys_sflist_merge_sflist(sys_sflist_t *list, sys_sflist_t *list_to_append)
    merge two sflists, appending the second one to the first
    When the operation is completed, the appending list is empty. This and other sys_sflist_*() functions are not thread safe.

    Parameters
    • list – A pointer on the list to affect
    • list_to_append – A pointer to the list to append.

static inline void sys_sflist_insert(sys_sflist_t *list, sys_sfnode_t *prev, sys_sfnode_t *node)
    Insert a node to the given list.
    This and other sys_sflist_*() functions are not thread safe.

    Parameters
    • list – A pointer on the list to affect
    • prev – A pointer on the previous node
    • node – A pointer on the node to insert

static inline sys_sfnode_t *sys_sflist_get_not_empty(sys_sflist_t *list)
    Fetch and remove the first node of the given list.
    List must be known to be non-empty. This and other sys_sflist_*() functions are not thread safe.

    Parameters
    • list – A pointer on the list to affect

    Returns
    A pointer to the first node of the list

static inline sys_sfnode_t *sys_sflist_get(sys_sflist_t *list)
    Fetch and remove the first node of the given list.
    This and other sys_sflist_*() functions are not thread safe.

    Parameters
    • list – A pointer on the list to affect

    Returns
    A pointer to the first node of the list (or NULL if empty)
static inline void sys_sflist_remove(sys_sflist_t *list, sys_sfnode_t *prev_node, sys_sfnode_t *node)

Remove a node.
This and other sys_sflist_*() functions are not thread safe.

Parameters
- list – A pointer on the list to affect
- prev_node – A pointer on the previous node (can be NULL, which means the node is the list's head)
- node – A pointer on the node to remove

static inline bool sys_sflist_find_and_remove(sys_sflist_t *list, sys_sfnode_t *node)

Find and remove a node from a list.
This and other sys_sflist_*() functions are not thread safe.

Parameters
- list – A pointer on the list to affect
- node – A pointer on the node to remove from the list

Returns
true if node was removed

static inline size_t sys_sflist_len(sys_sflist_t *list)

Compute the size of the given list in O(n) time.

Parameters
- list – A pointer on the list

Returns
an integer equal to the size of the list, or 0 if empty

### 3.5.2 Double-linked List

Similar to the single-linked list in many respects, Zephyr includes a double-linked implementation. This provides the same algorithmic behavior for all the existing slist operations, but also allows for constant-time removal and insertion (at all points: before or after the head, tail or any internal node). To do this, the list stores two pointers per node, and thus has somewhat higher runtime code and memory space needs.

A `sys_dlist_t` struct may be instantiated by the user in any accessible memory. It must be initialized with `sys_dlist_init()` or `SYS_DLIST_STATIC_INIT` before use. The `sys_dnode_t` struct is expected to be provided by the user for any nodes added to the list (typically embedded within the struct to be tracked, as described above). It must be initialized in zeroed/bss memory or with `sys_dnode_init()` before use.

Primitive operations may retrieve the head/tail of a list and the next/prev pointers of a node with `sys_dlist_peek_head()`, `sys_dlist_peek_tail()`, `sys_dlist_peek_next()` and `sys_dlist_peek_prev()`. These can all return NULL where appropriate (i.e. for empty lists, or nodes at the endpoints of the list).

A dlist can be modified in constant time by removing a node with `sys_dlist_remove()`, by adding a node to the head or tail of a list with `sys_dlist_prepend()` and `sys_dlist_append()`, or by inserting a node before an existing node with `sys_dlist_insert()`.

As for slist, each node in a dlist can be processed in a natural code block style using `SYS_DLIST_FOR_EACH_NODE`. This macro also exists in a “FROM_NODE” form which allows for iterating from a known starting point, a “SAFE” variant that allows for removing the node being inspected...
within the code block, a “CONTAINER” style that provides the pointer to a containing struct instead of the raw node, and a “CONTAINER_SAFE” variant that provides both properties.

Convenience utilities provided by dlist include `sys_dlist_insert_at()`, which inserts a node that linearly searches through a list to find the right insertion point, which is provided by the user as a C callback function pointer, and `sys_dnode_is_linked()`, which will affirmatively return whether or not a node is currently linked into a dlist or not (via an implementation that has zero overhead vs. the normal list processing).

**Double-linked List Internals**

Internally, the dlist implementation is minimal: the `sys_dlist_t` struct contains “head” and “tail” pointer fields, the `sys_dnode_t` contains “prev” and “next” pointers, and no other data is stored. But in practice the two structs are internally identical, and the list struct is inserted as a node into the list itself. This allows for a very clean symmetry of operations:

- An empty list has backpointers to itself in the list struct, which can be trivially detected.
- The head and tail of the list can be detected by comparing the prev/next pointers of a node vs. the list struct address.
- An insertion or deletion never needs to check for the special case of inserting at the head or tail. There are never any NULL pointers within the list to be avoided. Exactly the same operations are run, without tests or branches, for all list modification primitives.

Effectively, a dlist of N nodes can be thought of as a “ring” of “N+1” nodes, where one node represents the list tracking struct.

![Diagram of dlist internals](image1)

**Fig. 6:** A dlist containing three elements. Note that the list struct appears as a fourth “element” in the list.

![Diagram of dlist containing one element](image2)

**Fig. 7:** A dlist containing just one element.
Doubly-linked List API Reference

**Group** doubly-linked-list_apis

Doubly-linked list implementation.

Doubly-linked list implementation using inline macros/functions. This API is not thread safe, and thus if a list is used across threads, calls to functions must be protected with synchronization primitives.

The lists are expected to be initialized such that both the head and tail pointers point to the list itself. Initializing the lists in such a fashion simplifies the adding and removing of nodes to/from the list.

**Defines**

SYS_DLIST_FOR_EACH_NODE(__dl, __dn)

Provide the primitive to iterate on a list Note: the loop is unsafe and thus __dn should not be removed.

User **MUST** add the loop statement curly braces enclosing its own code:

```c
SYS_DLIST_FOR_EACH_NODE(l, n) {
    <user code>
}
```

This and other SYS_DLIST_*() macros are not thread safe.

**Parameters**

- __dl – A pointer on a sys_dlist_t to iterate on
- __dn – A sys_dnode_t pointer to peek each node of the list

SYS_DLIST_ITERATE_FROM_NODE(__dl, __dn)

Provide the primitive to iterate on a list, from a node in the list Note: the loop is unsafe and thus __dn should not be removed.

User **MUST** add the loop statement curly braces enclosing its own code:
SYS_DLIST_ITERATE_FROM_NODE(l, n) {
    <user code>
}

Like **SYS_DLIST_FOREACH()**, but \_\_dn already contains a node in the list where to start searching for the next entry from. If NULL, it starts from the head.

This and other SYS_DLIST\_\_() macros are not thread safe.

**Parameters**

- \_\_dl – A pointer on a sys_dlist_t to iterate on
- \_\_dn – A sys_dnode_t pointer to peek each node of the list; it contains the starting node, or NULL to start from the head

SYS_DLIST_FOREACH_SAFE(__dl, __dn, __dns)

Provide the primitive to safely iterate on a list Note: __dn can be removed, it will not break the loop.

User **MUST** add the loop statement curly braces enclosing its own code:

SYS_DLIST_FOREACH_SAFE(l, n, s) {
    <user code>
}

This and other SYS_DLIST\_\_() macros are not thread safe.

**Parameters**

- \_\_dl – A pointer on a sys_dlist_t to iterate on
- \_\_dn – A sys_dnode_t pointer to peek each node of the list
- \_\_dns – A sys_dnode_t pointer for the loop to run safely

SYS_DLIST_CONTAINER(__dn, __cn, __n)

Provide the primitive to resolve the container of a list node Note: it is safe to use with NULL pointer nodes.

**Parameters**

- \_\_dn – A pointer on a sys_dnode_t to get its container
- \_\_cn – Container struct type pointer
- \_\_n – The field name of sys_dnode_t within the container struct

SYS_DLIST_PEEK_HEAD_CONTAINER(__dl, __cn, __n)

Provide the primitive to peek container of the list head.

**Parameters**

- \_\_dl – A pointer on a sys_dlist_t to peek
- \_\_cn – Container struct type pointer
- \_\_n – The field name of sys_dnode_t within the container struct

SYS_DLIST_PEEK_NEXT_CONTAINER(__dl, __cn, __n)

Provide the primitive to peek the next container.

**Parameters**

- \_\_dl – A pointer on a sys_dlist_t to peek
- \_\_cn – Container struct type pointer
- \_\_n – The field name of sys_dnode_t within the container struct
SYS_DLIST_FOR_EACH_CONTAINER(__dl, __cn, __n)
Provide the primitive to iterate on a list under a container Note: the loop is unsafe and thus __cn should not be detached.
User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_DLIST_FOR_EACH_CONTAINER(l, c, n) {
    <user code>
}
```

Parameters
- __dl – A pointer on a sys_dlist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __n – The field name of sys_dnode_t within the container struct

SYS_DLIST_FOR_EACH_CONTAINER_SAFE(__dl, __cn, __cns, __n)
Provide the primitive to safely iterate on a list under a container Note: __cn can be detached, it will not break the loop.
User MUST add the loop statement curly braces enclosing its own code:

```c
SYS_DLIST_FOR_EACH_CONTAINER_SAFE(l, c, cn, n) {
    <user code>
}
```

Parameters
- __dl – A pointer on a sys_dlist_t to iterate on
- __cn – A pointer to peek each entry of the list
- __cns – A pointer for the loop to run safely
- __n – The field name of sys_dnode_t within the container struct

SYS_DLIST_STATIC_INIT(ptr_to_list)
Static initializer for a doubly-linked list.

Typedefs
typedef struct _dnode sys_dlist_t
Doubly-linked list structure.
typedef struct _dnode sys_dnode_t
Doubly-linked list node structure.

Functions
static inline void sys_dlist_init(sys_dlist_t *list)
initialize list to its empty state
Parameters
- list – the doubly-linked list
static inline void sys_dnode_init(sys_dnode_t *node)
    initialize node to its state when not in a list

Parameters
    • node – the node

static inline bool sys_dnode_is_linked(const sys_dnode_t *node)
    check if a node is a member of any list

Parameters
    • node – the node

Returns
    true if node is linked into a list, false if it is not

static inline bool sys_dlist_is_head(sys_dlist_t *list, sys_dnode_t *node)
    check if a node is the list's head

Parameters
    • list – the doubly-linked list to operate on
    • node – the node to check

Returns
    true if node is the head, false otherwise

static inline bool sys_dlist_is_tail(sys_dlist_t *list, sys_dnode_t *node)
    check if a node is the list's tail

Parameters
    • list – the doubly-linked list to operate on
    • node – the node to check

Returns
    true if node is the tail, false otherwise

static inline bool sys_dlist_is_empty(sys_dlist_t *list)
    check if the list is empty

Parameters
    • list – the doubly-linked list to operate on

Returns
    true if empty, false otherwise

static inline bool sys_dlist_has_multiple_nodes(sys_dlist_t *list)
    check if more than one node present

This and other sys_dlist_*() functions are not thread safe.

Parameters
    • list – the doubly-linked list to operate on

Returns
    true if multiple nodes, false otherwise

static inline sys_dnode_t *sys_dlist_peek_head(sys_dlist_t *list)
    get a reference to the head item in the list

Parameters
    • list – the doubly-linked list to operate on
Returns

a pointer to the head element, NULL if list is empty

static inline sys_dnode_t* sys_dlist_peek_head_not_empty(sys_dlist_t* list)

get a reference to the head item in the list

The list must be known to be non-empty.

Parameters

- list – the doubly-linked list to operate on

Returns

a pointer to the head element

static inline sys_dnode_t* sys_dlist_peek_next_no_check(sys_dlist_t* list, sys_dnode_t* node)

get a reference to the next item in the list, node is not NULL.

Faster than `sys_dlist_peek_next()` if node is known not to be NULL.

Parameters

- list – the doubly-linked list to operate on
- node – the node from which to get the next element in the list

Returns

a pointer to the next element from a node, NULL if node is the tail

static inline sys_dnode_t* sys_dlist_peek_next(sys_dlist_t* list, sys_dnode_t* node)

get a reference to the next item in the list

Parameters

- list – the doubly-linked list to operate on
- node – the node from which to get the next element in the list

Returns

a pointer to the next element from a node, NULL if node is the tail or NULL (when
node comes from reading the head of an empty list).

static inline sys_dnode_t* sys_dlist_peek_prev_no_check(sys_dlist_t* list, sys_dnode_t* node)

get a reference to the previous item in the list, node is not NULL.

Faster than `sys_dlist_peek_prev()` if node is known not to be NULL.

Parameters

- list – the doubly-linked list to operate on
- node – the node from which to get the previous element in the list

Returns

a pointer to the previous element from a node, NULL if node is the tail

static inline sys_dnode_t* sys_dlist_peek_prev(sys_dlist_t* list, sys_dnode_t* node)

get a reference to the previous item in the list

Parameters

- list – the doubly-linked list to operate on
- node – the node from which to get the previous element in the list

Returns

a pointer to the previous element from a node, NULL if node is the tail or NULL
(when node comes from reading the head of an empty list).
static inline sys_dnode_t *sys_dlist_peek_tail(sys_dlist_t *list)
    get a reference to the tail item in the list

    Parameters
    • list – the doubly-linked list to operate on

    Returns
    a pointer to the tail element, NULL if list is empty

static inline void sys_dlist_append(sys_dlist_t *list, sys_dnode_t *node)
    add node to tail of list

This and other sys_dlist_*() functions are not thread safe.

    Parameters
    • list – the doubly-linked list to operate on
    • node – the element to append

static inline void sys_dlist_prepend(sys_dlist_t *list, sys_dnode_t *node)
    add node to head of list

This and other sys_dlist_*() functions are not thread safe.

    Parameters
    • list – the doubly-linked list to operate on
    • node – the element to append

static inline void sys_dlist_insert(sys_dnode_t *successor, sys_dnode_t *node)
    Insert a node into a list.

    Parameters
    • successor – the position before which “node” will be inserted
    • node – the element to insert

static inline void sys_dlist_insert_at(sys_dlist_t *list, sys_dnode_t *node, int (*cond)(sys_dnode_t *node, void *data), void *data)
    insert node at position

    Parameters
    • list – the doubly-linked list to operate on
    • node – the element to insert
    • cond – a function that determines if the current node is the correct insert point
    • data – parameter to cond()

static inline void sys_dlist_remove(sys_dnode_t *node)
    remove a specific node from a list

The list is implicit from the node. The node must be part of a list. This and other sys_dlist_*() functions are not thread safe.

    Parameters
    • node – the node to remove
static inline sys_dnode_t *sys_dlist_get(sys_dlist_t *list)
get the first node in a list

This and other sys_dlist_*() functions are not thread safe.

Parameters
- list – the doubly-linked list to operate on

Returns
- the first node in the list, NULL if list is empty

static inline size_t sys_dlist_len(sys_dlist_t *list)
Compute the size of the given list in O(n) time.

Parameters
- list – A pointer on the list

Returns
- an integer equal to the size of the list, or 0 if empty

3.5.3 Multi Producer Single Consumer Packet Buffer

A Multi Producer Single Consumer Packet Buffer (MPSC_PBUF) is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that consumes the data. However, it is possible that another context may interfere to flush the data and never come back (panic case). Packet is produced in two steps: first requested amount of data is allocated, producer fills the data and commits it. Consuming a packet is also performed in two steps: consumer claims the packet, gets pointer to it and length and later on packet is freed. This approach reduces memory copying.

A MPSC Packet Buffer has the following key properties:

- Allocate, commit scheme used for packet producing.
- Claim, free scheme used for packet consuming.
- Allocator ensures that contiguous memory of requested length is allocated.
- Following policies can be applied when requested space cannot be allocated:
  - Overwrite - oldest entries are dropped until requested amount of memory can be allocated.
    For each dropped packet user callback is called.
  - No overwrite - When requested amount of space cannot be allocated, allocation fails.
- Dedicated, optimized API for storing short packets.
- Allocation with timeout.

Internals

Each packet in the buffer contains MPSC_PBUF specific header which is used for internal management. Header consists of 2 bit flags. In order to optimize memory usage, header can be added on top of the user header using MPSC_PBUF_HDR and remaining bits in the first word can be application specific. Header consists of following flags:

- valid - bit set to one when packet contains valid user packet
- busy - bit set when packet is being consumed (claimed but not free)

Header state:
Packet buffer space contains free space, valid user packets and internal skip packets. Internal skip packets indicates padding, e.g. at the of the buffer.

**Allocation** Using pairs for read and write indexes, available space is determined. If space can be allocated, temporary write index is moved and pointer to a space within buffer is returned. Packet header is reset. If allocation required wrapping of the write index, a skip packet is added to the end of buffer. If space cannot be allocated and overwrite is disabled then NULL pointer is returned or context blocks if allocation was with timeout.

**Allocation with overwrite** If overwrite is enabled, oldest packets are dropped until requested amount of space can be allocated. When packets are dropped busy flag is checked in the header to ensure that currently consumed packet is not overwritten. In that case, skip packet is added before busy packet and packets following the busy packet are dropped. When busy packet is being freed, such situation is detected and packet is converted to skip packet to avoid double processing.

**Usage**

**Packet header definition** Packet header details can be found in include/zephyr/sys/mpsc_packet.h. API functions can be found in include/zephyr/sys/mpsc_pbuf.h. Headers are split to avoid include spam when declaring the packet.

User header structure must start with internal header:

```c
#include <zephyr/sys/mpsc_packet.h>

struct foo_header {
    MPSC_PBUF_HDR;
    uint32_t length: 32 - MPSC_PBUF_HDR_BITS;
};
```

**Packet buffer configuration** Configuration structure contains buffer details, configuration flags and callbacks. Following callbacks are used by the packet buffer:

- Drop notification - callback called whenever a packet is dropped due to overwrite.
- Get packet length - callback to determine packet length

**Packet producing** Standard, two step method:

```c
foo_packet *packet = mpsc_pbuf_alloc(buffer, len, K_NO_WAIT);
fill_data(packet);
mpsc_pbuf_commit(buffer, packet);
```

Performance optimized storing of small packets:

- 32 bit word packet
• 32 bit word with pointer packet

Note that since packets are written by value, they should already contain valid bit set in the header.

```c
mpsc_pbuf_put_word(buffer, data);
mpsc_pbuf_put_word_ext(buffer, data, ptr);
```

Packet consuming  Two step method:

```c
foo_packet *packet = mpsc_pbuf_claim(buffer);
process(packet);
mpsc_pbuf_free(buffer, packet);
```

### 3.5.4 Single Producer Single Consumer Packet Buffer

A **Single Producer Single Consumer Packet Buffer (SPSC_PBUF)** is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that produces packets and a single context that consumes the data.

Implementation is focused on performance and memory footprint.

Packets are added to the buffer using `spsc_pbuf_write()` which copies a data into the buffer. If the buffer is full error is returned.

Packets are copied out of the buffer using `spsc_pbuf_read()`.

### 3.5.5 Balanced Red/Black Tree

For circumstances where sorted containers may become large at runtime, a list becomes problematic due to algorithmic costs of searching it. For these situations, Zephyr provides a balanced tree implementation which has runtimes on search and removal operations bounded at \(O(\log_2(N))\) for a tree of size \(N\). This is implemented using a conventional red/black tree as described by multiple academic sources.

The `rbtree` tracking struct for a rbtree may be initialized anywhere in user accessible memory. It should contain only zero bits before first use. No specific initialization API is needed or required.

Unlike a list, where position is explicit, the ordering of nodes within an rbtree must be provided as a predicate function by the user. A function of type `rb_lessthan_t()` should be assigned to the `less than fn` field of the `rbtree` struct before any tree operations are attempted. This function should, as its name suggests, return a boolean True value if the first node argument is “less than” the second in the ordering desired by the tree. Note that “equal” is not allowed, nodes within a tree must have a single fixed order for the algorithm to work correctly.

As with the slist and dlist containers, nodes within an rbtree are represented as a `rbnode` structure which exists in user-managed memory, typically embedded within the data structure being tracked in the tree. Unlike the list code, the data within an rbnode is entirely opaque. It is not possible for the user to extract the binary tree topology and “manually” traverse the tree as it is for a list.

Nodes can be inserted into a tree with `rb_insert()` and removed with `rb_remove()`. Access to the “first” and “last” nodes within a tree (in the sense of the order defined by the comparison function) is provided by `rb_get_min()` and `rb_get_max()`. There is also a predicate, `rb_contains()`, which returns a boolean True if the provided node pointer exists as an element within the tree. As described above, all of these routines are guaranteed to have at most log time complexity in the size of the tree.

There are two mechanisms provided for enumerating all elements in an rbtree. The first, `rb_walk()`, is a simple callback implementation where the caller specifies a C function pointer and an untyped argument.
to be passed to it, and the tree code calls that function for each node in order. This has the advantage of a very simple implementation, at the cost of a somewhat more cumbersome API for the user (not unlike ISO C’s `bsearch()` routine). It is a recursive implementation, however, and is thus not always available in environments that forbid the use of unbounded stack techniques like recursion.

There is also a `RB_FOR_EACH` iterator provided, which, like the similar APIs for the lists, works to iterate over a list in a more natural way, using a nested code block instead of a callback. It is also nonrecursive, though it requires log-sized space on the stack by default (however, this can be configured to use a fixed/maximally size buffer instead where needed to avoid the dynamic allocation). As with the lists, this is also available in a `RB_FOR_EACH_CONTAINER` variant which enumerates using a pointer to a container field and not the raw node pointer.

**Tree Internals**

As described, the Zephyr rbtree implementation is a conventional red/black tree as described pervasively in academic sources. Low level details about the algorithm are out of scope for this document, as they match existing conventions. This discussion will be limited to details notable or specific to the Zephyr implementation.

The core invariant guaranteed by the tree is that the path from the root of the tree to any leaf is no more than twice as long as the path to any other leaf. This is achieved by associating one bit of “color” with each node, either red or black, and enforcing a rule that no red child can be a child of another red child (i.e. that the number of black nodes on any path to the root must be the same, and that no more than that number of “extra” red nodes may be present). This rule is enforced by a set of rotation rules used to “fix” trees following modification.

![Fig. 9: A maximally unbalanced rbtree with a black height of two. No more nodes can be added underneath the rightmost node without rebalancing.](image-url)
These rotations are conceptually implemented on top of a primitive that “swaps” the position of one node with another in the list. Typical implementations effect this by simply swapping the nodes internal “data” pointers, but because the Zephyr `rbnode` is intrusive, that cannot work. Zephyr must include somewhat more elaborate code to handle the edge cases (for example, one swapped node can be the root, or the two may already be parent/child).

The `rbnode` struct for a Zephyr rbtree contains only two pointers, representing the “left”, and “right” children of a node within the binary tree. Traversal of a tree for rebalancing following modification, however, routinely requires the ability to iterate “upwards” from a node as well. It is very common for red/black trees in the industry to store a third “parent” pointer for this purpose. Zephyr avoids this requirement by building a “stack” of node pointers locally as it traverses downwards through the tree and updating it appropriately as modifications are made. So a Zephyr rbtree can be implemented with no more runtime storage overhead than a dlist.

These properties, of a balanced tree data structure that works with only two pointers of data per node and that works without any need for a memory allocation API, are quite rare in the industry and are somewhat unique to Zephyr.

Red/Black Tree API Reference

`group rbtree_apis` Balanced Red/Black Tree implementation.

This implements an intrusive balanced tree that guarantees O(log2(N)) runtime for all operations and amortized O(1) behavior for creation and destruction of whole trees. The algorithms and naming are conventional per existing academic and didactic implementations, c.f.:

https://en.wikipedia.org/wiki/Red%E2%80%93black_tree

The implementation is size-optimized to prioritize runtime memory usage. The data structure is intrusive, which is to say the `rbnode` handle is intended to be placed in a separate struct, in the same way as with other such structures (e.g. Zephyr’s `Doubly-linked list`), and requires no data pointer to be stored in the node. The color bit is unioned with a pointer (fairly common for such libraries). Most notably, there is no “parent” pointer stored in the node, the upper structure of the tree being generated dynamically via a stack as the tree is recursed. So the overall memory overhead of a node is just two pointers, identical with a doubly-linked list.

`Defines`

`RB_FOR_EACH(tree, node)` Walk a tree in-order without recursing.

While `rb_walk()` is very simple, recursing on the C stack can be clumsy for some purposes and on some architectures wastes significant memory in stack frames. This macro implements a non-recursive “foreach” loop that can iterate directly on the tree, at a moderate cost in code size.

Note that the resulting loop is not safe against modifications to the tree. Changes to the tree structure during the loop will produce incorrect results, as nodes may be skipped or duplicated. Unlike linked lists, no `_SAFE` variant exists.

Note also that the macro expands its arguments multiple times, so they should not be expressions with side effects.

`Parameters`

- `tree` – A pointer to a struct rbtree to walk
- `node` – The symbol name of a local struct rbnode* variable to use as the iterator
RB_FOR_EACH_CONTAINER(tree, node, field)
Loop over rbtree with implicit container field logic.
As for RB_FOR_EACH(), but “node” can have an arbitrary type containing a struct rbnode.

Parameters

- tree – A pointer to a struct rbtree to walk
- node – The symbol name of a local iterator
- field – The field name of a struct rbnode inside node

Typedefs

typedef bool (*rb_lessthan_t)(struct rbnode *a, struct rbnode *b)
Red/black tree comparison predicate.

Compares the two nodes and returns true if node A is strictly less than B according to the
tree's sorting criteria, false otherwise.

Note that during insert, the new node being inserted will always be “A”, where “B” is the
existing node within the tree against which it is being compared. This trait can be used
(with care!) to implement “most/least recently added” semantics between nodes which would
otherwise compare as equal.

typedef void (*rb_visit_t)(struct rbnode *node, void *cookie)
Prototype for node visitor callback.

- Param node
  Node being visited

- Param cookie
  User-specified data

Functions

void rb_insert(struct rbtree *tree, struct rbnode *node)
Insert node into tree.

void rb_remove(struct rbtree *tree, struct rbnode *node)
Remove node from tree.

static inline struct rbnode *rb_get_min(struct rbtree *tree)
Returns the lowest-sorted member of the tree.

static inline struct rbnode *rb_get_max(struct rbtree *tree)
Returns the highest-sorted member of the tree.

bool rb_contains(struct rbtree *tree, struct rbnode *node)
Returns true if the given node is part of the tree.

Note that this does not internally dereference the node pointer (though the tree's less_than
callback might!), it just tests it for equality with items in the tree. So it's feasible to use this to
implement a “set” construct by simply testing the pointer value itself.

static inline void rb_walk(struct rbtree *tree, rb_visit_t visit_fn, void *cookie)
Walk/enumerate a rbtree.

Very simple recursive enumeration. Low code size, but requiring a separate function can be
clumsy for the user and there is no way to break out of the loop early. See RB_FOR_EACH for
an iterative implementation.
struct rbnode
    #include <rb.h> Balanced red/black tree node structure.

struct rbtree
    #include <rb.h> Balanced red/black tree structure.

Public Members

struct rbnode *root
    Root node of the tree.

rb_lessthan_t lessthan_fn
    Comparison function for nodes in the tree.

3.5.6 Ring Buffers

A ring buffer is a circular buffer, whose contents are stored in first-in-first-out order.

For circumstances where an application needs to implement asynchronous “streaming” copying of data, Zephyr provides a struct ring_buf abstraction to manage copies of such data in and out of a shared buffer of memory.

Two content data modes are supported:

- **Byte mode**: raw bytes can be enqueued and dequeued.
- **Data item mode**: Multiple 32-bit word data items with metadata can be enqueued and dequeued from the ring buffer in chunks of up to 1020 bytes. Each data item also has two associated metadata values: a type identifier and a 16-bit integer value, both of which are application-specific.

While the underlying data structure is the same, it is not legal to mix these two modes on a single ring buffer instance. A ring buffer initialized with a byte count must be used only with the “bytes” API, one initialized with a word count must use the “items” calls.

- **Concepts**
  - Byte mode
  - Data item mode
  - Concurrency
  - Internal Operation
- **Implementation**
  - Defining a Ring Buffer
  - Enqueuing Data
  - Retrieving Data
- **Configuration Options**
- **API Reference**
Concepts

Any number of ring buffers can be defined (limited only by available RAM). Each ring buffer is referenced by its memory address.

A ring buffer has the following key properties:

- A **data buffer** of bytes or 32-bit words. The data buffer contains the raw bytes or 32-bit words that have been added to the ring buffer but not yet removed.

- A **data buffer size**, measured in bytes or 32-byte words. This governs the maximum amount of data (including possible metadata values) the ring buffer can hold.

A ring buffer must be initialized before it can be used. This sets its data buffer to empty. A struct `ring_buf` may be placed anywhere in user-accessible memory, and must be initialized with `ring_buf_init()` or `ring_buf_element_init()` before use. This must be provided a region of user-controlled memory for use as the buffer itself. Note carefully that the units of the size of the buffer passed change (either bytes or words) depending on how the ring buffer will be used later. Macros for combining these steps in a single static declaration exist for convenience. `RING_BUF_DECLARE` will declare and statically initialize a ring buffer with a specified byte count, where `RING_BUF_ITEM_DECLARE` will declare and statically initialize a buffer with a given count of 32 bit words. `RING_BUF_ITEM_SIZEOF` will compute the size in 32-bit words corresponding to a type or an expression. Note: rounds up if the size is not a multiple of 32 bits.

“Bytes” data may be copied into the ring buffer using `ring_buf_put()`, passing a data pointer and byte count. These bytes will be copied into the buffer in order, as many as will fit in the allocated buffer. The total number of bytes copied (which may be fewer than provided) will be returned. Likewise `ring_buf_get()` will copy bytes out of the ring buffer in the order that they were written, into a user-provided buffer, returning the number of bytes that were transferred.

To avoid multiply-copied-data situations, a “claim” API exists for byte mode. `ring_buf_put_claim()` takes a byte size value from the user and returns a pointer to memory internal to the ring buffer that can be used to receive those bytes, along with a size of the contiguous internal region (which may be smaller than requested). The user can then copy data into that region at a later time without assembling all the bytes in a single region first. When complete, `ring_buf_put_finish()` can be used to signal the buffer that the transfer is complete, passing the number of bytes actually transferred. At this point a new transfer can be initiated. Similarly, `ring_buf_get_claim()` returns a pointer to internal ring buffer data from which the user can read without making a verbatim copy, and `ring_buf_get_finish()` signals the buffer with how many bytes have been consumed and allows for a new transfer to begin.

“Items” mode works similarly to bytes mode, except that all transfers are in units of 32 bit words and all memory is assumed to be aligned on 32 bit boundaries. The write and read operations are `ring_buf_item_put()` and `ring_buf_item_get()`, and work otherwise identically to the bytes mode APIs. There no “claim” API provided for items mode. One important difference is that unlike `ring_buf_put()`, `ring_buf_item_put()` will not do a partial transfer; it will return an error in the case where the provided data does not fit in its entirety.

The user can manage the capacity of a ring buffer without modifying it using either `ring_buf_space_get()` or `ring_buf_item_space_get()` which returns the number of free bytes or free 32-bit item words respectively, or by testing the `ring_buf_is_empty()` predicate.

Finally, a `ring_buf_reset()` call exists to immediately empty a ring buffer, discarding the tracking of any bytes or items already written to the buffer. It does not modify the memory contents of the buffer itself, however.

**Byte mode** A byte mode ring buffer instance is declared using `RING_BUF_DECLARE()` and accessed using: `ring_buf_put_claim()`, `ring_buf_put_finish()`, `ring_buf_get_claim()`, `ring_buf_get_finish()`, `ring_buf_put()` and `ring_buf_get()`.

Data can be copied into the ring buffer (see `ring_buf_put()`) or ring buffer memory can be used directly by the user. In the latter case, the operation is split into three stages:
1. allocating the buffer \( \text{ring_buf_put_claim()} \) when user requests the destination location where data can be written.
2. writing the data by the user (e.g. buffer written by DMA).
3. indicating the amount of data written to the provided buffer \( \text{ring_buf_put_finish()} \). The amount can be less than or equal to the allocated amount.

Data can be retrieved from a ring buffer through copying (see \( \text{ring_buf_get()} \)) or accessed directly by address. In the latter case, the operation is split into three stages:

1. retrieving source location with valid data written to a ring buffer (see \( \text{ring_buf_get_claim()} \)).
2. processing data
3. freeing processed data (see \( \text{ring_buf_get_finish()} \)). The amount freed can be less than or equal or to the retrieved amount.

**Data item mode**  
A data item mode ring buffer instance is declared using \( \text{RING_BUF_ITEM_DECLARE()} \) and accessed using \( \text{ring_buf_item_put()} \) and \( \text{ring_buf_item_get()} \).

A ring buffer data item is an array of 32-bit words from 0 to 1020 bytes in length. When a data item is **enqueued** \( \text{ring_buf_item_put()} \) its contents are copied to the data buffer, along with its associated metadata values (which occupy one additional 32-bit word). If the ring buffer has insufficient space to hold the new data item the enqueue operation fails.

A data item is **dequeued** \( \text{ring_buf_item_get()} \) from a ring buffer by removing the oldest enqueued item. The contents of the dequeued data item, as well as its two metadata values, are copied to areas supplied by the retriever. If the ring buffer is empty, or if the data array supplied by the retriever is not large enough to hold the data item's data, the dequeue operation fails.

**Concurrency**  
The ring buffer APIs do not provide any concurrency control. Depending on usage (particularly with respect to number of concurrent readers/writers) applications may need to protect the ring buffer with mutexes and/or use semaphores to notify consumers that there is data to read.

For the trivial case of one producer and one consumer, concurrency control shouldn't be needed.

**Internal Operation**  
Data streamed through a ring buffer is always written to the next byte within the buffer, wrapping around to the first element after reaching the end, thus the “ring” structure. Internally, the struct \text{ring_buf} contains its own buffer pointer and its size, and also a set of “head” and “tail” indices representing where the next read and write operations may occur.

This boundary is invisible to the user using the normal put/get APIs, but becomes a barrier to the “claim” API, because obviously no contiguous region can be returned that crosses the end of the buffer. This can be surprising to application code, and produce performance artifacts when transfers need to happen close to the end of the buffer, as the number of calls to claim/finish needs to double for such transfers.

**Implementation**

**Defining a Ring Buffer**  
A ring buffer is defined using a variable of type \text{ring_buf}. It must then be initialized by calling \( \text{ring_buf_init()} \) or \( \text{ring_buf_item_init()} \).

The following code defines and initializes an empty data item mode ring buffer (which is part of a larger data structure). The ring buffer's data buffer is capable of holding 64 words of data and metadata information.

```c
#define MY_RING_BUF_WORDS 64

struct my_struct {
    struct ring_buf rb;
};
```
Alternatively, a ring buffer can be defined and initialized at compile time using one of two macros at file scope. Each macro defines both the ring buffer itself and its data buffer.

The following code defines a data item mode ring buffer:

```
#define MY_RING_BUF_WORDS 93
RING_BUF_ITEM_DECLARE(my_ring_buf, MY_RING_BUF_WORDS);
```

The following code defines a ring buffer intended to be used for raw bytes:

```
#define MY_RING_BUF_BYTES 93
RING_BUF_DECLARE(my_ring_buf, MY_RING_BUF_BYTES);
```

Enqueuing Data  Bytes are copied to a byte mode ring buffer by calling `ring_buf_put()`.

```
uint8_t my_data[MY_RING_BUF_BYTES];
uint32_t ret;
ret = ring_buf_put(&ring_buf, my_data, MY_RING_BUF_BYTES);
if (ret != MY_RING_BUF_BYTES) {
    /* not enough room, partial copy. */
    ...
}
```

Data can be added to a byte mode ring buffer by directly accessing the ring buffer’s memory. For example:

```
uint32_t size;
uint32_t rx_size;
uint8_t *data;
int err;

/* Allocate buffer within a ring buffer memory. */
size = ring_buf_put_claim(&ring_buf, &data, MY_RING_BUF_BYTES);

/* Work directly on a ring buffer memory. */
rx_size = uart_rx(data, size);

/* Indicate amount of valid data. rx_size can be equal or less than size. */
err = ring_buf_put_finish(&ring_buf, rx_size);
if (err != 0) {
    /* This shouldn’t happen unless rx_size > size */
    ...
}
```

A data item is added to a ring buffer by calling `ring_buf_item_put()`.
```c
uint32_t data[MY_DATA_WORDS];
int ret;

ret = ring_buf_item_put(&ring_buf, TYPE_FOO, 0, data, MY_DATA_WORDS);
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}

If the data item requires only the type or application-specific integer value (i.e. it has no data array), a size of 0 and data pointer of NULL can be specified.

```c
int ret;

ret = ring_buf_item_put(&ring_buf, TYPE_BAR, 17, NULL, 0);
if (ret == -EMSGSIZE) {
    /* not enough room for the data item */
    ...
}
```n

### Retrieving Data

Data bytes are copied out from a **byte mode** ring buffer by calling `ring_buf_get()`.

For example:

```c
uint8_t my_data[MY_DATA_BYTES];
size_t ret;

ret = ring_buf_get(&ring_buf, my_data, sizeof(my_data));
if (ret != sizeof(my_data)) {
    /* Fewer bytes copied. */
} else {
    /* Requested amount of bytes retrieved. */
    ...
}
```

Data can be retrieved from a **byte mode** ring buffer by direct operations on the ring buffer’s memory.

For example:

```c
uint32_t size;
uint32_t proc_size;
uint8_t *data;
int err;

/* Get buffer within a ring buffer memory. */
size = ring_buf_get_claim(&ring_buf, &data, MY_RING_BUF_BYTES);

/* Work directly on a ring buffer memory. */
proc_size = process(data, size);

/* Indicate amount of data that can be freed. proc_size can be equal or less than size. */
err = ring_buf_get_finish(&ring_buf, proc_size);
if (err != 0) {
    /* proc_size exceeds amount of valid data in a ring buffer. */
    ...
}
```
A data item is removed from a ring buffer by calling `ring_buf_item_get()`.

```c
uint32_t my_data[MY_DATA_WORDS];
uint16_t my_type;
uint8_t my_value;
uint8_t my_size;
int ret;

my_size = MY_DATA_WORDS;
ret = ring_buf_item_get(&ring_buf, &my_type, &my_value, my_data, &my_size);
if (ret == -EMSGSIZE) {
    printk("Buffer is too small, need %d uint32_t\n", my_size);
} else if (ret == -EAGAIN) {
    printk("Ring buffer is empty\n");
} else {
    printk("Got item of type %u value &u of size %u dwords\n", my_type, my_value, my_size);
    ...
}
```

Configuration Options

Related configuration options:

- CONFIG_RING_BUFFER: Enable ring buffer.

API Reference

The following ring buffer APIs are provided by `include/zephyr/sys/ring_buffer.h`:

**group ring_buffer_apis**

Simple ring buffer implementation.

**Defines**

RING_BUF_DECLARE(name, size8)

Define and initialize a ring buffer for byte data.

This macro establishes a ring buffer of an arbitrary size. The basic storage unit is a byte.

The ring buffer can be accessed outside the module where it is defined using:

```c
extern struct ring_buf <name>;
```

**Parameters**

- `name` – Name of the ring buffer.
- `size8` – Size of ring buffer (in bytes).

RING_BUF_ITEM_DECLARE(name, size32)

Define and initialize an “item based” ring buffer.

This macro establishes an “item based” ring buffer. Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

The ring buffer can be accessed outside the module where it is defined using:
extern struct ring_buf <name>;

Parameters

- name – Name of the ring buffer.
- size32 – Size of ring buffer (in 32-bit words).

RING_BUF_ITEM_DECLARE_SIZE(name, size32)
Define and initialize an “item based” ring buffer.
This exists for backward compatibility reasons. RING_BUF_ITEM_DECLARE should be used instead.

Parameters

- name – Name of the ring buffer.
- size32 – Size of ring buffer (in 32-bit words).

RING_BUF_ITEM_DECLARE_POW2(name, pow)
Define and initialize a power-of-2 sized “item based” ring buffer.
This macro establishes an “item based” ring buffer by specifying its size using a power of 2.
This exists mainly for backward compatibility reasons. RING_BUF_ITEM_DECLARE should be used instead.

Parameters

- name – Name of the ring buffer.
- pow – Ring buffer size exponent.

RING_BUF_ITEM_SIZEOF(expr)
Compute the ring buffer size in 32-bit needed to store an element.
The argument can be a type or an expression. Note: rounds up if the size is not a multiple of 32 bits.

Parameters

- expr – Expression or type to compute the size of

Functions

static inline void ring_buf_internal_reset(struct ring_buf *buf, int32_t value)
Function to force ring_buf internal states to given value.
Any value other than 0 makes sense only in validation testing context.

static inline void ring_buf_init(struct ring_buf *buf, uint32_t size, uint8_t *data)
Initialize a ring buffer for byte data.
This routine initializes a ring buffer, prior to its first use. It is only used for ring buffers not defined using RING_BUF_DECLARE.

Parameters

- buf – Address of ring buffer.
- size – Ring buffer size (in bytes).
- data – Ring buffer data area (uint8_t data[size]).
static inline void ring_buf_item_init(struct ring_buf *buf, uint32_t size, uint32_t *data)
    Initialize an “item based” ring buffer.
    This routine initializes a ring buffer, prior to its first use. It is only used for ring buffers not defined using RING_BUF_ITEM_DECLARE.
    Each data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

    Parameters
    • buf – Address of ring buffer.
    • size – Ring buffer size (in 32-bit words)
    • data – Ring buffer data area (uint32_t data[size]).

static inline bool ring_buf_is_empty(struct ring_buf *buf)
    Determine if a ring buffer is empty.

    Parameters
    • buf – Address of ring buffer.

    Returns
    true if the ring buffer is empty, or false if not.

static inline void ring_buf_reset(struct ring_buf *buf)
    Reset ring buffer state.

    Parameters
    • buf – Address of ring buffer.

static inline uint32_t ring_buf_space_get(struct ring_buf *buf)
    Determine free space in a ring buffer.

    Parameters
    • buf – Address of ring buffer.

    Returns
    Ring buffer free space (in bytes).

static inline uint32_t ring_buf_item_space_get(struct ring_buf *buf)
    Determine free space in an “item based” ring buffer.

    Parameters
    • buf – Address of ring buffer.

    Returns
    Ring buffer free space (in 32-bit words).

static inline uint32_t ring_buf_capacity_get(struct ring_buf *buf)
    Return ring buffer capacity.

    Parameters
    • buf – Address of ring buffer.

    Returns
    Ring buffer capacity (in bytes).
static inline uint32_t ring_buf_size_get(struct ring_buf *buf)
    Determine used space in a ring buffer.

Parameters

• buf – Address of ring buffer.

Returns

Ring buffer space used (in bytes).

uint32_t ring_buf_put_claim(struct ring_buf *buf, uint8_t **data, uint32_t size)
    Allocate buffer for writing data to a ring buffer.

With this routine, memory copying can be reduced since internal ring buffer can be used directly by the user. Once data is written to allocated area number of bytes written must be confirmed (see ring_buf_put_finish).

Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters

• data – [out] Pointer to the address. It is set to a location within ring buffer.

Returns

Size of allocated buffer which can be smaller than requested if there is not enough free space or buffer wraps.

int ring_buf_put_finish(struct ring_buf *buf, uint32_t size)
    Indicate number of bytes written to allocated buffers.

The number of bytes must be equal to or lower than the sum corresponding to all preceding ring_buf_put_claim invocations (or even 0). Surplus bytes will be returned to the available free buffer space.

Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item access (calls prefixed with ring_buf_item_).

Parameters

• buf – Address of ring buffer.

• size – Number of valid bytes in the allocated buffers.

Return values
## 3.5. Data Structures

- 0 – Successful operation.
- -EINVAL – Provided `size` exceeds free space in the ring buffer.

```c
uint32_t ring_buf_put(struct ring_buf *buf, const uint8_t *data, uint32_t size)
```

Write (copy) data to a ring buffer.

This routine writes data to a ring buffer `buf`.

### Warning:
Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

### Warning:
Ring buffer instance should not mix byte access and item access (calls prefixed with `ring_buf_item`).

### Parameters
- `buf` – Address of ring buffer.
- `data` – Address of data.
- `size` – Data size (in bytes).

### Return values
Number – of bytes written.

```c
uint32_t ring_buf_get_claim(struct ring_buf *buf, uint8_t **data, uint32_t size)
```

Get address of a valid data in a ring buffer.

With this routine, memory copying can be reduced since internal ring buffer can be used directly by the user. Once data is processed it must be freed using `ring_buf_get_finish`.

### Warning:
Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

### Warning:
Ring buffer instance should not mix byte access and item access (calls prefixed with `ring_buf_item`).

### Parameters
- `data` – [out] Pointer to the address. It is set to a location within ring buffer.

### Returns
Number of valid bytes in the provided buffer which can be smaller than requested if there is not enough free space or buffer wraps.

```c
int ring_buf_get_finish(struct ring_buf *buf, uint32_t size)
```

Indicate number of bytes read from claimed buffer.

The number of bytes must be equal or lower than the sum corresponding to all preceding `ring_buf_get_claim` invocations (or even 0). Surplus bytes will remain available in the buffer.
Warning: Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item mode (calls prefixed with ring_buf_item_).

Parameters
- buf – Address of ring buffer.
- size – Number of bytes that can be freed.

Return values
- 0 – Successful operation.
- -EINVAL – Provided size exceeds valid bytes in the ring buffer.

uint32_t ring_buf_get(struct ring_buf *buf, uint8_t *data, uint32_t size)
Read data from a ring buffer.

This routine reads data from a ring buffer buf.

Warning: Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Warning: Ring buffer instance should not mix byte access and item mode (calls prefixed with ring_buf_item_).

Parameters
- buf – Address of ring buffer.
- data – Address of the output buffer. Can be NULL to discard data.
- size – Data size (in bytes).

Return values
Number – of bytes written to the output buffer.

uint32_t ring_buf_peek(struct ring_buf *buf, uint8_t *data, uint32_t size)
Peek at data from a ring buffer.

This routine reads data from a ring buffer buf without removal.
Warning: Multiple calls to peek will result in the same data being 'peeked' multiple times. To remove data, use either ring_buf_get or ring_buf_get_claim followed by ring_buf_get_finish with a non-zero size.

Parameters
- buf – Address of ring buffer.
- data – Address of the output buffer. Cannot be NULL.
- size – Data size (in bytes).

Return values
Number – of bytes written to the output buffer.

int ring_buf_item_put(struct ring_buf *buf, uint16_t type, uint8_t value, uint32_t *data, uint8_t size32)

Write a data item to a ring buffer.

This routine writes a data item to ring buffer buf. The data item is an array of 32-bit words (from zero to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

Warning: Use cases involving multiple writers to the ring buffer must prevent concurrent write operations, either by preventing all writers from being preempted or by using a mutex to govern writes to the ring buffer.

Parameters
- buf – Address of ring buffer.
- type – Data item's type identifier (application specific).
- value – Data item's integer value (application specific).
- data – Address of data item.
- size32 – Data item size (number of 32-bit words).

Return values
- 0 – Data item was written.
- -EMSGSIZE – Ring buffer has insufficient free space.

int ring_buf_item_get(struct ring_buf *buf, uint16_t *type, uint8_t *value, uint32_t *data, uint8_t *size32)

Read a data item from a ring buffer.

This routine reads a data item from ring buffer buf. The data item is an array of 32-bit words (up to 1020 bytes in length), coupled with a 16-bit type identifier and an 8-bit integer value.

Warning: Use cases involving multiple reads of the ring buffer must prevent concurrent read operations, either by preventing all readers from being preempted or by using a mutex to govern reads to the ring buffer.

Parameters
- buf – Address of ring buffer.
- type – Area to store the data item's type identifier.
value – Area to store the data item’s integer value.

data – Area to store the data item. Can be NULL to discard data.

size32 – Size of the data item storage area (number of 32-bit chunks).

Return values

• 0 – Data item was fetched; size32 now contains the number of 32-bit words read into data area data.

• -EAGAIN – Ring buffer is empty.

• -EMSGSIZE – Data area data is too small; size32 now contains the number of 32-bit words needed.

3.6 Executing Time Functions

The timing functions can be used to obtain execution time of a section of code to aid in analysis and optimization.

Please note that the timing functions may use a different timer than the default kernel timer, where the timer being used is specified by architecture, SoC or board configuration.

3.6.1 Configuration

To allow using the timing functions, CONFIG_TIMING_FUNCTIONS needs to be enabled.

3.6.2 Usage

To gather timing information:

1. Call timing_init() to initialize the timer.

2. Call timing_start() to signal the start of gathering of timing information. This usually starts the timer.

3. Call timing_counter_get() to mark the start of code execution.

4. Call timing_counter_get() to mark the end of code execution.

5. Call timing_cycles_get() to get the number of timer cycles between start and end of code execution.

6. Call timing_cycles_to_ns() with total number of cycles to convert number of cycles to nanoseconds.

7. Repeat from step 3 to gather timing information for other blocks of code.

8. Call timing_stop() to signal the end of gathering of timing information. This usually stops the timer.

Example

This shows an example on how to use the timing functions:

```
#include <zephyr/timing/timing.h>

void gather_timing(void)
{

(continues on next page)

```c
timing_t start_time, end_time;
uint64_t total_cycles;
uint64_t total_ns;

timing_init();
timing_start();

start_time = timing_counter_get();
code_execution_to_be_measured();
end_time = timing_counter_get();

total_cycles = timing_cycles_get(&start_time, &end_time);
total_ns = timing_cycles_to_ns(total_cycles);

timing_stop();
```

### 3.6.3 API documentation

**group timing_api**

Timing Measurement APIs.

**Functions**

- **void timing_init(void)**
  - Initialize the timing subsystem.
  - Perform the necessary steps to initialize the timing subsystem.

- **void timing_start(void)**
  - Signal the start of the timing information gathering.
  - Signal to the timing subsystem that timing information will be gathered from this point forward.

- **void timing_stop(void)**
  - Signal the end of the timing information gathering.
  - Signal to the timing subsystem that timing information is no longer being gathered from this point forward.

- **static inline timing_t timing_counter_get(void)**
  - Return timing counter.

  **Returns**
  - Timing counter.

- **static inline uint64_t timing_cycles_get(void **start, void **end)**

  Get number of cycles between `start` and `end`.

  For some architectures or SoCs, the raw numbers from counter need to be scaled to obtain actual number of cycles.

**Parameters**
• start – Pointer to counter at start of a measured execution.
• end – Pointer to counter at stop of a measured execution.

Returns
Number of cycles between start and end.

static inline uint64_t timing_freq_get(void)
Get frequency of counter used (in Hz).

Returns
Frequency of counter used for timing in Hz.

static inline uint64_t timing_cycles_to_ns(uint64_t cycles)
Convert number of cycles into nanoseconds.

Parameters
• cycles – Number of cycles

Returns
Converted time value

static inline uint64_t timing_cycles_to_ns_avg(uint64_t cycles, uint32_t count)
Convert number of cycles into nanoseconds with averaging.

Parameters
• cycles – Number of cycles
• count – Times of accumulated cycles to average over

Returns
Converted time value

static inline uint32_t timing_freq_get_mhz(void)
Get frequency of counter used (in MHz).

Returns
Frequency of counter used for timing in MHz.

3.7 Object Cores

Object cores are a kernel debugging tool that can be used to both identify and perform operations on registered objects.
3.7.1 Object Core Concepts

Each instance of an object embeds an object core field named `obj_core`. Objects of the same type are linked together via their respective object cores to form a singly linked list. Each object core also links to the their respective object type. Each object type contains a singly linked list linking together all the object cores of that type. Object types are also linked together via a singly linked list. Together, this can allow debugging tools to traverse all the objects in the system.

Object cores have been integrated into following kernel objects:

- Condition Variables
- Events
- FIFOs and LIFOs
- Mailboxes
- Memory Slabs
- Message Queues
- Mutexes
- Pipes
- Semaphores
- Timers
- System Memory Blocks

Developers are free to integrate them if desired into other objects within their projects.

3.7.2 Object Core Statistics Concepts

A variety of kernel objects allow for the gathering and reporting of statistics. Object cores provide a uniform means to retrieve that information via object core statistics. When enabled, the object type contains a pointer to a statistics descriptor that defines the various operations that have been enabled for interfacing with the object's statistics. Additionally, the object core contains a pointer to the “raw” statistical information associated with that object. Raw data is the raw, unmanipulated data associated with the statistics. Queried data may be “raw”, but it may also have been manipulated in some way by calculation (such as determining an average).

The following table indicates both what objects have been integrated into the object core statistics as well as the structures used for both “raw” and “queried” data.

<table>
<thead>
<tr>
<th>Object</th>
<th>Raw Data Type</th>
<th>Query Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>struct mem_slab</td>
<td>struct mem_slab_info</td>
<td>struct sys_memory_stats</td>
</tr>
<tr>

<td>struct k_thread_runtime_stats</td>
</tr>
</tbody>
</table>

3.7.3 Implementation

Defining a New Object Type

An object type is defined using a global variable of type `k_obj_type`. It must be initialized before any objects of that type are initialized. The following code shows how a new object type can be initialized for use with object cores and object core statistics.
/* Unique object type ID */

#define K_OBJ_TYPE_MY_NEW_TYPE K_OBJ_TYPE_ID_GEN("UNIQ")

struct k_obj_type  my_obj_type;

struct my_obj_type_raw_info {
    ...
};

struct my_obj_type_query_stats {
    ...
};

struct my_new_obj {
    ...
    struct k_obj_core  obj_core;
    struct my_obj_type_raw_info  info;
};

struct k_obj_core_stats_desc  my_obj_type_stats_desc = {
    .raw_size = sizeof(struct my_obj_type_raw_stats),
    .query_size = sizeof(struct my_obj_type_query_stats),
    .raw = my_obj_type_stats_raw,
    .query = my_obj_type_stats_query,
    .reset = my_obj_type_stats_reset,
    .disable = NULL,  /* Stats gathering is always on */
    .enable = NULL,  /* Stats gathering is always on */
};

void my_obj_type_init(void)
{
    z_obj_type_init(&my_obj_type, K_OBJ_TYPE_MY_NEW_TYPE,
        offsetof(struct my_new_obj, obj_core);
    k_obj_type_stats_init(&my_obj_type, &my_obj_type_stats_desc);
}

### Initializing a New Object Core

Kernel objects that have already been integrated into the object core framework automatically have their object cores initialized when the object is initialized. However, developers that wish to add their own objects into the framework need to both initialize the object core and link it. The following code builds on the example above and initializes the object core.

void my_new_obj_init(struct my_new_obj *new_obj)
{
    ...
    k_obj_core_init(K_OBJ_CORE(new_obj), &my_obj_type);
    k_obj_core_link(K_OBJ_CORE(new_obj));
    k_obj_core_stats_register(K_OBJ_CORE(new_obj), &new_obj->raw_stats,
        sizeof(struct my_obj_type_raw_info));
}
Walking a List of Object Cores

Two routines exist for walking the list of object cores linked to an object type. These are `k_obj_type_walk_locked()` and `k_obj_type_walk_unlocked()`. The following code builds upon the example above and prints the addresses of all the objects of that new object type.

```c
int walk_op(struct k_obj_core *obj_core, void *data)
{
    uint8_t *ptr;
    ptr = obj_core;
    ptr -= obj_core->type->obj_core_offset;
    printk(">
```
```n, ptr);
    return 0;
}
```

void print_object_addresses(void)
{
    struct k_obj_type *obj_type;
    /* Find the object type */
    obj_type = k_obj_type_find(K_OBJ_TYPE_MY_NEW_TYPE);
    /* Walk the list of objects */
    k_obj_type_walk_unlocked(obj_type, walk_op, NULL);
```

Object Core Statistics Querying

The following code builds on the examples above and shows how an object integrated into the object core statistics framework can both retrieve queried data and reset the stats associated with the object.

```c
struct my_new_obj my_obj;
...

void my_func(void)
{
    struct my_obj_type_query_stats my_stats;
    int status;
    my_obj_type_init(&my_obj);
    ...
    status = k_obj_core_stats_query(K_OBJ_CORE(&my_obj),
                                    &my_stats, sizeof(my_stats));
    if (status != 0) {
        /* Failed to get stats */
        ...
```
```n} else {
    k_obj_core_stats_reset(K_OBJ_CORE(&my_obj));
```
```n
(continues on next page)"

3.7.5 API Reference

group obj_core_apis

Defines

K_OBJ_CORE(kobj)
    Convert kernel object pointer into its object core pointer.

K_OBJ_TYPE_ID_GEN(s)
    Generate new object type IDs based on a 4 letter string.

K_OBJ_TYPE_CONDVAR_ID
    Condition variable object type.
K_OBJ_TYPE_CPU_ID
CPU object type.

K_OBJ_TYPE_EVENT_ID
Event object type.

K_OBJ_TYPE_FIFO_ID
FIFO object type.

K_OBJ_TYPE_KERNEL_ID
Kernel object type.

K_OBJ_TYPE_LIFO_ID
LIFO object type.

K_OBJ_TYPE_MEM_BLOCK_ID
Memory block object type.

K_OBJ_TYPE_MBOX_ID
Mailbox object type.

K_OBJ_TYPE_MEM_SLAB_ID
Memory slab object type.

K_OBJ_TYPE_MSGQ_ID
Message queue object type.

K_OBJ_TYPE_MUTEX_ID
Mutex object type.

K_OBJ_TYPE_PIPE_ID
Pipe object type.

K_OBJ_TYPE_SEM_ID
Semaphore object type.

K_OBJ_TYPE_STACK_ID
Stack object type.

K_OBJ_TYPE_THREAD_ID
Thread object type.

K_OBJ_TYPE_TIMER_ID
Timer object type.

Functions
struct k_obj_type *k_obj_type_find(uint32_t type_id)

Find a specific object type by ID.

Given an object type ID, this function searches for the object type that is associated with the specified type ID type_id.

Parameters
• type_id – Type ID associated with object type

Return values
• NULL – if object type not found
• Pointer – to object type if found

int k_obj_type_walkLocked(struct k_obj_type *type, int (*func)(struct k_obj_core*, void*), void *data)

Walk the object type’s list of object cores.

This function takes a global spinlock and walks the object type’s list of object cores and invokes the callback function on each element while holding that lock. Although this will ensure that the list is not modified, one can expect a significant penalty in terms of performance and latency.

The callback function shall either return non-zero to stop further walking, or it shall return 0 to continue walking.

Parameters
• type – Pointer to the object type
• func – Callback to invoke on each object core of the object type
• data – Custom data passed to the callback

Return values
• non-zero – if walk is terminated by the callback; otherwise 0

int k_obj_type_walkUnlocked(struct k_obj_type *type, int (*func)(struct k_obj_core*, void*), void *data)

Walk the object type’s list of object cores.

This function is similar to k_obj_type_walkLocked() except that it walks the list without obtaining the global spinlock. No synchronization is provided here. Mutation of the list of objects while this function is in progress must be prevented at the application layer, otherwise undefined/unreliable behavior, corruption and/or crashes may result.

The callback function shall either return non-zero to stop further walking, or it shall return 0 to continue walking.

Parameters
• type – Pointer to the object type
• func – Callback to invoke on each object core of the object type
• data – Custom data passed to the callback

Return values
• non-zero – if walk is terminated by the callback; otherwise 0

void k_obj_core_init(struct k_obj_core *obj_core, struct k_obj_type *type)

Initialize the core of the kernel object.

Initializing the kernel object core associates it with the specified kernel object type.

Parameters
• obj_core – Pointer to the kernel object to initialize
• type – Pointer to the kernel object type

```c
void k_obj_core_link(struct k_obj_core *obj_core)
```

Link the kernel object to the kernel object type list.

A kernel object can be optionally linked into the kernel object type's list of objects. A kernel object must have been initialized before it can be linked. Linked kernel objects can be traversed and have information extracted from them by system tools.

**Parameters**

• obj_core – Pointer to the kernel object

```c
void k_obj_core_init_and_link(struct k_obj_core *obj_core, struct k_obj_type *type)
```

Automatically link the kernel object after initializing it.

A useful wrapper to both initialize the core of the kernel object and automatically link it into the kernel object type's list of objects.

**Parameters**

• obj_core – Pointer to the kernel object to initialize
• type – Pointer to the kernel object type

```c
void k_obj_core_unlink(struct k_obj_core *obj_core)
```

Unlink the kernel object from the kernel object type list.

Kernel objects can be unlinked from their respective kernel object type lists. If on a list, it must be done at the end of the kernel object's life cycle.

**Parameters**

• obj_core – Pointer to the kernel object

```c
struct k_obj_core_stats_desc
```

```c
#include <obj_core.h> Object core statistics descriptor.
```

**Public Members**

```c
size_t raw_size
```

Internal representation stats buffer size.

```c
size_t query_size
```

Stats buffer size used for reporting.

```c
int (*raw)(struct k_obj_core *obj_core, void *stats)
```

Function pointer to retrieve internal representation of stats.

```c
int (*query)(struct k_obj_core *obj_core, void *stats)
```

Function pointer to retrieve reported statistics.

```c
int (*reset)(struct k_obj_core *obj_core)
```

Function pointer to reset object's statistics.

```c
int (*disable)(struct k_obj_core *obj_core)
```

Function pointer to disable object's statistics gathering.

### 3.7. Object Cores
Function pointer to enable object's statistics gathering.

```c
int (*enable)(struct k_obj_core *obj_core)
```

Object type structure.

```c
struct k_obj_type
#include <obj_core.h> Object type structure.
```

**Public Members**

```c
sys_snodet node
Node within list of object types.
```

```c
sys_slistt list
List of objects of this object type.
```

```c
uint32_t id
Unique type ID.
```

```c
size_t obj_core_offset
Offset to obj_core field.
```

Object core structure.

```c
struct k_obj_core
#include <obj_core.h> Object core structure.
```

**Public Members**

```c
sys_snodet node
Object node within object type's list.
```

```c
struct k_obj_type *type
Object type to which object belongs.
```

Kernel object for gathering statistics.

```c
int k_obj_core_stats_register(struct k_obj_core *obj_core, void *stats, size_t stats_len)
```

Before a kernel object can gather statistics, it must be registered to do so. Registering will also automatically enable the kernel object to gather its statistics.

**Parameters**

- `obj_core` – Pointer to kernel object core
- `stats` – Pointer to raw kernel statistics
- `stats_len` – Size of raw kernel statistics buffer

**Return values**

- `0` – on success
int k_obj_core_stats_deregister(struct k_obj_core *obj_core)
Deregister kernel object from gathering statistics.
Deregistering a kernel object core from gathering statistics prevents it from gathering any
more statistics. It is expected to be invoked at the end of a kernel object's life cycle.

Parameters
• obj_core – Pointer to kernel object core

Return values
• 0 – on success
• -errno – on failure

int k_obj_core_stats_raw(struct k_obj_core *obj_core, void *stats, size_t stats_len)
Retrieve the raw statistics associated with the kernel object.
This function copies the raw statistics associated with the kernel object core specified by
obj_core into the buffer stats. Note that the size of the buffer (stats_len) must match the
size specified by the kernel object type's statistics descriptor.

Parameters
• obj_core – Pointer to kernel object core
• stats – Pointer to memory buffer into which to copy raw stats
• stats_len – Length of the memory buffer

Return values
• 0 – on success
• -errno – on failure

int k_obj_core_stats_query(struct k_obj_core *obj_core, void *stats, size_t stats_len)
Retrieve the statistics associated with the kernel object.
This function copies the statistics associated with the kernel object core specified by obj_core
into the buffer stats. Unlike the raw statistics this may report calculated values such as aver-
ages. Note that the size of the buffer (stats_len) must match the size specified by the kernel
object type's statistics descriptor.

Parameters
• obj_core – Pointer to kernel object core
• stats – Pointer to memory buffer into which to copy the queried stats
• stats_len – Length of the memory buffer

Return values
• 0 – on success
• -errno – on failure

int k_obj_core_stats_reset(struct k_obj_core *obj_core)
Reset the stats associated with the kernel object.
This function resets the statistics associated with the kernel object core specified by obj_core.

Parameters
• obj_core – Pointer to kernel object core

Return values
• 0 – on success
- `errno` – on failure

```c
int k_obj_core_stats_disable(struct k_obj_core *obj_core)
```

Stop gathering the stats associated with the kernel object.

This function temporarily stops the gathering of statistics associated with the kernel object core specified by `obj_core`. The gathering of statistics can be resumed by invoking `:c:func:k_obj_core_stats_enable`.

**Parameters**

- `obj_core` – Pointer to kernel object core

**Return values**

- `0` – on success
- `errno` – on failure

```c
int k_obj_core_stats_enable(struct k_obj_core *obj_core)
```

Reset the stats associated with the kernel object.

This function resumes the gathering of statistics associated with the kernel object core specified by `obj_core`.

**Parameters**

- `obj_core` – Pointer to kernel object core

**Return values**

- `0` – on success
- `errno` – on failure

### 3.8 Time Utilities

#### 3.8.1 Overview

*Uptime* in Zephyr is based on the a tick counter. With the default `CONFIG_TICKLESS_KERNEL` this counter advances at a nominally constant rate from zero at the instant the system started. The POSIX equivalent to this counter is something like `CLOCK_MONOTONIC` or, in Linux, `CLOCK_MONOTONIC_RAW`. `k_uptime_get()` provides a millisecond representation of this time.

Applications often need to correlate the Zephyr internal time with external time scales used in daily life, such as local time or Coordinated Universal Time. These systems interpret time in different ways and may have discontinuities due to leap seconds and local time offsets like daylight saving time.

Because of these discontinuities, as well as significant inaccuracies in the clocks underlying the cycle counter, the offset between time estimated from the Zephyr clock and the actual time in a “real” civil time scale is not constant and can vary widely over the runtime of a Zephyr application.

The time utilities API supports:

- converting between time representations
- synchronizing and aligning time scales

For terminology and concepts that support these functions see *Concepts Underlying Time Support in Zephyr*. 

---

**Chapter 3. Kernel**
3.8.2 Time Utility APIs

Representation Transformation

Time scale instants can be represented in multiple ways including:

- Seconds since an epoch. POSIX representations of time in this form include `time_t` and `struct timespec`, which are generally interpreted as a representation of “UNIX Time”.
- Calendar time as a year, month, day, hour, minutes, and seconds relative to an epoch. POSIX representations of time in this form include `struct tm`.

Keep in mind that these are simply time representations that must be interpreted relative to a time scale which may be local time, UTC, or some other continuous or discontinuous scale.

Some necessary transformations are available in standard C library routines. For example, `time_t` measuring seconds since the POSIX EPOCH is converted to `struct tm` representing calendar time with `gmtime()`. Sub-second timestamps like `struct timespec` can also use this to produce the calendar time representation and deal with sub-second offsets separately.

The inverse transformation is not standardized: APIs like `mktime()` expect information about time zones. Zephyr provides this transformation with `timeutil_timegm()` and `timeutil_timegm64()`.

Functions

```c
int64_t timeutil_timegm64(const struct tm *tm)
Convert broken-down time to a POSIX epoch offset in seconds.
```

See also:

Parameters

- `tm` – pointer to broken down time.

Returns

the corresponding time in the POSIX epoch time scale.

```c
time_t timeutil_timegm(const struct tm *tm)
Convert broken-down time to a POSIX epoch offset in seconds.
```

See also:

Parameters

- `tm` – pointer to broken down time.

Returns

the corresponding time in the POSIX epoch time scale. If the time cannot be represented then (time_t)-1 is returned and `errno` is set to `ERANGE`.
Time Scale Synchronization

There are several factors that affect synchronizing time scales:

- The rate of discrete instant representation change. For example, Zephyr uptime is tracked in ticks which advance at events nominally occurring at CONFIG_SYS_CLOCK_TICKS_PER_SEC Hertz, while an external time source may provide data in whole or fractional seconds (e.g., microseconds).
- The absolute offset required to align the two scales at a single instant.
- The relative error between observable instants in each scale, required to align multiple instants consistently. For example, a reference clock that’s conditioned by a 1-pulse-per-second GPS signal will be much more accurate than a Zephyr system clock driven by a RC oscillator with a +/- 250 ppm error.

Synchronization or alignment between time scales is done with a multi-step process:

- An instant in a time scale is represented by an (unsigned) 64-bit integer, assumed to advance at a fixed nominal rate.
- `timeutil_sync_config` records the nominal rates of a reference time scale/source (e.g., TAI) and a local time source (e.g., `k_uptime_ticks()`).
- `timeutil_sync_instant` records the representation of a single instant in both the reference and local time scales.
- `timeutil_sync_state` provides storage for an initial instant, a recently received second observation, and a skew that can adjust for relative errors in the actual rate of each time scale.
- `timeutil_sync_ref_from_local()` and `timeutil_sync_local_from_ref()` convert instants in one time scale to another taking into account skew that can be estimated from the two instances stored in the state structure by `timeutil_sync_estimate_skew()`.

```c
int timeutil_sync_state_update(struct timeutil_sync_state *tsp, const struct timeutil_sync_instant *inst)
```

Record a new instant in the time synchronization state.

Note that this updates only the latest persisted instant. The skew is not adjusted automatically.

**Parameters**

- `tsp` – pointer to a `timeutil_sync_state` object.
- `inst` – the new instant to be recorded. This becomes the base instant if there is no base instant, otherwise the value must be strictly after the base instant in both the reference and local time scales.

**Return values**

- 0 – if installation succeeded in providing a new base
- 1 – if installation provided a new latest instant
- -EINVAL – if the new instant is not compatible with the base instant

```c
int timeutil_sync_state_set_skew(struct timeutil_sync_state *tsp, float skew, const struct timeutil_sync_instant *base)
```

Update the state with a new skew and possibly base value.

Set the skew from a value retrieved from persistent storage, or calculated based on recent skew estimations including from `timeutil_sync_estimate_skew()`.
Optionally update the base timestamp. If the base is replaced the latest instant will be cleared until `timeutil_sync_state_update()` is invoked.

**Parameters**

- `tsp` – pointer to a time synchronization state.
- `skew` – the skew to be used. The value must be positive and shouldn’t be too far away from 1.
- `base` – optional new base to be set. If provided this becomes the base timestamp that will be used along with skew to convert between reference and local timescale instants. Setting the base clears the captured latest value.

**Returns**

- 0 if skew was updated
- `-EINVAL` if skew was not valid

```c
float timeutil_sync_estimate_skew(const struct timeutil_sync_state *tsp)
```

Estimate the skew based on current state.

Using the base and latest syncpoints from the state determine the skew of the local clock relative to the reference clock. See `timeutil_sync_state::skew`.

**Parameters**

- `tsp` – pointer to a time synchronization state. The base and latest syncpoints must be present and the latest syncpoint must be after the base point in the local time scale.

**Returns**

- the estimated skew, or zero if skew could not be estimated.

```c
int timeutil_sync_ref_from_local(const struct timeutil_sync_state *tsp, uint64_t local, uint64_t *refp)
```

Interpolate a reference timescale instant from a local instant.

**Parameters**

- `tsp` – pointer to a time synchronization state. This must have a base and a skew installed.
- `local` – an instant measured in the local timescale. This may be before or after the base instant.
- `refp` – where the corresponding instant in the reference timescale should be stored. A negative interpolated reference time produces an error. If interpolation fails the referenced object is not modified.

**Return values**

- 0 – if interpolated using a skew of 1
- 1 – if interpolated using a skew not equal to 1
- `-EINVAL` – the times synchronization state is not adequately initialized
- `refp` is null
- `-ERANGE` – the interpolated reference time would be negative

```c
int timeutil_sync_local_from_ref(const struct timeutil_sync_state *tsp, uint64_t ref, int64_t *localp)
```

Interpolate a local timescale instant from a reference instant.

**Parameters**
• **tsp** – pointer to a time synchronization state. This must have a base and a skew installed.

• **ref** – an instant measured in the reference timescale. This may be before or after the base instant.

• **localp** – where the corresponding instant in the local timescale should be stored. An interpolated value before local time 0 is provided without error. If interpolation fails the referenced object is not modified.

**Return values**

• 0 – if successful with a skew of 1

• 1 – if successful with a skew not equal to 1

• -EINVAL –
  – the time synchronization state is not adequately initialized
  – refp is null

```c
int32_t timeutil_sync_skew_to_ppb(float skew)
```

Convert from a skew to an error in parts-per-billion.

A skew of 1.0 has zero error. A skew less than 1 has a positive error (clock is faster than it should be). A skew greater than one has a negative error (clock is slower than it should be).

Note that due to the limited precision of float compared with double the smallest error that can be represented is about 120 ppb. A “precise” time source may have error on the order of 2000 ppb.

A skew greater than 3.14748 may underflow the 32-bit representation; this represents a clock running at less than 1/3 its nominal rate.

**Returns**

skew error represented as parts-per-billion, or INT32_MIN if the skew cannot be represented in the return type.

```c
#include <timeutil.h>

struct timeutil_sync_config
```

Immutable state for synchronizing two clocks.

Values required to convert durations between two time scales.

**Note:** The accuracy of the translation and calculated skew between sources depends on the resolution of these frequencies. A reference frequency with microsecond or nanosecond resolution would produce the most accurate tracking when the local reference is the Zephyr tick counter. A reference source like an RTC chip with 1 Hz resolution requires a much larger interval between sampled instants to detect relative clock drift.

**Public Members**

```c
uint32_t ref_Hz
```

The nominal instance counter rate in Hz.

This value is assumed to be precise, but may drift depending on the reference clock source.

The value must be positive.
\textbf{uint32_t local\_Hz}

The nominal local counter rate in Hz.

This value is assumed to be inaccurate but reasonably stable. For a local clock driven by a crystal oscillator an error of 25 ppm is common; for an RC oscillator larger errors should be expected. The timeutil\_sync infrastructure can calculate the skew between the local and reference clocks and apply it when converting between time scales.

The value must be positive.

\textbf{struct timeutil\_sync\_instant}

\begin{lstlisting}
#include <timeutil.h> Representation of an instant in two time scales.
\end{lstlisting}

Capturing the same instant in two time scales provides a registration point that can be used to convert between those time scales.

\textbf{Public Members}

\begin{itemize}
  \item \textbf{uint64_t ref}
    An instant in the reference time scale.
    This must never be zero in an initialized timeutil\_sync\_instant object.
  \item \textbf{uint64_t local}
    The corresponding instance in the local time scale.
    This may be zero in a valid timeutil\_sync\_instant object.
\end{itemize}

\textbf{struct timeutil\_sync\_state}

\begin{lstlisting}
#include <timeutil.h> State required to convert instants between time scales.
\end{lstlisting}

This state in conjunction with functions that manipulate it capture the offset information necessary to convert between two timescales along with information that corrects for skew due to inaccuracies in clock rates.

State objects should be zero-initialized before use.

\textbf{Public Members}

\begin{itemize}
  \item \textbf{const struct timeutil\_sync\_config *cfg}
    Pointer to reference and local rate information.
  \item \textbf{struct timeutil\_sync\_instant base}
    The base instant in both time scales.
  \item \textbf{struct timeutil\_sync\_instant latest}
    The most recent instant in both time scales.
    This is captured here to provide data for skew calculation.
  \item \textbf{float skew}
    The scale factor used to correct for clock skew.
    The nominal rate for the local counter is assumed to be inaccurate but stable, i.e. it will generally be some parts-per-million faster or slower than specified.
\end{itemize}
A duration in observed local clock ticks must be multiplied by this value to produce a
duration in ticks of a clock operating at the nominal local rate.

A zero value indicates that the skew has not been initialized. If the value is zero when
`base` is initialized the skew will be set to 1. Otherwise the skew is assigned through
`timeutil_sync_state_set_skew()`.

### 3.8.3 Concepts Underlying Time Support in Zephyr

Terms from ISO/TC 154/WG 5 N0038 (ISO/WD 8601-1) and elsewhere:

- A **time axis** is a representation of time as an ordered sequence of instants.
- A **time scale** is a way of representing an instant relative to an origin that serves as the epoch.
- A time scale is **monotonic** (increasing) if the representation of successive time instants never
decreases in value.
- A time scale is **continuous** if the representation has no abrupt changes in value, e.g. jumping
forward or back when going between successive instants.
- **Civil time** generally refers to time scales that legally defined by civil authorities, like local govern-
ments, often to align local midnight to solar time.

#### Relevant Time Scales

**International Atomic Time** (TAI) is a time scale based on averaging clocks that count in SI seconds. TAI
is a monotonic and continuous time scale.

**Universal Time** (UT) is a time scale based on Earth's rotation. UT is a discontinuous time scale as it
requires occasional adjustments (leap seconds) to maintain alignment to changes in Earth's rotation.
Thus the difference between TAI and UT varies over time. There are several variants of UT, with UTC
being the most common.

UT times are independent of location. UT is the basis for Standard Time (or “local time”) which is the
time at a particular location. Standard time has a fixed offset from UT at any given instant, primarily
influenced by longitude, but the offset may be adjusted (“daylight saving time”) to align standard time
to the local solar time. In a sense local time is “more discontinuous” than UT.

**POSIX Time** is a time scale that counts seconds since the “POSIX epoch” at 1970-01-01T00:00:00Z
(i.e. the start of 1970 UTC). **UNIX Time** is an extension of POSIX time using negative values to rep-
resent times before the POSIX epoch. Both of these scales assume that every day has exactly 86400
seconds. In normal use instants in these scales correspond to times in the UTC scale, so they inherit the
discontinuity.

The continuous analogue is **UNIX Leap Time** which is UNIX time plus all leap-second corrections added
after the POSIX epoch (when TAI-UTC was 8 s).

**Example of Time Scale Differences** A positive leap second was introduced at the end of 2016, in-
creasing the difference between TAI and UTC from 36 seconds to 37 seconds. There was no leap second
introduced at the end of 1999, when the difference between TAI and UTC was only 32 seconds. The
following table shows relevant civil and epoch times in several scales:
### Functional Requirements

The Zephyr tick counter has no concept of leap seconds or standard time offsets and is a continuous time scale. However, it can be relatively inaccurate, with drifts as much as three minutes per hour (assuming an RC timer with 5% tolerance).

There are two stages required to support conversion between Zephyr time and common human time scales:

- Translation between the continuous but inaccurate Zephyr time scale and an accurate external stable time scale;
- Translation between the stable time scale and the (possibly discontinuous) civil time scale.

The API around `timeutil_sync_state_update()` supports the first step of converting between continuous time scales.

The second step requires external information including schedules of leap seconds and local time offset changes. This may be best provided by an external library, and is not currently part of the time utility APIs.

### Selecting an External Source and Time Scale

If an application requires civil time accuracy within several seconds then UTC could be used as the stable time source. However, if the external source adjusts to a leap second there will be a discontinuity: the elapsed time between two observations taken at 1 Hz is not equal to the numeric difference between their timestamps.

For precise activities a continuous scale that is independent of local and solar adjustments simplifies things considerably. Suitable continuous scales include:

- GPS time: epoch of 1980-01-06T00:00:00Z, continuous following TAI with an offset of TAI-GPS=19 s.
- Bluetooth mesh time: epoch of 2000-01-01T00:00:00Z, continuous following TAI with an offset of -32.
- UNIX Leap Time: epoch of 1970-01-01T00:00:00Z, continuous following TAI with an offset of -8.

Because C and Zephyr library functions support conversion between integral and calendar time representations using the UNIX epoch, UNIX Leap Time is an ideal choice for the external time scale.

The mechanism used to populate synchronization points is not relevant: it may involve reading from a local high-precision RTC peripheral, exchanging packets over a network using a protocol like NTP or PTP, or processing NMEA messages received a GPS with or without a 1pps signal.

### 3.9 Utilities

This page contains reference documentation for `<sys/util.h>`, which provides miscellaneous utility functions and macros.

`group sys-util`
Defines

POINTER_TO_UINT(x)
   Cast x, a pointer, to an unsigned integer.

UINT_TO_POINTER(x)
   Cast x, an unsigned integer, to a void*.

POINTER_TO_INT(x)
   Cast x, a pointer, to a signed integer.

INT_TO_POINTER(x)
   Cast x, a signed integer, to a void*.

BITS_PER_LONG
   Number of bits in a long int.

BITS_PER_LONG_LONG
   Number of bits in a long long int.

GENMASK(h, l)
   Create a contiguous bitmask starting at bit position l and ending at position h.

GENMASK64(h, l)
   Create a contiguous 64-bit bitmask starting at bit position l and ending at position h.

LSB_GET(value)
   Extract the Least Significant Bit from value.

FIELD_GET(mask, value)
   Extract a bitfield element from value corresponding to the field mask mask.

FIELD_PREP(mask, value)
   Prepare a bitfield element using value with mask representing its field position and width.
   The result should be combined with other fields using a logical OR.

ZERO_OR_COMPILE_ERROR(cond)
   0 if cond is true-ish; causes a compile error otherwise.

IS_ARRAY(array)
   Zero if array has an array type, a compile error otherwise.
   This macro is available only from C, not C++.

ARRAY_SIZE(array)
   Number of elements in the given array.
   In C++, due to language limitations, this will accept as array any type that implements operator[]. The results may not be particularly meaningful in this case.
   In C, passing a pointer as array causes a compile error.

IS_ARRAY_ELEMENT(array, ptr)
   Whether ptr is an element of array.
   This macro can be seen as a slightly stricter version of PART_OF_ARRAY in that it also ensures that ptr is aligned to an array-element boundary of array.
   In C, passing a pointer as array causes a compile error.

Parameters

• array – the array in question
• ptr – the pointer to check

**Returns**
1 if ptr is part of array, 0 otherwise

**ARRAY_INDEX** (array, ptr)
Index of ptr within array.
With CONFIG_ASSERT=y, this macro will trigger a runtime assertion when ptr does not fall into the range of array or when ptr is not aligned to an array-element boundary of array.
In C, passing a pointer as array causes a compile error.

**Parameters**
• array – the array in question
• ptr – pointer to an element of array

**Returns**
the array index of ptr within array, on success

**PART_OF_ARRAY** (array, ptr)
Check if a pointer ptr lies within array.
In C but not C++, this causes a compile error if array is not an array (e.g. if ptr and array are mixed up).

**Parameters**
• array – an array
• ptr – a pointer

**Returns**
1 if ptr is part of array, 0 otherwise

**ARRAY_INDEX_FLOOR** (array, ptr)
Array-index of ptr within array, rounded down.
This macro behaves much like **ARRAY_INDEX** with the notable difference that it accepts any ptr in the range of array rather than exclusively a ptr aligned to an array-element boundary of array.
With CONFIG_ASSERT=y, this macro will trigger a runtime assertion when ptr does not fall into the range of array.
In C, passing a pointer as array causes a compile error.

**Parameters**
• array – the array in question
• ptr – pointer to an element of array

**Returns**
the array index of ptr within array, on success

**SAME_TYPE** (a, b)
Validate if two entities have a compatible type.

**Parameters**
• a – the first entity to be compared
• b – the second entity to be compared

**Returns**
1 if the two elements are compatible, 0 if they are not
CONTAINER_OF_VALIDATE(ptr, type, field)
    Validate CONTAINER_OF parameters, only applies to C mode.

CONTAINER_OF(ptr, type, field)
    Get a pointer to a structure containing the element.

Example:

```c
struct foo {
    int bar;
};

struct foo my_foo;
int *ptr = &my_foo.bar;
struct foo *container = CONTAINER_OF(ptr, struct foo, bar);
```

Above, `container` points at `my_foo`.

**Parameters**
- ptr – pointer to a structure element
- type – name of the type that `ptr` is an element of
- field – the name of the field within the struct `ptr` points to

**Returns**
- a pointer to the structure that contains `ptr`

 ROUND_UP(x, align)
    Value of `x` rounded up to the next multiple of `align`.

 ROUND_DOWN(x, align)
    Value of `x` rounded down to the previous multiple of `align`.

 WB_UP(x)
    Value of `x` rounded up to the next word boundary.

 WB_DN(x)
    Value of `x` rounded down to the previous word boundary.

 DIV_ROUND_UP(n, d)
    Divide and round up.

Example:

```c
DIV_ROUND_UP(1, 2); // 1
DIV_ROUND_UP(3, 2); // 2
```

**Parameters**
- n – Numerator.
- d – Denominator.

**Returns**
- The result of `n / d`, rounded up.

 DIV_ROUND_CLOSEST(n, d)
    Divide and round to the nearest integer.

Example:
DIV_ROUND_CLOSEST(5, 2); // 3
DIV_ROUND_CLOSEST(5, -2); // -3
DIV_ROUND_CLOSEST(5, 3); // 2

**Parameters**
- \( n \) – Numerator.
- \( d \) – Denominator.

**Returns**
The result of \( n \div d \), rounded to the nearest integer.

**ceiling_fraction(numerator, divider)**
Ceiling function applied to \( \text{numerator} \div \text{divider} \) as a fraction.

*Deprecated:* Use **DIV_ROUND_UP()** instead.

**MAX(a, b)**
Obtain the maximum of two values.

*Note:* Arguments are evaluated twice. Use **Z_MAX** for a GCC-only, single evaluation version

**Parameters**
- \( a \) – First value.
- \( b \) – Second value.

**Returns**
Maximum value of \( a \) and \( b \).

**MIN(a, b)**
Obtain the minimum of two values.

*Note:* Arguments are evaluated twice. Use **Z_MIN** for a GCC-only, single evaluation version

**Parameters**
- \( a \) – First value.
- \( b \) – Second value.

**Returns**
Minimum value of \( a \) and \( b \).

**CLAMP(val, low, high)**
Clamp a value to a given range.

*Note:* Arguments are evaluated multiple times. Use **Z_CLAMP** for a GCC-only, single evaluation version

**Parameters**
- \( \text{val} \) – Value to be clamped.
• low – Lowest allowed value (inclusive).
• high – Highest allowed value (inclusive).

**Returns**
Clamped value.

**IN_RANGE(val, min, max)**
Checks if a value is within range.

**Note:** val is evaluated twice.

**Parameters**
• val – Value to be checked.
• min – Lower bound (inclusive).
• max – Upper bound (inclusive).

**Return values**
• true – If value is within range
• false – If the value is not within range

**LOG2(x)**
Compute log2(x)

**Note:** This macro expands its argument multiple times (to permit use in constant expressions), which must not have side effects.

**Parameters**
• x – An unsigned integral value to compute logarithm of (positive only)

**Returns**
log2(x) when 1 \( \leq x \leq \max(x) \), -1 when \( x < 1 \)

**LOG2CEIL(x)**
Compute ceil(log2(x))

**Note:** This macro expands its argument multiple times (to permit use in constant expressions), which must not have side effects.

**Parameters**
• x – An unsigned integral value

**Returns**
ceil(log2(x)) when 1 \( \leq x \leq \max(type(x)) \), 0 when \( x < 1 \)

**NHPOT(x)**
Compute next highest power of two.
Equivalent to \( 2^\uparrow \text{ceil}(\log2(x)) \)
**Note:** This macro expands its argument multiple times (to permit use in constant expressions), which must not have side effects.

### Parameters
- **x** – An unsigned integral value

### Returns
- $2^\lceil \log_2(x) \rceil$ or 0 if $2^\lceil \log_2(x) \rceil$ would saturate 64-bits

**KB**(x)
- Number of bytes in x kibibytes.

**MB**(x)
- Number of bytes in x mebibytes.

**GB**(x)
- Number of bytes in x gibibytes.

**KHZ**(x)
- Number of Hz in x kHz.

**MHZ**(x)
- Number of Hz in x MHz.

**WAIT_FOR**(expr, timeout, delay_stmt)
- Wait for an expression to return true with a timeout.
- Spin on an expression with a timeout and optional delay between iterations
- Commonly needed when waiting on hardware to complete an asynchronous request to read/write-initialize/reset, but useful for any expression.

**Parameters**
- **expr** – Truth expression upon which to poll, e.g.: XYZREG & XYZREG_EN
- **timeout** – Timeout to wait for in microseconds, e.g.: 1000 (1ms)
- **delay_stmt** – Delay statement to perform each poll iteration e.g.: NULL, k_yield(), k_msleep(1) or k_busy_wait(1)

**Return values**
- **expr** – As a boolean return, if false then it has timed out.

**BIT**(n)
- Unsigned integer with bit position n set (signed in assembly language).

**BIT64**( _n )
- 64-bit unsigned integer with bit position _n set.

**WRITE_BIT**(var, bit, set)
- Set or clear a bit depending on a boolean value.
- The argument var is a variable whose value is written to as a side effect.

**Parameters**
- **var** – Variable to be altered
- **bit** – Bit number
- **set** – if 0, clears bit in var; any other value sets bit
MS_TH㬊(n)
Bit mask with bits 0 through n-1 (inclusive) set, or 0 if n is 0.

BIT64_M/repository/n(n)
64-bit bit mask with bits 0 through n-1 (inclusive) set, or 0 if n is 0.

IS_POWER_OF_TWO(x)
Check if a x is a power of two.

IS_SHIFTED_BIT_MASK(m, s)
Check if bits are set continuously from the specified bit.

The macro is not dependent on the bit-width.

Parameters
• m – Check whether the bits are set continuously or not.
• s – Specify the lowest bit for that is continuously set bits.

IS_BIT_MASK(m)
Check if bits are set continuously from the LSB.

Parameters
• m – Check whether the bits are set continuously from LSB.

IS_ENABLED(config_macro)
Check for macro definition in compiler-visible expressions.

This trick was pioneered in Linux as the config_enabled() macro. It has the effect of taking a macro value that may be defined to “1” or may not be defined at all and turning it into a literal expression that can be handled by the C compiler instead of just the preprocessor. It is often used with a CONFIG_FOO macro which may be defined to 1 via Kconfig, or left undefined.

That is, it works similarly to #if defined(CONFIG_FOO) except that its expansion is a C expression. Thus, much #ifdef usage can be replaced with equivalents like:

```c
if (IS_ENABLED(CONFIG_FOO)) {
    do_something_with_foo
}
```

This is cleaner since the compiler can generate errors and warnings for do_something_with_foo even when CONFIG_FOO is undefined.

Note: Use of IS_ENABLED in a #if statement is discouraged as it doesn't provide any benefit vs plain #if defined()

Parameters
• config_macro – Macro to check

Returns
1 if config_macro is defined to 1, 0 otherwise (including if config_macro is not defined)

COND_CODE_1(_flag, _if_1_code, _else_code)
Insert code depending on whether _flag expands to 1 or not.

This relies on similar tricks as IS Enabled(), but as the result of _flag expansion, results in either _if_1_code or _else_code is expanded.

To prevent the preprocessor from treating commas as argument separators, the _if_1_code and _else_code expressions must be inside brackets/parentheses: ( ). These are stripped away during macro expansion.

Example:
If `CONFIG_FLAG` is defined to 1, this expands to:

```c
uint32_t x;
```

It expands to `there_is_no_flag();` otherwise.

This could be used as an alternative to:

```c
#if defined(CONFIG_FLAG) && (CONFIG_FLAG == 1)
#define MAYBE_DECLARE(x) uint32_t x
#else
#define MAYBE_DECLARE(x) there_is_no_flag()
#endif
MAYBE_DECLARE(x);
```

However, the advantage of `COND_CODE_1()` is that code is resolved in place where it is used, while the `#if` method defines `MAYBE_DECLARE` on two lines and requires it to be invoked again on a separate line. This makes `COND_CODE_1()` more concise and also sometimes more useful when used within another macro's expansion.

**Note:** `_flag` can be the result of preprocessor expansion, e.g. an expression involving `NUM_VA_ARGS_LESS_1(...)`. However, `_if_1_code` is only expanded if `_flag` expands to the integer literal 1. Integer expressions that evaluate to 1, e.g. after doing some arithmetic, will not work.

**Parameters**

- `_flag` – evaluated flag
- `_if_1_code` – result if `_flag` expands to 1; must be in parentheses
- `_else_code` – result otherwise; must be in parentheses

`COND_CODE_0(_flag, _if_0_code, _else_code)`

Like `COND_CODE_1()` except tests if `_flag` is 0.

This is like `COND_CODE_1()`, except that it tests whether `_flag` expands to the integer literal 0. It expands to `_if_0_code` if so, and `_else_code` otherwise; both of these must be enclosed in parentheses.

**See also:**

`COND_CODE_1()`

**Parameters**

- `_flag` – evaluated flag
- `_if_0_code` – result if `_flag` expands to 0; must be in parentheses
- `_else_code` – result otherwise; must be in parentheses

`IF_ENABLED(_flag, _code)`

Insert code if `_flag` is defined and equals 1.

Like `COND_CODE_1()`, this expands to `_code` if `_flag` is defined to 1; it expands to nothing otherwise.
IF_ENABLED(CONFIG_FLAG, (uint32_t foo;))

If CONFIG_FLAG is defined to 1, this expands to:

uint32_t foo;

and to nothing otherwise.

It can be considered as a more compact alternative to:

```c
#if defined(CONFIG_FLAG) && (CONFIG_FLAG == 1)
uint32_t foo;
#endif
```

**Parameters**

- `_flag` – evaluated flag
- `_code` – result if `_flag` expands to 1; must be in parentheses

**IS_EMPTY(...)**

Check if a macro has a replacement expression.

If a is a macro defined to a nonempty value, this will return true, otherwise it will return false. It only works with defined macros, so an additional #ifdef test may be needed in some cases.

This macro may be used with `COND_CODE_1()` and `COND_CODE_0()` while processing `__VA_ARGS__` to avoid processing empty arguments.

Example:

```c
#define EMPTY
#define NON_EMPTY 1
#undef UNDEFINED
IS_EMPTY(EMPTY)
IS_EMPTY(NON_EMPTY)
IS_EMPTY(UNDEFINED)
#if defined(EMPTY) && IS_EMPTY(EMPTY) == true
some_conditional_code
#endif
```

In above examples, the invocations of `IS_EMPTY(...)` return true, false, and true; `some_conditional_code` is included.

**Parameters**

- `...` – macro to check for emptiness (may be `__VA_ARGS__`)

**IS_EQ(a, b)**

Like `a == b`, but does evaluation and short-circuiting at C preprocessor time.

This however only works for integer literal from 0 to 255.

**LIST_DROP_EMPTY(...)**

Remove empty arguments from list.

During macro expansion, `__VA_ARGS__` and other preprocessor generated lists may contain empty elements, e.g.:

```c
#define LIST ,a,b,,d,
```

Using EMPTY to show each empty element, LIST contains:
When processing such lists, e.g. using \texttt{FOR\_EACH()}, all empty elements will be processed, and may require filtering out. To make that process easier, it is enough to invoke \texttt{LIST\_DROP\_EMPTY} which will remove all empty elements.

Example:

\begin{verbatim}
LIST\_DROP\_EMPTY(LIST)
\end{verbatim}

expands to:

\begin{verbatim}
a, b, d
\end{verbatim}

\textbf{Parameters}

- \ldots{} – list to be processed

\texttt{EMPTY}

Macro with an empty expansion.

This trivial definition is provided for readability when a macro should expand to an empty result, which e.g. is sometimes needed to silence checkpatch.

Example:

\begin{verbatim}
#define LIST\_ITEM(n) , item\#n
\end{verbatim}

The above would cause checkpatch to complain, but:

\begin{verbatim}
#define LIST\_ITEM(n) EMPTY, item\#n
\end{verbatim}

would not.

\texttt{IDENTITY(V)}

Macro that expands to its argument.

This is useful in macros like \texttt{FOR\_EACH()} when there is no transformation required on the list elements.

\textbf{Parameters}

- \(V\) – any value

\texttt{GET\_ARG\_N(N, \ldots{} )}

Get n\textsuperscript{th} argument from argument list.

\textbf{Parameters}

- \(N\) – Argument index to fetch. Counter from 1.
- \ldots{} – Variable list of arguments from which one argument is returned.

\textbf{Returns}

N\textsuperscript{th} argument.

\texttt{GET\_ARGS\_LESS\_N(N, \ldots{} )}

Strips n first arguments from the argument list.

\textbf{Parameters}

- \(N\) – Number of arguments to discard.
- \ldots{} – Variable list of arguments.
**Returns**

argument list without N first arguments.

`UTIL_OR(a, b)`

Like `a || b`, but does evaluation and short-circuiting at C preprocessor time.

This is not the same as the binary `||` operator; in particular, `a` should expand to an integer literal 0 or 1. However, `b` can be any value.

This can be useful when `b` is an expression that would cause a build error when `a` is 1.

`UTIL_AND(a, b)`

Like `a && b`, but does evaluation and short-circuiting at C preprocessor time.

This is not the same as the binary `&&`, however; in particular, `a` should expand to an integer literal 0 or 1. However, `b` can be any value.

This can be useful when `b` is an expression that would cause a build error when `a` is 0.

`UTIL_INC(x)`

`UTIL_INC(x)` for an integer literal `x` from 0 to 255 expands to an integer literal whose value is `x+1`.

**See also:**

`UTIL_DEC(x)`

`UTIL_DEC(x)` for an integer literal `x` from 0 to 255 expands to an integer literal whose value is `x-1`.

**See also:**

`UTIL_INC(x)`

`UTIL_X2(y)`

`UTIL_X2(y)` for an integer literal `y` from 0 to 255 expands to an integer literal whose value is `2y`.

`LISTIFY(LEN, F, sep, ...)`

Generates a sequence of code with configurable separator.

Example:

```c
#define FOO(i, _) MY_PWM ## i
{ LISTIFY(PWM_COUNT, FOO, (,)) }
```

The above two lines expand to:

```c
{ MY_PWM0 , MY_PWM1 }
```

**Note:** Calling `LISTIFY` with undefined arguments has undefined behavior.

**Parameters**

- **LEN** – The length of the sequence. Must be an integer literal less than 255.
- **F** – A macro function that accepts at least two arguments: `F(i, ...)`. `F` is called repeatedly in the expansion. Its first argument `i` is the index in the sequence, and the variable list of arguments passed to `LISTIFY` are passed through to `F`. 

• `sep` – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.

**FOR_EACH**(`F, sep, ...`)

Call a macro `F` on each provided argument with a given separator between each call.

Example:

```c
#define F(x) int a##x
FOR_EACH(F, (;), 4, 5, 6);
```

This expands to:

```c
int a4;
int a5;
int a6;
```

**Parameters**

- `F` – Macro to invoke
- `sep` – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- `...` – Variable argument list. The macro `F` is invoked as `F(element)` for each element in the list.

**FOR_EACH_NONEMPTY_TERM**(`F, term, ...`)

Like **FOR_EACH()**, but with a terminator instead of a separator, and drops empty elements from the argument list.

The `sep` argument to **FOR_EACH**(`F, (sep), a, b`) is a separator which is placed between calls to `F`, like this:

```c
FOR_EACH(F, (sep), a, b) // F(a) sep F(b)
```

By contrast, the `term` argument to **FOR_EACH_NONEMPTY_TERM**(`F, (term), a, b`) is added after each time `F` appears in the expansion:

```c
FOR_EACH_NONEMPTY_TERM(F, (term), a, b) // F(a) term F(b) term
```

Further, any empty elements are dropped:

```c
FOR_EACH_NONEMPTY_TERM(F, (term), a, EMPTY, b) // F(a) term F(b) term
```

This is more convenient in some cases, because **FOR_EACH_NONEMPTY_TERM()** expands to nothing when given an empty argument list, and it’s often cumbersome to write a macro `F` that does the right thing even when given an empty argument.

One example is when `__VA_ARGS__` may or may not be empty, and the results are embedded in a larger initializer:

```c
#define SQUARE(x) ((x)*(x))
int my_array[] = {
    FOR_EACH_NONEMPTY_TERM(SQUARE, (,), FOO(...))
    FOR_EACH_NONEMPTY_TERM(SQUARE, (,), BAR(...))
    FOR_EACH_NONEMPTY_TERM(SQUARE, (,), BAZ(...))
};
```
This is more convenient than:

a. figuring out whether the FOO, BAR, and BAZ expansions are empty and adding a comma manually (or not) between \texttt{FOR\_EACH()} calls

b. rewriting SQUARE so it reacts appropriately when “x” is empty (which would be necessary if e.g. FOO expands to nothing)

Parameters

\begin{itemize}
  \item \texttt{F} – Macro to invoke on each nonempty element of the variable arguments
  \item \texttt{term} – Terminator (e.g. comma or semicolon) placed after each invocation of \texttt{F}. Must be in parentheses; this is required to enable providing a comma as separator.
  \item \ldots – Variable argument list. The macro \texttt{F} is invoked as \texttt{F(element)} for each nonempty element in the list.
\end{itemize}

\texttt{FOR\_EACH\_IDX(F, sep, ...)}

Call macro \texttt{F} on each provided argument, with the argument's index as an additional parameter.

This is like \texttt{FOR\_EACH()}, except \texttt{F} should be a macro which takes two arguments: \texttt{F(index, variable\_arg)}.

Example:

\begin{verbatim}
#define F(idx, x) int a##idx = x
FOR_EACH_IDX(F, (;), 4, 5, 6);
\end{verbatim}

This expands to:

\begin{verbatim}
int a0 = 4;
int a1 = 5;
int a2 = 6;
\end{verbatim}

Parameters

\begin{itemize}
  \item \texttt{F} – Macro to invoke
  \item \texttt{sep} – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
  \item \ldots – Variable argument list. The macro \texttt{F} is invoked as \texttt{F(index, element)} for each element in the list.
\end{itemize}

\texttt{FOR\_EACH\_FIXED\_ARG(F, sep, fixed\_arg, ...)}

Call macro \texttt{F} on each provided argument, with an additional fixed argument as a parameter.

This is like \texttt{FOR\_EACH()}, except \texttt{F} should be a macro which takes two arguments: \texttt{F(variable\_arg, fixed\_arg)}.

Example:

\begin{verbatim}
static void func(int val, void *dev);
FOR_EACH_FIXED_ARG(func, (;), dev, 4, 5, 6);
\end{verbatim}

This expands to:
func(4, dev);
func(5, dev);
func(6, dev);

Parameters

- `F` – Macro to invoke
- `sep` – Separator (e.g. comma or semicolon). Must be in parentheses; this is required to enable providing a comma as separator.
- `fixed_arg` – Fixed argument passed to `F` as the second macro parameter.
- `...` – Variable argument list. The macro `F` is invoked as `F(element, fixed_arg)` for each element in the list.

```
FOR_EACH_IDX_FIXED_ARG(F, sep, fixed_arg, ...)
```

Calls macro `F` for each variable argument with an index and fixed argument.

This is like the combination of `FOR_EACH_IDX()` with `FOR_EACH_FIXED_ARG()`.

Example:

```
#define F(idx, x, fixed_arg) int fixed_arg##idx = x
FOR_EACH_IDX_FIXED_ARG(F, (;), a, 4, 5, 6);
```

This expands to:

```
int a0 = 4;
int a1 = 5;
int a2 = 6;
```

Parameters

- `F` – Macro to invoke
- `sep` – Separator (e.g. comma or semicolon). Must be in parentheses; This is required to enable providing a comma as separator.
- `fixed_arg` – Fixed argument passed to `F` as the third macro parameter.
- `...` – Variable list of arguments. The macro `F` is invoked as `F(index, element, fixed_arg)` for each element in the list.

```
REVERSE_ARGS(...)
```

Reverse arguments order.

Parameters

- `...` – Variable argument list.

```
NUM_VA_ARGS_LESS_1(...)
```

Number of arguments in the variable arguments list minus one.

Parameters

- `...` – List of arguments

Returns

Number of variadic arguments in the argument list, minus one
MACRO_MAP_CAT(...)  
Mapping macro that pastes results together.  
This is similar to \textit{FOR\_EACH()} in that it invokes a macro repeatedly on each element of \_\_VA\_VARGS\_\_. However, unlike \textit{FOR\_EACH()}, \textit{MACRO\_MAP\_CAT()} pastes the results together into a single token.  
For example, with this macro FOO:  

```
# define FOO(x) item_##x##_
```

\textit{MACRO\_MAP\_CAT(FOO, a, b, c)}, expands to the token:  
```
item_a_item_b_item_c_
```

\textbf{Parameters}  
• ... – Macro to expand on each argument, followed by its arguments. (The macro should take exactly one argument.)  

\textbf{Returns}  
The results of expanding the macro on each argument, all pasted together

MACRO_MAP_CAT\_N(N, ...)  
Mapping macro that pastes a fixed number of results together.  
Similar to \textit{MACRO\_MAP\_CAT()}, but expects a fixed number of arguments. If more arguments are given than are expected, the rest are ignored.  

\textbf{Parameters}  
• \textbf{N} – Number of arguments to map  
• ... – Macro to expand on each argument, followed by its arguments. (The macro should take exactly one argument.)  

\textbf{Returns}  
The results of expanding the macro on each argument, all pasted together

\textbf{Functions}  
\texttt{static inline bool is\_power\_of\_two(unsigned int x)}  
Is \textit{x} a power of two?  

\textbf{Parameters}  
• \textbf{x} – value to check  

\textbf{Returns}  
true if \textit{x} is a power of two, false otherwise

\texttt{static inline int64\_t arithmetic\_shift\_right(int64\_t value, uint8\_t shift)}  
Arithmetic shift right.  

\textbf{Parameters}  
• \textbf{value} – value to shift  
• \textbf{shift} – number of bits to shift  

\textbf{Returns}  
value shifted right by \textit{shift}; opened bit positions are filled with the sign bit
static inline void bytecpy(void *dst, const void *src, size_t size)
byte by byte memcpy.
Copy size bytes of src into dest. This is guaranteed to be done byte by byte.

Parameters
- dst – Pointer to the destination memory.
- src – Pointer to the source of the data.
- size – The number of bytes to copy.

static inline void byteswp(void *a, void *b, size_t size)
byte by byte swap.
Swap size bytes between memory regions a and b. This is guaranteed to be done byte by byte.

Parameters
- a – Pointer to the the first memory region.
- b – Pointer to the the second memory region.
- size – The number of bytes to swap.

int char2hex(char c, uint8_t *x)
Convert a single character into a hexadecimal nibble.

Parameters
- c – The character to convert
- x – The address of storage for the converted number.

Returns
- Zero on success or (negative) error code otherwise.

int hex2char(uint8_t x, char *c)
Convert a single hexadecimal nibble into a character.

Parameters
- c – The number to convert
- x – The address of storage for the converted character.

Returns
- Zero on success or (negative) error code otherwise.

size_t bin2hex(const uint8_t *buf, size_t buflen, char *hex, size_t hexlen)
Convert a binary array into string representation.

Parameters
- buf – The binary array to convert
- buflen – The length of the binary array to convert
- hex – Address of where to store the string representation.
- hexlen – Size of the storage area for string representation.

Returns
- The length of the converted string, or 0 if an error occurred.

size_t hex2bin(const char *hex, size_t hexlen, uint8_t *buf, size_t buflen)
Convert a hexadecimal string into a binary array.

Parameters
- hex – The hexadecimal string to convert
• hexlen – The length of the hexadecimal string to convert.
• buf – Address of where to store the binary data
• buflen – Size of the storage area for binary data

Returns
The length of the binary array, or 0 if an error occurred.

static inline uint8_t bcd2bin(uint8_t bcd)
Convert a binary coded decimal (BCD 8421) value to binary.

Parameters
• bcd – BCD 8421 value to convert.

Returns
Binary representation of input value.

static inline uint8_t bin2bcd(uint8_t bin)
Convert a binary value to binary coded decimal (BCD 8421).

Parameters
• bin – Binary value to convert.

Returns
BCD 8421 representation of input value.

uint8_t u8_to_dec(char *buf, uint8_t buflen, uint8_t value)
Convert a uint8_t into a decimal string representation. The string is terminated
if there is enough space in buf.

Parameters
• buf – Address of where to store the string representation.
• buflen – Size of the storage area for string representation.
• value – The value to convert to decimal string

Returns
The length of the converted string (excluding terminator if any), or 0 if an error
occurred.

char *utf8_trunc(char *utf8_str)
Properly truncate a NULL-terminated UTF-8 string.
Take a NULL-terminated UTF-8 string and ensure that if the string has been truncated (by
setting the NULL terminator) earlier by other means, that the string ends with a properly
formatted UTF-8 character (1-4 bytes).

Parameters
• utf8_str – NULL-terminated string

Returns
Pointer to the utf8_str

char *utf8_lcpy(char *dst, const char *src, size_t n)
Copies a UTF-8 encoded string from src to dst.
The resulting dst will always be NULL terminated if n is larger than 0, and the dst string will
always be properly UTF-8 truncated.

Parameters
• dst – The destination of the UTF-8 string.
• src – The source string
• n – The size of the dst buffer. Maximum number of characters copied is n - 1.
  If 0 nothing will be done, and the dst will not be NULL terminated.

Returns
Pointer to the dst

3.10  Iterable Sections

This page contains the reference documentation for the iterable sections APIs, which can be
used for defining iterable areas of equally-sized data structures, that can be iterated on using
STRUCT_SECTION_FOREACH.

3.10.1  Usage

Iterable section elements are typically used by defining the data structure and associated initializer in a
common header file, so that they can be instantiated anywhere in the code base.

```c
struct my_data {
    int a, b;
};

#define DEFINE_DATA(name, _a, _b) \
    STRUCT_SECTION_ITERABLE(my_data, name) = { \
        .a = _a, \
        .b = _b, \
    }

... 
DEFINE_DATA(d1, 1, 2);
DEFINE_DATA(d2, 3, 4);
DEFINE_DATA(d3, 5, 6);
```

Then the linker has to be setup to place the place the structure in a contiguous segment using one of the
linker macros such as ITERABLE_SECTION_RAM or ITERABLE_SECTION_ROM. Custom linker snippets are
normally declared using one of the zephyr_linker_sources() CMake functions, using the appropriate
section identifier, DATA_SECTIONS for RAM structures and SECTIONS for ROM ones.

```c
# CMakeLists.txt
zephyr_linker_sources(DATA_SECTIONS iterables.ld)
```

```c
# iterables.ld
ITERABLE_SECTION_RAM(my_data, 4)
```

The data can then be accessed using STRUCT_SECTION_FOREACH.

```c
STRUCT_SECTION_FOREACH(my_data, data) {
    printk("%p: a: %d, b: %d\n", data, data->a, data->b);
}
```

Note: The linker is going to place the entries sorted by name, so the example above would visit d1, d2
and d3 in that order, regardless of how they were defined in the code.
3.10.2 API Reference

*group iterable_section_apis*

Iterable Sections APIs.

**Defines**

**ITERABLE_SECTION_ROM (struct_type, subalign)**
Define a read-only iterable section output.
Define an output section which will set up an iterable area of equally-sized data structures. For use with `STRUCT_SECTION_ITERABLE()`. Input sections will be sorted by name, per ld's `SORT_BY_NAME`.
This macro should be used for read-only data.
Note that this keeps the symbols in the image even though they are not being directly referenced. Use this when symbols are indirectly referenced by iterating through the section.

**ITERABLE_SECTION_ROM_NUMERIC (struct_type, subalign)**
Define a read-only iterable section output, sorted numerically.
This version of `ITERABLE_SECTION_ROM()` sorts the entries numerically, that is, `SECNAME_10` will come after `SECNAME_2`. _ separator is required, and up to 2 numeric digits are handled (0-99).

**See also:**

`ITERABLE_SECTION_ROM()`

**ITERABLE_SECTION_ROM_GC_ALLOWED (struct_type, subalign)**
Define a garbage collectable read-only iterable section output.
Define an output section which will set up an iterable area of equally-sized data structures. For use with `STRUCT_SECTION_ITERABLE()`. Input sections will be sorted by name, per ld's `SORT_BY_NAME`.
This macro should be used for read-only data.
Note that the symbols within the section can be garbage collected.

**ITERABLE_SECTION_RAM (struct_type, subalign)**
Define a read-write iterable section output.
Define an output section which will set up an iterable area of equally-sized data structures. For use with `STRUCT_SECTION_ITERABLE()`. Input sections will be sorted by name, per ld's `SORT_BY_NAME`.
This macro should be used for read-write data that is modified at runtime.
Note that this keeps the symbols in the image even though they are not being directly referenced. Use this when symbols are indirectly referenced by iterating through the section.

**ITERABLE_SECTION_RAM_NUMERIC (struct_type, subalign)**
Define a read-write iterable section output, sorted numerically.
This version of `ITERABLE_SECTION_RAM()` sorts the entries numerically, that is, `SECNAME10` will come after `SECNAME2`. Up to 2 numeric digits are handled (0-99).

**See also:**

`ITERABLE_SECTION_RAM()`
ITERABLE_SECTION_RAM_GC_ALLOWED(struct_type, subalign)

Define a garbage collectable read-write iterable section output.

Define an output section which will set up an iterable area of equally-sized data structures. For use with STRUCT_SECTION_ITERABLE(). Input sections will be sorted by name, per ld’s SORT_BY_NAME.

This macro should be used for read-write data that is modified at runtime.

Note that the symbols within the section can be garbage collected.

TYPE_SECTION_ITERABLE(type, varname, secname, section_postfix)

Defines a new element for an iterable section for a generic type.

Convenience helper combining __in_section() and Z_DECL_ALIGN(). The section name will be ‘.[SECNAME].static.[SECTION_POSTFIX]’

In the linker script, create output sections for these using ITERABLE_SECTION_ROM() or ITERABLE_SECTION_RAM().

Note: In order to store the element in ROM, a const specifier has to be added to the declaration: const TYPE_SECTION_ITERABLE(…);

Parameters

- type – [in] data type of variable
- varname – [in] name of variable to place in section
- section_postfix – [in] postfix to use in section name

TYPE_SECTION_START(secname)

iterable section start symbol for a generic type will return ‘.[OUT_TYPE]_list_start’.

Parameters

- secname – [in] type name of iterable section. For ‘struct foobar’ this would be TYPE_SECTION_START(foobar)

TYPE_SECTION_END(secname)

iterable section end symbol for a generic type will return ‘.<SECNAME>_list_end’.

Parameters

- secname – [in] type name of iterable section. For ‘struct foobar’ this would be TYPE_SECTION_START(foobar)

TYPE_SECTION_START_EXTERN(type, secname)

iterable section extern for start symbol for a generic type

Helper macro to give extern for start of iterable section. The macro typically will be called TYPE_SECTION_START_EXTERN(struct foobar, foobar). This allows the macro to hand different types as well as cases where the type and section name may differ.

Parameters

- type – [in] data type of section
- secname – [in] name of output section

3.10. Iterable Sections
TYPE_SECTION_END_EXTERN(type, secname)
   iterable section extern for end symbol for a generic type

Helper macro to give extern for end of iterable section. The macro typically will be called
TYPE_SECTION_END_EXTERN(struct foobar, foobar). This allows the macro to hand different
types as well as cases where the type and section name may differ.

Parameters
   • type – [in] data type of section
   • secname – [in] name of output section

TYPE_SECTION_FOREACH(type, secname, iterator)
   Iterate over a specified iterable section for a generic type.

   Iterator for structure instances gathered by TYPE_SECTION_ITERABLE(). The linker must
   provide a _<SECNAME>_list_start symbol and a _<SECNAME>_list_end symbol to mark
   the start and the end of the list of struct objects to iterate over. This is normally done using
   ITERABLE_SECTION_ROM() or ITERABLE_SECTION_RAM() in the linker script.

TYPE_SECTION_GET(type, secname, i, dst)
   Get element from section for a generic type.

   Note: There is no protection against reading beyond the section.

Parameters
   • type – [in] type of element
   • secname – [in] name of output section
   • i – [in] Index.
   • dst – [out] Pointer to location where pointer to element is written.

TYPE_SECTION_COUNT(type, secname, dst)
   Count elements in a section for a generic type.

Parameters
   • type – [in] type of element
   • secname – [in] name of output section
   • dst – [out] Pointer to location where result is written.

STRUCT_SECTION_START(struct_type)
   iterable section start symbol for a struct type

Parameters
   • struct_type – [in] data type of section

STRUCT_SECTION_START_EXTERN(struct_type)
   iterable section extern for start symbol for a struct

Helper macro to give extern for start of iterable section.

Parameters
   • struct_type – [in] data type of section
**STRUCT_SECTION_END**(struct_type)

iterable section end symbol for a struct type

**Parameters**

- struct_type – [in] data type of section

**STRUCT_SECTION_END_EXTERN**(struct_type)

iterable section extern for end symbol for a struct

Helper macro to give extern for end of iterable section.

**Parameters**

- struct_type – [in] data type of section

**STRUCT_SECTION_ITERABLE_ALTERNATE**(secname, struct_type, varname)

Defines a new element of alternate data type for an iterable section.

Special variant of **STRUCT_SECTION_ITERABLE()**, for placing alternate data types within the iterable section of a specific data type. The data type sizes and semantics must be equivalent!

**STRUCT_SECTION_ITERABLE_ARRAY_ALTERNATE**(secname, struct_type, varname, size)

Defines an array of elements of alternate data type for an iterable section.

**See also:**

**STRUCT_SECTION_ITERABLE_ALTERNATE**

**STRUCT_SECTION_ITERABLE**(struct_type, varname)

Defines a new element for an iterable section.

Convenience helper combining __in_section() and Z_DECL_ALIGN(). The section name is the struct type prepended with an underscore. The subsection is “static” and the subsubsection is the variable name.

In the linker script, create output sections for these using **ITERABLE_SECTION_ROM()** or **ITERABLE_SECTION_RAM()**.

**Note:** In order to store the element in ROM, a const specifier has to be added to the declaration: const **STRUCT_SECTION_ITERABLE**(…);

**STRUCT_SECTION_ITERABLE_ARRAY**(struct_type, varname, size)

Defines an array of elements for an iterable section.

**See also:**

**STRUCT_SECTION_ITERABLE**

**STRUCT_SECTION_ITERABLE_NAMED**(struct_type, name, varname)

Defines a new element for an iterable section with a custom name.

The name can be used to customize how iterable section entries are sorted.

**See also:**

**STRUCT_SECTION_ITERABLE()**

**STRUCT_SECTION_FOREACH_ALTERNATE**(secname, struct_type, iterator)

Iterate over a specified iterable section (alternate).

Iterator for structure instances gathered by **STRUCT_SECTION_ITERABLE()**. The linker must provide a _<SECNAME>_list_start symbol and a _<SECNAME>_list_end symbol to mark
the start and the end of the list of struct objects to iterate over. This is normally done using
ITERABLE_SECTION_ROM() or ITERABLE_SECTION_RAM() in the linker script.

```
STRUCT_SECTION_FOREACH(struct_type, iterator)
Iterate over a specified iterable section.
```

```
Iterator for structure instances gathered by STRUCT_SECTION_ITERABLE(). The linker must
provide a _<struct_type>_list_start symbol and a _<struct_type>_list_end symbol to mark
the start and the end of the list of struct objects to iterate over. This is normally done using
ITERABLE_SECTION_ROM() or ITERABLE_SECTION_RAM() in the linker script.
```

```
STRUCT_SECTION_GET(struct_type, i, dst)
Get element from section.
```

**Note:** There is no protection against reading beyond the section.

```
STRUCT_SECTION_COUNT(struct_type, dst)
Count elements in a section.
```

**Parameters**
- i -- [in] Index.
- dst -- [out] Pointer to location where pointer to element is written.

```
3.11 Code And Data Relocation
```

### 3.11.1 Overview

This feature will allow relocating .text, .rodata, .data, and .bss sections from required files and
place them in the required memory region. The memory region and file are given to the
scripts/build/gen_relocate_app.py script in the form of a string. This script is always invoked from in-
side cmake.

This script provides a robust way to re-order the memory contents without actually having to modify the
code. In simple terms this script will do the job of __attribute__((section("name"))) for a bunch of
files together.

### 3.11.2 Details

The memory region and file are given to the scripts/build/gen_relocate_app.py script in the form of a
string.

An example of such a string is: SRAM2:/home/xyz/zephyr/samples/hello_world/src/main.c, SRAM1:/home/xyz/zephyr/samples/hello_world/src/main2.c

This script is invoked with the following parameters: python3 gen_relocate_app.py -i
input_string -o generated_linker -c generated_code

Kconfig CONFIG_CODE_DATA_RELOCATION option, when enabled in prj.conf, will invoke the script and
do the required relocation.
This script also trigger the generation of linker_relocate.ld and code_relocation.c files. The linker_relocate.ld file creates appropriate sections and links the required functions or variables from all the selected files.

**Note:** The text section is split into 2 parts in the main linker script. The first section will have some info regarding vector tables and other debug related info. The second section will have the complete text section. This is needed to force the required functions and data variables to the correct locations. This is due to the behavior of the linker. The linker will only link once and hence this text section had to be split to make room for the generated linker script.

The code_relocation.c file has code that is needed for initializing data sections, and a copy of the text sections (if XIP). Also this contains code needed for bss zeroing and for data copy operations from ROM to required memory type.

**The procedure to invoke this feature is:**

- Enable `CONFIG_CODE_DATA_RELOCATION` in the `prj.conf` file
- Inside the CMakeLists.txt file in the project, mention all the files that need relocation.

  ```
  zephyr_code_relocate(FILES src/*.c LOCATION SRAM2)
  ```

  Where the first argument is the file/files and the second argument is the memory where it must be placed.

  **Note:** function `zephyr_code_relocate()` can be called as many times as required.

**Additional Configurations**

This section shows additional configuration options that can be set in CMakeLists.txt

- if the memory is SRAM1, SRAM2, CCD, or AON, then place the full object in the sections for example:

  ```
  zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2)
  zephyr_code_relocate(FILES src/file2.c LOCATION SRAM)
  ```

- if the memory type is appended with _DATA, _TEXT, _RODATA or _BSS, only the selected memory is placed in the required memory region. for example:

  ```
  zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2_DATA)
  zephyr_code_relocate(FILES src/file2.c LOCATION SRAM2_TEXT)
  ```

- Multiple regions can also be appended together such as: SRAM2_DATA_BSS. This will place data and bss inside SRAM2.

- Multiple files can be passed to the FILES argument, or CMake generator expressions can be used to relocate a comma-separated list of files:

  ```
  file(GLOB sources "file*.c")
  zephyr_code_relocate(FILES ${sources} LOCATION SRAM)
  zephyr_code_relocate(FILES ${<TARGET_PROPERTY:my_tgt,SOURCES>} LOCATION SRAM)
  ```

**NOCOPY flag**

When a NOCOPY option is passed to the `zephyr_code_relocate()` function, the relocation code is not generated in code_relocation.c. This flag can be used when we want to move the content of a specific file (or set of files) to a XIP area.
This example will place the .text section of the xip_external_flash.c file to the EXTFLASH memory region where it will be executed from (XIP). The .data will be relocated as usual into SRAM.

```c
zephyr_code_relocate(FILES src/xip_external_flash.c LOCATION EXTFLASH_TEXT
˓→NOCOPY)
zephyr_code_relocate(FILES src/xip_external_flash.c LOCATION SRAM_DATA)
```

### Relocating libraries

Libraries can be relocated using the LIBRARY argument to `zephyr_code_relocation()` with the library name. For example, the following snippet will relocate kernel code to ITCM and serial drivers to SRAM2:

```c
zephyr_code_relocate(LIBRARY kernel LOCATION ITCM_TEXT)
zephyr_code_relocate(LIBRARY drivers__serial LOCATION SRAM2)
```

### Samples/ Tests

A test showcasing this feature is provided at `$ZEPHYR_BASE/tests/application_development/code_relocation`

This test shows how the code relocation feature is used.

This test will place .text, .data, .bss from 3 files to various parts in the SRAM using a custom linker file derived from `include/zephyr/arch/arm/cortex_m/scripts/linker.ld`

A sample showcasing the NOCOPY flag is provided at `$ZEPHYR_BASE/samples/application_development/code_relocation_nocopy/`
Chapter 4

OS Services

4.1 Binary Descriptors

Binary Descriptors are constant data objects storing information about the binary executable. Unlike “regular” constants, binary descriptors are linked to a known offset in the binary, making them accessible to other programs, such as a different image running on the same device or a host tool. A few examples of constants that would make useful binary descriptors are: kernel version, app version, build time, compiler version, environment variables, compiling host name, etc.

Binary descriptors are created by using the DEFINE_BINDESC_* macros. For example:

```c
#include <zephyr/bindesc.h>

BINDESC_STR_DEFINE(my_string, 2, "Hello world!"); // Unique ID is 2
```

`my_string` could then be accessed using:

```c
printk("my_string: \%s\n", BINDESC_GET_STR(my_string));
```

But it could also be retrieved by `west bindesc`:

```
$ west bindesc custom_search STR 2 build/zephyr/zephyr.bin
"Hello world!"
```

4.1.1 Internals

Binary descriptors are implemented with a TLV (tag, length, value) header linked to a known offset in the binary image. This offset may vary between architectures, but generally the descriptors are linked as close to the beginning of the image as possible. In architectures where the image must begin with a vector table (such as ARM), the descriptors are linked right after the vector table. The reset vector points to the beginning of the text section, which is after the descriptors. In architectures where the image must begin with executable code (e.g. x86), a jump instruction is injected at the beginning of the image, in order to skip over the binary descriptors, which are right after the jump instruction.

Each tag is a 16 bit unsigned integer, where the most significant nibble (4 bits) is the type (currently uint, string or bytes), and the rest is the ID. The ID is globally unique to each descriptor. For example, the ID of the app version string is 0x800, and a string is denoted by 0x1, making the app version tag 0x1800. The length is a 16 bit number equal to the length of the data in bytes. The data is the actual descriptor value. All binary descriptor numbers (magic, tags, uints) are laid out in memory in the endianness native to the SoC. `west bindesc` assumes little endian by default, so if the image belongs to a big endian SoC, the appropriate flag should be given to the tool.
The binary descriptor header starts with the magic number 0xb9863e5a7ea46046. It’s followed by the TLVs, and ends with the DESCRIPTORS_END (0xffff) tag. The tags are always aligned to 32 bits. If the value of the previous descriptor had a non-aligned length, zero padding will be added to ensure that the current tag is aligned.

Putting it all together, here is what the example above would look like in memory (of a little endian SoC):

```
46 60 a4 7e 5a 3e 86 b9 02 10 0d 00 48 65 6c 6c 6f 20 77 6f 72 6c 64 21 00 00 00 | magic | tag | length| Hello world! | pad 
| end |
```

### 4.1.2 Usage

Binary descriptors are always created by the BINDESC_*_DEFINE macros. As shown in the example above, a descriptor can be generated from any string or integer, with any ID. However, it is recommended to comply with the standard tags defined in include/zephyr/bindesc.h, as that would have the following benefits:

1. The west bindesc tool would be able to recognize what the descriptor means and print a meaningful tag
2. It would enforce consistency between various apps from various sources
3. It allows upstream-ability of descriptor generation (see Standard Descriptors)

To define a descriptor with a standard tag, just use the tags included from bindesc.h:

```c
#include <zephyr/bindesc.h>

BINDESC_STR_DEFINE(app_version, BINDESC_ID_APP_VERSION_STRING, "1.2.3");
```

### Standard Descriptors

Some descriptors might be trivial to implement, and could therefore be implemented in a standard way in upstream Zephyr. These could then be enabled via Kconfig, instead of requiring every user to reimplement them. These include build times, kernel version, and host info. For example, to add the build date and time as a string, the following configs should be enabled:

```c
# Enable binary descriptors
CONFIG_BINDESC=y

# Enable definition of binary descriptors
CONFIG_BINDESC_DEFINE=y

# Enable default build time binary descriptors
CONFIG_BINDESC_DEFINE_BUILD_TIME=y
CONFIG_BINDESC_BUILD_DATE_TIME_STRING=y
```

To avoid collisions with user defined descriptors, the standard descriptors were allotted the range between 0x800-0xfff. This leaves 0x000-0x7ff to users. For more information read the help sections of these Kconfig symbols. By convention, each Kconfig symbol corresponds to a binary descriptor whose name is the Kconfig name (with CONFIG_BINDESC_ removed) in lower case. For example, CONFIG_BINDESC_KERNEL_VERSION_STRING creates a descriptor that can be accessed using BINDESC_GET_STR(kernel_version_string).
west bindesc tool

west is able to parse and display binary descriptors from a given executable image. For more information refer to west bindesc --help or the documentation.

4.1.3 API Reference

group bindesc_define

Binary Descriptor Definition.

Defines

BINDESC_ID_APP_VERSION_STRING
The app version string such as “1.2.3”.

BINDESC_ID_APP_VERSION_MAJOR
The app version major such as 1.

BINDESC_ID_APP_VERSION_MINOR
The app version minor such as 2.

BINDESC_ID_APP_VERSION_PATCHLEVEL
The app version patchlevel such as 3.

BINDESC_ID_APP_VERSION_NUMBER
The app version number such as 0x10203.

BINDESC_ID_KERNEL_VERSION_STRING
The kernel version string such as “3.4.0”.

BINDESC_ID_KERNEL_VERSION_MAJOR
The kernel version major such as 3.

BINDESC_ID_KERNEL_VERSION_MINOR
The kernel version minor such as 4.

BINDESC_ID_KERNEL_VERSION_PATCHLEVEL
The kernel version patchlevel such as 0.

BINDESC_ID_KERNEL_VERSION_NUMBER
The kernel version number such as 0x30400.
BINDESC_ID_BUILD_TIME_YEAR
The year the image was compiled in.

BINDESC_ID_BUILD_TIME_MONTH
The month of the year the image was compiled in.

BINDESC_ID_BUILD_TIME_DAY
The day of the month the image was compiled in.

BINDESC_ID_BUILD_TIME_HOUR
The hour of the day the image was compiled in.

BINDESC_ID_BUILD_TIME_MINUTE
The minute the image was compiled in.

BINDESC_ID_BUILD_TIME_SECOND
The second the image was compiled in.

BINDESC_ID_BUILD_TIME_UNIX
The UNIX time (seconds since midnight of 1970/01/01) the image was compiled in.

BINDESC_ID_BUILD_DATE_TIME_STRING
The date and time of compilation such as “2023/02/05 00:07:04”.

BINDESC_ID_BUILD_DATE_STRING
The date of compilation such as “2023/02/05”.

BINDESC_ID_BUILD_TIME_STRING
The time of compilation such as “00:07:04”.

BINDESC_ID_HOST_NAME
The name of the host that compiled the image.

BINDESC_ID_C_COMPILER_NAME
The C compiler name.

BINDESC_ID_C_COMPILER_VERSION
The C compiler version.

BINDESC_ID_CXX_COMPILER_NAME
The C++ compiler name.

BINDESC_ID_CXX_COMPILER_VERSION
The C++ compiler version.
BINDESC_STR_DEFINE(name, id, value)
Define a binary descriptor of type string.
Define a string that is registered in the binary descriptor header. The defined string can be accessed using BINDESC_GET_STR

**Note:** The defined string is not static, so its name must not collide with any other symbol in the executable.

**Parameters**
- **name** – Name of the descriptor
- **id** – Unique ID of the descriptor
- **value** – A string value for the descriptor

BINDESC_UINT_DEFINE(name, id, value)
Define a binary descriptor of type uint.
Define an integer that is registered in the binary descriptor header. The defined integer can be accessed using BINDESC_GET_UINT

**Note:** The defined integer is not static, so its name must not collide with any other symbol in the executable.

**Parameters**
- **name** – Name of the descriptor
- **id** – Unique ID of the descriptor
- **value** – An integer value for the descriptor

BINDESC_BYTES_DEFINE(name, id, value)
Define a binary descriptor of type bytes.
Define a uint8_t array that is registered in the binary descriptor header. The defined array can be accessed using BINDESC_GET_BYTES. The value should be given as an array literal, wrapped in parentheses, for example:

```
BINDESC_BYTES_DEFINE(name, id, ({1, 2, 3, 4}));
```

**Note:** The defined array is not static, so its name must not collide with any other symbol in the executable.

**Parameters**
- **name** – Name of the descriptor
- **id** – Unique ID of the descriptor
- **value** – A uint8_t array as data for the descriptor

BINDESC_GET_STR(name)
Get the value of a string binary descriptor.
Get the value of a string binary descriptor, previously defined by BINDESC_STR_DEFINE.
Parameters

- name – Name of the descriptor

BINDESC_GET_UINT(name)

Get the value of a uint binary descriptor.

Get the value of a uint binary descriptor, previously defined by BINDESC_UINT_DEFINE.

Parameters

- name – Name of the descriptor

BINDESC_GET_BYTES(name)

Get the value of a bytes binary descriptor.

Get the value of a string binary descriptor, previously defined by BINDESC_BYTES_DEFINE. The returned value can be accessed as an array:

```c
for (size_t i = 0; i < BINDESC_GET_SIZE(name); i++)
    BINDESC_GET_BYTES(name)[i];
```

Parameters

- name – Name of the descriptor

BINDESC_GET_SIZE(name)

Get the size of a binary descriptor.

Get the size of a binary descriptor. This is particularly useful for bytes binary descriptors where there's no null terminator.

Parameters

- name – Name of the descriptor

4.2 Cryptography

The crypto section contains information regarding the cryptographic primitives supported by the Zephyr kernel. Use the information to understand the principles behind the operation of the different algorithms and how they were implemented.

The following crypto libraries have been included:

4.2.1 TinyCrypt Cryptographic Library

Overview

The TinyCrypt Library provides an implementation for targeting constrained devices with a minimal set of standard cryptography primitives, as listed below. To better serve applications targeting constrained devices, TinyCrypt implementations differ from the standard specifications (see the Important Remarks section for some important differences). Certain cryptographic primitives depend on other primitives, as mentioned in the list below.

Aside from the Important Remarks section below, valuable information on the usage, security and technicalities of each cryptographic primitive are found in the corresponding header file.

- SHA-256:
  - Type of primitive: Hash function.
• HMAC-SHA256:
  – Type of primitive: Message authentication code.
  – Requires: SHA-256

• HMAC-PRNG:
  – Type of primitive: Pseudo-random number generator.
  – Standard Specification: NIST SP 800-90A.
  – Requires: SHA-256 and HMAC-SHA256.

• AES-128:
  – Type of primitive: Block cipher.
  – Requires: –

• AES-CBC mode:
  – Type of primitive: Encryption mode of operation.
  – Standard Specification: NIST SP 800-38A.
  – Requires: AES-128.

• AES-CTR mode:
  – Type of primitive: Encryption mode of operation.
  – Standard Specification: NIST SP 800-38A.
  – Requires: AES-128.

• AES-CMAC mode:
  – Type of primitive: Message authentication code.
  – Standard Specification: NIST SP 800-38B.
  – Requires: AES-128.

• AES-CCM mode:
  – Type of primitive: Authenticated encryption.
  – Standard Specification: NIST SP 800-38C.
  – Requires: AES-128.

• ECC-DH:
  – Type of primitive: Key exchange.
  – Requires: ECC auxiliary functions (ecc.h/c).

• ECC-DSA:
  – Type of primitive: Digital signature.
  – Requires: ECC auxiliary functions (ecc.h/c).
Design Goals

- Minimize the code size of each cryptographic primitive. This means minimize the size of a board-independent implementation, as presented in TinyCrypt. Note that various applications may require further features, optimizations with respect to other metrics and countermeasures for particular threats. These peculiarities would increase the code size and thus are not considered here.

- Minimize the dependencies among the cryptographic primitives. This means that it is unnecessary to build and allocate object code for more primitives than the ones strictly required by the intended application. In other words, one can select and compile only the primitives required by the application.

Important Remarks

The cryptographic implementations in TinyCrypt library have some limitations. Some of these limitations are inherent to the cryptographic primitives themselves, while others are specific to TinyCrypt. Some of these limitations are discussed in-depth below.

General Remarks

- TinyCrypt does not intend to be fully side-channel resistant. Due to the variety of side-channel attacks, many of them making certain boards vulnerable. In this sense, instead of penalizing all library users with side-channel countermeasures such as increasing the overall code size, TinyCrypt only implements certain generic timing-attack countermeasures.

Specific Remarks

- SHA-256:
  - The number of bits_hashed in the state is not checked for overflow. Note however that this will only be a problem if you intend to hash more than $2^{64}$ bits, which is an extremely large window.

- HMAC:
  - The HMAC verification process is assumed to be performed by the application. This compares the computed tag with some given tag. Note that conventional memory-comparison methods (such as memcmp function) might be vulnerable to timing attacks; thus be sure to use a constant-time memory comparison function (such as compare_constant_time function provided in lib/utils.c).

- HMAC-PRNG:
  - Before using HMAC-PRNG, you must find an entropy source to produce a seed. PRNGs only stretch the seed into a seemingly random output of arbitrary length. The security of the output is exactly equal to the unpredictability of the seed.
  - NIST SP 800-90A requires three items as seed material in the initialization step: entropy seed, personalization and a nonce (which is not implemented). TinyCrypt requires the personalization byte array and automatically creates the entropy seed using a mandatory call to the re-seed function.

- AES-128:
  - The current implementation does not support other key-lengths (such as 256 bits). Note that if you need AES-256, it doesn’t sound as though your application is running in a constrained environment. AES-256 requires keys twice the size as for AES-128, and the key schedule is 40% larger.

- CTR mode:
The AES-CTR mode limits the size of a data message they encrypt to \(2^{32}\) blocks. If you need to encrypt larger data sets, your application would need to replace the key after \(2^{32}\) block encryptions.

- **CBC mode:**
  - TinyCrypt CBC decryption assumes that the iv and the ciphertext are contiguous (as produced by TinyCrypt CBC encryption). This allows for a very efficient decryption algorithm that would not otherwise be possible.

- **CMAC mode:**
  - AES128-CMAC mode of operation offers 64 bits of security against collision attacks. Note however that an external attacker cannot generate the tags him/herself without knowing the MAC key. In this sense, to attack the collision property of AES128-CMAC, an external attacker would need the cooperation of the legal user to produce an exponentially high number of tags (e.g. \(2^{64}\)) to finally be able to look for collisions and benefit from them. As an extra precaution, the current implementation allows to at most \(2^{48}\) calls to `tc_cmac_update` function before re-calling `tc_cmac_setup` (allowing a new key to be set), as suggested in Appendix B of SP 800-38B.

- **CCM mode:**
  - There are a few tradeoffs for the selection of the parameters of CCM mode. In special, there is a tradeoff between the maximum number of invocations of CCM under a given key and the maximum payload length for those invocations. Both things are related to the parameter ‘q’ of CCM mode. The maximum number of invocations of CCM under a given key is determined by the nonce size, which is: \(15-q\) bytes. The maximum payload length for those invocations is defined as \(2^{8q}\) bytes.

  To achieve minimal code size, TinyCrypt CCM implementation fixes \(q = 2\), which is a quite reasonable choice for constrained applications. The implications of this choice are:

  The nonce size is: 13 bytes.

  The maximum payload length is: \(2^{16}\) bytes = 65 KB.

  The mac size parameter is an important parameter to estimate the security against collision attacks (that aim at finding different messages that produce the same authentication tag). TinyCrypt CCM implementation accepts any even integer between 4 and 16, as suggested in SP 800-38C.

  - TinyCrypt CCM implementation accepts associated data of any length between 0 and \((2^{16} - 2^{8}) = 65280\) bytes.

  - TinyCrypt CCM implementation accepts:
    * Both non-empty payload and associated data (it encrypts and authenticates the payload and only authenticates the associated data);
    * Non-empty payload and empty associated data (it encrypts and authenticates the payload);
    * Non-empty associated data and empty payload (it degenerates to an authentication-only mode on the associated data).

  - RFC-3610, which also specifies CCM, presents a few relevant security suggestions, such as: it is recommended for most applications to use a mac size greater than 8. Besides, it is emphasized that the usage of the same nonce for two different messages which are encrypted with the same key obviously destroys the security properties of CCM mode.

- **ECC-DH and ECC-DSA:**
  - TinyCrypt ECC implementation is based on nano-ecc (see https://github.com/iSECPartners/nano-ecc) which in turn is based on micro-ecc (see https://github.com/kmackay/micro-ecc).

    In the original nano and micro-ecc documentation, there is an important remark about the way integers are represented:
“Integer representation: To reduce code size, all large integers are represented using little-endian words - so the least significant word is first. You can use the ‘ecc_bytes2native()’ and ‘ecc_native2bytes()’ functions to convert between the native integer representation and the standardized octet representation.”

Examples of Applications

It is possible to do useful cryptography with only the given small set of primitives. With this list of primitives it becomes feasible to support a range of cryptography usages:

- Measurement of code, data structures, and other digital artifacts (SHA256);
- Generate commitments (SHA256);
- Construct keys (HMAC-SHA256);
- Extract entropy from strings containing some randomness (HMAC-SHA256);
- Construct random mappings (HMAC-SHA256);
- Construct nonces and challenges (HMAC-PRNG);
- Authenticate using a shared secret (HMAC-SHA256);
- Create an authenticated, replay-protected session (HMAC-SHA256 + HMAC-PRNG);
- Authenticated encryption (AES-128 + AES-CCM);
- Key-exchange (EC-DH);
- Digital signature (EC-DSA);

Test Vectors

The library provides a test program for each cryptographic primitive (see ‘test’ folder). Besides illustrating how to use the primitives, these tests evaluate the correctness of the implementations by checking the results against well-known publicly validated test vectors.

For the case of the HMAC-PRNG, due to the necessity of performing an extensive battery test to produce meaningful conclusions, we suggest the user to evaluate the unpredictability of the implementation by using the NIST Statistical Test Suite (see References).

For the case of the EC-DH and EC-DSA implementations, most of the test vectors were obtained from the site of the NIST Cryptographic Algorithm Validation Program (CAVP), see References.

4.2.2 Random Number Generation

The random API subsystem provides random number generation APIs in both cryptographically and non-cryptographically secure instances. Which random API to use is based on the cryptographic requirements of the random number. The non-cryptographic APIs will return random values much faster if non-cryptographic values are needed.

The cryptographically secure random functions shall be compliant to the FIPS 140-2 [?] recommended algorithms. Hardware based random-number generators (RNG) can be used on platforms with appropriate hardware support. Platforms without hardware RNG support shall use the CTR-DRBG algorithm. The algorithm can be provided by TinyCrypt or mbedTLS depending on your application performance and resource requirements.

**Note:** The CTR-DRBG generator needs an entropy source to establish and maintain the cryptographic security of the PRNG.

Kconfig Options

These options can be found in the following path `subsys/random/Kconfig`.

**CONFIG_TEST_RANDOM_GENERATOR**

For testing, this option allows a non-random number generator to be used and permits random number APIs to return values that are not truly random.

The random number generator choice group allows selection of the RNG source function for the system via the RNG_GENERATOR_CHOICE choice group. An override of the default value can be specified in the SOC or board .defconfig file by using:

```
choice RNG_GENERATOR_CHOICE
    default XOSHIRO_RANDOM_GENERATOR
endchoice
```

The random number generators available include:

- **CONFIG_TIMER_RANDOM_GENERATOR**
  
  enables number generator based on system timer clock. This number generator is not random and used for testing only.

- **CONFIG_ENTROPY_DEVICE_RANDOM_GENERATOR**
  
  enables a random number generator that uses the enabled hardware entropy gathering driver to generate random numbers.

- **CONFIG_XOSHIRO_RANDOM_GENERATOR**
  
  enables the Xoshiro128++ pseudo-random number generator, that uses the entropy driver as a seed source.

The CSPRNG_GENERATOR_CHOICE choice group provides selection of the cryptographically secure random number generator source function. An override of the default value can be specified in the SOC or board .defconfig file by using:

```
choice CSPRNG_GENERATOR_CHOICE
    default CTR_DRBG_CSPRNG_GENERATOR
endchoice
```

The cryptographically secure random number generators available include:

- **CONFIG_HARDWARE_DEVICE_CS_GENERATOR**
  
  enables a cryptographically secure random number generator using the hardware random generator driver
CONFIG_CTR_DRBG_CSPRNG_GENERATOR
   enables the CTR-DRBG pseudo-random number generator. The CTR-DRBG is a FIPS140-2 recom-
mended cryptographically secure random number generator.

Personalization data can be provided in addition to the entropy source to make the initialization of the
CTR-DRBG as unique as possible.

CONFIG_CS_CTR_DRBG_PERSONALIZATION
   CTR-DRBG Initialization Personalization string

API Reference

Related code samples
   • AWS IoT Core MQTT - Connect to AWS IoT Core and publish messages using MQTT.
   • Microsoft Azure IoT Hub MQTT - Connect to Azure IoT Hub and publish messages using MQTT.

random_api
   Random Function APIs.

Functions

uint32_t sys_rand32_get(void)
   Return a 32-bit random value that should pass general randomness tests.

   Note: The random value returned is not a cryptographically secure random number value.

   Returns
   32-bit random value.

void sys_rand_get(void *dst, size_t len)
   Fill the destination buffer with random data values that should pass general randomness tests.

   Note: The random values returned are not considered cryptographically secure random number values.

Parameters
   • dst – [out] destination buffer to fill with random data.
   • len – size of the destination buffer.

int sys_csrand_get(void *dst, size_t len)
   Fill the destination buffer with cryptographically secure random data values.

   Note: If the random values requested do not need to be cryptographically secure then use
   sys_rand_get() instead.

Parameters
   • dst – [out] destination buffer to fill.
• `len` – size of the destination buffer.

**Returns**

0 if success, -EIO if entropy reseed error

### 4.2.3 Crypto APIs

**Overview**

**API Reference**

**Generic API for crypto drivers**

**Related code samples**

- Crypto - Use the crypto APIs to perform various encryption/decryption operations.

```group crypto
Crypto APIs.
```

**Defines**

- `CAP_OPAQUE_KEY_HNDL`
- `CAP_RAW_KEY`
- `CAP_KEY_LOADING_API`
- `CAP_INPLACE_OPS`
  - Whether the output is placed in separate buffer or not.
- `CAP_SEPARATE_IO_BUFS`
- `CAP_SYNC_OPS`
  - These denotes if the output (completion of a cipher_xxx_op) is conveyed by the op function returning, or it is conveyed by an async notification.
- `CAP_ASYNC_OPS`
- `CAP_AUTONONCE`
  - Whether the hardware/driver supports autononce feature.
- `CAP_NO_IV_PREFIX`
  - Don’t prefix IV to cipher blocks.

**Functions**
static inline int crypto_query_hwcaps(const struct device *dev)

Query the crypto hardware capabilities.

This API is used by the app to query the capabilities supported by the crypto device. Based on
this the app can specify a subset of the supported options to be honored for a session during
cipher_begin_session().

Parameters

• dev – Pointer to the device structure for the driver instance.

Returns

bitmask of supported options.

struct crypto_driver_api

#include <crypto.h> Crypto driver API definition.

Ciphers API

group crypto_cipher

Crypto Cipher APIs.

Typedefs

typedef int (*block_op_t)(struct cipher_ctx *ctx, struct cipher_pkt *pkt)

typedef int (*cbc_op_t)(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *iv)

typedef int (*ctr_op_t)(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *ctr)

typedef int (*ccm_op_t)(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)

typedef int (*gcm_op_t)(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)

typedef void (*cipher_completion_cb)(struct cipher_pkt *completed, int status)

Enums

enum cipher_algo

Cipher Algorithm.

Values:

enumerator CRYPTO_CIPHER_ALGO_AES = 1

enum cipher_op

Cipher Operation.

Values:

equenumerator CRYPTO_CIPHER_OP_DECRYPT = 0
enumerator CRYPTO_CIPHER_OP_ENCRYPT = 1

enum cipher_mode
  Possible cipher mode options.
  More to be added as required.
  Values:

enumerator CRYPTO_CIPHER_MODE_ECB = 1
enumerator CRYPTO_CIPHER_MODE_CBC = 2
enumerator CRYPTO_CIPHER_MODE_CTR = 3
enumerator CRYPTO_CIPHER_MODE_CCM = 4
enumerator CRYPTO_CIPHER_MODE_GCM = 5

Functions

static inline int cipher_begin_session(const struct device *dev, struct cipher_ctx *ctx, enum cipher_algo algo, enum cipher_mode mode, enum cipher_op optype)

  Setup a crypto session.
  Initializes one time parameters, like the session key, algorithm and cipher mode which may remain constant for all operations in the session. The state may be cached in hardware and/or driver data state variables.

Parameters
  • dev – Pointer to the device structure for the driver instance.
  • ctx – Pointer to the context structure. Various one time parameters like key, keylength, etc. are supplied via this structure. The structure documentation specifies which fields are to be populated by the app before making this call.
  • algo – The crypto algorithm to be used in this session. e.g AES
  • mode – The cipher mode to be used in this session. e.g CBC, CTR
  • optype – Whether we should encrypt or decrypt in this session

Returns
  0 on success, negative errno code on fail.

static inline int cipher_free_session(const struct device *dev, struct cipher_ctx *ctx)

  Cleanup a crypto session.
  Clears the hardware and/or driver state of a previous session.

Parameters
  • dev – Pointer to the device structure for the driver instance.
  • ctx – Pointer to the crypto context structure of the session to be freed.

Returns
  0 on success, negative errno code on fail.
static inline int cipher_callback_set(const struct device *dev, cipher_completion_cb cb)
Registers an async crypto op completion callback with the driver.

The application can register an async crypto op completion callback handler to be invoked by
the driver, on completion of a prior request submitted via cipher_do_op(). Based on crypto
device hardware semantics, this is likely to be invoked from an ISR context.

**Parameters**
- `dev` – Pointer to the device structure for the driver instance.
- `cb` – Pointer to application callback to be called by the driver.

**Returns**
0 on success, -ENOTSUP if the driver does not support async op, negative errno
code on other error.

static inline int cipher_block_op(struct cipher_ctx *ctx, struct cipher_pkt *pkt)
Perform single-block crypto operation (ECB cipher mode).

This should not be overloaded to operate on multiple blocks for security reasons.

**Parameters**
- `ctx` – Pointer to the crypto context of this op.
- `pkt` – Structure holding the input/output buffer pointers.

**Returns**
0 on success, negative errno code on fail.

static inline int cipher_cbc_op(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *iv)
Perform Cipher Block Chaining (CBC) crypto operation.

**Parameters**
- `ctx` – Pointer to the crypto context of this op.
- `pkt` – Structure holding the input/output buffer pointers.
- `iv` – Initialization Vector (IV) for the operation. Same IV value should not be
  reused across multiple operations (within a session context) for security.

**Returns**
0 on success, negative errno code on fail.

static inline int cipher_ctr_op(struct cipher_ctx *ctx, struct cipher_pkt *pkt, uint8_t *iv)
Perform Counter (CTR) mode crypto operation.

**Parameters**
- `ctx` – Pointer to the crypto context of this op.
- `pkt` – Structure holding the input/output buffer pointers.
- `iv` – Initialization Vector (IV) for the operation. We use a split counter formed
  by appending IV and ctr. Consequently ivlen = keylen - ctrlen. ‘ctrlen’ is spec-
  ified during session setup through the ‘ctx.mode_params ctr_params.ctr_len’
  parameter. IV should not be reused across multiple operations (within a ses-
  sion context) for security. The non-IV part of the split counter is transparent to
  the caller and is fully managed by the crypto provider.

**Returns**
0 on success, negative errno code on fail.

static inline int cipher_ccm_op(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)
Perform Counter with CBC-MAC (CCM) mode crypto operation.

622 Chapter 4. OS Services
Zephyr Project Documentation, Release 3.5.0-rc1

Parameters

- **ctx** – Pointer to the crypto context of this op.
- **pkt** – Structure holding the input/output, Associated Data (AD) and auth tag buffer pointers.
- **nonce** – Nonce for the operation. Same nonce value should not be reused across multiple operations (within a session context) for security.

Returns

- 0 on success, negative errno code on fail.

```c
static inline int cipher_gcm_op(struct cipher_ctx *ctx, struct cipher_aead_pkt *pkt, uint8_t *nonce)
```

Perform Galois/Counter Mode (GCM) crypto operation.

Parameters

- **ctx** – Pointer to the crypto context of this op.
- **pkt** – Structure holding the input/output, Associated Data (AD) and auth tag buffer pointers.
- **nonce** – Nonce for the operation. Same nonce value should not be reused across multiple operations (within a session context) for security.

Returns

- 0 on success, negative errno code on fail.

```c
struct cipher_ops

#include <cipher.h>
```

```c
struct ccm_params

#include <cipher.h>
```

```c
struct ctr_params

#include <cipher.h>
```

```c
struct gcm_params

#include <cipher.h>
```

```c
struct cipher_ctx

#include <cipher.h> Structure encoding session parameters.
```

Refer to comments for individual fields to know the contract in terms of who fills what and when w.r.t begin_session() call.

Public Members

```c
struct cipher_ops ops

Place for driver to return function pointers to be invoked per cipher operation.
```

To be populated by crypto driver on return from begin_session() based on the algo/mode chosen by the app.

```c
union cipher_ctx.[anonymous] key

To be populated by the app before calling begin_session()
```
const struct device *device
The device driver instance this crypto context relates to.
Will be populated by the begin_session() API.

void *drv_sessn_state
If the driver supports multiple simultaneously crypto sessions, this will identify the specific
driver state this crypto session relates to.
Since dynamic memory allocation is not possible, it is suggested that at build time drivers
allocate space for the max simultaneous sessions they intend to support. To be populated
by the driver on return from begin_session().

void *app_sessn_state
Place for the user app to put info relevant stuff for resuming when completion callback
happens for async ops.
Totally managed by the app.

union cipher_ctx.[anonymous] mode_params
Cypher mode parameters, which remain constant for all ops in a session.
To be populated by the app before calling begin_session().

uint16_t keylen
Cryptographic keylength in bytes.
To be populated by the app before calling begin_session()

uint16_t flags
How certain fields are to be interpreted for this session.
(A bitmask of CAP_* below.) To be populated by the app before calling be-
gin_session(). An app can obtain the capability flags supported by a hw/driver by calling
crypto_query_hwcaps().

struct cipher_pkt
#include <cipher.h> Structure encoding IO parameters of one cryptographic operation like
encrypt/decrypt.
The fields which has not been explicitly called out has to be filled up by the app before making
the cipher_xxx_op() call.

Public Members

unsigned char *in_buf
Start address of input buffer.

int in_len
Bytes to be operated upon.

unsigned char *out_buf
Start of the output buffer, to be allocated by the application.
Can be NULL for in-place ops. To be populated with contents by the driver on return from
op / async callback.
int out_buf_max
  Size of the out_buf area allocated by the application.
  Drivers should not write past the size of output buffer.

int out_len
  To be populated by driver on return from cipher_xxx_op() and holds the size of the actual
  result.

struct cipher_ctx *ctx
  Context this packet relates to.
  This can be useful to get the session details, especially for async ops. Will be populated
  by the cipher_xxx_op() API based on the ctx parameter.

struct cipher_aead_pkt
  #include <cipher.h> Structure encoding IO parameters in AEAD (Authenticated Encryption
  with Associated Data) scenario like in CCM.
  App has to furnish valid contents prior to making cipher_ccm_op() call.

Public Members

uint8_t *ad
  Start address for Associated Data.
  This has to be supplied by app.

uint32_t ad_len
  Size of Associated Data.
  This has to be supplied by the app.

uint8_t *tag
  Start address for the auth hash.
  For an encryption op this will be populated by the driver when it returns from ci-
  pher_ccm_op call. For a decryption op this has to be supplied by the app.

4.3 Debugging

4.3.1 Thread analyzer

The thread analyzer module enables all the Zephyr options required to track the thread information, e.g.
thread stack size usage and other runtime thread runtime statistics.

The analysis is performed on demand when the application calls thread_analyzer_run() or
thread_analyzer_print().

For example, to build the synchronization sample with Thread Analyser enabled, do the following:

```
w west build -b qemu_x86 samples/synchronization/ -- -DCONFIG_QEMU_ICOUNT=n -
  -DCONFIG_THREAD_ANALYZER=y \
  -DCONFIG_THREAD_ANALYZER_USE_PRINTK=y -DCONFIG_THREAD_ANALYZER_AUTO=y \
  -DCONFIG_THREAD_ANALYZER_AUTO_INTERVAL=5
```
When you run the generated application in Qemu, you will get the additional information from Thread Analyzer:

```
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
  thread_b : STACK: unused 740 usage 284 / 1024 (27 %); CPU: 0 %
  thread_analyzer : STACK: unused 8 usage 504 / 512 (98 %); CPU: 0 %
  thread_a : STACK: unused 648 usage 376 / 1024 (36 %); CPU: 98 %
  idle : STACK: unused 204 usage 116 / 320 (36 %); CPU: 0 %
```

```

API documentation

**group thread_analyzer**

Module for analyzing threads.

This module implements functions and the configuration that simplifies thread analysis.

**Typedefs**

typedef void (*thread_analyzer_cb)(struct thread_analyzer_info *info)

Thread analyzer stack size callback function.

Callback function with thread analysis information.

**Param info**

Thread analysis information.

**Functions**

void thread_analyzer_run(thread_analyzer_cb cb)

Run the thread analyzer and provide information to the callback.

This function analyzes the current state for all threads and calls a given callback on every thread found.

**Parameters**

- cb – The callback function handler

void thread_analyzer_print(void)

Run the thread analyzer and print stack size statistics.

This function runs the thread analyzer and prints the output in standard form.

```c
#include <thread_analyzer.h>
```

**Public Members**

const char *name

The name of the thread or stringified address of the thread handle if name is not set.

size_t stack_size

The total size of the stack.

size_t stack_used

Stack size in used.

### 4.3.2 Core Dump

The core dump module enables dumping the CPU registers and memory content for offline debugging. This module is called when a fatal error is encountered and prints or stores data according to which backends are enabled.
Configuration

Configure this module using the following options.

- DEBUG_COREDUMP: enable the module.

Here are the options to enable output backends for core dump:

- DEBUG_COREDUMP_BACKEND_LOGGING: use log module for core dump output.
- DEBUG_COREDUMP_BACKEND_FLASH_PARTITION: use flash partition for core dump output.
- DEBUG_COREDUMP_BACKEND_NULL: fallback core dump backend if other backends cannot be enabled. All output is sent to null.

Here are the choices regarding memory dump:

- DEBUG_COREDUMP_MEMORY_DUMP_MIN: only dumps the stack of the exception thread, its thread struct, and some other bare minimal data to support walking the stack in the debugger. Use this only if absolute minimum of data dump is desired.

Additional memory can be included in a dump (even with the “DEBUG_COREDUMP_MEMORY_DUMP_MIN” config selected) through one or more coredump devices.

Usage

When the core dump module is enabled, during a fatal error, CPU registers and memory content are printed or stored according to which backends are enabled. This core dump data can be fed into a custom-made GDB server as a remote target for GDB (and other GDB compatible debuggers). CPU registers, memory content and stack can be examined in the debugger.

This usually involves the following steps:

1. Get the core dump log from the device depending on enabled backends. For example, if the log module backend is used, get the log output from the log module backend.

2. Convert the core dump log into a binary format that can be parsed by the GDB server. For example, scripts/coredump/coredump_serial_log_parser.py can be used to convert the serial console log into a binary file.

3. Start the custom GDB server using the script scripts/coredump/coredump_gdbserver.py with the core dump binary log file, and the Zephyr ELF file as parameters.

4. Start the debugger corresponding to the target architecture.

5. When DEBUG_COREDUMP_BACKEND_FLASH_PARTITION is enabled the core dump data is stored in the flash partition. The flash partition must be defined in the device tree:

```c
fl0 {  
  partitions {  
    coredump_partition: partition@255000 {  
      label = "coredump-partition";  
      reg = <0x255000 DT_SIZE_K(4)>;  
    };  
  };  
}
```

Note: Developers for Intel ADSP CAVS 15-25 platforms using ZEPHYR_TOOLCHAIN_VARIANT=zephyr should use the debugger in the xtensa-intel_apl_adsp toolchain of the SDK.
Example  This example uses the log module backend tied to serial console. This was done on qemu_x86 where a null pointer was dereferenced.

This is the core dump log from the serial console, and is stored in coredump.log:

```plaintext
Booting from ROM...*** Booting Zephyr OS build zephyr-v2.3.0-1840-g7bba91944a63 ***
Hello World! qemu_x86
E: Page fault at address 0x0 (error code 0x2)
E: Linear address not present in page tables
E: PDE: 0x0000000000115827 Writable, User, Execute Enabled
E: PTE: Non-present
E: EAX: 0x00000000, EBX: 0x00000000, ECX: 0x00119d74, EDX: 0x000003f8

```
Halting system

1. Run the core dump serial log converter:

   ```
   ./scripts/coredump/coredump_serial_log_parser.py coredump.log coredump.bin
   ```

2. Start the custom GDB server:

   ```
   ./scripts/coredump/coredump_gdbserver.py build/zephyr/zephyr.elf coredump.bin
   ```

3. Start GDB:

   ```
   <path to SDK>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb build/zephyr/zephyr.elf
   ```

4. Inside GDB, connect to the GDB server via port 1234:

   ```
   (gdb) target remote localhost:1234
   ```

5. Examine the CPU registers:

   ```
   (gdb) info registers
   ```

   Output from GDB:

   ```
   eax 0x0 0
   ecx 0x119d74 1154420
   edx 0x3f8 1016
   ebx 0x0 0
   esp 0x119d00 <z_main_stack+844>
   ebp 0x119d10 <z_main_stack+860>
   esi 0x0 0
   edi 0x101aa7 1055399
   eip 0x100459 <func_3+16>
   eflags 0x206 [ PF IF ]
   cs 0x8 8
   ss <unavailable>
   ds <unavailable>
   es <unavailable>
   fs <unavailable>
   gs <unavailable>
   ```

6. Examine the backtrace:

   ```
   (gdb) bt
   ```

   Output from GDB:

   ```
   #0 0x00100459 in func_3 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/src/main.c:14
   #1 0x00100477 in func_2 (addr=0x0) at zephyr/rtos/zephyr/samples/hello_world/ (continues on next page)
File Format

The core dump binary file consists of one file header, one architecture-specific block, and multiple memory blocks. All numbers in the headers below are little endian.

File Header  The file header consists of the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header version</td>
<td>uint16_t</td>
<td>Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.</td>
</tr>
<tr>
<td>Target code</td>
<td>uint16_t</td>
<td>Indicate which target (e.g. architecture or SoC) so the parser can instantiate the correct register block parser.</td>
</tr>
<tr>
<td>Pointer size</td>
<td>'uint8_t'</td>
<td>Size of uintptr_t in power of 2. (e.g. 5 for 32-bit, 6 for 64-bit). This is needed to accommodate 32-bit and 64-bit target in parsing the memory block addresses.</td>
</tr>
<tr>
<td>Flags</td>
<td>uint8_t</td>
<td>Reason for the fatal error, as the same in enum k_fatal_error_reason defined in include/zephyr/fatal.h</td>
</tr>
</tbody>
</table>

Architecture-specific Block  The architecture-specific block contains the byte stream of data specific to the target architecture (e.g. CPU registers)

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>char</td>
<td>A to indicate this is a architecture-specific block.</td>
</tr>
<tr>
<td>Header version</td>
<td>uint16_t</td>
<td>Identify the version of this block. To be interpreted by the target architecture specific block parser.</td>
</tr>
<tr>
<td>Number of bytes</td>
<td>uint16_t</td>
<td>Number of bytes following the header which contains the byte stream for target data. The format of the byte stream is specific to the target and is only being parsed by the target parser.</td>
</tr>
<tr>
<td>Register stream</td>
<td>byte</td>
<td>Contains target architecture specific data.</td>
</tr>
</tbody>
</table>

Memory Block  The memory block contains the start and end addresses and the data within the memory region.

4.3. Debugging
### Table 3: Memory Block

<table>
<thead>
<tr>
<th>Field</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>char</td>
<td>M to indicate this is a memory block.</td>
</tr>
<tr>
<td>Header version</td>
<td>uint16_t</td>
<td>Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.</td>
</tr>
<tr>
<td>Start address</td>
<td>uintptr_t</td>
<td>The start address of the memory region.</td>
</tr>
<tr>
<td>End address</td>
<td>uintptr_t</td>
<td>The end address of the memory region.</td>
</tr>
<tr>
<td>Memory stream</td>
<td>byte uint8_t</td>
<td>Contains the memory content between the start and end addresses.</td>
</tr>
</tbody>
</table>

### Adding New Target

The architecture-specific block is target specific and requires new dumping routine and parser for new targets. To add a new target, the following needs to be done:

1. Add a new target code to the enum `coredump_tgt_code` in `include/zephyr/debug/coredump.h`.
2. Implement `arch_coredump_tgt_code_get()` simply to return the newly introduced target code.
3. Implement `arch_coredump_info_dump()` to construct a target architecture block and call `coredump_buffer_output()` to output the block to core dump backend.
4. Add a parser to the core dump GDB stub scripts under `scripts/coredump/gdbstubs/`
   1. Extends the `gdbstubs.gdbstub.GdbStub` class.
   2. During `__init__`, store the GDB signal corresponding to the exception reason in `self.gdb_signal`.
   3. Parse the architecture-specific block from `self.logfile.get_arch_data()`. This needs to match the format as implemented in step 3 (inside `arch_coredump_info_dump()`).
   4. Implement the abstract method `handle_register_group_read_packet` where it returns the register group as GDB expected. Refer to GDB’s code and documentation on what it is expecting for the new target.
   5. Optionally implement `handle_register_single_read_packet` for registers not covered in the `g` packet.
5. Extend `get_gdbstub()` in `scripts/coredump/gdbstubs/__init__.py` to return the newly implemented GDB stub.

### API documentation

```
group coredump_apis
    Coredump APIs.

    Enums

    enum coredump_query_id
        Query ID.
        Values:
```

632 Chapter 4. OS Services
enumerator COREDUMP_QUERY_GET_ERROR
   Returns error code from backend.

enumerator COREDUMP_QUERY_HAS_STORED_DUMP
   Check if there is a stored coredump from backend.
   Returns:
   • 1 if there is a stored coredump, 0 if none.
   • -ENOTSUP if this query is not supported.
   • Otherwise, error code from backend.

enumerator COREDUMP_QUERY_GET_STORED_DUMP_SIZE
   Returns:
   • coredump raw size from backend, 0 if none.
   • -ENOTSUP if this query is not supported.
   • Otherwise, error code from backend.

enumerator COREDUMP_QUERY_MAX
   Max value for query ID.

enum coredump_cmd_id
   Command ID.
   Values:

enumerator COREDUMP_CMD_CLEAR_ERROR
   Clear error code from backend.
   Returns 0 if successful, failed otherwise.

enumerator COREDUMP_CMD_VERIFY_STORED_DUMP
   Verify that the stored coredump is valid.
   Returns:
   • 1 if valid.
   • 0 if not valid or no stored coredump.
   • -ENOTSUP if this command is not supported.
   • Otherwise, error code from backend.

enumerator COREDUMP_CMD_ERASE_STORED_DUMP
   Erase the stored coredump.
   Returns:
   • 0 if successful.
   • -ENOTSUP if this command is not supported.
   • Otherwise, error code from backend.

enumerator COREDUMP_CMD_COPY_STORED_DUMP
   Copy the raw stored coredump.
   Returns:
   • copied size if successful
   • 0 if stored coredump is not found
   • -ENOTSUP if this command is not supported.
• Otherwise, error code from backend.

enumerator COREDUMP_CMD_INVALIDATE_STORED_DUMP
   Invalidate the stored coredump.
   This is faster than erasing the whole partition.

Returns:
• 0 if successful.
• -ENOTSUP if this command is not supported.
• Otherwise, error code from backend.

enumerator COREDUMP_CMD_MAX
   Max value for command ID.

Functions

void coredump(unsigned int reason, const z_arch_esf_t *esf, struct k_thread *thread)
   Perform coredump.

   Normally, this is called inside z_fatal_error() to generate coredump when a fatal error is encountered. This can also be called on demand whenever a coredump is desired.

Parameters
• reason – Reason for the fatal error
• esf – Exception context
• thread – Thread information to dump

void coredump_memory_dump(uintptr_t start_addr, uintptr_t end_addr)
   Dump memory region.

Parameters
• start_addr – Start address of memory region to be dumped
• end_addr – End address of memory region to be dumped

void coredump_buffer_output(uint8_t *buf, size_t buflen)
   Output the buffer via coredump.

   This outputs the buffer of byte array to the coredump backend. For example, this can be called to output the coredump section containing registers, or a section for memory dump.

Parameters
• buf – Buffer to be send to coredump output
• buflen – Buffer length

int coredump_query(enum coredump_query_id query_id, void *arg)
   Perform query on coredump subsystem.

   Query the coredump subsystem for information, for example, if there is an error.

Parameters
• query_id – [in] Query ID
• arg – [inout] Pointer to argument for exchanging information

Returns
Depends on the query
int coredump_cmd(enum coredump_cmd_id query_id, void *arg)

Perform command on coredump subsystem.

Perform command on coredump subsystem, for example, output the stored coredump via logging.

Parameters

• cmd_id – [in] Command ID
• arg – [inout] Pointer to argument for exchanging information

Returns

Depends on the command

struct coredump_cmd_copy_arg

#include <coredump.h> Coredump copy command (CORE-DUMP_CMD_COPY_STORED_DUMP) argument definition.

Public Members

off_t offset

Copy offset.

uint8_t *buffer

Copy destination buffer.

size_t length

Copy length.

group arch-coredump

Functions

void arch_coredump_info_dump(const z_arch_esf_t *esf)

Architecture-specific handling during coredump.

This dumps architecture-specific information during coredump.

Parameters

• esf – Exception Stack Frame (arch-specific)

uint16_t arch_coredump_tgt_code_get(void)

Get the target code specified by the architecture.

4.3.3 GDB stub

• Overview
• Features
• Enabling GDB Stub
  – Using Serial Backend
Overview

The gdbstub feature provides an implementation of the GDB Remote Serial Protocol (RSP) that allows you to remotely debug Zephyr using GDB.

The protocol supports different connection types: serial, UDP/IP and TCP/IP. Zephyr currently supports only serial device communication.

The GDB program acts as the client while Zephyr acts as the server. When this feature is enabled, Zephyr stops its execution after `gdb_init()` starts gdbstub service and waits for a GDB connection. Once a connection is established it is possible to synchronously interact with Zephyr. Note that currently it is not possible to asynchronously send commands to the target.

Features

The following features are supported:

- Add and remove breakpoints
- Continue and step the target
- Print backtrace
- Read or write general registers
- Read or write the memory

Enabling GDB Stub

GDB stub can be enabled with the `CONFIG_GDBSTUB` option.

Using Serial Backend

The serial backend for GDB stub can be enabled with the `CONFIG_GDBSTUB_SERIAL_BACKEND` option.

Since serial backend utilizes UART devices to send and receive GDB commands,

- If there are spare UART devices on the board, set `zephyr,gdbstub-uart` property of the chosen node to the spare UART device so that `printk()` and log messages are not being printed to the same UART device used for GDB.
- For boards with only one UART device, `printk()` and logging must be disabled if they are also using the same UART device for output. GDB related messages may interleave with log messages which may have unintended consequences. Usually this can be done by disabling `CONFIG_PRINTK` and `CONFIG_LOG`.

Debugging

Using Serial Backend

1. Build with GDB stub and serial backend enabled.
2. Flash built image onto board and reset the board.
   - Execution should now be paused at `gdb_init()`.
3. Execute GDB on development machine and connect to the GDB stub.

    target remote <serial device>

For example,

    target remote /dev/ttyUSB1

4. GDB commands can be used to start debugging.

**Example**

This is an example using samples/subsys/debug/gdbstub to demonstrate how GDB stub works.

1. Open two terminal windows.
2. On the first terminal, build and run the sample:

    # From the root of the zephyr repository
    west build -b qemu_x86 samples/subsys/debug/gdbstub
    west build -t run

3. On the second terminal, start GDB:

    <SDK install directory>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb

    1. Tell GDB where to look for the built ELF file:

        (gdb) file <build directory>/zephyr/zephyr.elf

        Response from GDB:

        Reading symbols from <build directory>/zephyr/zephyr.elf...

    2. Tell GDB to connect to the server:

        (gdb) target remote localhost:5678

        Note that QEMU is setup to redirect the serial used for GDB stub in the Zephyr image to a networking port. Hence the connection to localhost, port 5678.

        Response from GDB:

        Remote debugging using :5678
        arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:232
        232 }  

        GDB also shows where the code execution is stopped. In this case, it is at arch/x86/core/ia32/gdbstub.c, line 232.

    3. Use command bt or backtrace to show the backtrace of stack frames.

        (gdb) bt
        #0 arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:232
        #1  0x00105068 in gdb_init (arg=0x0) at <ZEPHYR_BASE>/subsys/debug/gdbstub.
            __c:833
        #2  0x00109d6f in z_sys_init_run_level (level=0x1) at <ZEPHYR_BASE>/kernel/
            __device.c:72
        #3  0x0010a40b in z_cstart () at <ZEPHYR_BASE>/kernel/init.c:423
        #4  0x0010a5383 in z_x86_prep_c (arg=0x9500) at <ZEPHYR_BASE>/arch/x86/core/
            __prep_c.c:58
        #5  0x001000a9 in __csSet () at <ZEPHYR_BASE>/arch/x86/core/ia32/crt0.S:273

4.3. Debugging
4. Use command list to show the source code and surroundings where code execution is stopped.

```
(gdb) list
227  }
228
229  void arch_gdb_init(void)
230  {
231   __asm__ volatile ("int3");
232  }
233
234  /* Hook current IDT. */
235  _EXCEPTION_CONNECT_NOCODE(z_gdb_debug_isr, IV_DEBUG, 3);
236  _EXCEPTION_CONNECT_NOCODE(z_gdb_break_isr, IV_BREAKPOINT, 3);
```

5. Use command s or step to step through program until it reaches a different source line. Now that it finished executing `arch_gdb_init()` and is continuing in `gdb_init()`.

```
(gdb) s
arch_gdb_init (arg=0x0) at /home/dleung5/zephyr/rtos/zephyr/subsys/debug/gdbstub.
  → c:834
834   return 0;
```

```
(gdb) list
829   LOG_ERR("Could not initialize gdbstub backend.");
830   return -1;
831  }
832
833  arch_gdb_init();
834  return 0;
835  }
836
837  #ifdef CONFIG_XTENSA
838  /*
```

6. Use command br or break to setup a breakpoint. This example sets up a breakpoint at `main()`, and let code execution continue without any intervention using command c (or continue).

```
(gdb) break main
Breakpoint 1 at 0x1005a9: file <ZEPHYR_BASE>/samples/subsys/debug/gdbstub/src/main.c, line 32.
(gdb) continue
Continuing.
```

Once code execution reaches `main()`, execution will be stopped and GDB prompt returns.

```
Breakpoint 1, main () at <ZEPHYR_BASE>/samples/subsys(debug/gdbstub/src/main.
  → c:32
32   ret = test();
```

Now GDB is waiting at the beginning of `main()`:

```
(gdb) list
27
28   int main(void)
29  {
30     int ret;
31
(continues on next page)
To examine the value of `ret`, the command `p` or `print` can be used.

```
(gdb) p ret
$1 = 0x11318c
```

Since `ret` has not been assigned a value yet, what it contains is simply a random value.

If step (s or step) is used here, it will continue execution until `printk()` is reached, thus skipping the interior of `test()`. To examine code execution inside `test()`, a breakpoint can be set for `test()`, or simply using `si` (or `stepi`) to execute one machine instruction, where it has the side effect of going into the function.

```
(gdb) si
```

```
(gdb) list
8    #include <zephyr/sys/printk.h>
9
10   #define STACKSIZE 512
11
12   static int test(void)
13     {
14       int a;
15       int b;
16     17       a = 10;
18
19. Here, step can be used to go through all code inside `test()` until it returns. Or the command `finish` can be used to continue execution without intervention until the function returns.

```
(gdb) finish
Run till exit from #0 test() at <ZEPHYR_BASE>/samples/subsys/debug/gdbstub/src/main.c:13
0x001005ae in main () at <ZEPHYR_BASE>/samples/subsys/debug/gdbstub/src/main.c:32
Value returned is $2 = 0x1e
```

And now, execution is back to `main()`.

Examine `ret` again which should have the return value from `test()`. Sometimes, the assignment is not done until another `step` is issued, as in this case. This is due to the assignment code is done after returning from function. The assignment code is generated by the toolchain as machine instructions which are not visible when viewing the corresponding C source file.

```
(gdb) p ret
$3 = 0x11318c
(gdb) s
(gdb) p printk("%d\n", ret);
$4 = 0x1e
```
11. If continue is issued here, code execution will continue indefinitely as there are no break- points to further stop execution. Breaking execution in GDB via Ctrl-C does not currently work as the GDB stub does not support this functionality (yet).

### 4.3.4 Cortex-M Debug Monitor

Monitor mode debugging is a Cortex-M feature, that provides a non-halting approach to debugging. With this it’s possible to continue the execution of high-priority interrupts, even when waiting on a breakpoint. This strategy makes it possible to debug time-sensitive software, that would otherwise crash when the core halts (e.g. applications that need to keep communication links alive).

Zephyr provides support for enabling and configuring the Debug Monitor exception. It also contains a ready implementation of the interrupt, which can be used with SEGGER J-Link debuggers.

#### Configuration

Configure this module using the following options.

- **CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK**: enable the module. This option, by itself, requires an implementation of debug monitor interrupt that will be executed every time the program enters a breakpoint.

With a SEGGER debug probe, it’s possible to use a ready, SEGGER-provided implementation of the interrupt.

- **CONFIG_SEGGER_DEBUGMON**: enables SEGGER debug monitor interrupt. Can be used with SEGGER JLinkGDBServer and a SEGGER debug probe.

#### Usage

When monitor mode debugging is enabled, entering a breakpoint will not halt the processor, but rather generate an interrupt with ISR implemented under `z_arm_debug_monitor` symbol. `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK` configures this interrupt to be the lowest available priority, which will allow other interrupts to execute while processor spins on a breakpoint.

**Using SEGGER-provided ISR** The ready implementation provided with `CONFIG_SEGGER_DEBUGMON` provides functionality required to debug in the monitor mode using regular GDB commands. Steps to configure SEGGER debug monitor:

1. Build a sample with `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK` and `CONFIG_SEGGER_DEBUGMON` configs enabled.
2. Attach JLink GDB server to the target. Example linux command: `JLinkGDBServerCLExe -device <device> -if swd`.
3. Connect to the server with your GDB installation. Example linux command: `arm-none-eabi-gdb --ex="file build/zephyr.elf" --ex="target remote localhost:2331"`.

After these steps use regular gdb commands to debug your program.

**Using other custom ISR** In order to provide a custom debug monitor interrupt, override `z_arm_debug_monitor` symbol. Additionally, manual configuration of some registers is required (see debug monitor sample).
4.4 Device Management

4.4.1 MCUmgr

Overview

The management subsystem allows remote management of Zephyr-enabled devices. The following management operations are available:

- Image management
- File System management
- OS management
- Shell management
- Statistic management
- Zephyr-basic management

over the following transports:

- BLE (Bluetooth Low Energy)
- Serial (UART)
- UDP over IP

The management subsystem is based on the Simple Management Protocol (SMP) provided by MCUmgr, an open source project that provides a management subsystem that is portable across multiple real-time operating systems.

The management subsystem is located in subsys/mgmt/ inside of the Zephyr tree.

Additionally, there is a sample sample that provides management functionality over BLE and serial.

Command-line Tool

MCUmgr provides a command-line tool, mcumgr, for managing remote devices. The tool is written in the Go programming language.

**Note:** This tool is provided for evaluation use only and is not recommended for use in a production environment. It has known issues and will not respect the MCUmgr protocol properly e.g. when an error is received, instead of aborting will, in some circumstances, sit in an endless loop of sending the same command over and over again. A universal replacement for this tool is currently in development and once released, support for the go tool will be dropped entirely.

To install the tool:

```
go version < 1.18

go get github.com/apache/mynewt-mcumgr-cli/mcumgr
```

```
go version >= 1.18

go install github.com/apache/mynewt-mcumgr-cli/mcumgr@latest
```
Configuring the transport

There are two command-line options that are responsible for setting and configuring the transport layer to use when communicating with managed device:

- `--conntype` is used to choose the transport used, and
- `--connstring` is used to pass a comma separated list of options in the `key=value` format, where each valid key depends on the particular `conntype`.

Valid transports for `--conntype` are `serial`, `ble` and `udp`. Each transport expects a different set of `key=value` options:

**serial**

`--connstring` accepts the following `key` values:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dev</td>
<td>the device name for the OS <code>mcumgr</code> is running on (eg, <code>/dev/ttyUSB0</code>, <code>/dev/tty.usbserial</code>, <code>COM1</code>, etc).</td>
</tr>
<tr>
<td>baud</td>
<td>the communication speed; must match the baudrate of the device.</td>
</tr>
<tr>
<td>mtu</td>
<td>aka Maximum Transmission Unit, the maximum protocol packet size.</td>
</tr>
</tbody>
</table>

**ble**

`--connstring` accepts the following `key` values:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctrlr_name</td>
<td>an OS specific string for the controller name.</td>
</tr>
<tr>
<td>own_addr_type</td>
<td>can be one of <code>public</code>, <code>random</code>, <code>rpa_pub</code>, <code>rpa_rnd</code>, where <code>random</code> is the default.</td>
</tr>
<tr>
<td>peer_name</td>
<td>the name the peer BLE device advertises, this should match the configuration specified with <code>CONFIG_BT_DEVICE_NAME</code>.</td>
</tr>
<tr>
<td>peer_id</td>
<td>the peer BLE device address or UUID. Only required when <code>peer_name</code> was not given. The format depends on the OS where <code>mcumgr</code> is run, it is a 6 bytes hexadecimal string separated by colons on Linux, or a 128-bit UUID on macOS.</td>
</tr>
<tr>
<td>conn_timeout</td>
<td>a float number representing the connection timeout in seconds.</td>
</tr>
</tbody>
</table>

**udp**

`--connstring` takes the form `[addr]:port` where:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>addr</td>
<td>can be a DNS name (if it can be resolved to the device IP), IPv4 addr (app must be built with <code>CONFIG_MCUMGR_TRANSPORT_UDP_IPV4</code>), or IPv6 addr (app must be built with <code>CONFIG_MCUMGR_TRANSPORT_UDP_IPV6</code>)</td>
</tr>
<tr>
<td>port</td>
<td>any valid UDP port.</td>
</tr>
</tbody>
</table>

**Saving the connection config**

The transport configuration can be managed with the `conn` sub-command and later used with `--conn` (or `-c`) parameter to skip typing both `--conntype` and `--connstring`. For example a new config for a serial device that would require typing `mcumgr --conntype serial --connstring dev=/dev/ttyACM0, baud=115200, mtu=512` can be saved with:

```
mcumgr conn add acm0 type="serial" connstring="dev=/dev/ttyACM0, baud=115200, mtu=512"
```

Accessing this port can now be done with:

```
mcumgr -c acm0
```
## General options

Some options work for every `mcumgr` command and might be helpful to debug and fix issues with the communication, among them the following deserve special mention:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-l &lt;log-level&gt;</td>
<td>Configures the log level, which can be one of critical, error, warn, info or debug, from less to most verbose. When there are communication issues, <code>-lDEBUG</code> might be useful to dump the packets for later inspection.</td>
</tr>
<tr>
<td>-t &lt;timeout&gt;</td>
<td>Changes the timeout waiting for a response from the default of 10s to a given value. Some commands might take a long time of processing, eg, the erase before an image upload, and might need incrementing the timeout to a larger value.</td>
</tr>
<tr>
<td>-r &lt;tries&gt;</td>
<td>Changes the number of retries on timeout from the default of 1 to a given value.</td>
</tr>
</tbody>
</table>

## List of Commands

Not all commands defined by `mcumgr` (and SMP protocol) are currently supported on Zephyr. The ones that are supported are described in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>echo</td>
<td>Send data to a device and display the echoed back data. This command is part of the OS group, which must be enabled by setting <code>CONFIG_MCUMGR_GRP_OS</code>. The <code>echo</code> command itself can be enabled by setting <code>CONFIG_MCUMGR_GRP_OS_ECHO</code>.</td>
</tr>
<tr>
<td>fs</td>
<td>Access files on a device. More info in Filesystem Management.</td>
</tr>
<tr>
<td>image</td>
<td>Manage images on a device. More info in Image Management.</td>
</tr>
<tr>
<td>reset</td>
<td>Perform a soft reset of a device. This command is part of the OS group, which must be enabled by setting <code>CONFIG_MCUMGR_GRP_OS</code>. The <code>reset</code> command itself is always enabled and the time taken for a reset to happen can be set with <code>CONFIG_MCUMGR_GRP_OS_RESET_MS</code> (in ms).</td>
</tr>
<tr>
<td>shell</td>
<td>Execute a command in the remote shell. This option is disabled by default and can be enabled with <code>CONFIG_MCUMGR_GRP_SHELL = y</code>. To know more about the shell in Zephyr check Shell.</td>
</tr>
<tr>
<td>taskstat</td>
<td>Read task statistics from a device. This command is part of the OS group, which must be enabled by setting <code>CONFIG_MCUMGR_GRP_OS</code>. The taskstat command itself can be enabled by setting <code>CONFIG_MCUMGR_GRP_OS_TASKSTAT</code>. <code>CONFIG_THREAD_MONITOR</code> also needs to be enabled otherwise a <code>-8 (MGMT_ERR_ENOTSUP)</code> will be returned.</td>
</tr>
</tbody>
</table>

**Tip:** Running `mcumgr` with no parameters, or `-h` will display the list of commands.

**Tip:** `taskstat` has a few options that might require tweaking. The `CONFIG_THREAD_NAME` must be set to display the task names, otherwise the priority is displayed. Since the taskstat packets are large, they might need increasing the `CONFIG_MCUMGR_TRANSPORT_NETBUF_SIZE` option.

**Warning:** To display the correct stack size in the taskstat command, the `CONFIG_THREAD_STACK_INFO` option must be set. To display the correct stack usage in the taskstat command, both `CONFIG_THREAD_STACK_INFO` and `CONFIG_INIT_STACKS` options must be set.
J-Link Virtual MSD Interaction Note

On boards where a J-Link OB is present which has both CDC and MSC (virtual Mass Storage Device, also known as drag-and-drop) support, the MSD functionality can prevent MCUmgr commands over the CDC UART port from working due to how USB endpoints are configured in the J-Link firmware (for example on the Nordic nrf52840dk_nrf52840 board) because of limiting the maximum packet size (most likely to occur when using image management commands for updating firmware). This issue can be resolved by disabling MSD functionality on the J-Link device, follow the instructions on nordic_segger_msd to disable MSD support.

Image Management

The image management provided by mcumgr is based on the image format defined by MCUboot. For more details on the internals see MCUboot design and Signing Binaries.

To list available images in a device:

```
mcumgr <connection-options> image list
```

This should result in an output similar to this:

```
$ mcumgr -c acm0 image list
Images:
  image=0 slot=0
     version: 1.0.0
     bootable: true
     flags: active confirmed
     hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
Split status: N/A (0)
```

Where image is the number of the image pair in a multi-image system, and slot is the number of the slot where the image is stored, 0 for primary and 1 for secondary. This image being active and confirmed means it will run again on next reset. Also relevant is the hash, which is used by other commands to refer to this specific image when performing operations.

An image can be manually erased using:

```
mcumgr <connection-options> image erase
```

The behavior of erase is defined by the server (MCUmgr in the device). The current implementation is limited to erasing the image in the secondary partition.

To upload a new image:

```
mcumgr <connection-options> image upload [-n] [-e] [-u] [-w] <signed-bin>
```

- -n: This option allows uploading a new image to a specific set of images in a multi-image system, and is currently only supported by MCUboot when the CONFIG_MCUBOOT_SERIAL option is enabled.
- -e: This option avoids performing a full erase of the partition before starting a new upload.

**Tip:** The -e option should always be passed in because the upload command already checks if an erase is required, respecting the CONFIG_IMG_ERASE_PROGRESSIVELY setting.

**Tip:** If the upload command times out while waiting for a response from the device, -t might be used to increase the wait time to something larger than the default of 10s. See `general_options`. 
**Warning:** `mcumgr` does not understand `.hex` files, when uploading a new image always use the `.bin` file.

- `-u`: This option allows upgrading only to newer image version.
- `-w`: This option allows setting the maximum size for the window of outstanding chunks in transit. It is set to 5 by default.

**Tip:** If the option is set to a value lower than the default one, for example `-w 1`, less chunks are transmitted on the window, resulting in lower risk of errors. Conversely, setting a value higher than 5 increases risk of errors and may impact performance.

After an image upload is finished, a new image list would now have an output like this:

```
$ mcumgr -c acm0 image upload -e build/zephyr/zephyr.signed.bin
35.69 KiB / 92.92 KiB [==========>---------------] 38.41% 2.97 KiB/s 00m19
```

Now listing the images again:

```
$ mcumgr -c acm0 image list
Images:
  image=0 slot=0
  version: 1.0.0
  bootable: true
  flags: active confirmed
  hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
  image=0 slot=1
  version: 1.1.0
  bootable: true
  flags:
    hash: e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
Split status: N/A (0)
```

To test a new upgrade image the `test` command is used:

```
mcumgr <connection-options> image test <hash>
```

This command should mark a test upgrade, which means that after the next reboot the bootloader will execute the upgrade and jump into the new image. If no other image operations are executed on the newly running image, it will revert back to the image that was previously running on the device on the subsequent reset. When a test is requested, `flags` will be updated with `pending` to inform that a new image will be run after a reset:

```
$ mcumgr -c acm0 image test
→ e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
Images:
  image=0 slot=0
  version: 1.0.0
  bootable: true
  flags: active confirmed
  hash: 86dca73a3439112b310b5e033d811ec2df728d2264265f2046fced5a9ed00cc7
  image=0 slot=1
  version: 1.1.0
  bootable: true
  flags: pending
  hash: e8cf0dcef3ec8addee07e8c4d5dc89e64ba3fae46a2c5267fc4efbea4ca0e9f4
Split status: N/A (0)
```

4.4. Device Management
After a reset the output with change to:

```bash
$ mcumgr -c acm0 image list
Images:
  image=0 slot=0
  version: 1.1.0
  bootable: true
  flags: active
    hash: e8cf0dce3ec8adde07e8c4d5c89e64ba3f4e64a2c5267fc4efbea4ca0e9f4
  image=0 slot=1
  version: 1.0.0
  bootable: true
  flags: confirmed
    hash: 86dca73a343912b310b5e033d811ec2df728d2264f65f2046fced5a9ed00cc7
Split status: N/A (0)
```

**Tip:** It's important to mention that an upgrade only ever happens if the image is valid. The first thing MCUboot does when an upgrade is requested is to validate the image, using the SHA-256 and/or the signature (depending on the configuration). So before uploading an image, one way to be sure it is valid is to run `imgtool verify -k <your-signature-key> <your-image>`, where `-k <your-signature-key>` can be skipped if no signature validation was enabled.

The `confirmed` flag in the secondary slot tells that after the next reset a revert upgrade will be performed to switch back to the original layout.

The `confirm` command used to confirm that an image is OK and no revert should happen (empty hash required) is:

```bash
mcumgr <connection-options> image confirm ""
```

The `confirm` command can also be run passing in a hash so that instead of doing a test/revert procedure, the image in the secondary partition is directly upgraded to, eg:

```bash
mcumgr <connection-options> image confirm <hash>
```

**Tip:** The whole test/revert cycle does not need to be done using only the `mcumgr` command-line tool. A better alternative is to perform a test and allow the new running image to self-confirm after any checks by calling `boot_write_img_confirmed()`.

**Tip:** Building with `CONFIG_MCUMGR_GRP_IMG_VERBOSE_ERR` enables better error messages when failures happen (but increases the application size).

---

**Statistics Management**

Statistics are used for troubleshooting, maintenance, and usage monitoring; it consists basically of user-defined counters which are tightly connected to `mcumgr` and can be used to track any information for easy retrieval. The available sub-commands are:

```bash
mcumgr <connection-options> stat list
mcumgr <connection-options> stat <section-name>
```

Statistics are organized in sections (also called groups), and each section can be individually queried. Defining new statistics sections is done by using macros available under `zephyr/stats/stats.h`. Each section consists of multiple variables (or counters), all with the same size (16, 32 or 64 bits).
To create a new section `my_stats`:

```
STATS_SECT_START(my_stats)
  STATS_SECT_ENTRY(my_stat_counter1)
  STATS_SECT_ENTRY(my_stat_counter2)
  STATS_SECT_ENTRY(my_stat_counter3)
STATS_SECT_END;

STATS_SECT_DECL(my_stats) my_stats;
```

Each entry can be declared with `STATS_SECT_ENTRY` (or the equivalent `STATS_SECT_ENTRY32`, `STATS_SECT_ENTRY16` or `STATS_SECT_ENTRY64`). All statistics in a section must be declared with the same size.

The statistics counters can either have names or not, depending on the setting of the `CONFIG_STATS_NAMES` option. Using names requires an extra declaration step:

```
STATS_NAME_START(my_stats)
  STATS_NAME(my_stats, my_stat_counter1)
  STATS_NAME(my_stats, my_stat_counter2)
  STATS_NAME(my_stats, my_stat_counter3)
STATS_NAME_END(my_stats);
```

Tip: Disabling `CONFIG_STATS_NAMES` will free resources. When this option is disabled the `STATS_NAME*` macros output nothing, so adding them in the code does not increase the binary size.

Tip: `CONFIG_MCUMGR_GRP_STAT_MAX_NAME_LEN` sets the maximum length of a section name that can be accepted as parameter for showing the section data, and might require tweaking for long section names.

The final steps to use a statistics section is to initialize and register it:

```
rc = STATS_INIT_AND_REG(my_stats, STATS_SIZE_32, "my_stats");
assert (rc == 0);
```

In the running code a statistics counter can be incremented by 1 using `STATS_INC`, by N using `STATS_INCN` or reset with `STATS_CLEAR`.

Let's suppose we want to increment those counters by 1, 2 and 3 every second. To get a list of stats:

```
$ mcumgr --conn acm0 stat list
stat groups:
  my_stats
```

To get the current value of the counters in `my_stats`:

```
$ mcumgr --conn acm0 stat my_stats
stat group: my_stats
  13 my_stat_counter1
  26 my_stat_counter2
  39 my_stat_counter3

$ mcumgr --conn acm0 stat my_stats
stat group: my_stats
  16 my_stat_counter1
  32 my_stat_counter2
  48 my_stat_counter3
```
When `CONFIG_STATS_NAMES` is disabled the output will look like this:

```
$ mcumgr --conn acm0 stat my_stats
stat group: my_stats
  8 s0
 16 s1
 24 s2
```

### Filesystem Management

The filesystem module is disabled by default due to security concerns: because of a lack of access control by default, every file in the FS will be accessible, including secrets, etc. To enable it `CONFIG_MCUMGR_GRP_FS` must be set (y). Once enabled the following sub-commands can be used:

```
mcumgr <connection-options> fs download <remote-file> <local-file>
mcumgr <connection-options> fs upload <local-file> <remote-file>
```

Using the `fs` command, requires `CONFIG_FILE_SYSTEM` to be enabled, and that some particular filesystem is enabled and properly mounted by the running application, eg for littlefs this would mean enabling `CONFIG_FILE_SYSTEM_LITTLEFS`, defining a storage partition `Flash map` and mounting the filesystem in the startup (`fs_mount()`).

Uploading a new file to a littlefs storage, mounted under `/lfs`, can be done with:

```
$ mcumgr -c acm0 fs upload foo.txt /lfs/foo.txt
25
Done
```

Where 25 is the size of the file.

For downloading a file, let’s first use the `fs` command (`CONFIG_FILE_SYSTEM_SHELL` must be enabled) in a remote shell to create a new file:

```
uart:~$ fs write /lfs/bar.txt 41 42 43 44 31 32 33 34 0a
uart:~$ fs read /lfs/bar.txt
File size: 9
00000000 41 42 43 44 31 32 33 34 0A ABCD1234.
```

Now it can be downloaded using:

```
$ mcumgr -c acm0 fs download /lfs/bar.txt bar.txt
0
9
Done
$ cat bar.txt
ABCD1234
```

Where 0 is the return code, and 9 is the size of the file.

**Warning:** The commands might exhaust the system workqueue, if its size is not large enough, so increasing `CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE` might be required for correct behavior.

The size of the stack allocated buffer used to store the blocks, while transferring a file can be adjusted with `CONFIG_MCUMGR_GRP_FS_DL_CHUNK_SIZE`; this allows saving RAM resources.

**Tip:** `CONFIG_MCUMGR_GRP_FS_PATH_LEN` sets the maximum PATH accepted for a file name. It might
require tweaking for longer file names.

---

**Note:** To add security to the filesystem management group, callbacks for MCUmgr hooks can be registered by a user application when the upload/download functions are ran which allows the application to control if access to a file is allowed or denied. See the *MCUmgr Callbacks* section for details.

---

**Bootloader Integration**

The *Device Firmware Upgrade* subsystem integrates the management subsystem with the bootloader, providing the ability to send and upgrade a Zephyr image to a device.

Currently only the MCUboot bootloader is supported. See *MCUboot* for more information.

**Discord channel**

Developers welcome!

- Discord mcumgr channel: https://discord.com/invite/Ck7jw53nU2

**API Reference**

```c
typedef void *(*mgmt_alloc_rsp_fn)(const void *src_buf, void *arg)

Allocates a buffer suitable for holding a response.
If a source buf is provided, its user data is copied into the new buffer.

**Param src_buf**
An optional source buffer to copy user data from.

**Param arg**
Optional streamer argument.

**Return**
Newly-allocated buffer on success NULL on failure.
```

4.4. Device Management
typedef void (*mgmt_reset_buf_fn)(void *buf, void *arg)
Resets a buffer to a length of 0.
The buffer's user data remains, but its payload is cleared.

**Param buf**
The buffer to reset.

**Param arg**
Optional streamer argument.

typedef int (*mgmt_handler_fn)(struct smp_streamer *ctxt)
Processes a request and writes the corresponding response.
A separate handler is required for each supported op-ID pair.

**Param ctx**
The mcumgr context to use.

**Return**
0 if a response was successfully encoded, *mcumgr_err_t* code on failure.

**Enums**

enum mcumgr_op_t
Opcodes; encoded in first byte of header.
**Values:**

enumerator MGMT_OP_READ = 0
Read op-code.

enumerator MGMT_OP_READ_RSP
Read response op-code.

enumerator MGMT_OP_WRITE
Write op-code.

enumerator MGMT_OP_WRITE_RSP
Write response op-code.

enum mcumgr_group_t
MCUmgr groups.
The first 64 groups are reserved for system level mcumgr commands. Per-user commands are then defined after group 64.
**Values:**

enumerator MGMT_GROUP_ID_OS = 0
OS (operating system) group.

enumerator MGMT_GROUP_ID_IMAGE
Image management group, used for uploading firmware images.
enumerator MGMT_GROUP_ID_STAT
    Statistic management group, used for retrieving statistics.

enumerator MGMT_GROUP_ID_SETTINGS
    Settings management (config) group, used for reading/writing settings.

enumerator MGMT_GROUP_ID_LOG
    Log management group (unused)

enumerator MGMT_GROUP_ID_CRASH
    Crash group (unused)

enumerator MGMT_GROUP_ID_SPLIT
    Split image management group (unused)

enumerator MGMT_GROUP_ID_RUN
    Run group (unused)

enumerator MGMT_GROUP_ID_FS
    FS (file system) group, used for performing file IO operations.

enumerator MGMT_GROUP_ID_SHELL
    Shell management group, used for executing shell commands.

enumerator MGMT_GROUP_ID_PERUSER = 64
    User groups defined from 64 onwards.

enumerator ZEPHYR_MGMT_GRP_BASIC = (MGMT_GROUP_ID_PERUSER - 1)
    Zephyr-specific groups decrease from PERUSER to avoid collision with upstream and user-defined groups.
    Zephyr-specific: Basic group

enum mcumgr_err_t
    MCUmgr error codes.

Values:

enumerator MGMT_ERR_EOK = 0
    No error (success).

enumerator MGMT_ERR_EUNKNOWN
    Unknown error.

enumerator MGMT_ERR_ENOMEM
    Insufficient memory (likely not enough space for CBOR object).

enumerator MGMT_ERR_EINVAL
    Error in input value.
enumerator MGMT_ERR_ETIMEOUT
   Operation timed out.

enumerator MGMT_ERR_ENOENT
   No such file/entry.

enumerator MGMT_ERR_EBADSTATE
   Current state disallows command.

enumerator MGMT_ERR_EMSGSIZE
   Response too large.

enumerator MGMT_ERR_ENOTSUP
   Command not supported.

enumerator MGMT_ERR_ECORRUPT
   Corrupt.

enumerator MGMT_ERR_EBUSY
   Command blocked by processing of other command.

enumerator MGMT_ERR_EACCESSDENIED
   Access to specific function, command or resource denied.

enumerator MGMT_ERR_UNSUPPORTED_TOO_OLD
   Requested SMP MCUmgr protocol version is not supported (too old)

enumerator MGMT_ERR_UNSUPPORTED_TOO_NEW
   Requested SMP MCUmgr protocol version is not supported (too new)

enumerator MGMT_ERR_EPERUSER = 256
   User errors defined from 256 onwards.

Functions

void mgmt_register_group(struct mgmt_group *group)
   Registers a full command group.

   Parameters
   • group – The group to register.

void mgmt_unregister_group(struct mgmt_group *group)
   Unregisters a full command group.

   Parameters
   • group – The group to register.

const struct mgmt_handler *mgmt_find_handler(uint16_t group_id, uint16_t command_id)
   Finds a registered command handler.

   Parameters
• group_id – The group of the command to find.
• command_id – The ID of the command to find.

**Returns**
The requested command handler on success; NULL on failure.

```c
const struct mgmt_group *mgmt_find_group(uint16_t group_id)
```
Finds a registered command group.

**Parameters**
• group_id – The command group id to find.

**Returns**
The requested command group on success; NULL on failure.

```c
struct mgmt_handler
#include <mgmt.h> Read handler and write handler for a single command ID.
```

```c
struct mgmt_group
#include <mgmt.h> A collection of handlers for an entire command group.
```

**Public Members**

```c
sys_snodo_t node
Entry list node.
```

```c
const struct mgmt_handler *mg_handlers
Array of handlers; one entry per command ID.
```

```c
uint16_t mg_group_id
The numeric ID of this group.
```

### 4.4.2 MCUmgr handlers

**Overview**
MCUmgr functions by having group handlers which identify a group of functions relating to a specific management area, which is addressed with a 16-bit identification value, `mcumgr_group_t` contains the management groups available in Zephyr with their corresponding group ID values. The group ID is included in SMP headers to identify which group a command belongs to, there is also an 8-bit command ID which identifies the function of that group to execute - see *SMP Protocol Specification* for details on the SMP protocol and header. There can only be one registered group per unique ID.

**Implementation**
MCUmgr handlers can be added externally by application code or by module code, they do not have to reside in the upstream Zephyr tree to be usable. The first step to creating a handler is to create the folder structure for it, the typical Zephyr MCUmgr group layout is as follows:
Note that the header files in upstream Zephyr MCUmgr handlers reside in the `zephyr/include/zephyr/mgmt/mcumgr/GRP_NAME_MGMT` directory to allow the files to be globally included by applications.

**Initial header `GRP_NAME_MGMT.h`** The purpose of the header file is to provide defines which can be used by the MCUmgr handler itself and application code, e.g. to reference the command IDs for executing functions. An example file would look similar to:

```c
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 * SPDX-License-Identifier: Apache-2.0
 */
#ifndef H_EXAMPLE_MGMT_
#define H_EXAMPLE_MGMT_
#endif

/* Group ID for example management group. */
#define MGMT_GROUP_ID_EXAMPLE MGMT_GROUP_ID_PERUSER

/* Command IDs for example management group. */
#define EXAMPLE_MGMT_ID_TEST 0
#define EXAMPLE_MGMT_ID_OTHER 1

/* Command result codes for example management group. */
enum example_mgmt_err_code_t {
    /* No error, this is implied if there is no ret value in the response */
    EXAMPLE_MGMT_ERR_OK = 0,

    /* Unknown error occurred. */
    EXAMPLE_MGMT_ERR_UNKNOWN,

    /* The provided value is not wanted at this time. */
    EXAMPLE_MGMT_ERR_NOT_WANTED,

    /* The provided value was rejected by a hook. */
    EXAMPLE_MGMT_ERR_REJECTED_BY_HOOK,
};
```

(continues on next page)
This provides the defines for 2 command test and other and sets up the SMP version 2 error responses (which have unique error codes per group as opposed to the legacy SMP version 1 error responses that return a mcumgr_err_t - there should always be an OK error code with the value 0 and an unknown error code with the value 1. The above example then adds an error code of not wanted with value 2. In addition, the group ID is set to be MGMT_GROUP_ID_PERUSER, which is the start group ID for user-defined groups, note that group IDs need to be unique so other custom groups should use different values, a central index header file (as upstream Zephyr has) can be used to distribute group IDs more easily.

Initial header <grp_name>_mgmt_callbacks.h  The purpose of the header file is to provide defines which can be used by the MCUmgr handler itself and application code, e.g. to reference the command IDs for executing functions. An example file would look similar to:

```c
/* * Copyright (c) 2023 Nordic Semiconductor ASA * * SPDX-License-Identifier: Apache-2.0 */
#endif
#define H_MCUMGR_EXAMPLE_MGMT_CALLBACKS_
#include <stdint.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

#if !defined __cplusplus
extern "C" {
#endif

/* This is the event ID for the example group */
#define MGMT_EVT_GRP_EXAMPLE MGMT_EVT_GRP_USER_CUSTOM_START

/* MGMT event opcodes for example management group */
enum example_mgmt_group_events {
    /* Callback when the other command is received, data is example_mgmt_other_data */
    MGMT_EVT_OP_EXAMPLE_OTHER = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_EXAMPLE, 0),

    /* Used to enable all smp_group events */
    MGMT_EVT_OP_EXAMPLE_MGMT_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_EXAMPLE),
};

/* Structure provided in the #MGMT_EVT_OP_EXAMPLE_OTHER notification callback */
struct example_mgmt_other_data {
    uint32_t user_value;
};

#if !defined __cplusplus
}
#endif
```
This sets up a single event which application (or module) code can register for to receive a callback when the function handler is executed, which allows the flow of the handler to be changed (i.e. to return an error instead of continuing). The event group ID is set to `MGMT_EVT_GRP_USER_CUSTOM_START`, which is the start event ID for user-defined groups, note that event IDs need to be unique so other custom groups should use different values, a central index header file (as upstream Zephyr has) can be used to distribute event IDs more easily.

Initial source `<grp_name>_mgmt.c` The purpose of this source file is to handle the incoming MCUmgr commands, provide responses, and register the transport with MCUmgr so that commands will be sent to it. An example file would look similar to:

```c
/* * Copyright (c) 2023 Nordic Semiconductor ASA */
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/smp/smp.h>

{
    /* This function is called during system init before main() is invoked, if
     * the
     * handler needs to set anything up before it can be used, it should do it
     * here.
     * This register the group so that clients can call the function handlers.
     */
    mgmt_register_group(&example_mgmt_group);
}

(continues on next page)
The above code creates 2 function handlers, test which supports read requests and takes 2 required parameters, and other which supports write requests and takes 1 optional parameter, this function handler has an optional notification callback feature that allows other parts of the code to listen for the event and take any required actions that are necessary or prevent further execution of the function by returning an error, further details on MCUmgr callback functionality can be found on MCUmgr Callbacks.

Note that other code referencing callbacks for custom MCUmgr handlers needs to include both the base Zephyr callback include file and the custom handler callback file, only in-tree Zephyr handler headers are included when including the upstream Zephyr callback header file.

**Initial Kconfig** The purpose of the Kconfig file is to provide options which users can enable or change relating to the functionality of the handler being implemented. An example file would look similar to:

```
# Copyright Nordic Semiconductor ASA 2023. All rights reserved.
# SPDX-License-Identifier: Apache-2.0
# The Kconfig file is dedicated to example management group of
# of MCUmgr subsystem and provides Kconfig options to configure
# group commands behaviour and other aspects.
#
# Options defined in this file should be prefixed:
# MCUMGR_GRP_EXAMPLE_ -- general group options;
#
# When adding kconfig options, that control the same feature,
# try to group them together by the same stem after prefix.
if MCUMGR

    menuconfig MCUMGR_GRP_EXAMPLE_APP
        bool "MCUmgr handlers for example management (app)"
        select MCUMGR_GRP_EXAMPLE_APP
            default y
            help "Enables MCUmgr handlers for example management. This demonstrates the
file at application-level."
        if MCUMGR_GRP_EXAMPLE_APP

            config MCUMGR_GRP_EXAMPLE_APP
                bool "Other hook"
                depends on MCUMGR_GRP_EXAMPLE_APP
                help "Allows applications to receive callback when the "other" example
management function is called"
            endif
        endif

    if MCUMGR_GRP_EXAMPLE_APP

        module = MCUMGR_GRP_EXAMPLE
        module-str = mcumgr_grp_example
        source "subsys/logging/Kconfig.template.log_config"
    endif
endif
```

**Initial CMakeLists.txt** The CMakeLists.txt file is used by the build system to setup files to compile, include directories to add and specify options that can be changed. A basic file only need to include the
source files if the Kconfig options are enabled. An example file would look similar to:

**Zephyr module**

```c
# Copyright (c) 2023 Nordic Semiconductor ASA
# SPDX-License-Identifier: Apache-2.0

if(CONFIG_MCUMGR_GRP_EXAMPLE_MODULE)
    zephyr_library(mgmt_mcumgr_grp_example)
    # The below should be updated with the real name of the file
    zephyr_library_sources(src/example_mgmt.c)
    zephyr_include_directories(include)
endif()
```

**Application**

```c
if(CONFIG_MCUMGR_GRP_EXAMPLE_APP)
    target_sources(app PRIVATE example_as_module/src/example_mgmt.c)
    zephyr_include_directories(example_as_module/include)
endif()
```

**Including from application**

Application-specific MCUmgr handlers can be added by creating/editing application build files. Example modifications are shown below.

Example **CMakeLists.txt** The application CMakeLists.txt file can load the CMake file for the example MCUmgr handler by adding the following:

```c
add_subdirectory(mcumgr/grp/<grp_name>)
```

Example **Kconfig** The application Kconfig file can include the Kconfig file for the example MCUmgr handler by adding the following to the Kconfig file in the application directory (or creating it if it does not exist):

```c
rsource "mcumgr/grp/<grp_name>/Kconfig"

# Include Zephyr's Kconfig
source "Kconfig.zephyr"
```

**Including from Zephyr Module**

Zephyr **Modules (External projects)** can be used to add custom MCUmgr handlers to multiple different applications without needing to duplicate the code in each application's source tree, see **Module yaml file description** for details on how to set up the module files. Example files are shown below.

Example **zephyr/module.yml** This is an example file which can be used to load the Kconfig and CMake files from the root of the module directory, and would be placed at zephyr/module.yml:

```yaml
build:
    kconfig: Kconfig
    cmake: .
```

---

661
Example CMakeLists.txt  This is an example CMakeLists.txt file which loads the CMake file for the example MCUmgr handler, and would be placed at CMakeLists.txt:

```cmake
add_subdirectory(mcumgr/grp/<grp_name>)
```

Example Kconfig  This is an example Kconfig file which loads the Kconfig file for the example MCUmgr handler, and would be placed at Kconfig:

```kconfig
rsource "mcumgr/grp/<grp_name>/Kconfig"
```

Demonstration handler

There is a demonstration project which includes configuration for both application and zephyr module-MCUmgr handlers which can be used as a basis for created your own in tests/subsys/mgmt/mcumgr/handler_demo/.

4.4.3 MCUmgr Callbacks

Overview

MCUmgr has a customisable callback/notification system that allows application (and module) code to receive callbacks for MCUmgr events that they are interested in and react to them or return a status code to the calling function that provides control over if the action should be allowed or not. An example of this is with the fs_mgmt group, whereby file access can be gated, the callback allows the application to inspect the request path and allow or deny access to said file, or it can rewrite the provided path to a different path for transparent file redirection support.

Implementation

Enabling  The base callback/notification system can be enabled using CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS which will compile the registration and notification system into the code. This will not provide any callbacks by default as the callbacks that are supported by a build must also be selected by enabling the Kconfig's for the required callbacks (see Events for further details). A callback function with the `mgmt_cb` type definition can then be declared and registered by calling `mgmt_callback_register()` for the desired event inside of a `:c:struct` `mgmt_callback` structure. Handlers are called in the order that they were registered.

With the system enabled, a basic handler can be set up and defined in application code as per:

```c
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

struct mgmt_callback my_callback;

enum mgmt_cb_return my_function(uint32_t event, enum mgmt_cb_return prev_status,
                                 int32_t *rc, uint16_t *group, bool *abort_more,
                                 void *data, size_t data_size)
{
    if (event == MGMT_EVT_OP_CMD_DONE) {
        /* This is the event we registered for */
    }

    /* Return OK status code to continue with acceptance to underlying handler */
```

(continues on next page)
This code registers a handler for the `MGMT_EVT_OP_CMD_DONE` event, which will be called after a MCUmgr command has been processed and output generated, note that this requires that `CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS` be enabled to receive this callback.

Multiple callbacks can be setup to use a single function as a common callback, and many different functions can be used for each event by registering each group once, or all notifications for a whole group can be enabled by using one of the `MGMT_EVT_OP_*_ALL` events, alternatively a handler can setup for every notification by using `MGMT_EVT_OP_ALL`. When setting up handlers, events can be combined that are in the same group only, for example 5 img_mgmt callbacks can be setup with a single registration call, but to also setup a callback for an os_mgmt callback, this must be done as a separate registration. Group IDs are numerical increments, event IDs are bitmask values, hence the restriction.

As an example, the following registration is allowed, which will register for 3 SMP events with a single callback function in a single registration:

```c
my_callback.callback = my_function;
my_callback.event_id = (MGMT_EVT_OP_CMD_RECV | MGMT_EVT_OP_CMD_STATUS | MGMT_EVT_OP_CMD_DONE);
mgmt_callback_register(&my_callback);
```

The following code is not allowed, and will cause undefined operation, because it mixes the IMG management group with the OS management group whereby the group is **not** a bitmask value, only the event is:

```c
my_callback.callback = my_function;
my_callback.event_id = (MGMT_EVT_OP_IMG_MGMT_DFU_STARTED | MGMT_EVT_OP_OS_MGMT_RESET);
mgmt_callback_register(&my_callback);
```

### Events
Events can be selected by enabling their corresponding Kconfig option:

- `CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS`
  MCUmgr command status (`MGMT_EVT_OP_CMD_RECV`, `MGMT_EVT_OP_CMD_STATUS`, `MGMT_EVT_OP_CMD_DONE`)

- `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK`
  fs_mgmt file access (`MGMT_EVT_OP_FS_MGMT_FILE_ACCESS`)

- `CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK`
  img_mgmt upload check (`MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK`)

- `CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS`
  img_mgmt upload status (`MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED`, `MGMT_EVT_OP_IMG_MGMT_DFU_STARTED`, `MGMT_EVT_OP_IMG_MGMT_DFU_PENDING`, `MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED`)

- `CONFIG_MCUMGR_GRP_OS_RESET_HOOK`
  os_mgmt reset check (`MGMT_EVT_OP_OS_MGMT_RESET`)

---

4.4. Device Management
Actions Some callbacks expect a return status to either allow or disallow an operation, an example is the fs_mgmt access hook which allows for access to files to be allowed or denied. With these handlers, the first non-OK error code returned by a handler will be returned to the MCUmgr client.

An example of selectively denying file access:

```c
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>
#include <string.h>

struct mgmt_callback my_callback;

enum mgmt_cb_return my_function(uint32_t event, enum mgmt_cb_return prev_status, int32_t *rc, uint16_t *group, bool *abort_more, void *data, size_t data_size)
{
    /* Only run this handler if a previous handler has not failed */
    if (event == MGMT_EVT_OP_FS_MGMT_FILE_ACCESS && prev_status == MGMT_CB_OK) {
        struct fs_mgmt_file_access *fs_data = (struct fs_mgmt_file_access *)data;

        /* Check if this is an upload and deny access if it is, otherwise check the path and deny if is matches a name */
        if (fs_data->access == FS_MGMT_FILE_ACCESS_WRITE) {
            /* Return an access denied error code to the client and abort calling further handlers */
            *abort_more = true;
            *rc = MGMT_ERR_EACCESSDENIED;

            return MGMT_CB_ERROR_RC;
        } else if (strcmp(fs_data->filename, "/lfs1/false_deny.txt") == 0) {
            /* Return a no entry error code to the client, call additional handlers (which will have failed set to true) */
            *rc = MGMT_ERR_ENOENT;

            return MGMT_CB_ERROR_RC;
        }
    }

    /* Return OK status code to continue with acceptance to underlying handler */
    return MGMT_CB_OK;
}

int main()
{
    my_callback.callback = my_function;
    my_callback.event_id = MGMT_EVT_OP_FS_MGMT_FILE_ACCESS;
    mgmt_callback_register(&my_callback);
}
```

This code registers a handler for the `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` event, which will be called after a fs_mgmt file read/write command has been received to check if access to the file should be allowed.
or not, note that this requires that CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK be enabled to receive this callback. Two types of errors can be returned, the \texttt{rc} parameter can be set to an \texttt{mcumgr_err_t} error code and \texttt{MGMT_CB_ERROR_RC} can be returned, or a group error code (introduced with version 2 of the MCUmgr protocol) can be set by setting the group value to the group and \texttt{rc} value to the group error code and returning \texttt{MGMT_CB_ERROR_ERR}.

**MCUmgr Command Callback Usage/Adding New Event Types**

To add a callback to a MCUmgr command, \texttt{mgmt_callback_notify()} can be called with the event ID and, optionally, a data struct to pass to the callback (which can be modified by handlers). If no data needs to be passed back, \texttt{NULL} can be used instead, and size of the data set to 0.

An example MCUmgr command handler:

```c
#include <zephyr/kernel.h>
#include <zcbor_common.h>
#include <zcbor_encode.h>
#include <zephyr/mgmt/mcumgr/smp/smp.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

#define MGMT_EVT_GRP_USER_ONE MGMT_EVT_GRP_USER_CUSTOM_START

enum user_one_group_events {
    /**< Callback on first post, data is test_struct. */
    MGMT_EVT_OP_USER_ONE_FIRST = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 0),

    /**< Callback on second post, data is test_struct. */
    MGMT_EVT_OP_USER_ONE_SECOND = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 1),

    /**< Used to enable all user_one events. */
    MGMT_EVT_OP_USER_ONE_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_USER_ONE),
};

struct test_struct {
    uint8_t some_value;
};

static int test_command(struct mgmt_ctxt *ctxt)
{
    int rc;
    int err_rc;
    uint16_t err_group;
    zcbor_state_t *zse = ctxt->cnbe->zs;
    bool ok;
    struct test_struct test_data = {
        .some_value = 8,
    };

    rc = mgmt_callback_notify(MGMT_EVT_OP_USER_ONE_FIRST, &test_data,
                                sizeof(test_data), &err_rc, &err_group);

    if (rc != MGMT_CB_OK) {
        /* A handler returned a failure code */
        if (rc == MGMT_CB_ERROR_RC) {
            /* The failure code is the RC value */
            return err_rc;
        }
    }
```

(continues on next page)
/* The failure is a group and ID error value */
ok = smp_add_cmd_err(zse, err_group, (uint16_t)err_rc);
goto end;
}

/* All handlers returned success codes */
ok = zcbor_tstr_put_lit(zse, "output_value") &&
zcbor_int32_put(zse, 1234);
end:
rc = (ok ? MGMT_ERR_EOK : MGMT_ERR_EMSGSIZE);
return rc;
}

If no response is required for the callback, the function call be called and casted to void.

Migration

If there is existing code using the previous callback system(s) in Zephyr 3.2 or earlier, then it will need to be migrated to the new system. To migrate code, the following callback registration functions will need to be migrated to register for callbacks using `mgmt_callback_register()` (note that `CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS` will need to be set to enable the new notification system in addition to any migrations):

- **mgmt_evt**
  Using `MGMT_EVT_OP_CMD_RECV`, `MGMT_EVT_OP_CMD_STATUS`, or `MGMT_EVT_OP_CMD_DONE` as drop-in replacements for events of the same name, where the provided data is `mgmt_evt_op_cmd_arg`. `CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS` needs to be set.

- **fs_mgmt_register_evt_cb**
  Using `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` where the provided data is `fs_mgmt_file_access`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS` needs to be set.

- **img_mgmt_register_callbacks**
  Using `MGMT_EVT_OP_IMG_MGMT_DFU_STARTED` if `dfu_started_cb` was used, `MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED` if `dfu_stopped_cb` was used, `MGMT_EVT_OP_IMG_MGMT_DFU_PENDING` if `dfu_pending_cb` was used or `MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED` if `dfu_confirmed_cb` was used. These call-backs do not have any return status. `CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS` needs to be set.

- **img_mgmt_set_upload_cb**
  Using `MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK` where the provided data is `img_mgmt_upload_check`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK` needs to be set.

- **os_mgmt_register_reset_evt_cb**
  Using `MGMT_EVT_OP_OS_MGMT_RESET`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code
to the client (MGMT_ERR_ACCESSDENIED can be used for an access denied error). CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS needs to be set.

API Reference

group mcumgr_callback_api

MCUmgr callback API.

Defines

MGMT_EVT_GET_GROUP(event)
Get group from event.

MGMT_EVT_GET_ID(event)
Get event ID from event.

MGMT_CB_ERROR_RET

Typedefs

typedef enum mgmt_cb_return (*mcumgr_callback)(uint32_t event, enum mgmt_cb_return prev_status, int32_t *rc, uint16_t *group, bool *abort_more, void *data, size_t data_size)

Function to be called on MGMT notification/event.

This callback function is used to notify an application or system about a MCUmgr mgmt event.

Param event
mcumgr_op_t.

Param prev_status
mgmt_cb_return of the previous handler calls, if it is an error then it will be the first error that was returned by a handler (i.e. this handler is being called for a notification only, the return code will be ignored).

Param rc
If prev_status is MGMT_CB_ERROR_RC then this is the SMP error that was returned by the first handler that failed. If prev_status is MGMT_CB_ERROR_ERR then this will be the group error rc code returned by the first handler that failed. If the handler wishes to raise an SMP error, this must be set to the mcumgr_err_t status and MGMT_CB_ERROR_RC must be returned by the function, if the handler wishes to raise a ret error, this must be set to the group ret status and MGMT_CB_ERROR_ERR must be returned by the function.

Param group
If prev_status is MGMT_CB_ERROR_ERR then this is the group of the ret error that was returned by the first handler that failed. If the handler wishes to raise a ret error, this must be set to the group ret status and MGMT_CB_ERROR_ERR must be returned by the function.

Param abort_more
Set to true to abort further processing by additional handlers.

Param data
Optional event argument.

Param data_size
Size of optional event argument (0 if no data is provided).
**Return**

`mgmt_cb_return` indicating the status to return to the calling code (only checked when this is the first failure reported by a handler).

** Enums **

```c
enum mgmt_cb_return
   MGMT event callback return value.

   Values:

   enumerator MGMT_CB_OK
      No error.

   enumerator MGMT_CB_ERROR_RC
      SMP protocol error and err_rc contains the mcumgr_err_t error code.

   enumerator MGMT_CB_ERROR_ERR
      Group (application-level) error and err_group contains the group ID that caused the error and err_rc contains the error code of that group to return.
```

```c
enum mgmt_cb_groups
   MGMT event callback group IDs.

   Note that this is not a 1:1 mapping with mcumgr_group_t values.

   Values:

   enumerator MGMT_EVT_GRP_ALL = 0

   enumerator MGMT_EVT_GRP_SMP

   enumerator MGMT_EVT_GRP_OS

   enumerator MGMT_EVT_GRP_IMG

   enumerator MGMT_EVT_GRP_FS

   enumerator MGMT_EVT_GRP_SETTINGS

   enumerator MGMT_EVT_GRP_USER_CUSTOM_START = MGMT_GROUP_ID_PERUSER
```

```c
enum smp_all_events
   MGMT event opcodes for all command processing.

   Values:

   enumerator MGMT_EVT_OP_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_ALL)
      Used to enable all events.
```
enum smp_group_events
  MGMT event opcodes for base SMP command processing.
  Values:

  enumerator MGMT_EVT_OP_CMD_RECV = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_SMP, 0)
    Callback when a command is received, data is mgmt_evt_op_cmd_arg().

  enumerator MGMT_EVT_OP_CMD_STATUS = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_SMP, 1)
    Callback when a status is updated, data is mgmt_evt_op_cmd_arg().

  enumerator MGMT_EVT_OP_CMD_DONE = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_SMP, 2)
    Callback when a command has been processed, data is mgmt_evt_op_cmd_arg().

  enumerator MGMT_EVT_OP_CMD_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_SMP)
    Used to enable all smp_group events.

enum fs_mgmt_group_events
  MGMT event opcodes for filesystem management group.
  Values:

  enumerator MGMT_EVT_OP_FS_MGMT_FILE_ACCESS =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_FS, 0)
    Callback when a file has been accessed, data is fs_mgmt_file_access().

  enumerator MGMT_EVT_OP_FS_MGMT_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_FS)
    Used to enable all fs_mgmt_group events.

enum img_mgmt_group_events
  MGMT event opcodes for image management group.
  Values:

  enumerator MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 0)
    Callback when a client sends a file upload chunk, data is img_mgmt_upload_check().

  enumerator MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 1)
    Callback when a DFU operation is stopped.

  enumerator MGMT_EVT_OP_IMG_MGMT_DFU_STARTED =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 2)
    Callback when a DFU operation is started.

  enumerator MGMT_EVT_OP_IMG_MGMT_DFU_PENDING =
    MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 3)
    Callback when a DFU operation has finished being transferred.
enumerator MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_IMG, 4)
    Callback when an image has been confirmed.

enumerator MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK_WRITE_COMPLETE = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP/img, 5)
    Callback when an image write command has finished writing to flash.

enumerator MGMT_EVT_OP_IMG_MGMT_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_IMG)
    Used to enable all img_mgmt_group events.

enum os_mgmt_group_events
    MGMT event opcodes for operating system management group.
    Values:
    enumerator MGMT_EVT_OP_OS_MGMT_RESET = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_OS, 0)
        Callback when a reset command has been received, data is os_mgmt_reset_data.
    enumerator MGMT_EVT_OP_OS_MGMT_INFO_CHECK = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_OS, 1)
        Callback when an info command is processed, data is os_mgmt_info_check.
    enumerator MGMT_EVT_OP_OS_MGMT_INFO_APPEND = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_OS, 2)
        Callback when an info command needs to output data, data is os_mgmt_info_append.
    enumerator MGMT_EVT_OP_OS_MGMT_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_OS)
        Used to enable all os_mgmt_group events.

enum settings_mgmt_group_events
    MGMT event opcodes for settings management group.
    Values:
    enumerator MGMT_EVT_OP_SETTINGS_MGMT_ACCESS = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_SETTINGS, 0)
        Callback when a setting is read/written/deleted.
    enumerator MGMT_EVT_OP_SETTINGS_MGMT_ALL = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_SETTINGS)
        Used to enable all settings_mgmt_group events.

Functions

uint8_t mgmt_evt_get_index(uint32_t event)
    Get event ID index from event.

Parameters
    • event – Event to get ID index from.
Returns

Event index.

enum mgmt_cb_return mgmt_callback_notify(uint32_t event, void *data, size_t data_size, int32_t *err_rc, uint16_t *err_group)

This function is called to notify registered callbacks about mcumgr notifications/events.

Parameters

- **event** – mcumgr_op_t.
- **data** – Optional event argument.
- **data_size** – Size of optional event argument (0 if none).
- **err_rc** – Pointer to rc value.
- **err_group** – Pointer to group value.

Returns

mgmt_cb_return either MGMT_CB_OK if all handlers returned it, or MGMT_CB_ERROR_RC if the first failed handler returned an SMP error (in which case err_rc will be updated with the SMP error) or MGMT_CB_ERROR_ERR if the first failed handler returned a ret group and error (in which case err_group will be updated with the failed group ID and err_rc will be updated with the group-specific error code).

void mgmt_callback_register(struct mgmt_callback *callback)

Register event callback function.

Parameters

- **callback** – Callback struct.

void mgmt_callback_unregister(struct mgmt_callback *callback)

Unregister event callback function.

Parameters

- **callback** – Callback struct.

struct mgmt_callback

#include <callbacks.h> MGMT callback struct.

Public Members

sys_snodet node

Entry list node.

mgmt_cb callback

Callback that will be called.

uint32_t event_id

MGMT_EVT_[...]. Event ID for handler to be called on.

This has special meaning if MGMT_EVT_OP_ALL is used (which will cover all events for all groups), or MGMT_EVT_OP_*_MGMT_ALL (which will cover all events for a single group). For events that are part of a single group, they can be or’d together for this to have one registration trigger on multiple events, please note that this will only work for a single group, to register for events in different groups, they must be registered separately.
struct mgmt_evt_op_cmd_arg
#include <callbacks.h> Arguments for MGMT_EVT_OP_CMD_RECV, MGMT_EVT_OP_CMD_STATUS and MGMT_EVT_OP_CMD_DONE.

Public Members

uint16_t group
mcumgr_group_t

uint8_t id
Message ID within group.

int err
mcumgr_err_t, used in MGMT_EVT_OP_CMD_DONE

int status
img_mgmt_id_upload_t, used in MGMT_EVT_OP_CMD_STATUS

MCUmgr fs_mgmt callback API.

Enums

enum fs_mgmt_file_access_types
The type of operation that is being requested for a given file access callback.
Values:

enumerator FS_MGMT_FILE_ACCESS_READ
Access to read file (file upload).

enumerator FS_MGMT_FILE_ACCESS_WRITE
Access to write file (file download).

enumerator FS_MGMT_FILE_ACCESS_STATUS
Access to get status of file.

enumerator FS_MGMT_FILE_ACCESS_HASH_CHECKSUM
Access to calculate hash or checksum of file.

struct fs_mgmt_file_access
#include <fs_mgmt_callbacks.h> Structure provided in the MGMT_EVT_OP_FS_MGMT_FILE_ACCESS notification callback: This callback function is used to notify the application about a pending file read/write request and to authorise or deny it.

Access will be allowed so long as all notification handlers return MGMT_ERR_EOK, if one returns an error then access will be denied.
Public Members

```c
enum fs_mgmt_file_access_types access
    Specifies the type of the operation that is being requested.
```

```c
char *filename
    Path and filename of file be accesses, note that this can be changed by handlers to redirect
    file access if needed (as long as it does not exceed the maximum path string size).
```

MCUmgr img_mgmt callback API.

```c
struct img_mgmt_upload_check
    #include <img_mgmt_callbacks.h> Structure provided in the
    MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK notification callback: This callback function
    is used to notify the application about a pending firmware upload packet from a client and
    authorise or deny it.
```

Upload will be allowed so long as all notification handlers return `MGMT_ERR_EOK`, if one
returns an error then the upload will be denied.

Public Members

```c
struct img_mgmt_upload_action *action
    Action to take.
```

```c
struct img_mgmt_upload_req *req
    Upload request information.
```

MCUmgr os_mgmt callback API.

```c
struct os_mgmt_reset_data
    #include <os_mgmt_callbacks.h> Structure provided in the
    MGMT_EVT_OP_OS_MGMT_RESET notification callback: This callback function is used
    to notify the application about a pending device reboot request and to authorise or deny it.
```

Public Members

```c
bool force
    Contains the value of the force parameter.
```

MCUmgr settings_mgmt callback API.

 Enums

```c
enum settings_mgmt_access_types
    Values:
```

```c
enumerator SETTINGS_ACCESS_READ
enumerator SETTINGS_ACCESS_WRITE
```
enumerator SETTINGS_ACCESS_DELETE

enumerator SETTINGS_ACCESS_COMMIT

enumerator SETTINGS_ACCESS_LOAD

enumerator SETTINGS_ACCESS_SAVE

struct settings_mgmt_access
{
    #include <settings_mgmt_callbacks.h>

    Structure provided in the
    MGMT_EVT_OP_SETTINGS_MGMT_ACCESS notification callback: This callback function
    is used to notify the application about a pending setting read/write/delete/load/save/commit
    request and to authorise or deny it.

    Access will be allowed so long as no handlers return an error, if one returns an error then
    access will be denied.

Public Members

enum settings_mgmt_access_types access

    Type of access.

    char *name

    Key name for accesses (only set for SETTINGS_ACCESS_READ, SETTINGS_ACCESS_WRITE and SETTINGS_ACCESS_DELETE).

    Note that this can be changed by handlers to redirect settings access if needed
    (as long as it does not exceed the maximum setting string size) if CONFIG_MCUMGR_GRP_SETTINGS_BUFFER_TYPE_STACK is selected, of maximum size
    CONFIG_MCUMGR_GRP_SETTINGS_NAME_LEN.

    Note: This string must be NULL terminated.

    const uint8_t *val

    Data provided by the user (only set for SETTINGS_ACCESS_WRITE)

    const size_t *val_length

    Length of data provided by the user (only set for SETTINGS_ACCESS_WRITE)

4.4.4 Fixing and backporting fixes to Zephyr v2.7 MCUmgr

The processes described in this document apply to both the zephyr repository itself and the MCUmgr
module defined in west.yml.

Note: Currently, the backporting process, described in this document, is required only when providing
changes to Zephyr version 2.7 LTS

There are two different processes: one for issues that have also been fixed in the current version of
Zephyr (backports), and one for issues that are being fixed only in a previous version.

The upstream MCUmgr repository is located in this page. The Zephyr fork used in version 2.7 and earlier
is located here. Versions of Zephyr past 2.7 use the MCUmgr library that is part of the Zephyr code base.
Possible origins of a code change

In Zephyr version 2.7 and earlier, you must first apply the fix to the upstream repository of MCUmgr and then bring it to Zephyr with snapshot updates.

As such, there are four possible ways to apply a change to the 2.7 branch:

- The fix, done directly to the Zephyr held code of the MCUmgr library, is backported to the v2.7-branch.
- The fix, ported to the Zephyr held code from the upstream repository, is backported to the v2.7-branch.
- The fix, done upstream and no longer relevant to the current version, is directly backported to the v2.7-branch.
- The fix, not present upstream and not relevant for the current version of Zephyr, is directly applied to the v2.7-branch.

The first three cases are cases of backports, the last one is a case of a new fix and has no corresponding fix in the current version.

Applying fixes to previous versions of MCUmgr

This section indicates how to apply fixes to previous versions of MCUmgr.

Creating a bug report

Every proposed fix requires a bug report submitted for the specified version of Zephyr affected by the bug.

In case the reported bug in a previous version has already been fixed in the current version, the description of the bug must be copied with the following:

- Additional references to the bug in the current version
- The PR for the current version
- The SHAs of the commits, if the PR has already been merged

You must also apply the backport v2.7-branch label to the bug report.

Creating the pull request for the fix

You can either create a backport pull request or a new-fix pull request.

Creating backport pull requests

Backporting a fix means that some or all of the fix commits, as they exist in the current version, are ported to a previous version.

**Note:** Backporting requires the fix for the current version to be already merged.

To create a backport pull request, do the following:

1. Port the fix commits from the current version to the previous version. Even if some of the commits require changes, keep the commit messages of all the ported commits as close to the ones in the original commits as possible, adding the following line:

   "Backporting commit <sha>"

   ``<sha>` indicates the SHA of the commit after it has been already merged in the current version.

   1. Create the pull request selecting v2.7-branch as the merge target.
2. Update `west.yml` within Zephyr, creating a pull-request to update the MCUmgr library referenced in Zephyr 2.7.

**Creating new-fix pull requests**  
When the fix needed does not have a corresponding fix in the current version, the bug report must follow the ordinary process.
1. Create the pull request selecting `v2.7-branch` as the merge target.
2. Update `west.yml` within Zephyr, creating a pull-request to update the MCUmgr library referenced in Zephyr 2.7.

**Configuration management**

This chapter describes the maintainers’ side of accepting and merging fixes and backports.

**Prerequisites**  
As a maintainer, these are the steps required before proceeding with the merge process:
1. Check if the author has followed the correct steps that are required to apply the fix, as described in *Applying fixes to previous versions of MCUmgr*.
   1. Ensure that the author of the fix has also provided the `west.yml` update for Zephyr 2.7.

The specific merging process depends on where the fix comes from and whether it is a backport or a new fix.

**Merging a backported fix**  
There are two possible sources of backports:
- The Zephyr code base
- A direct fix from upstream

Both cases are similar and differ only in the branch name.

To merge a backported fix after the pull request for the fix has gone through the review process, as a maintainer, do the following:
1. Create a branch named as follow:

   ```
   backport-<source>-<pr_num>-to_v2.7-branch
   ```

   `<source>` can be one of the following:
   - `upstream` - if the fix has originally been merged to the upstream repository.
   - `zephyr` - if the fix has been applied to the Zephyr internal MCUmgr library (past 2.7 versions).

   `<pr_num>` is the number of the original pull request that has already been merged.

   For example, a branch named `backport-upstream-137-to-v2.7-branch` indicates a backport of pull request 137, which has already been merged to the upstream repository of MCUmgr.
2. Push the reviewed pull-request branch to the newly created branch and merge the backport branch to `v2.7-branch`.

**Merging a new fix**  
Merging a new fix, that is not a backport of either any upstream or Zephyr fix, does not require any special treatment. Apply the fix directly at the top of `v2.7-branch`.

**Merge west.yml**  
As an MCUmgr maintainer, you may not be able to merge the `west.yml` update, to introduce the fix to Zephyr. However, you are responsible for such a merge to happen as soon as possible after the MCUmgr fixes have been applied to the `v2.7-branch` of the MCUmgr.
### 4.4.5 SMP Protocol Specification

This is description of Simple Management Protocol, SMP, that is used by MCUmgr to pass requests to devices and receive responses from them.

SMP is an application layer protocol. The underlying transport layer is not in scope of this documentation.

**Note:** SMP in this context refers to SMP for MCUmgr (Simple Management Protocol), it is unrelated to SMP in Bluetooth (Security Manager Protocol), but there is an MCUmgr SMP transport for Bluetooth.

#### Frame: The envelope

Each frame consists of a header and data. The `Data Length` field in the header may be used for reassembly purposes if underlying transport layer supports fragmentation. Frames are encoded in “Big Endian” (Network endianness) when fields are more than one byte long, and takes the following form:

<table>
<thead>
<tr>
<th>3</th>
<th>7 6 5 4 3 2 1 0</th>
<th>2</th>
<th>7 6 5 4 3 2 1 0</th>
<th>1</th>
<th>7 6 5 4 3 2 1 0</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Res</td>
<td>Ver</td>
<td>OP</td>
<td>Flags</td>
<td>Data Length</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Group ID</td>
<td>Sequence Num</td>
<td>Command ID</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Data ...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** The original specification states that SMP should support receiving both the “Little-endian” and “Big-endian” frames but in reality the MCUmgr library is hardcoded to always treat “Network” side as “Big-endian”.

Data is optional and is not present when `Data Length` is zero. The encoding of data depends on the target of group/ID.

A description of the various fields and their meaning:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Res</td>
<td>This is reserved, not-used field and must be always set to 0.</td>
</tr>
<tr>
<td>Ver</td>
<td>This indicates the version of the protocol being used, this should be set to 0b01 to use the newer SMP transport where error codes are more detailed and returned in the map, otherwise left as 0b00 to use the legacy SMP protocol. Versions 0b10 and 0b11 are reserved for future use and should not be used.</td>
</tr>
<tr>
<td>OP</td>
<td><code>mcumgr_op_t</code>, determines whether information is written to a device or requested from it and whether a packet contains request to an SMP server or response from it.</td>
</tr>
<tr>
<td>Flags</td>
<td>Reserved for flags; there are no flags defined yet, the field should be set to 0</td>
</tr>
<tr>
<td>Data Length</td>
<td>Length of the Data field</td>
</tr>
<tr>
<td>Group ID</td>
<td><code>mcumgr_group_t</code>, see Management Group ID's for further details.</td>
</tr>
<tr>
<td>Sequence Num</td>
<td>This is a frame sequence number. The number is increased by one with each request frame.</td>
</tr>
<tr>
<td>Command ID</td>
<td>This is a command, within Group.</td>
</tr>
<tr>
<td>Data</td>
<td>This is data payload of the <code>Data Length</code> size. It is optional as <code>Data Length</code> may be set to zero, which means that no data follows the header.</td>
</tr>
</tbody>
</table>
**Note:** Contents of Data depends on a value of an OP, a Group ID, and a Command ID.

**Management Group ID’s** The SMP protocol supports predefined common groups and allows user-defined groups. The following table presents a list of common groups:

<table>
<thead>
<tr>
<th>Decimal ID</th>
<th>Group description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Default/OS Management Group</td>
</tr>
<tr>
<td>1</td>
<td>Application/software image management group</td>
</tr>
<tr>
<td>2</td>
<td>Statistics management</td>
</tr>
<tr>
<td>3</td>
<td>Settings (Config) Management Group</td>
</tr>
<tr>
<td>4</td>
<td>Application/system log management (currently not used by Zephyr)</td>
</tr>
<tr>
<td>5</td>
<td>Run-time tests (unused by Zephyr)</td>
</tr>
<tr>
<td>6</td>
<td>Split image management (unused by Zephyr)</td>
</tr>
<tr>
<td>7</td>
<td>Test crashing application (unused by Zephyr)</td>
</tr>
<tr>
<td>8</td>
<td>File management</td>
</tr>
<tr>
<td>9</td>
<td>Shell management</td>
</tr>
<tr>
<td>63</td>
<td>Zephyr specific basic commands group</td>
</tr>
<tr>
<td>64</td>
<td>This is the base group for defining an application specific management groups.</td>
</tr>
</tbody>
</table>

The payload for above groups, except for user groups (64 and above) is always CBOR encoded. The group 64, and above can define their own scheme for data communication.

**Minimal response**

Regardless of a command issued, as long as there is SMP client on the other side of a request, a response should be issued containing the header followed by CBOR map container. Lack of response is only allowed when there is no SMP service or device is non-responsive.

**Minimal response SMP data** Minimal response is:

SMP version 2

```json
{
   (str)"err" : {
      (str)"group" : (uint)
      (str)"rc" : (uint)
   }
}
```

SMP version 1 (and non-group SMP version 2)

```json
{
   (str)"rc" : (int)
}
```

where:

- "err" - > mcumgr_group_t group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- "group" contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- "rc" - > mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
Note that in the case of a successful command, an empty map will be returned (rc/err is only returned if there is an error condition, therefore if only an empty map is returned or a response lacks these, the request can be considered as being successful. For SMP version 2, errors relating to SMP itself that are not group specific will still be returned as rc errors, SMP version 2 clients must therefore be able to handle both types of errors.

Specifications of management groups supported by Zephyr

Default/OS Management Group  OS management group defines following commands:

<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Echo</td>
</tr>
<tr>
<td>1</td>
<td>Console/Terminal echo control; unimplemented by Zephyr</td>
</tr>
<tr>
<td>2</td>
<td>Task Statistics</td>
</tr>
<tr>
<td>3</td>
<td>Memory pool statistics</td>
</tr>
<tr>
<td>4</td>
<td>Date-time string; unimplemented by Zephyr</td>
</tr>
<tr>
<td>5</td>
<td>System reset</td>
</tr>
<tr>
<td>6</td>
<td>MCUMGR parameters</td>
</tr>
<tr>
<td>7</td>
<td>OS/Application info</td>
</tr>
<tr>
<td>8</td>
<td>Bootloader information</td>
</tr>
</tbody>
</table>

Echo command  Echo command responses by sending back string that it has received.

Echo request  Echo request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or 2</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
   (str)"d" : (str)
}
```

where:

```
"d"  string to be replied by echo service.
```

Echo response  Echo response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>When request OP was 0</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>0</td>
<td>When request OP was 2</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
   (str)"r" : (str)
}
```
In case of error the CBOR data takes the form:

**SMP version 2**

```
{  
    (str)"err" : {  
        (str)"group" : (uint)  
        (str)"rc" : (uint)  
    }  
}
```

**SMP version 1 (and non-group SMP version 2)**

```
{  
    (str)"rc" : (int)  
}
```

where:

- "r" replying echo string.
- "err" -> *mcumgr_group_t* group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- "err" -> contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- "rc" *mcumgr_err_t* only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

**Task statistics command** The command responds with some system statistics.

**Task statistics request** Task statistics request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>2</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data.

**Task statistics response** Task statistics response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>2</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```
{  
    (str)"tasks" : {  
        (str)<task_name> : {  
            (str)"prio" : (uint)  
            (str)"tid" : (uint)  
            (str)"state" : (uint)  
            (str)"stkuse" : (uint)  
            (str)"stksiz" : (uint)  
            (str)"cswcnt" : (uint)  
        }  
    }  
}
```
In case of error the CBOR data takes the form:

SMP version 2

```json
{
    (str)"err" : {
        (str)"group" : (uint)
        (str)"rc" : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```json
{
    (str)"rc" : (int)
}
```

where:

- `<task_name>` string identifying task.
- "prio" task priority.
- "tid" numeric task ID.
- "state" numeric task state.
- "stkuse" task's/thread's stack usage.
- "stksiz" task's/thread's stack size.
- "cswcnt" task's/thread's context switches.
- "runtime" task's/thread's runtime in "ticks".
- "last_checkin" set to 0 by Zephyr.
- "next_checkin" set to 0 by Zephyr.
- "err" -> `mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- "err" -> contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- "rc" only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

**Note:** The unit for "stkuse" and "stksiz" is system dependent and in case of Zephyr this is number of 4 byte words.

**Memory pool statistics** The command is used to obtain information on memory pools active in running system.

**Memory pool statistic request** Memory pool statistics request header fields:
The command sends an empty CBOR map as data.

**Memory pool statistics response**  Memory pool statistics response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>3</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
  "pool_name": {
    "blksz": (int),
    "nblks": (int),
    "nfree": (int),
    "min": (int)
  }
  ...
}
```

In case of error the CBOR data takes the form:

**SMP version 2**

```json
{
  "err": {
    "group": (uint),
    "rc": (uint)
  }
}
```

**SMP version 1 (and non-group SMP version 2)**

```json
{
  "rc": (int)
}
```

where:

- `<pool_name>` string representing the pool name, used as a key for dictionary with pool statistics data.
- "blksz" size of the memory block in the pool.
- "nblks" number of blocks in the pool.
- "nfree" number of free blocks.
- "min" lowest number of free blocks the pool reached during run-time.
- "err" -> `mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- "err" -> `mcumgr_err_t` contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- "rc" `mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
Date-time command The command allows to obtain string representing current time-date on a device or set a new time to a device. The time format used, by both set and get operations, is:

“yyyy-MM-dd’T’HH:mm:ss.SSSSSSZZZZZ”

Date-time get The command allows to obtain date-time from a device.

Date-time get request Date-time request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data.

Date-time get response Date-time get response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```
{
    (str)"datetime" : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group" : (uint)
        (str)"rc" : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc" : (int)
}
```

where:

| “datetime” | String in format: yyyy-MM-dd ’T’ HH:mm:ss.SSSSSSZZZZZ. |
| “err” -> | mcumgr_group_t group of the group-based error code. Only appears if an error is returned when using SMP version 2. |
| “group” | contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2. |
| “rc” -> | mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2. |

Date-time set The command allows to set date-time to a device.
Date-time set request  Date-time set request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

CBOR data of response:

```json
{
  (str)"datetime" : (str)
}
```

where:

"datetime"  String in format: yyyy-MM-dd'T'HH:mm:ss.SSSSSSSZZZZZ.

Date-time set response  Date-time set response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```json
{
  (str)"err" : {
    (str)"group" : (uint)
    (str)"rc" : (uint)
  }
}
```

SMP version 1 (and non-group SMP version 2)

```json
{
  (str)"rc" : (int)
}
```

where:

"err" -> mcumgr_group_t  group of the group-based error code. Only appears if an error is returned when using SMP version 2.

"group" contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.

"rc" mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

System reset  Performs reset of system. The device should issue response before resetting so that the SMP client could receive information that the command has been accepted. By default, this command is accepted in all conditions, however if the CONFIG_MCUMGR_GRP_OS_RESET_HOOK is enabled and an application registers a callback, the callback will be called when this command is issued and can be used to perform any necessary tidy operations prior to the module rebooting, or to reject the reset request outright altogether with an error response. For details on this functionality, see ref: mcumgr_callbacks.
System reset request  System reset request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>0</td>
<td>5</td>
</tr>
</tbody>
</table>

Normally the command sends an empty CBOR map as data, but if a previous reset attempt has responded with “rc” equal to \texttt{MCMT\_ERR\_EBUSY} then the following map may be sent to force a reset:

```
{
  (opt)"force" : (int)
}
```

where:

- "force"  Force reset if value > 0, optional if 0.

System reset response  System reset response header fields

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>0</td>
<td>5</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
  (str)"err" : {
    (str)"group" : (uint)
    (str)"rc" : (uint)
  }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
  (str)"rc" : (int)
}
```

where:

- "err"  -> \texttt{mcumgr\_group\_t} group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- "group"  contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- "rc"  -> \texttt{mcumgr\_err\_t} only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

MCUmgm Parameters  Used to obtain parameters of mcumgr library.
**MCUmgr Parameters Request**  
MCUmgr parameters request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data.

**MCUmgr Parameters Response**  
MCUmgr parameters response header fields

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```
{
    (str)"buf_size" : (uint),
    (str)"buf_count" : (uint)
}
```

In case of error the CBOR data takes the form:

**SMP version 2**

```
{
    (str)"err" : {
        (str)"group" : (uint),
        (str)"rc" : (uint)
    }
}
```

**SMP version 1 (and non-group SMP version 2)**

```
{
    (str)"rc" : (int)
}
```

where:

- **"buf_size"** Single SMP buffer size, this includes SMP header and CBOR payload.
- **"buf_count"** Number of SMP buffers supported.
- **"err" -> mcumgr_group_t** group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- **"group"**
- **"err" -> mcumgr_group_t** contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- **"rc"**
- **"rc" mcumgr_err_t** only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

**OS/Application Info**  
Used to obtain information on running image, similar functionality to the **linux uname command**, allowing details such as kernel name, kernel version, build date/time, processor type and application-defined details to be returned. This functionality can be enabled with **CONFIG_MCUMGR_GRP_OS_INFO**.
OS/Application Info Request  OS/Application info request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>7</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
    (str, opt)"format" : (str)
}
```

where:

“format” Format specifier of returned response, fields are appended in their natural ascending index order, not the order of characters that are received by the command. Format specifiers: *s Kernel name *n Node name *r Kernel release *v Kernel version *b Build date and time (requires CONFIG_MCUMGR_GRP_OS_INFO_BUILD_DATE_TIME) *m Machine *p Processor *i Hardware platform *o Operating system *a All fields (shorthand for all above options) If this option is not provided, the s Kernel name option will be used.

OS/Application Info Response  OS/Application info response header fields

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>7</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
    (str)"output" : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```json
{
    (str)"err" : {
        (str)"group" : (uint)
        (str)"rc" : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```json
{
    (str)"rc" : (int)
}
```

where:
Bootloader Information  Allows retrieving information about the on-board bootloader and its parameters.

Bootloader Information Request  Bootloader information request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>8</td>
</tr>
</tbody>
</table>

CBOR data of request:

```
{
  (str[opt])"query" : (str)
}
```

where:

"query"  Is string representing query for parameters, with no restrictions how the query looks like as processing of query is left for bootloader backend. If there is no query, then response will return string identifying the bootloader.

Bootloader Information Response  Bootloader information response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>8</td>
</tr>
</tbody>
</table>

In case when no “query” has been provided in request, CBOR data of response:

```
{
  (str)"bootloader" : (str)
}
```

where:

"bootloader"  String representing bootloader name

In case when “query” is provided:

```
{
  (str,opt)<response> : ()
  ...
}
```
where:

Response to “query”. This is optional and may be left out in case when query yields no response, SMP version 2 error code of `OS_MGMT_ERR_QUERY_YIELDS_NO_ANSWER` is expected. Response may have more than one parameter reported back or it may be a map, that is dependent on bootloader backend and query.

Parameter characteristic information.

Parameter may be accompanied by additional, parameter specific, information keywords with assigned values.

In case of error the CBOR data takes the form:

SMP version 2

```
{
  (str)"err" : {
    (str)"group" : (uint)
    (str)"rc" : (uint)
  }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
  (str)"rc" : (int)
}
```

where:

| “err”  | `mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2. |
| “group” |
| “err”  | contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2. |
| “rc”    | `mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2. |

**Bootloader Information: MCUboot** In case when MCUboot is application bootloader, empty request will be responded with:

```
{
  (str)"bootloader" : (str)"MCUboot"
}
```

Currently “MCUboot” supports querying for mode of operation:

```
{
  (str)"query" : (str)"mode"
}
```

Response to “mode” is:

```
{
  (str)"mode" : (int)
  (str,opt)"no-downgrade" : (bool)
}
```
where “mode” is one of:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Unknown mode of MCUboot.</td>
</tr>
<tr>
<td>0</td>
<td>MCUboot is in single application mode.</td>
</tr>
<tr>
<td>1</td>
<td>MCUboot is in swap using scratch partition mode.</td>
</tr>
<tr>
<td>2</td>
<td>MCUboot is in overwrite (upgrade-only) mode.</td>
</tr>
<tr>
<td>3</td>
<td>MCUboot is in swap without scratch mode.</td>
</tr>
<tr>
<td>4</td>
<td>MCUboot is in DirectXIP without revert mode.</td>
</tr>
<tr>
<td>5</td>
<td>MCUboot is in DirectXIP with revert mode.</td>
</tr>
<tr>
<td>6</td>
<td>MCUboot is in RAM loader mode.</td>
</tr>
</tbody>
</table>

The no-downgrade field is a flag, which is always sent when true, indicating that MCUboot has downgrade prevention enabled; downgrade prevention means that if the uploaded image has a lower version than the currently running application, it will not be used for an update by MCUboot.

MCUmgr may reject images with a lower version in this configuration.

**Application/software image management group**

Application/software image management group defines following commands:

<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>State of images</td>
</tr>
<tr>
<td>1</td>
<td>Image upload</td>
</tr>
<tr>
<td>2</td>
<td>File (reserved but not supported by Zephyr)</td>
</tr>
<tr>
<td>3</td>
<td>Corelist (reserved but not supported by Zephyr)</td>
</tr>
<tr>
<td>4</td>
<td>Coreload (reserved but not supported by Zephyr)</td>
</tr>
<tr>
<td>5</td>
<td>Image erase</td>
</tr>
</tbody>
</table>

**Notion of “slots” and “images” in Zephyr**

The “slot” and “image” definition comes from mcuboot where “image” would consist of two “slots”, further named “primary” and “secondary”; the application is supposed to run from the “primary slot” and update is supposed to be uploaded to the “secondary slot”; the mcuboot is responsible in swapping slots on boot. This means that pair of slots is dedicated to single upgradable application. In case of Zephyr this gets a little bit confusing because DTS will use “slot0_partition” and “slot1_partition”, as label of fixed-partition dedicated to single application, but will name them as “image-0” and “image-1” respectively.

Currently Zephyr supports at most two images, in which case mapping is as follows:

<table>
<thead>
<tr>
<th>Image</th>
<th>Slot labels</th>
<th>Slot Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>“slot0_partition” “slot1_partition”</td>
<td>“image-0” “image-1”</td>
</tr>
<tr>
<td>2</td>
<td>“slot2_partition” “slot3_partition”</td>
<td>“image-2” “image-3”</td>
</tr>
</tbody>
</table>

**State of images**

The command is used to set state of images and obtain list of images with their current state.

**Get state of images request**

Get state of images request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

The command sends sends empty CBOR map as data.
Get state of images response  Get state of images response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

**Note:** Below definition of the response contains “image” field that has been marked as optional (opt): the field may not appear in response when target application does not support more than one image. The field is mandatory when application supports more than one application image to allow identifying which image information is listed.

A response will only contain information for valid images, if an image can not be identified as valid it is simply skipped.

CBOR data of successful response:

```json
{
  (str)"images" : [
    {
      (str,opt)"image" : (uint),
      (str)"slot" : (uint),
      (str)"version" : (str),
      (str,opt)*"hash" : (byte str),
      (str,opt)"bootable" : (bool),
      (str,opt)"pending" : (bool),
      (str,opt)"confirmed" : (bool),
      (str,opt)"active" : (bool),
      (str,opt)"permanent" : (bool)
    }
    ...
  ]
  (str,opt)"splitStatus" : (int)
}
```

In case of error the CBOR data takes the form:

**SMP version 2**

```json
{
  (str)"err" : {
    (str)"group" : (uint),
    (str)"rc" : (uint)
  }
}
```

**SMP version 1 (and non-group SMP version 2)**

```json
{
  (str)"rc" : (int),
  (str,opt)"rsn" : (str)
}
```

where:
Set state of image request

Set state of image request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

Note: For more information on how does image/slots function, please refer to the MCUBoot documentation https://docs.mcuboot.com/design.html#image-slots. For information on MCUboot image format, please refer to the MCUBoot documentation https://docs.mcuboot.com/design.html#image-format.
If “confirm” is false or not provided, an image with the “hash” will be set for test, which means that it will not be marked as permanent and upon hard reset the previous application will be restored to the primary slot. In case when “confirm” is true, the “hash” is optional as the currently running application will be assumed as target for confirmation.

**Set state of image response**  The response takes the same format as *Get state of images response*.

**Image upload**  The image upload command allows to update application image.

**Image upload request**  The image upload request is sent for each chunk of image that is uploaded, until complete image gets uploaded to a device.

Image upload request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
  (str, opt)"image" : (uint),
  (str, opt)"len" : (uint),
  (str)"off" : (uint),
  (str, opt)"sha" : (byte str),
  (str)"data" : (byte str),
  (str, opt)"upgrade" : (bool)
}
```

where:

- “image” optional image number, it does not have to appear in request at all, in which case it is assumed to be 0. Should only be present when “off” is 0.
- “len” optional length of an image. Must appear when “off” is 0.
- “off” offset of image chunk the request carries.
- “sha” SHA256 hash of an upload; this is used to identify an upload session (e.g. to allow MCUmgr to continue a broken session), and for image verification purposes. This must be a full SHA256 hash of the whole image being uploaded, or not included if the hash is not available (in which case, upload session continuation and image verification functionality will be unavailable). Should only be present when “off” is 0.
- “data” image data to write at provided offset.
- “upgrade” optional flag that states that only upgrade should be allowed, so if the version of uploaded software is not higher than already on a device, the image upload will be rejected. Zephyr compares major, minor and revision (x.y.z) by default unless `CONFIG_MCUMGR_GRP_IMG_VERSION_CMP_USE_BUILD_NUMBER` is set, whereby it will compare build numbers too. Should only be present when “off” is 0.

**Note:** There is no field representing size of chunk that is carried as “data” because that information is
embedded within “data” field itself.

**Note:** It is possible that a server will respond to an upload with “off” of 0, this may happen if an upload on another transport (or outside of MCUmgr entirely) is started, if the device has rebooted or if a packet has been lost. If this happens, a client must re-send all the required and optional fields that it sent in the original first packet so that the upload state can be re-created by the server. If the original fields are not included, the upload will be unable to continue.

The MCUmgr library uses “sha” field to tag ongoing update session, to be able to continue it in case when it gets broken, and for upload verification purposes. If library gets request with “off” equal zero it checks stored “sha” within its state and if it matches it will respond to update client application with offset that it should continue with. If this hash is not available (e.g. because a file is being streamed) then it must not be provided, image verification and upload session continuation features will be unavailable in this case.

**Image upload response**  Image upload response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```
{
  (str,opt)"off" : (uint)
  (str,opt)"match" : (bool)
}
```

In case of error the CBOR data takes the form:

**SMP version 2**

```
{
  (str)"err" : {
    (str)"group" : (uint)
    (str)"rc" : (uint)
  }
}
```

**SMP version 1 (and non-group SMP version 2)**

```
{
  (str)"rc" : (int)
  (str,opt)"rsn" : (str)
}
```

where:
The “off” field is only included in responses to successfully processed requests; if “rc” is negative then “off” may not appear.

**Image erase**  The command is used for erasing image slot on a target device.

**Note:**  This is synchronous command which means that a sender of request will not receive response until the command completes, which can take a long time.

**Image erase request**  Image erase request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>5</td>
</tr>
</tbody>
</table>

CBOR data of request:

```
{  
   (str,opt)"slot" : (uint)  
}
```

where:

“slot” optional slot number, it does not have to appear in the request at all, in which case it is assumed to be 1.

**Image erase response**  Image erase response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1</td>
<td>5</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{  
   (str)"err" : {  
      (str)"group" : (uint)  
   }  
}```

(continues on next page)
SMP version 1 (and non-group SMP version 2)

```plaintext
{
    (str)"rc" : (int)
    (str, opt)"rsn" : (str)
}
```

where:

- "err" -> mcumgr_group_t group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- "err" -> contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- "rc" mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
- "rsn" optional string that clarifies reason for an error; specifically useful when rc is MGMT_ERR_EUNKNOWN.

**Note:** Response from Zephyr running device may have “rc” value of MGMT_ERR_EBADSTATE, which means that the secondary image has been marked for next boot already and may not be erased.

**Statistics management** Statistics management allows to obtain data gathered by Statistics subsystem of Zephyr, enabled with CONFIG_STATS.

Statistics management group defines commands:

<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Group data</td>
</tr>
<tr>
<td>1</td>
<td>List groups</td>
</tr>
</tbody>
</table>

**Statistics: group data** The command is used to obtain data for group specified by a name. The name is one of group names as registered, with STATS_INIT_AND_REG macro or stats_init_and_reg() function call, within module that gathers the statistics.

**Statistics: group data request** Statistics group data request header:

```
OP  Group ID  Command ID
0   2         0
```

CBOR data of request:

```plaintext`
{
    (str)"name" : (str)
}
```
where:

<table>
<thead>
<tr>
<th>“name”</th>
<th>group name.</th>
</tr>
</thead>
</table>

**Statistics: group data response**

Statistics group data response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
  "name" : (str)
  "fields" : {
    <entry_name> : (uint)
  }
}
```

In case of error the CBOR data takes the form:

**SMP version 2**

```json
{
  "err" : {
    "group" : (uint)
    "rc" : (uint)
  }
}
```

**SMP version 1 (and non-group SMP version 2)**

```json
{
  "rc" : (int)
}
```

where:

| “name” | this is name of group the response contains data for. |
| “fields” | this is map of entries within groups that consists of pairs where the entry name is mapped to value it represents in statistics. |
| <entry_name> | single entry to value mapping; value is hardcoded to unsigned integer type, in a CBOR meaning. |
| “err” -> mcumgr_group_t | group of the group-based error code. Only appears if an error is returned when using SMP version 2. |
| “group” | contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2. |
| “rc” | mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2. |

**Statistics: list of groups**

The command is used to obtain list of groups of statistics that are gathered on a device. This is a list of names as given to groups with STATS_INIT_AND_REG macro or stats_init_and_reg() function calls, within module that gathers the statistics; this means that this command may be considered optional as it is known during compilation what groups will be included into build and listing them is not needed prior to issuing a query.
Statistics: list of groups request

Statistics group list request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data.

Statistics: list of groups response

Statistics group list request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```
{
    (str)"stat_list" : [
        (str)<stat_group_name>, ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group" : (uint),
        (str)"rc" : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc" : (int)
}
```

where:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>“stat_list”</td>
<td>array of strings representing group names; this array may be empty if there are no groups.</td>
</tr>
<tr>
<td>“err”</td>
<td>group of the group-based error code. Only appears if an error is returned when using SMP version 2.</td>
</tr>
<tr>
<td>“group”</td>
<td>contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.</td>
</tr>
<tr>
<td>“rc”</td>
<td>mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.</td>
</tr>
</tbody>
</table>

Settings (Config) Management Group

Settings management group (known as Configuration Manager in the original MCUmgr repository) defines the following commands:
<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Read/write setting</td>
</tr>
<tr>
<td>1</td>
<td>Delete setting</td>
</tr>
<tr>
<td>2</td>
<td>Commit settings</td>
</tr>
<tr>
<td>3</td>
<td>Load/Save settings</td>
</tr>
</tbody>
</table>

Note that the Zephyr version adds additional commands and features which are not supported by the original upstream version, however, the original client functionality should work for read/write functionality.

**Read/write setting command**  
Read/write setting command allows updating a setting entry on a device or getting the current value of a setting from a device.

**Read setting request**  
Read setting request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
    "name": (str),
    "max_size": (uint)
}
```

where:

<table>
<thead>
<tr>
<th>“name”</th>
<th>string of the setting to retrieve</th>
</tr>
</thead>
<tbody>
<tr>
<td>“max_size”</td>
<td>optional maximum size of data to return</td>
</tr>
</tbody>
</table>

**Read setting response**  
Read setting response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
    "val": (bstr),
    "max_size": (uint)
}
```

In case of error the CBOR data takes the form:

**SMP version 2**

```json
{
    "err": {
        "group": (uint),
        "rc": (uint)
    }
}
```

(continues on next page)
SMP version 1

```json
{
  (str)"rc"   : (int)
}
```

where:

| “val” | binary string of the returned data, note that the underlying data type cannot be specified through this and must be known by the client. |
| “max_size” | will be set if the maximum supported data size is smaller than the maximum requested data size, and contains the maximum data size which the device supports, equivalent to kconfig:option:CONFIG_MCUMGR_GRP_SETTINGS_NAME_LEN. |
| “err” -> “group” | mcumgr_group_t group of the group-based error code. Only appears if an error is returned when using SMP version 2. |
| “err” -> “rc” | contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2. |
| “rc” | mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1. |

Write setting request  Write setting request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
  (str)"name"   : (str)
  (str)"val"   : (bstr)
}
```

where:

| “name” | string of the setting to update/set |
| “val” | value to set the setting to |

Write setting response  Write setting response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2
Delete setting command  Delete setting command allows deleting a setting on a device.

Delete setting request  Delete setting request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of request:

```
{
  (str)"name" : (str)
}
```

where:

| “name” | string of the setting to delete |

Delete setting response  Delete setting response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>3</td>
<td>1</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
  (str)"err" : {
    (str)"group" : (uint)
  }
}
```
Commit settings command  Commit settings command allows committing all settings that have been set but not yet applied on a device.

Commit settings request  Commit settings request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>

The command sends sends empty CBOR map as data.

Commit settings response  Commit settings response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```json
{
    (str)'err' : {
        (str)'group' : (uint)
        (str)'rc' : (uint)
    }
}
```

SMP version 1

```json
{
    (str)'rc' : (int)
}
```
where:

```
"err" -> mcumgr_group_t group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"group" contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc" mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1.
```

Load/Save settings command  Load/Save settings command allows loading/saving all serialized items from/to persistent storage on a device.

Load settings request  Load settings request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

The command sends empty CBOR map as data.

Load settings response  Load settings response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{  
  (str)"err" : {
    (str)"group" : (uint)
    (str)"rc" : (uint)
  }
}
```

SMP version 1

```
{  
  (str)"rc" : (int)
}
```

where:

```
"err" -> mcumgr_group_t group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"group" contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc" mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1.
```
Save settings request  Save settings request header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td></td>
<td>3</td>
</tr>
</tbody>
</table>

The command sends empty CBOR map as data.

Save settings response  Save settings response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td></td>
<td>3</td>
</tr>
</tbody>
</table>

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

**SMP version 2**

```
{
  (str)"err" : {
    (str)"group" : (uint),
    (str)"rc"  : (uint)
  }
}
```

**SMP version 1**

```
{
  (str)"rc"  : (int)
}
```

where:

- **“err”** -> mcumgr_group_t group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- **“group”**
- **“err”** -> mcumgr_err_t contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- **“rc”**

**Settings access callback**  There is a settings access MCUmgr callback available (see MCUmgr Callbacks for details on callbacks) which allows for applications/modules to know when settings management commands are used and, optionally, block access (for example through the use of a security mechanism). This callback can be enabled with CONFIG_MCUMGR_GRP_SETTINGS_ACCESS_HOOK, registered with the event MGMT_EVT_OP_SETTINGS_MGMT_ACCESS, whereby the supplied callback data is settings_mgmt_access.

**File management**  The file management group provides commands that allow to upload and download files to/from a device.

File management group defines following commands:
### File download
Command allows to download contents of an existing file from specified path of a target device. Client applications must keep track of data they have already downloaded and where their position in the file is (MCUmgr will cache these also), and issue subsequent requests, with modified offset, to gather the entire file. Request does not carry size of requested chunk, the size is specified by application itself. Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached and another transport does not make use of uploading/downloading files using fs_mgmt), but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed.

**Note:** By default, all file upload/download requests are unconditionally allowed. However, if the Kconfig option `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` (see MCUmgr callbacks), which allows for allowing or declining access to reading/writing a particular file, or for rewriting the path supplied by the client.

#### File download request
File download request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
   "off" : (uint),
   "name" : (str)
}
```

where:

- "off" offset to start download at
- "name" absolute path to a file

#### File download response
File download response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of successful response:
In case of error the CBOR data takes the form:

**SMP version 2**

```
{
    (str)"err" : {
        (str)"group" : (uint)
        (str)"rc" : (uint)
    }
}
```

**SMP version 1 (and non-group SMP version 2)**

```
{
    (str)"rc" : (int)
}
```

where:

- **"off"** offset the response is for.
- **"data"** chunk of data read from file; it is CBOR encoded stream of bytes with embedded size; "data" appears only in responses where "rc" is 0.
- **"len"** length of file, this field is only mandatory when "off" is 0.
- **"err"** -> **mcuMgr_group_t** group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- **"group"** contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- **"rc"** **mcuMgr_err_t** only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

**File upload** Allows to upload a file to a specified location. Command will automatically overwrite existing file or create a new one if it does not exist at specified path. The protocol supports stateless upload where each requests carries different chunk of a file and it is client side responsibility to track progress of upload.

Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached, but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed. Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached and another transport does not make use of uploading/downloading files using fs_mgmt), but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed.

**Note:** Weirdly, the current Zephyr implementation is half-stateless as is able to hold single upload context, holding information on ongoing upload, that consists of bool flag indicating in-progress upload, last successfully uploaded offset and total length only.

**Note:** By default, all file upload/download requests are unconditionally allowed. However, if the Kconfig option `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` (see MCUmgr callbacks), which allows for
allowing or declining access to reading/writing a particular file, or for rewriting the path supplied by the client.

**File upload request**  File upload request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>8</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```
{
  (str)'off' : (uint),
  (str)'data' : (str),
  (str)'name' : (str),
  (str, opt)'len' : (uint)
}
```

where:

<table>
<thead>
<tr>
<th>“off”</th>
<th>offset to start/continue upload at.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“data”</td>
<td>chunk of data to write to the file; it is CBOR encoded with length embedded.</td>
</tr>
<tr>
<td>“name”</td>
<td>absolute path to a file.</td>
</tr>
<tr>
<td>“len”</td>
<td>length of file, this field is only mandatory when “off” is 0.</td>
</tr>
</tbody>
</table>

**File upload response**  File upload response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>8</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```
{
  (str)'off' : (uint)
}
```

In case of error the CBOR data takes the form:

where:

<table>
<thead>
<tr>
<th>“off”</th>
<th>offset of last successfully written data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>“err” -&gt; “group”</td>
<td>mcumgr_group_t group of the group-based error code. Only appears if an error is returned when using SMP version 2.</td>
</tr>
<tr>
<td>“err” -&gt; “rc”</td>
<td>contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.</td>
</tr>
<tr>
<td>“rc”</td>
<td>mcumgr_err_t only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.</td>
</tr>
</tbody>
</table>

**File status**  Command allows to retrieve status of an existing file from specified path of a target device.
File status request

File status request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of request:

```
{
  (str)"name" : (str)
}
```

where:

```
"name"  absolute path to a file.
```

File status response

File status response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8</td>
<td>1</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```
{
  (str)"len" : (uint)
}
```

In case of error the CBOR data takes form:

SMP version 2

```
{
  (str)"err" : {
    (str)"group" : (uint)
    (str)"rc"   : (uint)
  }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
  (str)"rc"   : (int)
}
```

where:

```
"len"  length of file (in bytes).
"err"  ->  mcumgr_group_t  group of the group-based error code. Only appears if an error is re-
"group" turned when using SMP version 2.
"err"  ->  mcumgr_err_t  contains the index of the group-based error code. Only appears if non-zero (error con-
"rc"    ->                 condition) when using SMP version 2.
"rc"    ->  mcumgr_err_t  only appears if non-zero (error condition) when using SMP version 1 or
            for SMP errors when using SMP version 2.
```
**File hash/checksum**  Command allows to generate a hash/checksum of an existing file at a specified path on a target device. Note that kernel heap memory is required for buffers to be allocated for this to function, and large stack memory buffers are required for generation of the output hash/checksum. Requires CONFIG_MCUMGR_GRP_FS_CHECKSUM_HASH to be enabled for the base functionality, supported hash/checksum are opt-in with CONFIG_MCUMGR_GRP_FS_CHECKSUM_IEEE_CRC32 or CONFIG_MCUMGR_GRP_FS_CHECKSUM_SHA256.

**File hash/checksum request**  File hash/checksum request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8</td>
<td>2</td>
</tr>
</tbody>
</table>

CBOR data of request:

```json
{
    (str)"name" : (str),
    (str, opt)"type" : (str),
    (str, opt)"off" : (uint),
    (str, opt)"len" : (uint)
}
```

where:

- **"name"** absolute path to a file.
- **"type"** type of hash/checksum to perform Hash/checksum types or omit to use default.
- **"off"** offset to start hash/checksum calculation at (optional, 0 if not provided).
- **"len"** maximum length of data to read from file to generate hash/checksum with (optional, full file size if not provided).

### Hash/checksum types

<table>
<thead>
<tr>
<th>String name</th>
<th>Hash/checksum</th>
<th>Byte string</th>
<th>Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>crc32</td>
<td>IEEE CRC32 checksum</td>
<td>No</td>
<td>4</td>
</tr>
<tr>
<td>sha256</td>
<td>SHA256 (Secure Hash Algorithm)</td>
<td>Yes</td>
<td>32</td>
</tr>
</tbody>
</table>

Note that the default type will be crc32 if it is enabled, or sha256 if crc32 is not enabled.

**File hash/checksum response**  File hash/checksum response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8</td>
<td>2</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
    (str)"type" : (str),
    (str, opt)"off" : (uint),
    (str)"len" : (uint),
    (str)"output" : (uint or bstr)
}
```
In case of error the CBOR data takes the form:

**SMP version 2**

```json
{
    (str)"err" : {
        (str)"group" : (uint)
        (str)"rc" : (uint)
    }
}
```

**SMP version 1 (and non-group SMP version 2)**

```json
{
    (str)"rc" : (int)
}
```

where:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;type&quot;</td>
<td>type of hash/checksum that was performed <a href="#">Hash/checksum types</a></td>
</tr>
<tr>
<td>&quot;off&quot;</td>
<td>offset that hash/checksum calculation started at (only present if not 0).</td>
</tr>
<tr>
<td>&quot;len&quot;</td>
<td>length of input data used for hash/checksum generation (in bytes).</td>
</tr>
<tr>
<td>&quot;output&quot;</td>
<td>output hash/checksum.</td>
</tr>
<tr>
<td>&quot;err&quot;</td>
<td>contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.</td>
</tr>
<tr>
<td>&quot;group&quot;</td>
<td><code>mcumgr_group_t</code> group of the group-based error code. Only appears if an error is returned when using SMP version 2.</td>
</tr>
<tr>
<td>&quot;rc&quot;</td>
<td><code>mcumgr_err_t</code> only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.</td>
</tr>
</tbody>
</table>

**Supported file hash/checksum types** Command allows listing which hash and checksum types are available on a device. Requires Kconfig `CONFIG_MCUMGR_GRP_FS_CHECKSUM_HASH_SUPPORTED_CMD` to be enabled.

**Supported file hash/checksum types request** Supported file hash/checksum types request header:

```plaintext
<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>3</td>
</tr>
</tbody>
</table>
```

The command sends empty CBOR map as data.

**Supported file hash/checksum types response** Supported file hash/checksum types response header:

```plaintext
<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>3</td>
</tr>
</tbody>
</table>
```

CBOR data of successful response:

```json
{
    (str)"types" : {
        (str)<hash_checksum_name> : {
            (str)"format" : (uint)
        }
    }
}
```
In case of error the CBOR data takes form:

**SMP version 2**

```c
{
    (str)"err" : {
        (str)"group" : (uint)
        (str)"rc" : (uint)
    }
}
```

**SMP version 1 (and non-group SMP version 2)**

```c
{
    (str)"rc" : (int)
}
```

where:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;hash_checksum&gt;</code></td>
<td>name of the hash/checksum type <em>Hash/checksum types.</em></td>
</tr>
<tr>
<td>“format”</td>
<td>format that the hash/checksum returns where 0 is for numerical and 1 is for byte array.</td>
</tr>
<tr>
<td>“size”</td>
<td>size (in bytes) of output hash/checksum response.</td>
</tr>
<tr>
<td>“err” -&gt; “group”</td>
<td><code>mcumgr_group_t</code> group of the group-based error code. Only appears if an error is returned when using SMP version 2.</td>
</tr>
<tr>
<td>“err” -&gt; “rc”</td>
<td>contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.</td>
</tr>
<tr>
<td>“rc”</td>
<td><code>mcumgr_err_t</code> only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.</td>
</tr>
</tbody>
</table>

**File close** Command allows closing any open file handles held by `fs_mgmt upload/download` requests that might have stalled or be incomplete.

**File close request** File close request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>8</td>
<td>4</td>
</tr>
</tbody>
</table>

The command sends empty CBOR map as data.

**File close response** File close response header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>8</td>
<td>4</td>
</tr>
</tbody>
</table>
The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

**SMP version 2**

```cbor
{
    (str)"err" : {
        (str)"group" : (uint)
        (str)"rc" : (uint)
    }
}
```

**SMP version 1 (and non-group SMP version 2)**

```cbor
{
    (str)"rc" : (int)
}
```

where:

- "err" -> `mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
- "err" -> contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
- "rc" only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

**Shell management**  Shell management allows passing commands to the shell subsystem over the SMP protocol.

Shell management group defines following commands:

<table>
<thead>
<tr>
<th>Command ID</th>
<th>Command description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Shell command line execute</td>
</tr>
</tbody>
</table>

**Shell command line execute**  The command allows to execute command line in a similar way to typing it into a shell, but both a request and a response are transported over SMP.

**Shell command line execute request**  Execute command request header:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>9</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of request:

```cbor
{
    (str)"argv" : [
        (str)<cmd>
        (str,opt)<arg>
        ...
    ]
}
```
where:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>argv</strong></td>
<td>array consisting of strings representing command and its arguments.</td>
</tr>
<tr>
<td><strong>&lt;cmd&gt;</strong></td>
<td>command to be executed.</td>
</tr>
<tr>
<td><strong>&lt;arg&gt;</strong></td>
<td>optional arguments to command.</td>
</tr>
</tbody>
</table>

Shell command line execute response  Command line execute response header fields:

<table>
<thead>
<tr>
<th>OP</th>
<th>Group ID</th>
<th>Command ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>9</td>
<td>0</td>
</tr>
</tbody>
</table>

CBOR data of successful response:

```json
{
    (str)"o" : (str),
    (str)"ret" : (int)
}
```

In case of error the CBOR data takes the form:

**SMP version 2**

```json
{
    (str)"err" : {
        (str)"group" : (uint),
        (str)"rc" : (uint)
    }
}
```

**SMP version 1 (and non-group SMP version 2)**

```json
{
    (str)"rc" : (int)
}
```

where:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>&quot;o&quot;</strong></td>
<td>command output.</td>
</tr>
<tr>
<td><strong>&quot;ret&quot;</strong></td>
<td>return code from shell command execution.</td>
</tr>
<tr>
<td><strong>&quot;err&quot;</strong></td>
<td>group of the group-based error code. Only appears if an error is returned when using SMP version 2.</td>
</tr>
<tr>
<td><strong>&quot;group&quot;</strong></td>
<td>contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.</td>
</tr>
<tr>
<td><strong>&quot;rc&quot;</strong></td>
<td>only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.</td>
</tr>
</tbody>
</table>

**Note:** In older versions of Zephyr, “rc” was used for both the mcumgr status code and shell command execution return code, this legacy behaviour can be restored by enabling `CONFIG_MCUMGR_GRP_SHELL_LEGACY_RC_RETURN_CODE`

**4.4.6 SMP Transport Specification**

The documents specifies information needed for implementing server and client side SMP transports.
BLE (Bluetooth Low Energy)

MCUmgr Clients need to use following BLE Characteristics, when implementing SMP client:

- **Service UUID**: 8D53DC1D-1DB7-4CD3-868B-8A527460AA84
- **Characteristic UUID**: DA2E7828-FBCE-4E01-AE9E-261174997C48

All SMP communication utilizes a single GATT characteristic. An SMP request is sent via a GATT Write Without Response command. An SMP response is sent in the form of a GATT Notification.

If an SMP request or response is too large to fit in a single GATT command, the sender fragments it across several packets. No additional framing is introduced when a request or response is fragmented; the payload is simply split among several packets. Since GATT guarantees ordered delivery of packets, the SMP header in the first fragment contains sufficient information for reassembly.

UART/serial and console

SMP protocol specification by MCUmgr subsystem of Zephyr uses basic framing of data to allow multiplexing of UART channel. Multiplexing requires prefixing each frame with two byte marker and terminating it with newline. Currently MCUmgr imposes a 127 byte limit on frame size, although there are no real protocol constraints that require that limit. The limit includes the prefix and the newline character, so the allowed payload size is actually 124 bytes.

Although no such transport exists in Zephyr, it is possible to implement MCUmgr client/server over UART transport that does not have framing at all, or uses hardware serial port control, or other means of framing.

Frame fragmenting  SMP protocol over serial is fragmented into MTU size frames; each frame consists of two byte start marker, body and terminating newline character.

There are four types of types of frames: initial, partial, partial-final and initial-final; each frame type differs by start marker and/or body contents.

Frame formats  Initial frame requires to be followed by optional sequence of partial frames and finally by partial-final frame. Body is always Base64 encoded, so the body size, here described as MTU - 3, is able to actually carry N = (MTU - 3) / 4 * 3 bytes of raw data.

Body of initial frame is preceded by two byte total packet length, encoded in Big Endian, and equals size of a raw body plus two bytes, size of CRC16; this means that actual body size allowed into an initial frame is N - 2.

If a body size is smaller than N - 4, than it is possible to carry entire body with preceding length and following it CRC in a single frame, here called initial-final; for the description of initial-final frame look below.

Initial frame format:

<table>
<thead>
<tr>
<th>Content</th>
<th>Size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x06 0x09</td>
<td>2 bytes</td>
<td>Frame start marker</td>
</tr>
<tr>
<td>&lt;base64-i&gt;</td>
<td>no more than MTU - 3 bytes</td>
<td>Base64 encoded body</td>
</tr>
<tr>
<td>0x0a</td>
<td>1 byte</td>
<td>Frame termination</td>
</tr>
</tbody>
</table>

<base64-i> is Base64 encoded body of format:
Initial-final frame format is similar to initial frame format, but differs by `<base64-i>` definition. `<base64-i>` of initial-final frame, is Base64 encoded data taking form:

Partial frame is continuation after previous initial or other partial frame. Partial frame takes form:

The `<base64-i>` of partial frame is Base64 encoding of data, taking form:

The `<base64-i>` of partial-final frame is Base64 encoding of data, taking form:

**CRC Details**  The CRC16 included in final type frames is calculated over only raw data and does not include packet length. CRC16 polynomial is 0x1021 and initial value is 0.

**API Reference**

*group mcumgr_transport_smp*

MCUmgr transport SMP API.
Typedefs

typedef int (*smp_transport_out_fn)(struct net_buf *nb)
SMP transmit callback for transport.

The supplied net_buf is always consumed, regardless of return code.

**Param nb**
The net_buf to transmit.

**Return**
0 on success, mcumgr_err_t code on failure.

typedef uint16_t (*smp_transport_get_mtu_fn)(const struct net_buf *nb)
SMP MTU query callback for transport.

The supplied net_buf should contain a request received from the peer whose MTU is being queried. This function takes a net_buf parameter because some transports store connection-specific information in the net_buf user header (e.g., the BLE transport stores the peer address).

**Param nb**
Contains a request from the relevant peer.

**Return**
The transport’s MTU; 0 if transmission is currently not possible.

typedef int (*smp_transport_ud_copy_fn)(struct net_buf *dst, const struct net_buf *src)
SMP copy user_data callback.

The supplied src net_buf should contain a user_data that cannot be copied using regular memcpy function (e.g., the BLE transport net_buf user_data stores the connection reference that has to be incremented when is going to be used by another buffer).

**Param dst**
Source buffer user_data pointer.

**Param src**
Destination buffer user_data pointer.

**Return**
0 on success, mcumgr_err_t code on failure.

typedef void (*smp_transport_ud_free_fn)(void *ud)
SMP free user_data callback.

This function frees net_buf user data, because some transports store connection-specific information in the net_buf user data (e.g., the BLE transport stores the connection reference that has to be decreased).

**Param ud**
Contains a user_data pointer to be freed.

typedef bool (*smp_transport_query_valid_check_fn)(struct net_buf *nb, void *arg)
Function for checking if queued data is still valid.

This function is used to check if queued SMP data is still valid e.g. on a remote device disconnecting, this is triggered when smp_rx_remove_invalid() is called.

**Param nb**
net buf containing queued request.
**Param arg**
Argument provided when calling `smp_rx_remove_invalid()` function.

**Return**
false if data is no longer valid/should be freed, true otherwise.

**Enums**

```c
enum smp_transport_type
    SMP transport type for client registration.

Values:

enumerator SMP_SERIAL_TRANSPORT = 0
    SMP serial.

denumerator SMP_BLUETOOTH_TRANSPORT
    SMP bluetooth.

denumerator SMP_SHELL_TRANSPORT
    SMP shell.

denumerator SMP_UDP_IPV4_TRANSPORT
    SMP UDP IPv4.

denumerator SMP_UDP_IPV6_TRANSPORT
    SMP UDP IPv6.

denumerator SMP_USER_DEFINED_TRANSPORT
    SMP user defined type.
```

**Functions**

```c
int smp_transport_init(struct smp_transport *smpt)
Initializes a Zephyr SMP transport object.

Parameters
• smpt – The transport to construct.

Returns
0 If successful

Returns
Negative errno code if failure.
```

```c
void smp_rx_remove_invalid(struct smp_transport *zst, void *arg)
Used to remove queued requests for an SMP transport that are no longer valid.

A `smp_transport_query_valid_check_fn()` function must be registered for this to function. If
the `smp_transport_query_valid_check_fn()` function returns false during a callback, the queried
command will classed as invalid and dropped.

Parameters
• zst – The transport to use.
```
arg – Argument provided to callback `smp_transport_query_valid_check_fn()` function.

```c
void smp_rx_clear(struct smp_transport *zst)
Used to clear pending queued requests for an SMP transport.
```

**Parameters**

- zst – The transport to use.

```c
void smp_client_transport_register(struct smp_client_transport_entry *entry)
Register a Zephyr SMP transport object for client.
```

**Parameters**

- entry – The transport to construct.

```c
struct smp_transport *smp_client_transport_get(int smpt_type)
Discover a registered SMP transport client object.
```

**Parameters**

- smpt_type – Type of transport

**Returns**

Pointer to registered object. Unknown type return NULL.

```c
struct smp_transport_api_t
#include <smp.h> Function pointers of SMP transport functions, if a handler is NULL then it is not supported/implemented.
```

**Public Members**

```c
smp_transport_out_fn output
Transport's send function.
```

```c
smp_transport_get_mtu_fn get_mtu
Transport's get-MTU function.
```

```c
smp_transport_ud_copy_fn ud_copy
Transport buffer user_data copy function.
```

```c
smp_transport_ud_free_fn ud_free
Transport buffer user_data free function.
```

```c
smp_transport_query_valid_check_fn query_valid_check
Transport's check function for if a query is valid.
```

```c
struct smp_transport
#include <smp.h> SMP transport object for sending SMP responses.
```

```c
struct smp_client_transport_entry
#include <smp.h> SMP Client transport structure.
```
Public Members

```c
struct smp_transport *smpt
    Transport structure pointer.

int smpt_type
    Transport type.
```

### 4.4.7 Device Firmware Upgrade

**Overview**

The Device Firmware Upgrade subsystem provides the necessary frameworks to upgrade the image of a Zephyr-based application at run time. It currently consists of two different modules:

- `subsys/dfu/boot/`: Interface code to bootloaders
- `subsys/dfu/img_util/`: Image management code

The DFU subsystem deals with image management, but not with the transport or management protocols themselves required to send the image to the target device. For information on these protocols and frameworks please refer to the *Device Management* section.

**Flash Image**  The flash image API as part of the Device Firmware Upgrade (DFU) subsystem provides an abstraction on top of Flash Stream to simplify writing firmware image chunks to flash.

**API Reference**

```c
group flash_img_api
    Abstraction layer to write firmware images to flash.
```

#### Functions

**int flash_img_init_id(struct flash_img_context *ctx, uint8_t area_id)**

Initialize context needed for writing the image to the flash.

**Parameters**

- `ctx` – context to be initialized
- `area_id` – flash area id of partition where the image should be written

**Returns**

0 on success, negative errno code on fail

**int flash_img_init(struct flash_img_context *ctx)**

Initialize context needed for writing the image to the flash.

**Parameters**

- `ctx` – context to be initialized

**Returns**

0 on success, negative errno code on fail
size_t flash_img_bytes_written(struct flash_img_context *ctx)
    Read number of bytes of the image written to the flash.

    Parameters
        • ctx – context

    Returns
        Number of bytes written to the image flash.

int flash_img_buffered_write(struct flash_img_context *ctx, const uint8_t *data, size_t len, bool flush)
    Process input buffers to be written to the image slot 1.
    flash memory in single blocks. Will store remainder between calls.
    A final call to this function with flush set to true will write out the remaining block buffer to flash. Since flash is written to in blocks, the contents of flash from the last byte written up to the next multiple of CONFIG_IMG_BLOCK_BUF_SIZE is padded with 0xff.

    Parameters
        • ctx – context
        • data – data to write
        • len – Number of bytes to write
        • flush – when true this forces any buffered data to be written to flash

    Returns
        0 on success, negative errno code on fail

int flash_img_check(struct flash_img_context *ctx, const struct flash_img_check *fic, uint8_t area_id)
    Verify flash memory length bytes integrity from a flash area.
    The start point is indicated by an offset value.
    The function is enabled via CONFIG_IMG_ENABLE_IMAGE_CHECK Kconfig options.

    Parameters
        • ctx – [in] context.
        • fic – [in] flash img check data.
        • area_id – [in] flash area id of partition where the image should be verified.

    Returns
        0 on success, negative errno code on fail

struct flash_img_context
    #include <flash_img.h>

struct flash_img_check
    #include <flash_img.h> Structure for verify flash region integrity.
    Match vector length is fixed and depends on size from hash algorithm used to verify flash integrity. The current available algorithm is SHA-256.

Public Members

size_t clen
    Match vector data.
The MCUboot API is provided to get version information and boot status of application images. It allows to select application image and boot type for the next boot.

**API Reference**

*group* mcuboot_api

MCUboot public API for MCUboot control of image boot process.

**Defines**

- **BOOT_SWAP_TYPE_NONE**
  Attempt to boot the contents of slot 0.

- **BOOT_SWAP_TYPE_TEST**
  Swap to slot 1.
  Absent a confirm command, revert back on next boot.

- **BOOT_SWAP_TYPE_PERM**
  Swap to slot 1, and permanently switch to booting its contents.

- **BOOT_SWAP_TYPE_REVERT**
  Swap back to alternate slot.
  A confirm changes this state to NONE.

- **BOOT_SWAP_TYPE_FAIL**
  Swap failed because image to be run is not valid.

- **BOOT_IMG_VER_STRLEN_MAX**

- **BOOT_UPGRADE_TEST**
  Boot upgrade request modes.

- **BOOT_UPGRADE_PERMANENT**

**Functions**

```c
int boot_read_bank_header(uint8_t area_id, struct mcuboot_img_header *header, size_t header_size)
```

Read the MCUboot image header information from an image bank.

This attempts to parse the image header, From the start of the `area_id` image.

**Parameters**

- `area_id` – *flash_area* ID of image bank which stores the image.
- `header` – On success, the returned header information is available in this structure.
- `header_size` – Size of the header structure passed by the caller. If this is not large enough to contain all of the necessary information, an error is returned.
Returns
Zero on success, a negative value on error.

bool boot_is_img_confirmed(void)
Check if the currently running image is confirmed as OK.

MCUboot can perform “test” upgrades. When these occur, a new firmware image is installed and booted, but the old version will be reverted at the next reset unless the new image explicitly marks itself OK.

This routine can be used to check if the currently running image has been marked as OK.

See also:
boot_write_img_confirmed()

Returns
True if the image is confirmed as OK, false otherwise.

int boot_write_img_confirmed(void)
Marks the currently running image as confirmed.

This routine attempts to mark the currently running firmware image as OK, which will install it permanently, preventing MCUboot from reverting it for an older image at the next reset.

This routine is safe to call if the current image has already been confirmed. It will return a successful result in this case.

Returns
0 on success, negative errno code on fail.

int boot_write_img_confirmed_multi(int image_index)
Marks the image with the given index in the primary slot as confirmed.

This routine attempts to mark the firmware image in the primary slot as OK, which will install it permanently, preventing MCUboot from reverting it for an older image at the next reset.

This routine is safe to call if the current image has already been confirmed. It will return a successful result in this case.

Parameters
• image_index – Image pair index.

Returns
0 on success, negative errno code on fail.

int mcuboot_swap_type(void)
Determines the action, if any, that mcuboot will take on the next reboot.

Returns
a BOOT_SWAP_TYPE_[... ] constant on success, negative errno code on fail.

int mcuboot_swap_type_multi(int image_index)
Determines the action, if any, that mcuboot will take on the next reboot.

Parameters
• image_index – Image pair index.

Returns
a BOOT_SWAP_TYPE_[... ] constant on success, negative errno code on fail.
int boot_request_upgrade(int permanent)
    Marks the image in slot 1 as pending.
    On the next reboot, the system will perform a boot of the slot 1 image.

    Parameters
    • permanent – Whether the image should be used permanently or only tested once:
      BOOT_UPGRADE_TEST=run image once, then confirm or revert.
      BOOT_UPGRADE_PERMANENT=run image forever.

    Returns
    0 on success, negative errno code on fail.

int boot_request_upgrade_multi(int image_index, int permanent)
    Marks the image with the given index in the secondary slot as pending.
    On the next reboot, the system will perform a boot of the secondary slot image.

    Parameters
    • image_index – Image pair index.
    • permanent – Whether the image should be used permanently or only tested once:
      BOOT_UPGRADE_TEST=run image once, then confirm or revert.
      BOOT_UPGRADE_PERMANENT=run image forever.

    Returns
    0 on success, negative errno code on fail.

int boot_erase_img_bank(uint8_t area_id)
    Erase the image Bank.

    Parameters
    • area_id – flash_area ID of image bank to be erased.

    Returns
    0 on success, negative errno code on fail.

ssize_t boot_get_area_trailer_status_offset(uint8_t area_id)
    Get the offset of the status in the image bank.

    Parameters
    • area_id – flash_area ID of image bank to get the status offset

    Returns
    a positive offset on success, negative errno code on fail

ssize_t boot_get_trailer_status_offset(size_t area_size)
    Get the offset of the status from an image bank size.

    Parameters
    • area_size – size of image bank

    Returns
    offset of the status. When negative the status will not fit the given size

struct mcuboot_img_sem_ver
    #include <mcuboot.h> MCUboot image header representation for image version.
    The header for an MCUboot firmware image contains an embedded version number, in semantic versioning format. This structure represents the information it contains.
struct mcuboot_img_header_v1
#include <mcuboot.h> Model for the MCUboot image header as of version 1.
This represents the data present in the image header, in version 1 of the header format.
Some information present in the header but not currently relevant to applications is omitted.

Public Members

uint32_t image_size
The size of the image, in bytes.

struct mcuboot_img_sem_ver sem_ver
The image version.

struct mcuboot_img_header
#include <mcuboot.h> Model for the MCUBoot image header.
This contains the decoded image header, along with the major version of MCUboot that the
header was built for.
(The MCUboot project guarantees that incompatible changes to the image header will result
in major version changes to the bootloader itself, and will be detectable in the persistent
representation of the header.)

Public Members

uint32_t mcuboot_version
The version of MCUboot the header is built for.
The value 1 corresponds to MCUboot versions 1.x.y.

struct mcuboot_img_header_v1 v1
Header information for MCUboot version 1.

union mcuboot_img_header.[anonymous] h
The header information.
It is only valid to access fields in the union member corresponding to the mcuboot_version
field above.

Bootloaders

MCUboot Zephyr is directly compatible with the open source, cross-RTOS MCUboot boot loader. It
interfaces with MCUboot and is aware of the image format required by it, so that Device Firmware
Upgrade is available when MCUboot is the boot loader used with Zephyr. The source code itself is hosted
in the MCUboot GitHub Project page.
In order to use MCUboot with Zephyr you need to take the following into account:
1. You will need to define the flash partitions required by MCUboot; see Flash map for details.
2. You will have to specify your flash partition as the chosen code partition
3. Your application’s .conf file needs to enable the CONFIG_BOOTLOADER_MCUBOOT Kconfig option in order for Zephyr to be built in an MCUboot-compatible manner.

4. You need to build and flash MCUboot itself on your device.

5. You might need to take precautions to avoid mass erasing the flash and also to flash the Zephyr application image at the correct offset (right after the bootloader).

More detailed information regarding the use of MCUboot with Zephyr can be found in the MCUboot with Zephyr documentation page on the MCUboot website.

### 4.4.8 Over-the-Air Update

#### Overview

Over-the-Air (OTA) Update is a method for delivering firmware updates to remote devices using a network connection. Although the name implies a wireless connection, updates received over a wired connection (such as Ethernet) are still commonly referred to as OTA updates. This approach requires server infrastructure to host the firmware binary and implement a method of signaling when an update is available. Security is a concern with OTA updates; firmware binaries should be cryptographically signed and verified before upgrading.

The Device Firmware Upgrade section discusses upgrading Zephyr firmware using MCUboot. The same method can be used as part of OTA. The binary is first downloaded into an unoccupied code partition, usually named slot1_partition, then upgraded using the MCUboot process.

#### Examples of OTA

**Golioth**  
Golioth is an IoT management platform that includes OTA updates. Devices are configured to observe your available firmware revisions on the Golioth Cloud. When a new version is available, the device downloads and flashes the binary. In this implementation, the connection between cloud and device is secured using TLS/DTLS, and the signed firmware binary is confirmed by MCUboot before the upgrade occurs.

1. A working sample can be found on the Golioth Zephyr-SDK repository
2. The Golioth OTA documentation includes complete information about the versioning process

**Eclipse hawkBit™**  
Eclipse hawkBit™ is an update server framework that uses polling on a REST api to detect firmware updates. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is a hawkbit-api sample included in the Zephyr mgmt-samples section.

**UpdateHub**  
UpdateHub is a platform for remotely updating embedded devices. Updates can be manually triggered or monitored via polling. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is an updatehub-fota sample included in the Zephyr mgmt-samples section.
SMP Server  A Simple Management Protocol (SMP) server can be used to update firmware via Bluetooth Low Energy (BLE) or UDP. *MCUmgr* is used to send a signed firmware binary to the remote device where it is verified by MCUboot before the upgrade occurs.

There is an smp-svr sample included in the Zephyr mgmt-samples section.

**Lightweight M2M (LWM2M)**  The *Lightweight M2M (LWM2M)* protocol includes support for firmware update via `CONFIG_LWM2M_FIRMWARE_UPDATE_OBJ_SUPPORT`. Devices securely connect to an LwM2M server using DTLS. A lwm2m-client sample is available but it does not demonstrate the firmware update feature.

### 4.4.9 EC Host Command

**Overview**

The host command protocol defines the interface for a host, or application processor, to communicate with a target embedded controller (EC). The EC Host command subsystem implements the target side of the protocol, generating responses to commands sent by the host. The host command protocol interface supports multiple versions, but this subsystem implementation only support protocol version 3.

**Architecture**

The Host Command subsystem contains a few components:

- Backend
- General handler
- Command handler

The backend is a layer between a peripheral driver and the general handler. It is responsible for sending and receiving commands via chosen peripheral.

The general handler validates data from the backend e.g. check sizes, checksum, etc. If the command is valid and the user has provided a handler for a received command id, the command handler is called.
SHI (Serial Host Interface) is different to this because it is used only for communication with a host. SHI does not have API itself, thus the backend and peripheral driver layers are combined into one backend layer.
Another case is SPI. Unfortunately, the current SPI API can't be used to handle the host commands communication. The main issues are unknown command size sent by the host (the SPI transaction sends/receives specific number of bytes) and need to constant sending status byte (the SPI module is enabled and disabled per transaction). It forces implementing the SPI driver within a backend, as it is done for SHI. That means a SPI backend has to be implemented per chip family. However, it can be changed in the future once the SPI API is extended to host command needs. Please check the discussion.

That approach requires configuring the SPI dts node in a special way. The main compatible string of a SPI node has changed to use the Host Command version of a SPI driver. The rest of the properties should be configured as usual. Example of the SPI node for STM32:

```c
&spi1 {
    /* Change the compatible string to use the Host Command version of the
       * STM32 SPI driver */
    compatible = "st,stm32-spi-host-cmd";
    status = "okay";

    dmases = <&dma2 3 3 0x38440 0x03>,
             <&dma2 0 3 0x38480 0x03>;
    dma-names = "tx", "rx";
    /* This field is used to point at our CS pin */
    cs-gpios = <&gpioa 4 (GPIO_ACTIVE_LOW | GPIO_PULL_UP)>;
};
```

The STM32 SPI host command backend driver supports the `st,stm32h7-spi` and `st,stm32-spi-fifo` variant implementations. To enable these variants, append the corresponding compatible string. For example, to enable FIFO support and support for the STM32H7 SoCs, modify the compatible string as shown.
The chip that runs Zephyr is a SPI slave and the `cs-gpios` property is used to point our CS pin. For the SPI, it is required to set the backend chosen node `zephyr,host-cmd-spi-backend`.

The supported backend and peripheral drivers:

- Simulator
- SHI - ITE and NPCX
- eSPI - any eSPI slave driver that support `CONFIG_ESPI_PERIPHERAL_EC_HOST_CMD` and `CONFIG_ESPI_PERIPHERAL_CUSTOM_OPCODE`
- UART - any UART driver that supports the asynchronous API
- SPI - STM32

**Initialization**

If the application configures one of the following backend chosen nodes and `CONFIG_EC_HOST_CMD_INITIALIZE_AT_BOOT` is set, then the corresponding backend initializes the host command subsystem by calling `ec_host_cmd_init()`:

- `zephyr,host-cmd-espi-backend`
- `zephyr,host-cmd-shi-backend`
- `zephyr,host-cmd-uart-backend`
- `zephyr,host-cmd-spi-backend`

If no backend chosen node is configured, the application must call the `ec_host_cmd_init()` function directly. This way of initialization is useful if a backend is chosen in runtime based on e.g. GPIO state.

**Buffers**

The host command communication requires buffers for rx and tx. The buffers are be provided by the general handler if `CONFIG_EC_HOST_CMD_HANDLER_RX_BUFFER_SIZE > 0` for rx buffer and `CONFIG_EC_HOST_CMD_HANDLER_TX_BUFFER_SIZE > 0` for the tx buffer. The shared buffers are useful for applications that use multiple backends. Defining separate buffers by every backend would increase the memory usage. However, some buffers can be defined by a peripheral driver e.g. eSPI. These ones should be reused as much as possible.

**Logging**

The host command has an embedded logging system of the ongoing communication. The are a few logging levels:

- `LOG_INF` is used to log a command id of a new command and not success responses. Repeats of the same command are not logged
- `LOG_DBG` logs every command, even repeats
- `LOG_DBG + CONFIG_EC_HOST_CMD_LOG_DBG_BUFFERS` logs every command and responses with the data buffers
API Reference

```c
#define EC_HOST_CMD_INTERFACE

EC_HOST_CMD_HANDLER(_id, _function, _version_mask, _request_type, _response_type)

Statically define and register a host command handler.
Helper macro to statically define and register a host command handler that has a compile-
time-fixed sizes for its both request and response structures.

Parameters

- _id – Id of host command to handle request for.
- _function – Name of handler function.
- _version_mask – The bitfield of all versions that the _function supports. E.g. BIT(0) corresponds to version 0.
- _request_type – The datatype of the request parameters for _function.
- _response_type – The datatype of the response parameters for _function.

EC_HOST_CMD_HANDLER_UNBOUND(_id, _function, _version_mask)

Statically define and register a host command handler without sizes.
Helper macro to statically define and register a host command handler whose request or
response structure size is not known as compile time.

Parameters

- _id – Id of host command to handle request for.
- _function – Name of handler function.
- _version_mask – The bitfield of all versions that the _function supports. E.g. BIT(0) corresponds to version 0.

Typedefs

typedef int (*ec_host_cmd_backend_api_init)(const struct ec_host_cmd_backend *backend,
struct ec_host_cmd_rx_ctx *rx_ctx, struct ec_host_cmd_tx_buf *tx)

Initialize a host command backend.
This routine initializes a host command backend. It includes initialization a device used to
communication and setting up buffers. This function is called by the ec_host_cmd_init func-
tion.

Param backend
   [in] Pointer to the backend structure for the driver instance.

Param rx_ctx
   [inout] Pointer to the receive context object. These objects are used to receive
data from the driver when the host sends data. The buf member can be assigned
by the backend.

Param tx
   [inout] Pointer to the transmit buffer object. The buf and len_max members can
be assigned by the backend. These objects are used to send data by the backend
with the ec_host_cmd_backend_api_send function.
```
Retval 0
  if successful

typedef int (*ec_host_cmd_backend_api_send)(const struct ec_host_cmd_backend *backend)
  Sends data to the host.
  Sends data from tx buf that was passed via ec_host_cmd_backend_api_init function.
  
  **Param backend**
  Pointer to the backed to send data.

  Retval 0
  if successful.

typedef void (*ec_host_cmd_user_cb_t)(const struct ec_host_cmd_rx_ctx *rx_ctx, void *user_data)

typedef enum ec_host_cmd_status (*ec_host_cmd_handler_cb)(struct ec_host_cmd_handler_args *args)

**Enums**

enum ec_host_cmd_status
  Host command response codes (16-bit).
  
  **Values:**

  enumerator EC_HOST_CMD_SUCCESS = 0
  Host command was successful.

  enumerator EC_HOST_CMD_INVALID_COMMAND = 1
  The specified command id is not recognized or supported.

  enumerator EC_HOST.Cmd.ERROR = 2
  Generic Error.

  enumerator EC_HOST_CMD_INVALID_PARAM = 3
  One of more of the input request parameters is invalid.

  enumerator EC_HOST_CMD_ACCESS_DENIED = 4
  Host command is not permitted.

  enumerator EC_HOST_CMD_INVALID_RESPONSE = 5
  Response was invalid (e.g. not version 3 of header).

  enumerator EC_HOST_CMD_INVALID_VERSION = 6
  Host command id version unsupported.

  enumerator EC_HOST_CMD_INVALID_CHECKSUM = 7
  Checksum did not match.
enumerator EC_HOST_CMD_IN_PROGRESS = 8
A host command is currently being processed.

enumerator EC_HOST_CMD_UNAVAILABLE = 9
Requested information is currently unavailable.

group

desc
enumerator EC_HOST_CMD_TIMEOUT = 10
Timeout during processing.

desc
enumerator EC_HOST_CMD_OVERFLOW = 11
Data or table overflow.

desc
enumerator EC_HOST_CMD_INVALID_HEADER = 12
Header is invalid or unsupported (e.g.
not version 3 of header).

desc
enumerator EC_HOST_CMD_REQUEST_TRUNCATED = 13
Did not receive all expected request data.

desc
enumerator EC_HOST_CMD_RESPONSE_TOO_BIG = 14
Response was too big to send within one response packet.

desc
enumerator EC_HOST_CMD_BUS_ERROR = 15
Error on underlying communication bus.

desc
enumerator EC_HOST_CMD_BUSY = 16
System busy.
Should retry later.

desc
enumerator EC_HOST_CMD_INVALID_HEADER_VERSION = 17
Header version invalid.

desc
enumerator EC_HOST_CMD_INVALID_HEADER_CRC = 18
Header CRC invalid.

desc
enumerator EC_HOST_CMD_INVALID_DATA_CRC = 19
Data CRC invalid.

desc
enumerator EC_HOST_CMD_DUP_UNAVAILABLE = 20
Can’t resend response.

desc
enumerator EC_HOST_CMD_MAX = UINT16_MAX

enum ec_host_cmd_log_level

Values:

desc
enumerator EC_HOST_CMD_DEBUG_OFF
enumerator EC_HOST_CMD_DEBUG_NORMAL
enumerator EC_HOST_CMD_DEBUG_EVERY
enumerator EC_HOST_CMD_DEBUG_PARAMS
enumerator EC_HOST_CMD_DEBUG_MODES

Functions

struct ec_host_cmd_backend *ec_host_cmd_backend_get_espi(const struct device *dev)
Get the eSPI Host Command backend pointer.
Get the eSPI pointer backend and pass a pointer to eSPI device instance that will be used for the Host Command communication.

Parameters
• dev – Pointer to eSPI device instance.

Return values
The – eSPI backend pointer.

struct ec_host_cmd_backend *ec_host_cmd_backend_get_shi_npcx(void)
Get the SHI NPCX Host Command backend pointer.

Return values
the – SHI NPCX backend pointer

struct ec_host_cmd_backend *ec_host_cmd_backend_get_shi_ite(void)
Get the SHI ITE Host Command backend pointer.

Return values
the – SHI ITE backend pointer

struct ec_host_cmd_backend *ec_host_cmd_backend_get_uart(const struct device *dev)
Get the UART Host Command backend pointer.
Get the UART pointer backend and pass a pointer to UART device instance that will be used for the Host Command communication.

Parameters
• dev – Pointer to UART device instance.

Return values
The – UART backend pointer.

struct ec_host_cmd_backend *ec_host_cmd_backend_get_spi(struct gpio_dt_spec *cs)
Get the SPI Host Command backend pointer.
Get the SPI pointer backend and pass a chip select pin that will be used for the Host Command communication.

Parameters
• cs – Chip select pin.

Return values
The – SPI backend pointer.
int ec_host_cmd_init(struct ec_host_cmd_backend *backend)
Initialize the host command subsystem.

This routine initializes the host command subsystem. It includes initialization of a backend and the handler. When the application configures the zephyr/host-cmd-espi-backend/zephyr/host-cmd-shi-backend/ zephyr/host-cmd-uart-backend chosen node and CONFIG_EC_HOST_CMD_INITIALIZE_AT_BOOT is set, the chosen backend automatically calls this routine at CONFIG_EC_HOST_CMD_INIT_PRIORITY. Applications that require a run-time selection of the backend must set CONFIG_EC_HOST_CMD_INITIALIZE_AT_BOOT to n and must explicitly call this routine.

Parameters
  • backend – [in] Pointer to the backend structure to initialize.

Return values
  0 – if successful

int ec_host_cmd_send_response(enum ec_host_cmd_status status, const struct ec_host_cmd_handler_args *args)
Send the host command response.

This routine sends the host command response. It should be used to send IN_PROGRESS status or if the host command handler doesn't return e.g. reboot command.

Parameters
  • status – [in] Host command status to be sent.
  • args – [in] Pointer of a structure passed to the handler.

Return values
  0 – if successful.

void ec_host_cmd_rx_notify(void)
Signal a new host command.

Signal that a new host command has been received. The function should be called by a backend after copying data to the rx buffer and setting the length.

void ec_host_cmd_set_user_cb(ec_host_cmd_user_cb_t cb, void *user_data)
Install a user callback for receiving a host command.

It allows installing a custom procedure needed by a user after receiving a command.

Parameters
  • cb – [in] A callback to be installed.
  • user_data – [in] User data to be passed to the callback.

const struct ec_host_cmd *ec_host_cmd_get_hc(void)
Get the main ec host command structure.

This routine returns a pointer to the main host command structure. It allows the application code to get inside information for any reason e.g. the host command thread id.

Return values
  A – pointer to the main host command structure

FUNC_NORETURN void ec_host_cmd_task(void)
The thread function for Host Command subsystem.

This routine calls the Host Command thread entry function. If CONFIG_EC_HOST_CMD_DEDICATED_THREAD is not defined, a new thread is not created, and this function has to be called by application code. It doesn't return.
int ec_host_cmd_add_suppressed(uint16_t cmd_id)
    Add a suppressed command.
    Suppressed commands are not logged. Add a command to be suppressed.

    Parameters
    • cmd_id – [in] A command id to be suppressed.

    Return values
    0 – if successful, -EIO if exceeded max number of suppressed commands.

struct ec_host_cmd_rx_ctx
    #include <backend.h> Context for host command backend and handler to pass rx data.

Public Members

    uint8_t *buf
        Buffer to hold received data.
        The buffer is provided by the handler if CONFIG_EC_HOST_CMD_HANDLER_RX_BUFFER_SIZE > 0. Otherwise, the backend should provide the buffer on its own and overwrites buf pointer in the init function.

    size_t len
        Number of bytes written to buf by backend.

struct ec_host_cmd_tx_buf
    #include <backend.h> Context for host command backend and handler to pass tx data.

Public Members

    void *buf
        Data to write to the host The buffer is provided by the handler if CONFIG_EC_HOST_CMD_HANDLER_TX_BUFFER_SIZE > 0.
        Otherwise, the backend should provide the buffer on its own and overwrites buf pointer and len_max in the init function.

    size_t len
        Number of bytes to write from buf.

    size_t len_max
        Size of buf.

struct ec_host_cmd_backend_api
    #include <backend.h>

struct ec_host_cmd
    #include <ec_host_cmd.h>
Public Members

```c
struct k_sem rx_ready
```

The backend gives `rx_ready` (by calling the `ec_host_cmd_send_receive` function), when data in `rx_ctx` are ready.

The handler takes `rx_ready` to read data in `rx_ctx`.

```c
eum ec_host_cmd_status rx_status
```

Status of the `rx` data checked in the `ec_host_cmd_send_received` function.

```c
ec_host_cmd_user_cb_t user_cb
```

User callback after receiving a command.

It is called by the `ec_host_cmd_send_received` function.

```c
struct ec_host_cmd_handler_args
```

```c
#include <ec_host_cmd.h>
```

Arguments passed into every installed host command handler.

Public Members

```c
void *reserved
```

Reserved for compatibility.

```c
uint16_t command
```

Command identifier.

```c
uint8_t version
```

The version of the host command that is being requested.

This will be a value that has been static registered as valid for the handler.

```c
const void *input_buf
```

The incoming data that can be cast to the handlers request type.

```c
uint16_t input_buf_size
```

The number of valid bytes that can be read from `input_buf`.

```c
void *output_buf
```

The data written to this buffer will be send to the host.

```c
uint16_t output_buf_max
```

Maximum number of bytes that can be written to the `output_buf`.

```c
uint16_t output_buf_size
```

Number of bytes of `output_buf` to send to the host.

```c
struct ec_host_cmd_handler
```

```c
#include <ec_host_cmd.h>
```

Structure use for statically registering host command handlers.
Public Members

\texttt{ec\_host\_cmd\_handler\_cb} \texttt{handler}

Callback routine to process commands that match \texttt{id}.

\texttt{uint16\_t} \texttt{id}

The numerical command \texttt{id} used as the lookup for commands.

\texttt{uint16\_t} \texttt{version\_mask}

The bitfield of all versions that the \texttt{handler} supports, where each bit value represents that the \texttt{handler} supports that version.

E.g. \texttt{BIT(0)} corresponds to version 0.

\texttt{uint16\_t} \texttt{min\_rqt\_size}

The minimum \texttt{input\_buf\_size} enforced by the framework before passing to the handler.

\texttt{uint16\_t} \texttt{min\_rsp\_size}

The minimum \texttt{output\_buf\_size} enforced by the framework before passing to the handler.

\texttt{struct} \texttt{ec\_host\_cmd\_request\_header}

\texttt{#include <ec\_host\_cmd.h>} Header for requests from host to embedded controller.

Represent the over-the-wire header in LE format for host command requests. This represent version 3 of the host command header. The requests are always sent from host to embedded controller.

Public Members

\texttt{uint8\_t} \texttt{prtcl\_ver}

Should be 3.

The EC will return \texttt{EC\_HOST\_CMD\_INVALID\_HEADER} if it receives a header with a version it doesn't know how to parse.

\texttt{uint8\_t} \texttt{checksum}

Checksum of response and data; sum of all bytes including checksum.

Should total to 0.

\texttt{uint16\_t} \texttt{cmd\_id}

Id of command that is being sent.

\texttt{uint8\_t} \texttt{cmd\_ver}

Version of the specific \texttt{cmd\_id} being requested.

Valid versions start at 0.

\texttt{uint8\_t} \texttt{reserved}

Unused byte in current protocol version; set to 0.
uint16_t data_len
    Length of data which follows this header.

struct ec_host_cmd_response_header
    #include <ec_host_cmd.h> Header for responses from embedded controller to host.
    Represent the over-the-wire header in LE format for host command responses. This represent version 3 of the host command header. Responses are always sent from embedded controller to host.

Public Members

uint8_t prtcl_ver
    Should be 3.

uint8_t checksum
    Checksum of response and data; sum of all bytes including checksum.
    Should total to 0.

uint16_t result
    A ec_host_cmd_status response code for specific command.

uint16_t data_len
    Length of data which follows this header.

uint16_t reserved
    Unused bytes in current protocol version; set to 0.

4.4.10 SMP Groups

4.5 Digital Signal Processing (DSP)

- Using zDSP
- Optimizing for your architecture
- API Reference

The DSP API provides an architecture agnostic way for signal processing. Currently, the API will work on any architecture but will likely not be optimized. The status of the various architectures can be found below:
4.5.1 Using zDSP

zDSP provides various backend options which are selected automatically for the application. By default, including the CMSIS module will enable all architectures to use the zDSP APIs. This can be done by setting:

```c
CONFIG_CMSIS_DSP=y
```

If your application requires some additional customization, it’s possible to enable `CONFIG_DSP_BACKEND_CUSTOM` which means that the application is responsible for providing the implementation of the zDSP library.

4.5.2 Optimizing for your architecture

If your architecture is showing as `Unoptimized`, it’s possible to add a new zDSP backend to better support it. To do that, a new Kconfig option should be added to `subsys/dsp/Kconfig` along with the required dependencies and the default set for `DSP_BACKEND` Kconfig choice.

Next, the implementation should be added at `subsys/dsp/<backend>/` and linked in at `subsys/dsp/CMakeLists.txt`. To add architecture-specific attributes, its corresponding Kconfig option should be added to `subsys/dsp/Kconfig` and use them to update `DSP_DATA` and `DSP_STATIC_DATA` in `include/zephyr/dsp/dsp.h`.

4.5.3 API Reference

```c
typedef int8_t q7_t
8-bit fractional data type in 1.7 format.

typedef int16_t q15_t
16-bit fractional data type in 1.15 format.
```

4.5. Digital Signal Processing (DSP)
typedef int32_t q31_t
  32-bit fractional data type in 1.31 format.

typedef int64_t q63_t
  64-bit fractional data type in 1.63 format.

typedef __fp16 float16_t
  16-bit floating point type definition.

typedef float float32_t
  32-bit floating-point type definition.

typedef double float64_t
  64-bit floating-point type definition.

4.6 File Systems

Zephyr RTOS Virtual Filesystem Switch (VFS) allows applications to mount multiple file systems at diff-
ferent mount points (e.g., /fatfs and /lfs). The mount point data structure contains all the necessary
information required to instantiate, mount, and operate on a file system. The File system Switch decou-
uples the applications from directly accessing an individual file system's specific API or internal functions
by introducing file system registration mechanisms.

In Zephyr, any file system implementation or library can be plugged into or pulled out through a file
system registration API. Each file system implementation must have a globally unique integer identifier;
use FS_TYPE_EXTERNAL_BASE to avoid clashes with in-tree identifiers.

```c
int fs_register(int type, const struct fs_file_system_t *fs);
int fs_unregister(int type, const struct fs_file_system_t *fs);
```

Zephyr RTOS supports multiple instances of a file system by making use of the mount point as the disk
volume name, which is used by the file system library while formatting or mounting a disk.

A file system is declared as:

```c
static struct fs_mount_t mp = {
  .type = FS_FATFS,
  .mnt_point = FATFS_MNTP,
  .fs_data = &fat_fs,
};
```

where

- FS_FATFS is the file system type like FATFS or LittleFS.
- FATFS_MNTP is the mount point where the file system will be mounted.
- fat_fs is the file system data which will be used by fs_mount() API.

4.6.1 Samples

Samples for the VFS are mainly supplied in samples/subsys/fs, although various examples of the VFS
usage are provided as important functionalities in samples for different subsystems. Here is the list of
samples worth looking at:
• samples/subsys/fs/fat_fs is an example of FAT file system usage with SDHC media;
• samples/subsys/shell/fs is an example of Shell fs subsystem, using internal flash partition formatted to LittleFS;
• samples/subsys/usb/mass/ example of USB Mass Storage device that uses FAT FS driver with RAM or SPI connected FLASH, or LittleFS in flash, depending on the sample configuration.

4.6.2 API Reference

Related code samples
• File system manipulation - Use file system API with various filesystems and storage devices.
• File system shell - Access a LittleFS file system partition in flash using the file system shell.
• Format filesystem - Format different storage devices for different file systems.
• LittleFS filesystem - Use file system API over LittleFS.
• USB Mass Storage - Expose board's RAM or FLASH as a USB disk using USB Mass Storage driver.

```c

group file_system_api
    File System APIs.

    fs_open open and creation mode flags

    FS_0_READ
        Open for read flag.

    FS_0_WRITE
        Open for write flag.

    FS_0_RDWR
        Open for read-write flag combination.

    FS_0_MODE_MASK
        Bitmask for read and write flags.

    FS_0_CREATE
        Create file if it does not exist.

    FS_0_APPEND
        Open/create file for append.

    FS_0_FLAGS_MASK
        Bitmask for open/create flags.

    FS_0_MASK
        Bitmask for open flags.
```

4.6. File Systems
fs_seek whence parameter values

**FS_SEEK_SET**
Seek from the beginning of file.

**FS_SEEK_CUR**
Seek from a current position.

**FS_SEEK_END**
Seek from the end of file.

Defines

**FS_MOUNT_FLAG_NO_FORMAT**
Flag prevents formatting device if requested file system not found.

**FS_MOUNT_FLAG_READ_ONLY**
Flag makes mounted file system read-only.

**FS_MOUNT_FLAG_AUTOMOUNT**
Flag used in pre-defined mount structures that are to be mounted on startup.
This flag has no impact in user-defined mount structures.

**FS_MOUNT_FLAG_USE_DISK_ACCESS**
Flag requests file system driver to use Disk Access API.
When the flag is set to the `fs_mount_t.flags` prior to `fs_mount` call, a file system needs to use the Disk Access API, otherwise mount callback for the driver should return -ENOSUP; when the flag is not set the file system driver should use Flash API by default, unless it only supports Disk Access API. When file system will use Disk Access API and the flag is not set, the mount callback for the file system should set the flag on success.

**FSTAB_ENTRY_DT_MOUNT_FLAGS(node_id)**
Get the common mount flags for an fstab entry.

- **Parameters**
  - `node_id` – the node identifier for a child entry in a zephyr,fstab node.

- **Returns**
  a value suitable for initializing an `fs_mount_t` flags member.

**FS_FSTAB_ENTRY(node_id)**
The name under which a zephyr,fstab entry mount structure is defined.

- **Parameters**
  - `node_id` – the node identifier for a child entry in a zephyr,fstab node.

**FS_FSTAB_DECLARE_ENTRY(node_id)**
Generate a declaration for the externally defined fstab entry.
This will evaluate to the name of a struct `fs_mount_t` object.

- **Parameters**
  - `node_id` – the node identifier for a child entry in a zephyr,fstab node.
Enums

code

```c
enum fs_dir_entry_type
   Enumeration for directory entry types.

   Values:

   enumerator FS_DIR_ENTRY_FILE = 0
       Identifier for file entry.

   enumerator FS_DIR_ENTRY_DIR
       Identifier for directory entry.
```

code

```c
enum [anonymous]
   Enumeration to uniquely identify file system types.

   Zephyr supports in-tree file systems and external ones. Each requires a unique identifier used
   to register the file system implementation and to associate a mount point with the file system
   type. This anonymous enum defines global identifiers for the in-tree file systems.

   External file systems should be registered using unique identifiers starting at
   FS_TYPE_EXTERNAL_BASE. It is the responsibility of applications that use external file
   systems to ensure that these identifiers are unique if multiple file system implementations are
   used by the application.

   Values:

   enumerator FS_FATFS = 0
       Identifier for in-tree FatFS file system.

   enumerator FS_LITTLEFS
       Identifier for in-tree LittleFS file system.

   enumerator FS_EXT2
       Identifier for in-tree Ext2 file system.

   enumerator FS_TYPE_EXTERNAL_BASE
       Base identifier for external file systems.
```

Functions

```c
static inline void fs_file_t_init(struct fs_file_t *zfp)
   Initialize fs_file_t object.

   Initializes the fs_file_t object; the function needs to be invoked on object before first use with
   fs_open.

   Parameters

   • zfp – Pointer to file object
```

```c
static inline void fs_dir_t_init(struct fs_dir_t *zdp)
   Initialize fs_dir_t object.

   Initializes the fs_dir_t object; the function needs to be invoked on object before first use with
   fs_opendir.
```
Parameters

- `zfp` – Pointer to file object

```c
int fs_open(struct fs_file_t *zfp, const char *file_name, fs_mode_t flags)
```

Open or create file.

Opens or possibly creates a file and associates a stream with it.

`flags` can be 0 or a binary combination of one or more of the following identifiers:

- `FS_O_READ` open for read
- `FS_O_WRITE` open for write
- `FS_O_RDWR` open for read/write (`FS_O_READ | FS_O_WRITE`)
- `FS_O_CREATE` create file if it does not exist
- `FS_O_APPEND` move to end of file before each write

If `flags` are set to 0 the function will attempt to open an existing file with no read/write access; this may be used to e.g. check if the file exists.

Parameters

- `zfp` – Pointer to a file object
- `file_name` – The name of a file to open
- `flags` – The mode flags

Return values

- 0 – on success;
- -EBUSY – when `zfp` is already used;
- -EINVAL – when a bad file name is given;
- -EROFS – when opening read-only file for write, or attempting to create a file on a system that has been mounted with the `FS_MOUNT_FLAG_READ_ONLY` flag;
- -ENOENT – when the file path is not possible (bad mount point);
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – an other negative errno code, depending on a file system back-end.

```c
int fs_close(struct fs_file_t *zfp)
```

Close file.

Flushes the associated stream and closes the file.

Parameters

- `zfp` – Pointer to the file object

Return values

- 0 – on success;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – a negative errno code on error.

```c
int fs_unlink(const char *path)
```

Unlink file.

Deletes the specified file or directory.

Parameters
- path – Path to the file or directory to delete

**Return values**
- 0 – on success;
- -EINVAL – when a bad file name is given;
- -EROFS – if file is read-only, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – an other negative errno code on error.

```c
int fs_rename(const char *from, const char *to)
```

Rename file or directory.

Performs a rename and / or move of the specified source path to the specified destination. The source path can refer to either a file or a directory. All intermediate directories in the destination path must already exist. If the source path refers to a file, the destination path must contain a full filename path, rather than just the new parent directory. If an object already exists at the specified destination path, this function causes it to be unlinked prior to the rename (i.e., the destination gets clobbered).

**Note:** Current implementation does not allow moving files between mount points.

**Parameters**
- from – The source path
- to – The destination path

**Return values**
- 0 – on success;
- -EINVAL – when a bad file name is given, or when rename would cause move between mount points;
- -EROFS – if file is read-only, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – an other negative errno code on error.

```c
ssize_t fs_read(struct fs_file_t *zfp, void *ptr, size_t size)
```

Read file.

Reads up to size bytes of data to ptr pointed buffer, returns number of bytes read. A returned value may be lower than size if there were fewer bytes available than requested.

**Parameters**
- zfp – Pointer to the file object
- ptr – Pointer to the data buffer
- size – Number of bytes to be read

**Return values**
- >=0 – a number of bytes read, on success;
- -EBADF – when invoked on zfp that represents unopened/closed file;
- -ENOTSUP – when not implemented by underlying file system driver;
- `<0` – a negative errno code on error.

### ssize_t fs_write(struct fs_file_t *zfp, const void *ptr, size_t size)

Write file.

Attempts to write `size` number of bytes to the specified file. If a negative value is returned from the function, the file pointer has not been advanced. If the function returns a non-negative number that is lower than `size`, the global `errno` variable should be checked for an error code, as the device may have no free space for data.

**Parameters**
- `zfp` – Pointer to the file object
- `ptr` – Pointer to the data buffer
- `size` – Number of bytes to be written

**Return values**
- `>=0` – a number of bytes written, on success;
- `-EBADF` – when invoked on `zfp` that represents unopened/closed file;
- `-ENOTSUP` – when not implemented by underlying file system driver;
- `<0` – an other negative errno code on error.

### int fs_seek(struct fs_file_t *zfp, off_t offset, int whence)

Seek file.

Moves the file position to a new location in the file. The `offset` is added to file position based on the `whence` parameter.

**Parameters**
- `zfp` – Pointer to the file object
- `offset` – Relative location to move the file pointer to
- `whence` – Relative location from where offset is to be calculated.
  - `FS_SEEK_SET` for the beginning of the file;
  - `FS_SEEK_CUR` for the current position;
  - `FS_SEEK_END` for the end of the file.

**Return values**
- `0` – on success;
- `-EBADF` – when invoked on `zfp` that represents unopened/closed file;
- `-ENOTSUP` – if not supported by underlying file system driver;
- `<0` – an other negative errno code on error.

### off_t fs_tell(struct fs_file_t *zfp)

Get current file position.

Retrieves and returns the current position in the file stream.

The current revision does not validate the file object.

**Parameters**
- `zfp` – Pointer to the file object

**Return values**
- `>=0` – a current position in file;
Zephyr Project Documentation, Release 3.5.0-rc1

-EBADF – when invoked on zfp that represents unopened/closed file;
-ENOTSUP – if not supported by underlying file system driver;
<0 – an other negative errno code on error.

```c
int fs_truncate(struct fs_file_t *zfp, off_t length)
```

Truncate or extend an open file to a given size.

Truncates the file to the new length if it is shorter than the current size of the file. Expands the file if the new length is greater than the current size of the file. The expanded region would be filled with zeroes.

**Note:** In the case of expansion, if the volume got full during the expansion process, the function will expand to the maximum possible length and return success. Caller should check if the expanded size matches the requested length.

**Parameters**

- `zfp` – Pointer to the file object
- `length` – New size of the file in bytes

**Return values**

- 0 – on success;
- -EBADF – when invoked on zfp that represents unopened/closed file;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – an other negative errno code on error.

```c
int fs_sync(struct fs_file_t *zfp)
```

Flush cached write data buffers of an open file.

The function flushes the cache of an open file; it can be invoked to ensure data gets written to the storage media immediately, e.g. to avoid data loss in case if power is removed unexpectedly.

**Note:** Closing a file will cause caches to be flushed correctly so the function need not be called when the file is being closed.

**Parameters**

- `zfp` – Pointer to the file object

**Return values**

- 0 – on success;
- -EBADF – when invoked on zfp that represents unopened/closed file;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – a negative errno code on error.

```c
int fs_mkdir(const char *path)
```

Directory create.

Creates a new directory using specified path.

**Parameters**

- `path` – Path to the directory to create
Return values

• 0 – on success;
• -EEXIST – if entry of given name exists;
• -EROFS – if path is within read-only directory, or when file system has been mounted with the FS_MOUNT_FLAG_READ_ONLY flag;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – an other negative errno code on error

int fs_opendir(struct fs_dir_t *zdp, const char *path)
Directory open.

Opens an existing directory specified by the path.

Parameters

• zdp – Pointer to the directory object
• path – Path to the directory to open

Return values

• 0 – on success;
• -EINVAL – when a bad directory path is given;
• -EBUSY – when zdp is already used;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – a negative errno code on error.

int fs_readdir(struct fs_dir_t *zdp, struct fs_dirent *entry)
Directory read entry.

Reads directory entries of an open directory. In end-of-dir condition, the function will return 0 and set the entry->name[0] to 0.

Note: Most existing underlying file systems do not generate POSIX special directory entries “.” or “..”. For consistency the abstraction layer will remove these from lower layer results so higher layers see consistent results.

Parameters

• zdp – Pointer to the directory object
• entry – Pointer to zfs_dirent structure to read the entry into

Return values

• 0 – on success or end-of-dir;
• -ENOTENT – when no such directory found;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – a negative errno code on error.

int fs_closedir(struct fs_dir_t *zdp)
Directory close.

Closes an open directory.

Parameters

• zdp – Pointer to the directory object
Return values

- 0 – on success;
- -ENOTSUP – when not implemented by underlying file system driver;
- <0 – a negative errno code on error.

int fs_mount (struct fs_mount_t *mp)
Mount filesystem.
Perform steps needed for mounting a file system like calling the file system specific mount function and adding the mount point to mounted file system list.

Note: Current implementation of ELM FAT driver allows only following mount points: “/RAM:”, “/NAND:”, “/CF:”, “/SD:”, “/SD2:”, “/USB:”, “/USB2:”, “/USB3:” or mount points that consist of single digit, e.g. “/0:”, “/1:” and so forth.

Parameters

- mp – Pointer to the fs_mount_t structure. Referenced object is not changed if the mount operation failed. A reference is captured in the fs infrastructure if the mount operation succeeds, and the application must not mutate the structure contents until fsUnmount is successfully invoked on the same pointer.

Return values

- 0 – on success;
- -ENODIR – when file system type has not been registered;
- -ENOTSUP – when not supported by underlying file system driver; when FS_MOUNT_FLAG_USE_DISK_ACCESS is set but driver does not support it.
- -EROFS – if system requires formatting but FS_MOUNT_FLAG_READ_ONLY has been set;
- <0 – an other negative errno code on error.

int fsUnmount (struct fs_mount_t *mp)
Unmount filesystem.
Perform steps needed to unmount a file system like calling the file system specific unmount function and removing the mount point from mounted file system list.

Parameters

- mp – Pointer to the fs_mount_t structure

Return values

- 0 – on success;
- -EINVAL – if no system has been mounted at given mount point;
- -ENOTSUP – when not supported by underlying file system driver;
- <0 – an other negative errno code on error.

int fs_readmount (int *index, const char **name)
Get path of mount point at index.
This function iterates through the list of mount points and returns the directory name of the mount point at the given index. On success index is incremented and name is set to the mount directory name. If a mount point with the given index does not exist, name will be set to NULL.

Parameters
• index – Pointer to mount point index
• name – Pointer to pointer to path name

**Return values**
• 0 – on success;
• -ENOENT – if there is no mount point with given index.

```c
int fs_stat(const char *path, struct fs_dirent *entry)
```

File or directory status.
Checks the status of a file or directory specified by the `path`.

**Note:** The file on a storage device may not be updated until it is closed.

**Parameters**
• `path` – Path to the file or directory
• `entry` – Pointer to the `zfs_dirent` structure to fill if the file or directory exists.

**Return values**
• 0 – on success;
• -EINVAL – when a bad directory or file name is given;
• -ENOENT – when no such directory or file is found;
• -ENOTSUP – when not supported by underlying file system driver;
• <0 – negative errno code on error.

```c
int fs_statvfs(const char *path, struct fs_statvfs *stat)
```

Retrieves statistics of the file system volume.
Returns the total and available space in the file system volume.

**Parameters**
• `path` – Path to the mounted directory
• `stat` – Pointer to the `zfs_statvfs` structure to receive the fs statistics.

**Return values**
• 0 – on success;
• -EINVAL – when a bad path to a directory, or a file, is given;
• -ENOTSUP – when not implemented by underlying file system driver;
• <0 – an other negative errno code on error.

```c
int fs_mkfs(int fs_type, uintptr_t dev_id, void *cfg, int flags)
```

Create fresh file system.

**Parameters**
• `fs_type` – Type of file system to create.
• `dev_id` – Id of storage device.
• `cfg` – Backend dependent init object. If NULL then default configuration is used.
• `flags` – Additional flags for file system implementation.

**Return values**
### 4.6. File Systems

- 0 – on success;
- `<0` – negative `errno` code on error.

```c
int fs_register(int type, const struct fs_file_system_t *fs)
```

Register a file system.

Register file system with virtual file system. Number of allowed file system types to be registered is controlled with the `CONFIG_FILE_SYSTEM_MAX_TYPES` Kconfig option.

**Parameters**
- `type` – Type of file system (ex: `FS_FATFS`)
- `fs` – Pointer to File system

**Return values**
- 0 – on success;
- `-EALREADY` – when a file system of a given type has already been registered;
- `-ENOMEM` – when there is no space left, in file system registry, to add this file system type.

```c
int fs_unregister(int type, const struct fs_file_system_t *fs)
```

Unregister a file system.

Unregister file system from virtual file system.

**Parameters**
- `type` – Type of file system (ex: `FS_FATFS`)
- `fs` – Pointer to File system

**Return values**
- 0 – on success;
- `-EINVAL` – when file system of a given type has not been registered.

```c
struct fs_mount_t
```

`#include <fs.h>` File system mount info structure.

**Public Members**

```c
sys_dnode_t node
```

Entry for the `fs_mount_list` list.

```c
int type
```

File system type.

```c
const char *mnt_point
```

Mount point directory name (ex: `"/fatfs"`)

```c
void *fs_data
```

Pointer to file system specific data.

```c
void *storage_dev
```

Pointer to backend storage device.
size_t mountp_len
    Length of Mount point string.

const struct fs_file_system_t *fs
    Pointer to File system interface of the mount point.

uint8_t flags
    Mount flags.

struct fs dirent
    #include <fs.h> Structure to receive file or directory information.
    Used in functions that read the directory entries to get file or directory information.

Public Members

enum fs_dir_entry_type type
    File/directory type (FS_DIR_ENTRY_FILE or FS_DIR_ENTRY_DIR)

cchar name[MAX_FILE_NAME + 1]
    Name of file or directory.

size_t size
    Size of file (0 if directory).

struct fs_statvfs
    #include <fs.h> Structure to receive volume statistics.
    Used to retrieve information about total and available space in the volume.

Public Members

unsigned long f_bsize
    Optimal transfer block size.

unsigned long f_frsize
    Allocation unit size.

unsigned long f_blocks
    Size of FS in f_frsize units.

unsigned long f_bfree
    Number of free blocks.

struct fs_file_t
    #include <fs_interface.h> File object representing an open file.
    The object needs to be initialized with fs_file_t_init().
Public Members

void *filep
Pointer to file object structure.

const struct fs_mount_t *mp
Pointer to mount point structure.

fs_mode_t flags
Open/create flags.

struct fs_dir_t
#include <fs_interface.h> Directory object representing an open directory.
The object needs to be initialized with fs_dir_t_init().

Public Members

void *dirp
Pointer to directory object structure.

const struct fs_mount_t *mp
Pointer to mount point structure.

struct fs_file_system_t
#include <fs_sys.h> File System interface structure.

File operations

int (*open)(struct fs_file_t *filp, const char *fs_path, fs_mode_t flags)
Opens or creates a file, depending on flags given.

  Param filp
  File to open/create.

  Param fs_path
  Path to the file.

  Param flags
  Flags for opening/creating the file.

  Return
  0 on success, negative errno code on fail.

ssize_t (*read)(struct fs_file_t *filp, void *dest, size_t nbytes)
Reads nbytes number of bytes.

  Param filp
  File to read from.

  Param dest
  Destination buffer.

  Param nbytes
  Number of bytes to read.

  Return
  Number of bytes read on success, negative errno code on fail.
ssize_t (*write)(struct fs_file_t *filp, const void *src, size_t nbytes)
Writes nbytes number of bytes.
  
  **Param** filp
  File to write to.
  
  **Param** src
  Source buffer.
  
  **Param** nbytes
  Number of bytes to write.
  
  **Return**
  Number of bytes written on success, negative errno code on fail.

int (*lseek)(struct fs_file_t *filp, off_t off, int whence)
Moves the file position to a new location in the file.
  
  **Param** filp
  File to move.
  
  **Param** off
  Relative offset from the position specified by whence.
  
  **Param** whence
  Position in the file. Possible values: SEEK_CUR, SEEK_SET, SEEK_END.
  
  **Return**
  New position in the file or negative errno code on fail.

off_t (*tell)(struct fs_file_t *filp)
Retrieves the current position in the file.
  
  **Param** filp
  File to get the current position from.
  
  **Return**
  Current position in the file or negative errno code on fail.

int (*truncate)(struct fs_file_t *filp, off_t length)
Truncates/expands the file to the new length.
  
  **Param** filp
  File to truncate/expand.
  
  **Param** length
  New length of the file.
  
  **Return**
  0 on success, negative errno code on fail.

int (*sync)(struct fs_file_t *filp)
Flushes the cache of an open file.
  
  **Param** filp
  File to flush.
  
  **Return**
  0 on success, negative errno code on fail.

int (*close)(struct fs_file_t *filp)
Flushes the associated stream and closes the file.
  
  **Param** filp
  File to close.
  
  **Return**
  0 on success, negative errno code on fail.

**Directory operations**
int (*opendir)(struct fs_dir_t *dirp, const char *fs_path)
    Opens an existing directory specified by the path.
    
    **Param dirp**
    Directory to open.
    
    **Param fs_path**
    Path to the directory.
    
    **Return**
    0 on success, negative errno code on fail.

int (*readdir)(struct fs_dir_t *dirp, struct fs_dirent *entry)
    Reads directory entries of an open directory.
    
    **Param dirp**
    Directory to read from.
    
    **Param entry**
    Next directory entry in the dirp directory.
    
    **Return**
    0 on success, negative errno code on fail.

int (*closedir)(struct fs_dir_t *dirp)
    Closes an open directory.
    
    **Param dirp**
    Directory to close.
    
    **Return**
    0 on success, negative errno code on fail.

**File system level operations**

int (*mount)(struct fs_mount_t *mountp)
    Mounts a file system.
    
    **Param mountp**
    Mount point.
    
    **Return**
    0 on success, negative errno code on fail.

int (*unmount)(struct fs_mount_t *mountp)
    Unmounts a file system.
    
    **Param mountp**
    Mount point.
    
    **Return**
    0 on success, negative errno code on fail.

int (*unlink)(struct fs_mount_t *mountp, const char *name)
    Deletes the specified file or directory.
    
    **Param mountp**
    Mount point.
    
    **Param name**
    Path to the file or directory to delete.
    
    **Return**
    0 on success, negative errno code on fail.

int (*rename)(struct fs_mount_t *mountp, const char *from, const char *to)
    Renames a file or directory.
Param mountp
  Mount point.
Param from
  Path to the file or directory to rename.
Param to
  New name of the file or directory.
Return
  0 on success, negative errno code on fail.

int (*mkdir)(struct fs_mount_t *mountp, const char *name)
Creates a new directory using specified path.
  Param mountp
    Mount point.
  Param name
    Path to the directory to create.
  Return
    0 on success, negative errno code on fail.

int (*stat)(struct fs_mount_t *mountp, const char *path, struct fs_dirent *entry)
Checks the status of a file or directory specified by the path.
  Param mountp
    Mount point.
  Param path
    Path to the file or directory.
  Param entry
    Directory entry.
  Return
    0 on success, negative errno code on fail.

int (*statvfs)(struct fs_mount_t *mountp, const char *path, struct fs_statvfs *stat)
Returns the total and available space on the file system volume.
  Param mountp
    Mount point.
  Param path
    Path to the file or directory.
  Param stat
    File system statistics.
  Return
    0 on success, negative errno code on fail.

int (*mkfs)(uintptr_t dev_id, void *, int flags)
Formats a device to specified file system type.

Note: This operation destroys existing data on the target device.

Param dev_id
  Device identifier.
Param cfg
  File system configuration.
Param flags
  Formatting flags.
Return
  0 on success, negative errno code on fail.
4.7 Formatted Output

Applications as well as Zephyr itself requires infrastructure to format values for user consumption. The standard C99 library `printf()` functionality fulfills this need for streaming output devices or memory buffers, but in an embedded system devices may not accept streamed data and memory may not be available to store the formatted output.

Internal Zephyr API traditionally provided this both for `printf()` and for Zephyr's internal minimal libc, but with separate internal interfaces. Logging, tracing, shell, and other applications made use of either these APIs or standard libc routines based on build options.

The `cbprintf()` public APIs convert C99 format strings and arguments, providing output produced one character at a time through a callback mechanism, replacing the original internal functions and providing support for almost all C99 format specifications. Existing use of `snprintf()` C libraries in Zephyr can be converted to `snprintfcb()` to avoid pulling in libc implementations.

Several Kconfig options control the set of features that are enabled, allowing some control over features and memory usage:

- `CONFIG_CBPRINTF_FULL_INTEGRAL` or `CONFIG_CBPRINTF_REDUCED_INTEGRAL`
- `CONFIG_CBPRINTF_FP_SUPPORT`
- `CONFIG_CBPRINTF_FP_A_SUPPORT`
- `CONFIG_CBPRINTF_FP_ALWAYS_A`
- `CONFIG_CBPRINTF_N_SPECIFIER`

`CONFIG_CBPRINTF_LIBC_SUBSTS` can be used to provide functions that behave like standard libc functions but use the selected `cbprintf` formatter rather than pulling in another formatter from libc. In addition, `CONFIG_CBPRINTF_NANO` can be used to revert back to the very space-optimized but limited formatter used for `printf()` before this capability was added.

4.7.1 Cbprintf Packaging

Typically, strings are formatted synchronously when a function from `printf` family is called. However, there are cases when it is beneficial that formatting is deferred. In that case, a state (format string and arguments) must be captured. Such state forms a self-contained package which contains format string and arguments. Additionally, package may contain copies of strings which are part of a format string (format string or any `%s` argument). Package primary content resembles `va_list` stack frame thus standard formatting functions are used to process a package. Since package contains data which is processed as `va_list` frame, strict alignment must be maintained. Due to required padding, size of the package depends on alignment. When package is copied, it should be copied to a memory block with the same alignment as origin.

Package can have following variants:

- **Self-contained** - non read-only strings appended to the package. String can be formatted from such package as long as there is access to read-only string locations. Package may contain information where read-only strings are located within the package. That information can be used to convert packet to fully self-contained package.
- **Fully self-contained** - all strings are appended to the package. String can be formatted from such package without any external data.
- **Transient** - only arguments are stored. Package contain information where pointers to non read-only strings are located within the package. Optionally, it may contain read-only string location information. String can be formatted from such package as long as non read-only strings are still valid and read-only strings are accessible. Alternatively, package can be converted to **self-contained** package or **fully self-contained** if information about read-only string locations is present in the package.
Package can be created using two methods:

- **runtime** - using `cbprintf_package()` or `cbvprintf_package()`. This method scans format string and based on detected format specifiers builds the package.
- **static** - types of arguments are detected at compile time by the preprocessor and package is created as simple assignments to a provided memory. This method is significantly faster than runtime (more than 15 times) but has following limitations: requires `_Generic` keyword (C11 feature) to be supported by the compiler and cannot distinguish between `%p` and `%s` if char pointer is used. It treats all (unsigned) char pointers as `%s` thus it will attempt to append string to a package. It can be handled correctly during conversion from **transient** package to **self-contained** package using `CBPRINTF_PACKAGE_CONVERT_PTR_CHECK` flag. However, it requires access to the format string and it is not always possible thus it is recommended to cast char pointers used for `%p` to `void *`. There is a logging warning generated by `cbprintf_package_convert()` called with `CBPRINTF_PACKAGE_CONVERT_PTR_CHECK` flag when char pointer is used with `%p.`

Several Kconfig options control behavior of the packaging:

- `CONFIG_CBPRINTF_PACKAGE_LONDDOUBLE`
- `CONFIG_CBPRINTF_STATIC_PACKAGE_CHECK_ALIGNMENT`

**Cbprintf package conversion**

It is possible to convert package to a variant which contains more information, e.g **transient** package can be converted to **self-contained**. Conversion to **fully self-contained** package is possible if `CBPRINTF_PACKAGE_ADD_RO_STR_POS` flag was used when package was created.

`cbprintf_package_copy()` is used to calculate space needed for the new package and to copy and convert a package.

**Cbprintf package format**

Format of the package contains paddings which are platform specific. Package consists of header which contains size of package (excluding appended strings) and number of appended strings. It is followed by the arguments which contains alignment paddings and resembles `va_list` stack frame. It is followed by data associated with character pointer arguments used by the string which are not appended to the string (but may be appended later by `cbprintf_package_convert()`). Finally, package, optionally, contains appended strings. Each string contains 1 byte header which contains index of the location where address argument is stored. During packaging address is set to null and before string formatting it is updated to point to the current string location within the package. Updating address argument must happen just before string formatting since address changes whenever package is copied.

</tr>
</tbody>
</table>

**Warning:** If CONFIG_MINIMAL_LIBC is selected in combination with CONFIG_CBPRINTF_NANO formatting with C standard library functions like printf or snprintf is limited. Among other things the %n specifier, most format flags, precision control, and floating point are not supported.

**Limitations and recommendations**

- **C11 _Generic** support is required by the compiler to use static (fast) packaging.
- It is recommended to cast any character pointer used with %p format specifier to other pointer type (e.g. void *). If format string is not accessible then only static packaging is possible and it will append all detected strings. Character pointer used for %p will be considered as string pointer. Copying from unexpected location can have serious consequences (e.g., memory fault or security violation).

**4.7.2 API Reference**

**group cbprintf_apis**

**Defines**

`CBPRINTF_PACKAGE_ALIGNMENT`

Required alignment of the buffer used for packaging.

`CBPRINTF_MUST_RUNTIME_PACKAGE(flags, ...)`

Determine if string must be packaged in run time.

Static packaging can be applied if size of the package can be determined at compile time. In general, package size can be determined at compile time if there are no string arguments which might be copied into package body if they are considered transient.
Note: By default any char pointers are considered to be pointing at transient strings. This can be narrowed down to non const pointers by using CBPRINTF_PACKAGE_CONST_CHAR_RO.

Parameters

- ... – String with arguments.
- flags – option flags. See Package flags.

Return values

- 1 – if string must be packaged in run time.
- 0 – string can be statically packaged.

CBPRINTF_STATIC_PACKAGE(packaged, inlen, outlen, align_offset, flags, ...)

Statically package string.

Build string package from formatted string. It assumes that formatted string is in the read only memory.

If _Generic is not supported then runtime packaging is performed.

Parameters

- packaged – pointer to where the packaged data can be stored. Pass a null pointer to skip packaging but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. It must be aligned to the size of the longest argument. It is recommended to use CBPRINTF_PACKAGE_ALIGNMENT for alignment.
- inlen – set to the number of bytes available at packaged. If packaged is NULL the value is ignored.
- outlen – variable updated to the number of bytes required to completely store the packed information. If input buffer was too small it is set to -ENOSPC.
- align_offset – input buffer alignment offset in bytes. Where offset 0 means that buffer is aligned to CBPRINTF_PACKAGE_ALIGNMENT. Xtensa requires that packaged is aligned to CBPRINTF_PACKAGE_ALIGNMENT so it must be multiply of CBPRINTF_PACKAGE_ALIGNMENT or 0.
- flags – option flags. See Package flags.
- ... – formatted string with arguments. Format string must be constant.

Typedefs

typedef int (*cbprintf_cb)()

Signature for a cbprintf callback function.

This function expects two parameters:

- c a character to output. The output behavior should be as if this was cast to an unsigned char.
- ctx a pointer to an object that provides context for the output operation.

The declaration does not specify the parameter types. This allows a function like fputc to be used without requiring all context pointers to be to a FILE object.
Return
the value of c cast to an unsigned char then back to int, or a negative error code
that will be returned from cbprintf().

typedef int (*cbprintf_convert_cb)(const void *buf, size_t len, void *ctx)
Signature for a cbprintf multibyte callback function.

return Amount of copied data or negative error code.

Param buf
data.

Param len
data length.

Param ctx
a pointer to an object that provides context for the operation.

typedef int (*cbvprintf_external_formatter_func)(cbprintf_cb out, void *ctx, const char *fmt, va_list ap)
Signature for a external formatter function identical to cbvprintf.
This function expects the following parameters:

Param out
the function used to emit each generated character.

Param ctx
a pointer to an object that provides context for the external formatter.

Param fmt
a standard ISO C format string with characters and conversion specifications.

Param ap
captured stack arguments corresponding to the conversion specifications found
within fmt.

Return
vprintf like return values: the number of characters printed, or a negative error
value returned from external formatter.

Functions

int cbprintf_package(void *packaged, size_t len, uint32_t flags, const char *format, ...)
Capture state required to output formatted data later.

Like cbprintf() but instead of processing the arguments and emitting the formatted results
immediately all arguments are captured so this can be done in a different context, e.g. when
the output function can block.

In addition to the values extracted from arguments this will ensure that copies are made of the
necessary portions of any string parameters that are not confirmed to be stored in read-only
memory (hence assumed to be safe to refer to directly later).

Parameters

• packaged – pointer to where the packaged data can be stored. Pass a null
pointer to store nothing but still calculate the total space required. The data
stored here is relocatable, that is it can be moved to another contiguous block
of memory. However, under condition that alignment is maintained. It must be
aligned to at least the size of a pointer.
• `len` – this must be set to the number of bytes available at `packaged` if it is not null. If `packaged` is null then it indicates hypothetical buffer alignment offset in bytes compared to CBPRINTF_PACKAGE_ALIGNMENT alignment. Buffer alignment offset impacts returned size of the package. Xtensa requires that buffer is always aligned to CBPRINTF_PACKAGE_ALIGNMENT so it must be multiply of CBPRINTF_PACKAGE_ALIGNMENT or 0 when `packaged` is null.

• `flags` – option flags. See Package flags.

• `format` – a standard ISO C format string with characters and conversion specifications.

• `...` – arguments corresponding to the conversion specifications found within `format`.

Return values

• `nonegative` – the number of bytes successfully stored at `packaged`. This will not exceed `len`.

• `-EINVAL` – if `format` is not acceptable

• `-EFAULT` – if `packaged` alignment is not acceptable

• `-ENOSPC` – if `packaged` was not null and the space required to store exceed `len`.

```c
int cbvprintf_package(void *packaged, size_t len, uint32_t flags, const char *format, va_list ap)
```

Capture state required to output formatted data later.

Like `cbprintf()` but instead of processing the arguments and emitting the formatted results immediately all arguments are captured so this can be done in a different context, e.g. when the output function can block.

In addition to the values extracted from arguments this will ensure that copies are made of the necessary portions of any string parameters that are not confirmed to be stored in read-only memory (hence assumed to be safe to refer to directly later).

Parameters

• `packaged` – pointer to where the packaged data can be stored. Pass a null pointer to store nothing but still calculate the total space required. The data stored here is relocatable, that is it can be moved to another contiguous block of memory. The pointer must be aligned to a multiple of the largest element in the argument list.

• `len` – this must be set to the number of bytes available at `packaged`. Ignored if `packaged` is NULL.

• `flags` – option flags. See Package flags.

• `format` – a standard ISO C format string with characters and conversion specifications.

• `ap` – captured stack arguments corresponding to the conversion specifications found within `format`.

Return values

• `nonegative` – the number of bytes successfully stored at `packaged`. This will not exceed `len`.

• `-EINVAL` – if `format` is not acceptable

• `-ENOSPC` – if `packaged` was not null and the space required to store exceed `len`.

```c
int cbprintf_package_convert(void *in_packaged, size_t in_len, cbprintf_convert_cb cb, void *ctx, uint32_t flags, uint16_t *strl, size_t strl_len)
```

Chapter 4. OS Services
Convert a package.

Converting may include appending strings used in the package to the package body. If input package was created with CBPRINTF_PACKAGE_ADD_RO_STR_POS or CBPRINTF_PACKAGE_ADD_RW_STR_POS, it contains information where strings are located within the package. This information can be used to copy strings during the conversion.

cb is called with portions of the output package. At the end of the conversion cb is called with null buffer.

**Parameters**

- `in_packaged` – Input package.
- `in_len` – Input package length. If 0 package length will be retrieved from the `in_packaged`
- `cb` – callback called with portions of the converted package. If null only length of the output package is calculated.
- `ctx` – Context provided to the `cb`.
- `flags` – Flags. See Package convert flags.
- `strl` – `[inout]` if `packaged` is null, it is a pointer to the array where `strl_len` first string lengths will is stored. If `packaged` is not null, it contains lengths of first `strl_len` strings. It can be used to optimize copying so that string length is calculated only once (at length calculation phase when `packaged` is null.)
- `strl_len` – Number of elements in `strl` array.

**Return values**

- Positive – output package size.
- -ENOSPC – if `packaged` was not null and the space required to store exceed `len`.

```c
static inline int cbprintf_package_copy(void *in_packaged, size_t in_len, void *packaged, size_t len, uint32_t flags, uint16_t *strl, size_t strl_len)
```

Copy package with optional appending of strings. `cbprintf_package_convert` is used to convert and store converted package in the new location.

**Parameters**

- `in_packaged` – Input package.
- `in_len` – Input package length. If 0 package length will be retrieved from the `in_packaged`
- `packaged` – `[out]` Output package. If null only length of the output package is calculated.
- `len` – Available space in the location pointed by `packaged`. Not used when `packaged` is null.
- `flags` – Flags. See Package convert flags.
- `strl` – `[inout]` if `packaged` is null, it is a pointer to the array where `strl_len` first string lengths will is stored. If `packaged` is not null, it contains lengths of first `strl_len` strings. It can be used to optimize copying so that string length is calculated only once (at length calculation phase when `packaged` is null.)
- `strl_len` – Number of elements in `strl` array.

**Return values**

- Positive – Output package size.
- -ENOSPC – if `packaged` was not null and the space required to store exceed `len`.
static inline int cbprintf_fsc_package(void *in_packaged, size_t in_len, void *packaged, size_t len)

Convert package to fully self-contained (fsc) package.

Package may not be self contain since strings by default are stored by address. Package may be partially self-contained when transient (not read only) strings are appended to the package. Such package can be decoded only when there is an access to read-only strings.

Fully self-contained has (fsc) contains all strings used in the package. A package can be converted to fsc package if it was create with CBPRINTF_PACKAGE_ADD_RO_STR_POS flag. Such package will contain necessary data to find read only strings in the package and copy them into the package body.

Parameters

- `in_packaged` – pointer to original package created with CBPRINTF_PACKAGE_ADD_RO_STR_POS.
- `in_len` – `in_packaged` length.
- `packaged` – pointer to location where fully self-contained version of the input package will be written. Pass a null pointer to calculate space required.
- `len` – must be set to the number of bytes available at `packaged`. Not used if `packaged` is null.

Return values

- nonegative – the number of bytes successfully stored at `packaged`. This will not exceed `len`. If `packaged` is null, calculated length.
- -ENOSPC – if `packaged` was not null and the space required to store exceed `len`.
- -EINVAL – if `in_packaged` is null.

int cbprintf_external(cbprintf_cb out, cbvprintf_external_formatter_func formatter, void *ctx, void *packaged)

Generate the output for a previously captured format operation using an external formatter.

Note: Memory indicated by `packaged` will be modified in a non-destructive way, meaning that it could still be reused with this function again.

Parameters

- `out` – the function used to emit each generated character.
- `formatter` – external formatter function.
- `ctx` – a pointer to an object that provides context for the external formatter.
- `packaged` – the data required to generate the formatted output, as captured by `cbprintf_package()` or `cbvprintf_package()`. The alignment requirement on this data is the same as when it was initially created.

Returns

printf like return values: the number of characters printed, or a negative error value returned from external formatter.

int cbprintf(cbprintf_cb out, void *ctx, const char *format, ...)

*printf-like output through a callback.

This is essentially printf() except the output is generated character-by-character using the provided `out` function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.
All formatting specifiers of C99 are recognized, and most are supported if the functionality is enabled.

**Note:** The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

### Parameters

- `out` – the function used to emit each generated character.
- `ctx` – context provided when invoking `out`
- `format` – a standard ISO C format string with characters and conversion specifications.
- `...` – arguments corresponding to the conversion specifications found within `format`.

### Returns

the number of characters printed, or a negative error value returned from invoking `out`.

```c
static inline int cbvprintf(cbprintf_cb out, void *ctx, const char *format, va_list ap)
```

varargs-aware `printf`-like output through a callback.

This is essentially vsprintf() except the output is generated character-by-character using the provided `out` function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.

**Note:** This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

**Note:** The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

### Parameters

- `out` – the function used to emit each generated character.
- `ctx` – context provided when invoking `out`
- `format` – a standard ISO C format string with characters and conversion specifications.
- `ap` – a reference to the values to be converted.

### Returns

the number of characters generated, or a negative error value returned from invoking `out`.

```c
static inline int cbvprintf_tagged_args(cbprintf_cb out, void *ctx, const char *format, va_list ap)
```

varargs-aware `printf`-like output through a callback with tagged arguments.

This is essentially vsprintf() except the output is generated character-by-character using the provided `out` function. This allows formatting text of unbounded length without incurring the cost of a temporary buffer.

Note that the argument list `ap` are tagged.

---

4.7. Formatted Output 765
Note: This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

Note: The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

- `out` – the function used to emit each generated character.
- `ctx` – context provided when invoking out
- `format` – a standard ISO C format string with characters and conversion specifications.
- `ap` – a reference to the values to be converted.

Returns

the number of characters generated, or a negative error value returned from invoking `out`.

```c
static inline int cbpprintf(cbprintf_cb out, void *ctx, void *packaged)
Generate the output for a previously captured format operation.
```

Note: Memory indicated by `packaged` will be modified in a non-destructive way, meaning that it could still be reused with this function again.

Parameters

- `out` – the function used to emit each generated character.
- `ctx` – context provided when invoking out
- `packaged` – the data required to generate the formatted output, as captured by `cbprintf_package()` or `cbvprintf_package()`. The alignment requirement on this data is the same as when it was initially created.

Returns

the number of characters printed, or a negative error value returned from invoking `out`.

```c
int fprintfcb(FILE *stream, const char *format, ...)
fprintf using Zephyrs cbprintf infrastructure.
```

return The number of characters printed.

Note: This function is available only when CONFIG_CBPRINTF_LIBC_SUBSTS is selected.

Note: The functionality of this function is significantly reduced when CONFIG_CBPRINTF_NANO is selected.

Parameters

- `stream` – the stream to which the output should be written.
• `format` – a standard ISO C format string with characters and conversion specifications.
• `...` – arguments corresponding to the conversion specifications found within `format`.

```c
int vfprintfcb(FILE *stream, const char *format, va_list ap)
```

vprintf using Zephyrs cbprintf infrastructure.

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

### Parameters

- `stream` – the stream to which the output should be written.
- `format` – a standard ISO C format string with characters and conversion specifications.
- `ap` – a reference to the values to be converted.

### Returns

The number of characters printed.

```c
int printfcb(const char *format, ...)
```

printf using Zephyrs cbprintf infrastructure.

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

### Parameters

- `format` – a standard ISO C format string with characters and conversion specifications.
- `...` – arguments corresponding to the conversion specifications found within `format`.

### Returns

The number of characters printed.

```c
int vprintfcb(const char *format, va_list ap)
```

vprintf using Zephyrs cbprintf infrastructure.

**Note:** This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

**Note:** The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.
Parameters

- `format` – a standard ISO C format string with characters and conversion specifications.
- `ap` – a reference to the values to be converted.

Returns

The number of characters printed.

```c
int snprintfcb(char *str, size_t size, const char *format, ...)
```

snprintf using Zephyrs cbprintf infrastructure.

Note: This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

Note: The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

Parameters

- `str` – where the formatted content should be written
- `size` – maximum number of characters for the formatted output, including the terminating null byte.
- `format` – a standard ISO C format string with characters and conversion specifications.
- `...` – arguments corresponding to the conversion specifications found within `format`.

Returns

The number of characters that would have been written to `str`, excluding the terminating null byte. This is greater than the number actually written if `size` is too small.

```c
int vsnprintfcb(char *str, size_t size, const char *format, va_list ap)
```

vsnprintf using Zephyrs cbprintf infrastructure.

Note: This function is available only when `CONFIG_CBPRINTF_LIBC_SUBSTS` is selected.

Note: The functionality of this function is significantly reduced when `CONFIG_CBPRINTF_NANO` is selected.

Parameters

- `str` – where the formatted content should be written
- `size` – maximum number of characters for the formatted output, including the terminating null byte.
- `format` – a standard ISO C format string with characters and conversion specifications.
- `ap` – a reference to the values to be converted.
Returns
The number of characters that would have been written to str, excluding the terminating null byte. This is greater than the number actually written if size is too small.

4.8 Input

The input subsystem provides an API for dispatching input events from input devices to the application.

4.8.1 Input Events

The subsystem is built around the input_event structure. An input event represents a change in an individual event entity, for example the state of a single button, or a movement in a single axis.

The input_event structure describes the specific event, and includes a synchronization bit to indicate that the device reached a stable state, for example when the events corresponding to multiple axes of a multi-axis device have been reported.

4.8.2 Input Devices

An input device can report input events directly using input_report() or any related function; for example buttons or other on-off input entities would use input_report_key().

Complex devices may use a combination of multiple events, and set the sync bit once the output is stable.

The input_report* functions take a device pointer, which is used to indicate which device reported the event and can be used by subscribers to only receive events from a specific device. If there’s no actual device associated with the event, it can be set to NULL, in which case only subscribers with no device filter will receive the event.

4.8.3 Application API

An application can register a callback using the INPUT_CALLBACK_DEFINE macro. If a device node is specified, the callback is only invoked for events from the specific device, otherwise the callback will receive all the events in the system. This is the only type of filtering supported, any more complex filtering logic has to be implemented in the callback itself.

The subsystem can operate synchronously or by using an event queue, depending on the CONFIG_INPUT_MODE option. If the input thread is used, all the events are added to a queue and executed in a common input thread. If the thread is not used, the callback are invoked directly in the input driver context.

The synchronous mode can be used in a simple application to keep a minimal footprint, or in a complex application with an existing event model, where the callback is just a wrapper to pipe back the event in a more complex application specific event system.

4.8.4 Kscan Compatibility

Input devices generating X/Y/Touch events can be used in existing applications based on the Keyboard Scan API by enabling both CONFIG_INPUT and CONFIG_KSCAN, defining a zephyr,kscan-input node as a child node of the corresponding input device and pointing the zephyr,keyboard-scan chosen node to the compatibility device node, for example:
Zephyr Project Documentation, Release 3.5.0-rc1

chosen {
    zephyr,keyboard-scan = &kscan_input;
};

ft5336@38 {
    ...
    kscan_input: kscan-input {
        compatible = "zephyr,kscan-input";
    };
};

group input_interface
    Input Interface.

Defines

INPUT_CALLBACK_DEFINE(_dev, _callback)
    Register a callback structure for input events.
    The _dev field can be used to only invoke callback for events generated by a specific device.
    Setting dev to NULL causes callback to be invoked for every event.

    Parameters
    - _dev – device pointer or NULL.
    - _callback – The callback function.

Functions

int input_report(const struct device *dev, uint8_t type, uint16_t code, int32_t value, bool sync, k_timeout_t timeout)
    Report a new input event.
    This causes all the listeners for the specified device to be triggered, either synchronously or through the input thread if utilized.

    Parameters
    - dev – Device generating the event or NULL.
    - type – Event type (see INPUT_EV_CODES).
    - code – Event code (see INPUT_KEY_CODES, INPUT BTN_CODES, INPUT ABS_CODES, INPUT REL_CODES, INPUT MSC_CODES).
    - value – Event value.
    - sync – Set the synchronization bit for the event.
• timeout – Timeout for reporting the event, ignored if CONFIG_INPUT_MODE_SYNCHRONOUS is used.

**Return values**

• 0 – if the message has been processed.
• negative – if CONFIG_INPUT_MODE_THREAD is enabled and the message failed to be enqueued.

static inline int input_report_key(const struct device *dev, uint16_t code, int32_t value, bool sync, k_timeout_t timeout)

Report a new **INPUT_EV_KEY** input event, note that value is converted to either 0 or 1.

**See also:**

*input_report() for more details.*

static inline int input_report_rel(const struct device *dev, uint16_t code, int32_t value, bool sync, k_timeout_t timeout)

Report a new **INPUT_EV_REL** input event.

**See also:**

*input_report() for more details.*

static inline int input_report_abs(const struct device *dev, uint16_t code, int32_t value, bool sync, k_timeout_t timeout)

Report a new **INPUT_EV_ABS** input event.

**See also:**

*input_report() for more details.*

bool input_queue_empty(void)

Returns true if the input queue is empty.

This can be used to batch input event processing until the whole queue has been emptied. Always returns true if CONFIG_INPUT_MODE_SYNCHRONOUS is enabled.

struct input_event

`#include <input.h>` Input event structure.

This structure represents a single input event, for example a key or button press for a single button, or an absolute or relative coordinate for a single axis.

**Public Members**

const struct device *dev

Device generating the event or NULL.

uint8_t sync

Sync flag.

uint8_t type

Event type (see **INPUT_EV_CODES**).
uint16_t code

int32_t value
   Event value.

struct input_listener
   #include <input.h> Input listener callback structure.

Public Members

const struct device *dev
dev
   device pointer or NULL.

void (*callback)(struct input_event *evt)
   The callback function.

4.9 Interprocessor Communication (IPC)

4.9.1 IPC service

- Overview
- Simple data exchange
- Data exchange using the no-copy API
  - Backends
  - API Reference
- IPC service API
- IPC service backend API

The IPC service API provides an interface to exchange data between two domains or CPUs.

Overview

An IPC service communication channel consists of one instance and one or several endpoints associated with the instance.

An instance is the external representation of a physical communication channel between two domains or CPUs. The actual implementation and internal representation of the instance is peculiar to each backend.
An individual instance is not used to send data between domains/CPUs. To send and receive the data, the user must create (register) an endpoint in the instance. This allows for the connection of the two domains of interest.

It is possible to have zero or multiple endpoints for one single instance, possibly with different priorities, and to use each to exchange data. Endpoint prioritization and multi-instance ability highly depend on the backend used.

The endpoint is an entity the user must use to send and receive data between two domains (connected by the instance). An endpoint is always associated to an instance.

The creation of the instances is left to the backend, usually at init time. The registration of the endpoints is left to the user, usually at run time.

The API does not mandate a way for the backend to create instances but it is strongly recommended to use the devicetree to retrieve the configuration parameters for an instance. Currently, each backend defines its own DT-compatible configuration that is used to configure the interface at boot time.

The following usage scenarios are supported:

- Simple data exchange.
- Data exchange using the no-copy API.

### Simple data exchange

To send data between domains or CPUs, an endpoint must be registered onto an instance.

See the following example:

```c
#include <zephyr/include/ipc_service.h>

static void bound_cb(void *priv)
{
    /* Endpoint bounded */
}

static void recv_cb(const void *data, size_t len, void *priv)
{
    /* Data received */
}

static struct ipc_ept_cfg ept0_cfg = {
    .name = "ept0",
    .cb = {
        .bound = bound_cb,
        .received = recv_cb,
    },
};

int main(void)
{
    const struct device *inst0;
    struct ipc_ept ept0;
    int ret;
```

(continues on next page)
Data exchange using the no-copy API

If the backend supports the no-copy API you can use it to directly write and read to and from shared memory regions.

See the following example:

```c
#include <zephyr/include/ipc_service.h>
#include <stdint.h>
#include <string.h>

static struct ipc_ept ept0;

static void bound_cb(void *priv)
{
    /* Endpoint bounded */
}

static void recv_cb_nocopy(const void *data, size_t len, void *priv)
{
    int ret;

    ret = ipc_service_hold_rx_buffer(&ept0, (void *)data);
    /* Process directly or put the buffer somewhere else and release. */
    ret = ipc_service_release_rx_buffer(&ept0, (void *)data);
}

static struct ipc_ept_cfg ept0_cfg = {
    .name = "ept0",
    .cb = {
        .bound = bound_cb,
        .received = recv_cb,
    },
};

int main(void)
{
    const struct device *inst0;
    int ret;

    inst0 = DEVICE_DT_GET(DT_NODELABEL(ipc0));
    ret = ipc_service_open_instance(inst0);
    ret = ipc_service_register_endpoint(inst0, &ept0, &ept0_cfg);

    /* Wait for endpoint bound (bound_cb called) */
    unsigned char message[] = "hello world";
    ret = ipc_service_send(&ept0, &message, sizeof(message));
}
```
void *data;
unsigned char message[] = "hello world";
uint32_t len = sizeof(message);

ret = ipc_service_get_tx_buffer(&ept0, &data, &len, K_FOREVER);
memcpy(data, message, len);
ret = ipc_service_send_nocopy(&ept0, data, sizeof(message));
}

Backends
The requirements needed for implementing backends give flexibility to the IPC service. These allow for the addition of dedicated backends having only a subsets of features for specific use cases.

The backend must support at least the following:

- The init-time creation of instances.
- The run-time registration of an endpoint in an instance.

Additionally, the backend can also support the following:

- The run-time deregistration of an endpoint from the instance.
- The run-time closing of an instance.
- The no-copy API.

Each backend can have its own limitations and features that make the backend unique and dedicated to a specific use case. The IPC service API can be used with multiple backends simultaneously, combining the pros and cons of each backend.

ICMsg backend
The inter core messaging backend (ICMsg) is a lighter alternative to the heavier RPMsg static vrings backend. It offers a minimal feature set in a small memory footprint. The ICMsg backend is build on top of Single Producer Single Consumer Packet Buffer.

Overview
The ICMsg backend uses shared memory and MBOX devices for exchanging data. Shared memory is used to store the data, MBOX devices are used to signal that the data has been written.

The backend supports the registration of a single endpoint on a single instance. If the application requires more than one communication channel, you must define multiple instances, each having its own dedicated endpoint.

Configuration
The backend is configured via Kconfig and devicetree. When configuring the backend, do the following:

- Define two memory regions and assign them to tx-region and rx-region of an instance. Ensure that the memory regions used for data exchange are unique (not overlapping any other region) and accessible by both domains (or CPUs).

- Define MBOX devices which are used to send the signal that informs the other domain (or CPU) that data has been written. Ensure that the other domain (or CPU) is able to receive the signal.

See the following configuration example for one of the instances:
You must provide a similar configuration for the other side of the communication (domain or CPU) but you must swap the MBOX channels and memory regions (tx-region and rx-region).

**Bonding** When the endpoint is registered, the following happens on each domain (or CPU) connected through the IPC instance:

1. The domain (or CPU) writes a magic number to its tx-region of the shared memory. #. It then sends a signal to the other domain or CPU, informing that the data has been written. Sending the signal to the other domain or CPU is repeated with timeout specified by `CONFIG_IPC_SERVICE_ICMSG_BOND_NOTIFY_REPEAT_TO_MS` option. #. When the signal from the other domain or CPU is received, the magic number is read from rx-region. If it is correct, the bonding process is finished and the backend informs the application by calling `ipc_service_cb.bound` callback.

**Samples**
- `ipc-icmsg`

**API Reference**

**IPC service API**

**group ipc_service_api**
IPC Service API.

**Functions**

`int ipc_service_open_instance(const struct device *instance)`
Open an instance.

Function to be used to open an instance before being able to register a new endpoint on it.

**Parameters**
• instance – [in] Instance to open.

Return values
• -EINVAL – when instance configuration is invalid.
• -EIO – when no backend is registered.
• -EALREADY – when the instance is already opened (or being opened).
• 0 – on success or when not implemented on the backend (not needed).
• other – errno codes depending on the implementation of the backend.

int ipc_service_close_instance(const struct device *instance)
Close an instance.
Function to be used to close an instance. All bounded endpoints must be deregistered using
ipc_service_deregister_endpoint before this is called.

Parameters
• instance – [in] Instance to close.

Return values
• -EINVAL – when instance configuration is invalid.
• -EIO – when no backend is registered.
• -EALREADY – when the instance is not already opened.
• -EBUSY – when an endpoint exists that hasn't been deregistered
• 0 – on success or when not implemented on the backend (not needed).
• other – errno codes depending on the implementation of the backend.

int ipc_service_register_endpoint(const struct device *instance, struct ipc_ept *ept, const struct ipc_ept_cfg *cfg)
Register IPC endpoint onto an instance.
Registers IPC endpoint onto an instance to enable communication with a remote device.
The same function registers endpoints for both host and remote devices.

Note: Keep the variable pointed by cfg alive when endpoint is in use.

Parameters
• instance – [in] Instance to register the endpoint onto.
• cfg – [in] Endpoint configuration.

Return values
• -EIO – when no backend is registered.
• -EINVAL – when instance, endpoint or configuration is invalid.
• -EBUSY – when the instance is busy.
• 0 – on success.
• other – errno codes depending on the implementation of the backend.
int ipc_service_deregister_endpoint(struct ipc_ept *ept)
Deregister an IPC endpoint from its instance.
Deregisters an IPC endpoint from its instance.
The same function deregisters endpoints for both host and remote devices.

Parameters

Return values
- -EIO – when no backend is registered.
- -EINVAL – when instance, endpoint or configuration is invalid.
- -ENOTENT – when the endpoint is not registered with the instance.
- -EBUSY – when the instance is busy.
- 0 – on success.
- other – errno codes depending on the implementation of the backend.

int ipc_service_send(struct ipc_ept *ept, const void *data, size_t len)
Send data using given IPC endpoint.

Parameters
- data – [in] Pointer to the buffer to send.
- len – [in] Number of bytes to send.

Return values
- -EIO – when no backend is registered or send hook is missing from backend.
- -EINVAL – when instance or endpoint is invalid.
- -ENOENT – when the endpoint is not registered with the instance.
- -EBADMSG – when the data is invalid (i.e. invalid data format, invalid length, ...)
- -EBUSY – when the instance is busy.
- -ENOMEM – when no memory / buffers are available.
- bytes – number of bytes sent.
- other – errno codes depending on the implementation of the backend.

int ipc_service_get_tx_buffer_size(struct ipc_ept *ept)
Get the TX buffer size.
Get the maximal size of a buffer which can be obtained by ipc_service_get_tx_buffer

Parameters

Return values
- -EIO – when no backend is registered or send hook is missing from backend.
- -EINVAL – when instance or endpoint is invalid.
- -ENOTENT – when the endpoint is not registered with the instance.
- -ENOTSUP – when the operation is not supported by backend.
- size – TX buffer size on success.
int ipc_service_get_tx_buffer(struct ipc_ept *ept, void **data, uint32_t *size, k_timeout_t wait)

Get an empty TX buffer to be sent using `ipc_service_send_nocopy`.

This function can be called to get an empty TX buffer so that the application can directly put its data into the sending buffer without copy from an application buffer.

It is the application responsibility to correctly fill the allocated TX buffer with data and passing correct parameters to `ipc_service_send_nocopy` function to perform data no-copy-send mechanism.

The size parameter can be used to request a buffer with a certain size:

- if the size can be accommodated the function returns no errors and the buffer is allocated
- if the requested size is too big, the function returns -ENOMEM and the the buffer is not allocated.
- if the requested size is '0' the buffer is allocated with the maximum allowed size.

In all the cases on return the size parameter contains the maximum size for the returned buffer.

When the function returns no errors, the buffer is intended as allocated and it is released under two conditions: (1) when sending the buffer using `ipc_service_send_nocopy` (and in this case the buffer is automatically released by the backend), (2) when using `ipc_service_drop_tx_buffer` on a buffer not sent.

**Parameters**

- *data* – [out] Pointer to the empty TX buffer.
- *size* – [inout] Pointer to store the requested TX buffer size. If the function returns -ENOMEM, this parameter returns the maximum allowed size.

**Return values**

- -EIO – when no backend is registered or send hook is missing from backend.
- -EINVAL – when instance or endpoint is invalid.
- -ENODENT – when the endpoint is not registered with the instance.
- -ENOTSUP – when the operation or the timeout is not supported by backend.
- -ENOBUFS – when there are no TX buffers available.
- -EALREADY – when a buffer was already claimed and not yet released.
- -ENOMEM – when the requested size is too big (and the size parameter contains the maximum allowed size).
- 0 – on success.
- other – errno codes depending on the implementation of the backend.

int ipc_service_drop_tx_buffer(struct ipc_ept *ept, const void *data)

Drop and release a TX buffer.

Drop and release a TX buffer. It is possible to drop only TX buffers obtained by using `ipc_service_get_tx_buffer`.

**Parameters**

Send data in a TX buffer reserved by `ipc_service_get_tx_buffer` using the given IPC endpoint.

The application has to take the responsibility for getting the TX buffer using `ipc_service_get_tx_buffer` and filling the TX buffer with the data.

After the `ipc_service_send_nocopy` function is issued the TX buffer is no more owned by the sending task and must not be touched anymore unless the function fails and returns an error. If this function returns an error, `ipc_service_drop_tx_buffer` can be used to drop the TX buffer.

**Parameters**

- `data` – [in] Pointer to the buffer to send obtained by `ipc_service_get_tx_buffer`.
- `len` – [in] Number of bytes to send.

**Return values**

- `-EIO` – when no backend is registered or send hook is missing from backend.
- `-EINVAL` – when instance or endpoint is invalid.
- `-ENOTRFMT` – when the endpoint is not registered with the instance.
- `-ENOTSUP` – when this is not supported by backend.
- `-EALREADY` – when the buffer was already dropped.
- `-ENXIO` – when the buffer was not obtained using `ipc_service_get_tx_buffer`
- `0` – on success.
- `other` – errno codes depending on the implementation of the backend.

```
int ipc_service_send_nocopy(struct ipc_ept *ept, const void *data, size_t len)
```

Holds the RX buffer for usage outside the receive callback.

Calling this function prevents the receive buffer from being released back to the pool of shmem buffers. This function can be called in the receive callback when the user does not want to copy the message out in the callback itself.

After the message is processed, the application must release the buffer using the `ipc_service_release_rx_buffer` function.

**Parameters**

- `data` – [in] Pointer to the RX buffer to hold.
Return values

- -EIO – when no backend is registered or release hook is missing from backend.
- -EINVAL – when instance or endpoint is invalid.
- -ENOTREG – when the endpoint is not registered with the instance.
- -EALREADY – when the buffer data has been held already.
- -ENOTSUP – when this is not supported by the backend.
- 0 – on success.
- other – errno codes depending on the implementation of the backend.

int ipc_service_release_rx_buffer(struct ipc_ept *ept, void *data)

Release the RX buffer for future reuse.

When supported by the backend, this function can be called after the received message has been processed and the buffer can be marked as reusable again.

It is possible to release only RX buffers on which `ipc_service_hold_rx_buffer` was previously used.

Parameters

- data – [in] Pointer to the RX buffer to release.

Return values

- -EIO – when no backend is registered or release hook is missing from backend.
- -EINVAL – when instance or endpoint is invalid.
- -ENOTREG – when the endpoint is not registered with the instance.
- -EALREADY – when the buffer data has been already released.
- -ENOTSUP – when this is not supported by the backend.
- -ENXIO – when the buffer was not held before using `ipc_service_hold_rx_buffer`.
- 0 – on success.
- other – errno codes depending on the implementation of the backend.

struct ipc_service_cb

#include <ipc_service.h> Event callback structure.

It is registered during endpoint registration. This structure is part of the endpoint configuration.

Public Members

void (*_bind)(void *priv)

Bind was successful.

This callback is called when the endpoint binding is successful.

Param priv

[in] Private user data.
void (*received)(const void *data, size_t len, void *priv)
New packet arrived.
This callback is called when new data is received.

**Note:** When `ipc_service_hold_rx_buffer` is not used, the data buffer is to be considered released and available again only when this callback returns.

```c
void (*error)(const char *message, void *priv)
An error occurred.
```

- **Param message**
  - [in] Error message.
- **Param priv**
  - [in] Private user data.

```c
struct ipc_ept
#include <ipc_service.h> Endpoint instance.
Token is not important for user of the API. It is implemented in a specific backend.
```

**Public Members**

```c
const struct device *instance
Instance this endpoint belongs to.
```

```c
void *token
Backend-specific token used to identify an endpoint in an instance.
```

```c
struct ipc_ept_cfg
#include <ipc_service.h> Endpoint configuration structure.
```

**Public Members**

```c
const char *name
Name of the endpoint.
```

```c
int prio
Endpoint priority.
If the backend supports priorities.
```

```c
struct ipc_service_cb cb
Event callback structure.
```
void *priv

Private user data.

**IPC service backend API**

```c
#include <ipc_service_backend.h>  // IPC backend configuration structure.

This structure is used for configuration backend during registration.
```

**Public Members**

```c
int (*open_instance)(const struct device *instance)

Pointer to the function that will be used to open an instance.

**Param instance**
- [in] Instance pointer.

**Retval**
- **-EALREADY** when the instance is already opened.
- **0** on success
- **other** errno codes depending on the implementation of the backend.

int (*close_instance)(const struct device *instance)

Pointer to the function that will be used to close an instance.

**Param instance**
- [in] Instance pointer.

**Retval**
- **-EALREADY** when the instance is not already inited.
- **0** on success
- **other** errno codes depending on the implementation of the backend.

int (*send)(const struct device *instance, void *token, const void *data, size_t len)

Pointer to the function that will be used to send data to the endpoint.

**Param instance**
- [in] Instance pointer.

**Param token**

**Param data**
- [in] Pointer to the buffer to send.

**Param len**
- [in] Number of bytes to send.

**Retval**
- **-EINVAL** when instance is invalid.
- **-ENOENT** when the endpoint is not registered with the instance.
Retval -EBADMSG  
when the message is invalid.

Retval -EBUSY  
when the instance is busy or not ready.

Retval -ENOMEM  
when no memory / buffers are available.

Retval bytes  
number of bytes sent.

Retval other  
errno codes depending on the implementation of the backend.

int (*register_endpoint)(const struct device *instance, void **token, const struct ipc_ept_cfg *cfg)

Pointer to the function that will be used to register endpoints.

Param instance  
[in] Instance to register the endpoint onto.

Param token  
[out] Backend-specific token.

Param cfg  
[in] Endpoint configuration.

Retval -EINVAL  
when the endpoint configuration or instance is invalid.

Retval -EBUSY  
when the instance is busy or not ready.

Retval 0  
on success

Retval other  
errno codes depending on the implementation of the backend.

int (*deregister_endpoint)(const struct device *instance, void *token)

Pointer to the function that will be used to deregister endpoints.

Param instance  
[in] Instance from which to deregister the endpoint.

Param token  

Retval -EINVAL  
when the endpoint configuration or instance is invalid.

Retval -ENOENT  
when the endpoint is not registered with the instance.

Retval -EBUSY  
when the instance is busy or not ready.

Retval 0  
on success

Retval other  
errno codes depending on the implementation of the backend.

int (*get_tx_buffer_size)(const struct device *instance, void *token)

Pointer to the function that will return the TX buffer size.

Param instance  
[in] Instance pointer.

Param token  

Retval -EINVAL  
when instance is invalid.

Retval -ENOENT  
when the endpoint is not registered with the instance.
Retval -ENOTSUP
  when the operation is not supported.

Retval size
  TX buffer size on success.

Retval other
  errno codes depending on the implementation of the backend.

int (*get_tx_buffer)(const struct device *instance, void *token, void **data, uint32_t *len, k_timeout_t wait)
  Pointer to the function that will return an empty TX buffer.
  
  Param instance
    [in] Instance pointer.
  
  Param token
  
  Param data
    [out] Pointer to the empty TX buffer.
  
  Param len
    [inout] Pointer to store the TX buffer size.
  
  Param wait
    [in] Timeout waiting for an available TX buffer.

Retval -EINVAL
  when instance is invalid.

Retval -ENOENT
  when the endpoint is not registered with the instance.

Retval -ENOTSUP
  when the operation or the timeout is not supported.

Retval -ENOBUFS
  when there are no TX buffers available.

Retval -EALREADY
  when a buffer was already claimed and not yet released.

Retval -ENOMEM
  when the requested size is too big (and the size parameter contains the maximum allowed size).

Retval 0
  on success

Retval other
  errno codes depending on the implementation of the backend.

int (*drop_tx_buffer)(const struct device *instance, void *token, const void *data)
  Pointer to the function that will drop a TX buffer.
  
  Param instance
    [in] Instance pointer.
  
  Param token
  
  Param data
    [in] Pointer to the TX buffer.

Retval -EINVAL
  when instance is invalid.

Retval -ENOENT
  when the endpoint is not registered with the instance.

Retval -ENOTSUP
  when this function is not supported.

Retval -EALREADY
  when the buffer was already dropped.

Retval 0
  on success

Retval other
  errno codes depending on the implementation of the backend.
epsilon codes depending on the implementation of the backend.

```c
int (*send_nocopy)(const struct device *instance, void *token, const void *data, size_t len)
    Pointer to the function that will be used to send data to the endpoint when the TX buffer
    has been obtained using \texttt{ipc\_service\_get\_tx\_buffer}.

- **Param instance**
  - [in] Instance pointer.

- **Param token**

- **Param data**
  - [in] Pointer to the buffer to send.

- **Param len**
  - [in] Number of bytes to send.

- **Retval**
  - -EINVAL when instance is invalid.
  - -ENOENT when the endpoint is not registered with the instance.
  - -EBADMSG when the data is invalid (i.e. invalid data format, invalid length, \ldots)
  - -EBUSY when the instance is busy or not ready.

int (*hold_rx_buffer)(const struct device *instance, void *token, void *data)
    Pointer to the function that will hold the RX buffer.

- **Param instance**
  - [in] Instance pointer.

- **Param token**

- **Param data**
  - [in] Pointer to the RX buffer to hold.

- **Retval**
  - -EINVAL when instance is invalid.
  - -ENOENT when the endpoint is not registered with the instance.
  - -EALREADY when the buffer data has been already hold.
  - -ENOTSUP when this function is not supported.

int (*release_rx_buffer)(const struct device *instance, void *token, void *data)
    Pointer to the function that will release the RX buffer.

- **Param instance**
  - [in] Instance pointer.

- **Param token**

- **Param data**
  - [in] Pointer to the RX buffer to release.

- **Retval**
  - -EINVAL when instance is invalid.
```
Retval -ENOENT
when the endpoint is not registered with the instance.
Retval -EALREADY
when the buffer data has been already released.
Retval -ENOTSUP
when this function is not supported.
Retval 0
  on success
Retval other
  errno codes depending on the implementation of the backend.

4.10 Linkable Loadable Extensions (LLEXT)

The llext subsystem provides a toolbox for extending the functionality of an application at runtime with linkable loadable code.

Extensions can be loaded from precompiled ELF formatted data which is verified, loaded, and linked with other extensions. Extensions can be manipulated and introspected to some degree, as well as unloaded when no longer needed.

An extension may be loaded using any implementation of a llext_loader which has a set of function pointers that provide the necessary functionality to read the ELF data. A loader also provides some minimal context (memory) needed by the llext_load() function. An implementation over a buffer containing an ELF in addressable memory in memory is available as llext_buf_loader.

4.10.1 API Reference

Related code samples
- Linkable loadable extensions shell module - Manage loadable extensions using shell commands.

group llext
  Linkable loadable extensions.

Enums

class enum llext_mem
  Enum of memory regions for lookup tables.
  Values:

  enumerator LLEXT_MEM_TEXT

  enumerator LLEXT_MEM_DATA

  enumerator LLEXT_MEM_RODATA

  enumerator LLEXT_MEM_BSS

  enumerator LLEXT_MEM_COUNT
Functions

sys_slist_t *llext_list(void)
List head of loaded extensions.

struct llext *llext_by_name(const char *name)
Find an llext by name.

Parameters
• name – [in] String name of the llext

Return values
• NULL – if no llext not found
• llext – if llext found

int llext_load(struct llext_loader *loader, const char *name, struct llext **ext)
Load and link an extension.
Loads relevant ELF data into memory and provides a structure to work with it.

Only relocatable ELF files are currently supported (partially linked).

Parameters
• loader – [in] An extension loader that provides input data and context
• name – [in] A string identifier for the extension
• ext – [out] A pointer to a statically allocated llext struct

Return values
• 0 – Success
• -ENOMEM – Not enough memory
• -EINVAL – Invalid ELF stream

void llext_unload(struct llext *ext)
Unload an extension.

Parameters
• ext – [in] Extension to unload

const void *const llext_find_sym(const struct llext_symtable *sym_table, const char *sym_name)
Find the address for an arbitrary symbol name.

Parameters
• sym_table – [in] Symbol table to lookup symbol in, if NULL uses base table
• sym_name – [in] Symbol name to find

Return values
• NULL – if no symbol found
• addr – Address of symbol in memory if found

int llext_call_fn(struct llext *ext, const char *sym_name)
Call a function by name.

Expects a symbol representing a void fn(void) style function exists and may be called.

Parameters
• ext – [in] Extension to call function in
• **sym_name** – *[in]* Function name (exported symbol) in the extension

**Return values**

• 0 – success
• -EINVAL – invalid symbol name

```c
void arch_elf_relocate(elf_rel_t *rel, uintptr_t opaddr, uintptr_t opval)
```

Architecture specific function for updating op codes given a relocation.

Elf files contain a series of relocations described in a section. These relocation instructions are architecture specific and each architecture supporting extensions must implement this. They are instructions on how to rewrite opcodes given the actual placement of some symbolic data such as a section, function, or object.

**Parameters**

• **rel** – *[in]* Relocation data provided by elf
• **opaddr** – *[in]* Address of operation to rewrite with relocation
• **opval** – *[in]* Value of looked up symbol to relocate

```c
struct llext
```

#include `<llext.h>` Linkable loadable extension.

**Public Members**

char name[16]

Name of the llext.

```c
void *mem[LLEXT_MEM_COUNT]
```

Lookup table of llext memory regions.

```c
size_t mem_size
```

Total size of the llext memory usage.

```c
struct llext_symtable sym_tab
```

Exported symbols from the llext, may be linked against by other llext.

`group llext_symbols`

Linkable loadable extension symbol.

**Defines**

```c
EXPORT_SYMBOL(x)
```

Export a constant symbol to a table of symbols.

Takes a symbol (function or object) by symbolic name and adds the name and address of the symbol to a table of symbols that may be used for linking.

**Parameters**

• **x** – Symbol to export
struct llext_const_symbol
#include <symbol.h> Constant symbols are unchangeable named memory addresses.
Symbols may be named function or global objects that have been exported for linking. These
constant symbols are useful in the base image as they may be placed in ROM.

Public Members

const char *const name
   Name of symbol.

const void *const addr
   Address of symbol.

struct llext_symbol
#include <symbol.h> Symbols are named memory addresses.
Symbols may be named function or global objects that have been exported for linking. These
are mutable and should come from extensions where the location may need updating depend-
ing on where memory is placed.

Public Members

char *name
   Name of symbol.

void *addr
   Address of symbol.

struct llext_symtable
#include <symbol.h> A symbol table.
An array of symbols

Public Members

size_t sym_cnt
   Number of symbols in the table.

struct llext_symbol *syms
   Array of symbols.

\textit{group} llext_loader
   Loader context for llext.

4.10. Linkable Loadable Extensions (LLEXT)
### Enums

**enum llext_section**

Enum of sections for lookup tables.

*Values:*

enumerator LLEXT_SECT_TEXT

enumerator LLEXT_SECT_DATA

enumerator LLEXT_SECT_RODATA

enumerator LLEXT_SECT_BSS

enumerator LLEXT_SECT_REL_TEXT

enumerator LLEXT_SECT_REL_DATA

enumerator LLEXT_SECT_REL_RODATA

enumerator LLEXT_SECT_REL_BSS

enumerator LLEXT_SECT_SYMTAB

enumerator LLEXT_SECT_STRTAB

enumerator LLEXT_SECT_SHSTRTAB

enumerator LLEXT_SECT_COUNT

**struct llext_loader**

`:include <loader.h>` Linkable loadable extension loader context.

### Public Members

**int (*)read(struct llext_loader *ldr, void *out, size_t len)**

Read (copy) from the loader. Copies len bytes into buf from the current position of the loader.

**Param ldr**

[in] Loader

**Param out**

[in] Output location

**Param len**

[in] Length to copy into the output location

**Retval 0**

Success
**Retval -errno**
Error reading (any errno)

```c
int (*seek)(struct llext_loader *s, size_t pos)
```
Seek to a new absolute location.
Changes the location of the loader position to a new absolute given position.

**Param ldr**
[in] Loader

**Param pos**
[in] Position in stream to move loader

**Retval 0**
Success

**Retval -errno**
Error reading (any errno)

```c
#include <buf_loader.h>
```
An extension loader from a provided buffer containing an ELF.

**Public Members**

```c
struct llext_loader loader
```
Extension loader.

## 4.11  Logging

- **Global Kconfig Options**
- **Usage**
  - Logging in a module
  - Logging in a module instance
  - Controlling the logging
- **Logging panic**
- **Printk**
- **Architecture**
The logging API provides a common interface to process messages issued by developers. Messages are passed through a frontend and are then processed by active backends. Custom frontend and backends can be used if needed.

Summary of the logging features:

- Deferred logging reduces the time needed to log a message by shifting time consuming operations to a known context instead of processing and sending the log message when called.
- Multiple backends supported (up to 9 backends).
- Custom frontend support. It can work together with backends.
- Compile time filtering on module level.
- Run time filtering independent for each backend.
- Additional run time filtering on module instance level.
- Timestamping with user provided function. Timestamp can have 32 or 64 bits.
- Dedicated API for dumping data.
- Dedicated API for handling transient strings.
- Panic support - in panic mode logging switches to blocking, synchronous processing.
- Printk support - printk message can be redirected to the logging.
- Design ready for multi-domain/multi-processor system.
- Support for logging floating point variables and long long arguments.
- Built-in copying of transient strings used as arguments.
- Support for multi-domain logging.

Logging API is highly configurable at compile time as well as at run time. Using Kconfig options (see Global Kconfig Options) logs can be gradually removed from compilation to reduce image size and execution time when logs are not needed. During compilation logs can be filtered out on module basis and severity level.
Logs can also be compiled in but filtered on run time using dedicate API. Run time filtering is independent for each backend and each source of log messages. Source of log messages can be a module or specific instance of the module.

There are four severity levels available in the system: error, warning, info and debug. For each severity level the logging API (include/zephyr/logging/log.h) has set of dedicated macros. Logger API also has macros for logging data.

For each level following set of macros are available:

- **LOG_X** for standard printf-like messages, e.g. `LOG_ERR`.
- **LOG_HEXDUMP_X** for dumping data, e.g. `LOG_HEXDUMP_WRN`.
- **LOG_INST_X** for standard printf-like message associated with the particular instance, e.g. `LOG_INST_INF`.
- **LOG_INST_HEXDUMP_X** for dumping data associated with the particular instance, e.g. `LOG_HEXDUMP_INST_DBG`.

There are two configuration categories: configurations per module and global configuration. When logging is enabled globally, it works for modules. However, modules can disable logging locally. Every module can specify its own logging level. The module must define the `LOG_LEVEL` macro before using the API. Unless a global override is set, the module logging level will be honored. The global override can only increase the logging level. It cannot be used to lower module logging levels that were previously set higher. It is also possible to globally limit logs by providing maximal severity level present in the system, where maximal means lowest severity (e.g. if maximal level in the system is set to info, it means that errors, warnings and info levels are present but debug messages are excluded).

Each module which is using the logging must specify its unique name and register itself to the logging. If module consists of more than one file, registration is performed in one file but each file must define a module name.

Logger’s default frontend is designed to be thread safe and minimizes time needed to log the message. Time consuming operations like string formatting or access to the transport are not performed by default when logging API is called. When logging API is called a message is created and added to the list. Dedicated, configurable buffer for pool of log messages is used. There are 2 types of messages: standard and hexdump. Each message contain source ID (module or instance ID and domain ID which might be used for multiprocessor systems), timestamp and severity level. Standard message contains pointer to the string and arguments. Hexdump message contains copied data and string.

### 4.11.1 Global Kconfig Options

These options can be found in the following path `subsys/logging/Kconfig`.

**CONFIG_LOG**: Global switch, turns on/off the logging.

Mode of operations:

- **CONFIG_LOG_MODE_DEFERRED**: Deferred mode.
- **CONFIG_LOG_MODE_IMMEDIATE**: Immediate (synchronous) mode.
- **CONFIG_LOG_MODE_MINIMAL**: Minimal footprint mode.

Filtering options:

- **CONFIG_LOG_RUNTIME_FILTERING**: Enables runtime reconfiguration of the filtering.
- **CONFIG_LOG_DEFAULT_LEVEL**: Default level, sets the logging level used by modules that are not setting their own logging level.
- **CONFIG_LOG_OVERRIDE_LEVEL**: It overrides module logging level when it is not set or set lower than the override value.
- **CONFIG_LOG_MAX_LEVEL**: Maximal (lowest severity) level which is compiled in.
Processing options:

- `CONFIG_LOG_MODE_OVERFLOW`: When new message cannot be allocated, oldest one are discarded.
- `CONFIG_LOG_BLOCK_IN_THREAD`: If enabled and new log message cannot be allocated thread context will block for up to `CONFIG_LOG_BLOCK_IN_THREAD_TIMEOUT_MS` or until log message is allocated.
- `CONFIG_LOG_PRINTK`: Redirect printk calls to the logging.
- `CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD`: When number of buffered log messages reaches the threshold dedicated thread (see `log_thread_set()`) is waken up. If `CONFIG_LOG_PROCESS_THREAD` is enabled then this threshold is used by the internal thread.
- `CONFIG_LOG_PROCESS_THREAD`: When enabled, logging thread is created which handles log processing.
- `CONFIG_LOG_PROCESS_THREAD_STARTUP_DELAY_MS`: Delay in milliseconds after which logging thread is started.
- `CONFIG_LOG_BUFFER_SIZE`: Number of bytes dedicated for the circular packet buffer.
- `CONFIG_LOG_FRONTEND`: Direct logs to a custom frontend.
- `CONFIG_LOG_FRONTEND_ONLY`: No backends are used when messages goes to frontend.
- `CONFIG_LOG_CUSTOM_HEADER`: Injects an application provided header into log.h
- `CONFIG_LOG_TIMESTAMP_64BIT`: 64 bit timestamp.

Formatting options:

- `CONFIG_LOG_FUNC_NAME_PREFIX_ERR`: Prepend standard ERROR log messages with function name. Hexdump messages are not prepended.
- `CONFIG_LOG_FUNC_NAME_PREFIX_WRN`: Prepend standard WARNING log messages with function name. Hexdump messages are not prepended.
- `CONFIG_LOG_FUNC_NAME_PREFIX_INF`: Prepend standard INFO log messages with function name. Hexdump messages are not prepended.
- `CONFIG_LOG_FUNC_NAME_PREFIX_DBG`: Prepend standard DEBUG log messages with function name. Hexdump messages are not prepended.
- `CONFIG_LOG_BACKEND_SHOW_COLOR`: Enables coloring of errors (red) and warnings (yellow).
- `CONFIG_LOG_BACKEND_FORMAT_TIMESTAMP`: If enabled timestamp is formatted to `hh:mm:ss:mmm,uuu`. Otherwise is printed in raw format.

Backend options:

- `CONFIG_LOG_BACKEND_UART`: Enabled built-in UART backend.

### 4.11.2 Usage

**Logging in a module**

In order to use logging in the module, a unique name of a module must be specified and module must be registered using `LOG_MODULE_REGISTER`. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (`CONFIG_LOG_DEFAULT_LEVEL`) is used if custom log level is not provided.

```c
#include <zephyr/logging/log.h>
LOG_MODULE_REGISTER(foo, CONFIG_FOO_LOG_LEVEL);
```

If the module consists of multiple files, then `LOG_MODULE_REGISTER()` should appear in exactly one of them. Each other file should use `LOG_MODULE_DECLARE` to declare its membership in the module. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (`CONFIG_LOG_DEFAULT_LEVEL`) is used if custom log level is not provided.
In order to use logging API in a function implemented in a header file `LOG_MODULE_DECLARE` macro must be used in the function body before logging API is called. Optionally, a compile time log level for the module can be specified as the second parameter. Default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if custom log level is not provided.

```c
#include <zephyr/logging/log.h>

static inline void foo(void)
{
    LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);
    LOG_INF("foo");
}
```

Dedicated Kconfig template (subsys/logging/Kconfig.template.log_config) can be used to create local log level configuration.

Example below presents usage of the template. As a result CONFIG_FOO_LOG_LEVEL will be generated:

```c
module = FOO
module-str = foo
source "subsys/logging/Kconfig.template.log_config"
```

Logging in a module instance

In case of modules which are multi-instance and instances are widely used across the system enabling logs will lead to flooding. Logger provide the tools which can be used to provide filtering on instance level rather than module level. In that case logging can be enabled for particular instance.

In order to use instance level filtering following steps must be performed:

- a pointer to specific logging structure is declared in instance structure. `LOG_INSTANCE_PTR_DECLARE` is used for that.

```c
#include <zephyr/logging/log_instance.h>

struct foo_object {
    LOG_INSTANCE_PTR_DECLARE(log);
    uint32_t id;
};
```

- module must provide macro for instantiation. In that macro, logging instance is registered and log instance pointer is initialized in the object structure.

```c
#define FOO_OBJECT_DEFINE(_name)
    LOG_INSTANCE_REGISTER(foo, _name, CONFIG_FOO_LOG_LEVEL) \
    struct foo_object _name = {
        LOG_INSTANCE_PTR_INIT(log, foo, _name) \
    }
```

Note that when logging is disabled logging instance and pointer to that instance are not created.

In order to use the instance logging API in a source file, a compile-time log level must be set using `LOG_LEVEL_SET`. 
In order to use the instance logging API in a header file, a compile-time log level must be set using `LOG_LEVEL_SET`.

```c
static inline void foo_init(foo_object *f)
{
    LOG_LEVEL_SET(CONFIG_FOO_LOG_LEVEL);
    LOG_INST_INF(f->log, "Initialized.");
}
```

### Controlling the logging

By default, logging processing in deferred mode is handled internally by the dedicated task which starts automatically. However, it might not be available if multithreading is disabled. It can also be disabled by unsetting `CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD`. In that case, logging can be controlled using API defined in `include/zephyr/logging/log_ctrl.h`. Logging must be initialized before it can be used. Optionally, user can provide function which returns timestamp value. If not provided, `k_cycle_get` or `k_cycle_get_32` is used for timestamping. `log_process()` function is used to trigger processing of one log message (if pending). Function returns true if there is more messages pending. However, it is recommended to use macro wrappers (`LOG_INIT` and `LOG_PROCESS`) which handles case when logging is disabled.

Following snippet shows how logging can be processed in simple forever loop.

```c
#include <zephyr/log_ctrl.h>

int main(void)
{
    LOG_INIT();
    /* If multithreading is enabled provide thread id to the logging. */
    log_thread_set(k_current_get());

    while (1) {
        if (LOG_PROCESS() == false) {
            /* sleep */
        }
    }
}
```

If logs are processed from a thread (user or internal) then it is possible to enable a feature which will wake up processing thread when certain amount of log messages are buffered (see `CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD`).

### 4.11.3 Logging panic

In case of error condition system usually can no longer rely on scheduler or interrupts. In that situation deferred log message processing is not an option. Logger controlling API provides a function for entering into panic mode (`log_panic()`) which should be called in such situation.
When `log_panic()` is called, _panic_ notification is sent to all active backends. Once all backends are notified, all buffered messages are flushed. Since that moment all logs are processed in a blocking way.

### 4.11.4 Printk

Typically, logging and `printk()` is using the same output for which they compete. This can lead to issues if the output does not support preemption but also it may result in the corrupted output because logging data is interleaved with printk data. However, it is possible to redirect printk messages to the logging subsystem by enabling `CONFIG_LOG_PRINTK`. In that case, printk entries are treated as log messages with level 0 (they cannot be disabled). When enabled, logging manages the output so there is no interleaving. However, in the deferred mode it changes the behavior of the printk because output is delayed until logging thread processes the data. `CONFIG_LOG_PRINTK` is by default enabled.

### 4.11.5 Architecture

Logging consists of 3 main parts:

- Frontend
- Core
- Backends

Log message is generated by a source of logging which can be a module or instance of a module.

#### Default Frontend

Default frontend is engaged when logging API is called in a source of logging (e.g. `LOG_INF`) and is responsible for filtering a message (compile and run time), allocating buffer for the message, creating the message and committing that message. Since logging API can be called in an interrupt, frontend is optimized to log the message as fast as possible.

#### Log message

Log message contains message descriptor (source, domain and level), timestamp, formatted string details (see *Cbprintf Packaging*) and optional data. Log messages are stored in a continuous block of memory. Memory is allocated from a circular packet buffer (*Multi Producer Single Consumer Packet Buffer*). It has few consequences:

- Each message is self-contained, continuous block of memory thus it is suited for copying the message (e.g. for offline processing).
- Messages must be sequentially freed. Backend processing is synchronous. Backend can make a copy for deferred processing.

Log message has following format:
Log message allocation  It may happen that frontend cannot allocate a message. It happens if system is generating more log messages than it can process in certain time frame. There are two strategies to handle that case:

- No overflow - new log is dropped if space for a message cannot be allocated.
- Overflow - oldest pending messages are freed, until new message can be allocated. Enabled by CONFIG_LOG_MODE_OVERFLOW. Note that it degrades performance thus it is recommended to adjust buffer size and amount of enabled logs to limit dropping.

Run-time filtering  If run-time filtering is enabled, then for each source of logging a filter structure in RAM is declared. Such filter is using 32 bits divided into ten 3 bit slots. Except slot 0, each slot stores current filter for one backend in the system. Slot 0 (bits 0-2) is used to aggregate maximal filter setting for given source of logging. Aggregate slot determines if log message is created for given entry since it indicates if there is at least one backend expecting that log entry. Backend slots are examined when message is processed by the core to determine if message is accepted by the given backend. Contrary to compile time filtering, binary footprint is increased because logs are compiled in.

In the example below backend 1 is set to receive errors (slot 1) and backend 2 up to info level (slot 2). Slots 3-9 are not used. Aggregated filter (slot 0) is set to info level and up to this level message from that particular source will be buffered.

<table>
<thead>
<tr>
<th>slot 0</th>
<th>slot 1</th>
<th>slot 2</th>
<th>slot 3</th>
<th>...</th>
<th>slot 9</th>
</tr>
</thead>
<tbody>
<tr>
<td>INF</td>
<td>ERR</td>
<td>INF</td>
<td>OFF</td>
<td>...</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Custom Frontend

Custom frontend is enabled using CONFIG_LOG_FRONTEND. Logs are directed to functions declared in include/zephyr/logging/log_frontend.h. If option CONFIG_LOG_FRONTEND_ONLY is enabled then log message is not created and no backend is handled. Otherwise, custom frontend can coexist with backends.

In some cases, logs need to be redirected at the macro level. For these cases, CONFIG_LOG_CUSTOM_HEADER can be used to inject an application provided header named zephyr_custom_log.h at the end of include/zephyr/logging/log.h.

1 Depending on the platform and the timestamp size fields may be swapped.
2 It may be required for cbprintf package alignment
Logging strings

String arguments are handled by `Cbprintf Packaging`. See `Limitations and recommendations` for limitations and recommendations.

Multi-domain support

More complex systems can consist of multiple domains where each domain is an independent binary. Examples of domains are a core in a multicore SoC or one of the binaries (Secure or Nonsecure) on an ARM TrustZone core.

Tracing and debugging on a multi-domain system is more complex and requires an efficient logging system. Two approaches can be used to structure this logging system:

- Log inside each domain independently. This option is not always possible as it requires that each domain has an available backend (for example, UART). This approach can also be troublesome to use and not scalable, as logs are presented on independent outputs.

- Use a multi-domain logging system where log messages from each domain end up in one root domain, where they are processed exactly as in a single domain case. In this approach, log messages are passed between domains using a connection between domains created from the backend on one side and linked to the other.

The `Log link` is an interface introduced in this multi-domain approach. The `Log link` is responsible for receiving any log message from another domain, creating a copy, and putting that local log message copy (including remote data) into the message queue. This specific log link implementation matches the complementary backend implementation to allow log messages exchange and logger control like configuring filtering, getting log source names, and so on.

There are three types of domains in a multi-domain system:

- The end domain has the logging core implementation and a cross-domain backend. It can also have other backends in parallel.

- The relay domain has one or more links to other domains but does not have backends that output logs to the user. It has a cross-domain backend either to another relay or to the root domain.

- The root domain has one or multiple links and a backend that outputs logs to the user.

See the following image for an example of a multi-domain setup:

In this architecture, a link can handle multiple domains. For example, let’s consider an SoC with two ARM Cortex-M33 cores with TrustZone: cores A and B (see the example illustrated above). There are four domains in the system, as each core has both a Secure and a Nonsecure domain. If core A nonsecure (A_NS) is the root domain, it has two links: one to core A secure (A_NS-A_S) and one to core B nonsecure (A_NS-B_NS). B_NS domain has one link, to core B secure B_NS-B_S, and a backend to A_NS.

Since in all instances there is a standard logging subsystem, it is always possible to have multiple backends and simultaneously output messages to them. An example of this is shown in the illustration above as a dotted UART backend on the B_NS domain.

Domain ID The source of each log message can be identified by the following fields in the header: `source_id` and `domain_id`.

The value assigned to the `domain_id` is relative. Whenever a domain creates a log message, it sets its `domain_id` to 0. When a message crosses the domain, `domain_id` changes as it is increased by the link offset. The link offset is assigned during the initialization, where the logger core is iterating over all the registered links and assigned offsets.

The first link has the offset set to 1. The following offset equals the previous link offset plus the number of domains in the previous link.

The following example is shown below, where the assigned `domain_ids` are shown for each domain:
Fig. 1: Multi-domain example

Fig. 2: Domain IDs assigning example
Let’s consider a log message created on the $B_S$ domain:

1. Initially, it has its `domain_id` set to 0.
2. When the $B_NS$-$B_S$ link receives the message, it increases the `domain_id` to 1 by adding the $B_NS$-$B_S$ offset.
3. The message is passed to $A_NS$.
4. When the $A_NS$-$B_NS$ link receives the message, it adds the offset (2) to the `domain_id`. The message ends up with the `domain_id` set to 3, which uniquely identifies the message originator.

**Cross-domain log message** In most cases, the address space of each domain is unique, and one domain cannot access directly the data in another domain. For this reason, the backend can partially process the message before it is passed to another domain. Partial processing can include converting a string package to a fully self-contained version (copying read-only strings to the package body).

Each domain can have a different timestamp source in terms of frequency and offset. Logging does not perform any timestamp conversion.

**Runtime filtering** In the single-domain case, each log source has a dedicated variable with runtime filtering for each backend in the system. In the multi-domain case, the originator of the log message is not aware of the number of backends in the root domain.

As such, to filter logs in multiple domains, each source requires a runtime filtering setting in each domain on the way to the root domain. As the number of sources in other domains is not known during the compilation, the runtime filtering of remote sources must use dynamically allocated memory (one word per source). When a backend in the root domain changes the filtering of the module from a remote domain, the local filter is updated. After the update, the aggregated filter (the maximum from all the local backends) is checked and, if changed, the remote domain is informed about this change. With this approach, the runtime filtering works identically in both multi-domain and single-domain scenarios.

**Message ordering** Logging does not provide any mechanism for synchronizing timestamps across multiple domains:

- If domains have different timestamp sources, messages will be processed in the order of arrival to the buffer in the root domain.
- If domains have the same timestamp source or if there is an out-of-bound mechanism that recalculates timestamps, there are 2 options:
  - Messages are processed as they arrive in the buffer in the root domain. Messages are unordered but they can be sorted by the host as the timestamp indicates the time of the message generation.
  - Links have dedicated buffers. During processing, the head of each buffer is checked and the oldest message is processed first.

With this approach, it is possible to maintain the order of the messages at the cost of a suboptimal memory utilization (since the buffer is not shared) and increased processing latency (see `CONFIG_LOG_PROCESSING_LATENCY_US`).

**Logging backends**

Logging backends are registered using `LOG_BACKEND_DEFINE`. The macro creates an instance in the dedicated memory section. Backends can be dynamically enabled (`log_backend_enable()`) and disabled. When Run-time filtering is enabled, `log_filter_set()` can be used to dynamically change filtering of a module logs for given backend. Module is identified by source ID and domain ID. Source ID can be retrieved if source name is known by iterating through all registered sources.
Logging supports up to 9 concurrent backends. Log message is passed to the each backend in processing phase. Additionally, backend is notified when logging enter panic mode with log_backend_panic(). On that call backend should switch to synchronous, interrupt-less operation or shut down itself if that is not supported. Occasionally, logging may inform backend about number of dropped messages with log_backend_dropped(). Message processing API is version specific.

log_backend_msg2_process() is used for processing message. It is common for standard and hexdump messages because log message hold string with arguments and data. It is also common for deferred and immediate logging.

**Message formatting**  Logging provides set of function that can be used by the backend to format a message. Helper functions are available in include/zephyr/logging/log_output.h.

Example message formatted using log_output_msg2_process().

```
[00:00:00.000,274] <info> sample_instance.inst1: logging message
```

**Dictionary-based Logging**

Dictionary-based logging, instead of human readable texts, outputs the log messages in binary format. This binary format encodes arguments to formatted strings in their native storage formats which can be more compact than their text equivalents. For statically defined strings (including the format strings and any string arguments), references to the ELF file are encoded instead of the whole strings. A dictionary created at build time contains the mappings between these references and the actual strings. This allows the offline parser to obtain the strings from the dictionary to parse the log messages. This binary format allows a more compact representation of log messages in certain scenarios. However, this requires the use of an offline parser and is not as intuitive to use as text-based log messages.

Note that long double is not supported by Python's struct module. Therefore, log messages with long double will not display the correct values.

**Configuration**  Here are kconfig options related to dictionary-based logging:

- **CONFIG_LOG_DICTIONARY_SUPPORT** enables dictionary-based logging support. This should be selected by the backends which require it.

- The UART backend can be used for dictionary-based logging. These are additional config for the UART backend:
  - **CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX** tells the UART backend to output hexadecimal characters for dictionary based logging. This is useful when the log data needs to be captured manually via terminals and consoles.
  - **CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_BIN** tells the UART backend to output binary data.

**Usage**  When dictionary-based logging is enabled via enabling related logging backends, a JSON database file, named log_dictionary.json, will be created in the build directory. This database file contains information for the parser to correctly parse the log data. Note that this database file only works with the same build, and cannot be used for any other builds.

To use the log parser:

```
./scripts/logging/dictionary/log_parser.py <build dir>/log_dictionary.json <log data file>
```

The parser takes two required arguments, where the first one is the full path to the JSON database file, and the second part is the file containing log data. Add an optional argument --hex to the end if the log data file contains hexadecimal characters (e.g. when
CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX=y). This tells the parser to convert the hexadecimal characters to binary before parsing.

Please refer to the logging-dictionary sample to learn more on how to use the log parser.

### 4.11.6 Recommendations

The are following recommendations:

- Enable `CONFIG_LOG_SPEED` to slightly speed up deferred logging at the cost of slight increase in memory footprint.
- Compiler with C11 `_Generic` keyword support is recommended. Logging performance is significantly degraded without it. See [Cbprintf Packaging](#).
- It is recommended to cast pointer to `const char *` when it is used with `%s` format specifier and it points to a constant string.
- It is recommended to cast pointer to `char *` when it is used with `%s` format specifier and it points to a transient string.
- It is recommended to cast character pointer to non character pointer (e.g., `void *`) when it is used with `%p` format specifier.

```c
LOG_WRN("%s", str);
LOG_WRN("%p", (void *)str);
```

### 4.11.7 Benchmark

Benchmark numbers from tests/subsys/logging/log_benchmark performed on qemu_x86. It is a rough comparison to give a general overview.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Time (us)</th>

</tr>
</tbody>
</table>

**Benchmark details**

### 4.11.8 Stack usage

When logging is enabled it impacts stack usage of the context that uses logging API. If stack is optimized it may lead to stack overflow. Stack usage depends on mode and optimization. It also significantly varies between platforms. In general, when `CONFIG_LOG_MODE_DEFERRED` is used stack usage is smaller since

---

\(^3\) `CONFIG_LOG_SPEED` enabled.

\(^4\) Number of log messages with various number of arguments that fits in 2048 bytes dedicated for logging.

\(^5\) Logging subsystem memory footprint in tests/subsys/logging/log_benchmark where filtering and formatting features are not used.

\(^6\) Logging subsystem memory footprint in samples/subsys/logging/logger.

\(^7\) Average size of a log message (excluding string) with 2 arguments on Cortex M3
logging is limited to creating and storing log message. When CONFIG_LOG_MODE_IMMEDIATE is used then log message is processed by the backend which includes string formatting. In case of that mode, stack usage will depend on which backends are used.

tests/subsys/logging/log_stack test is used to characterize stack usage depending on mode, optimization and platform used. Test is using only the default backend.

Some of the platforms characterization for log message with two integer arguments listed below:

4.11.9 API Reference

Logger API

Related code samples

- BLE logging backend - Send log messages over BLE using the BLE logging backend.
- Dictionary-based logging - Output binary log data using the dictionary-based logging API.
- Logging - Output log messages to the console using the logging subsystem.

group log_api

Defines

LOG_ERR(...) 
Writes an ERROR level message to the log.
It's meant to report severe errors, such as those from which it's not possible to recover.

Parameters

- ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_WRN(...) 
Writes a WARNING level message to the log.
It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters

- ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INF(...) 
Writes an INFO level message to the log.
It's meant to write generic user oriented messages.

Parameters
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_DBG(...)  
Writes a DEBUG level message to the log.  
It’s meant to write developer oriented information.  

Parameters  
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_PRINTF(...)  
Unconditionally print raw log message.  
The result is same as if printk was used but it goes through logging infrastructure thus utilizes logging mode, e.g. deferred mode.  

Parameters  
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_RAW(...)  
Unconditionally print raw log message.  
Provided string is printed as is without appending any characters (e.g., color or newline).  

Parameters  
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_ERR(_log_inst, ...)  
Writes an ERROR level message associated with the instance to the log.  
Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It’s meant to report severe errors, such as those from which it’s not possible to recover.  

Parameters  
• _log_inst – Pointer to the log structure associated with the instance.  
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_WRN(_log_inst, ...)  
Writes a WARNING level message associated with the instance to the log.  
Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It’s meant to register messages related to unusual situations that are not necessarily errors.  

Parameters  
• _log_inst – Pointer to the log structure associated with the instance.  
• ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG_INST_INF(_log_inst, ...)  
Writes an INFO level message associated with the instance to the log.
Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to write generic user oriented messages.

Parameters

- \_log\_inst – Pointer to the log structure associated with the instance.
- ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG\_INST\_DBG(_log\_inst, ...)

Writes a DEBUG level message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It's meant to write developer oriented information.

Parameters

- \_log\_inst – Pointer to the log structure associated with the instance.
- ... – A string optionally containing printk valid conversion specifier, followed by as many values as specifiers.

LOG\_HEXDUMP\_ERR(_data, _length, _str)

Writes an ERROR level hexdump message to the log.

It's meant to report severe errors, such as those from which it's not possible to recover.

Parameters

- \_data – Pointer to the data to be logged.
- \_length – Length of data (in bytes).
- \_str – Persistent, raw string.

LOG\_HEXDUMP\_WRN(_data, _length, _str)

Writes a WARNING level message to the log.

It's meant to register messages related to unusual situations that are not necessarily errors.

Parameters

- \_data – Pointer to the data to be logged.
- \_length – Length of data (in bytes).
- \_str – Persistent, raw string.

LOG\_HEXDUMP\_INF(_data, _length, _str)

Writes an INFO level message to the log.

It's meant to write generic user oriented messages.

Parameters

- \_data – Pointer to the data to be logged.
- \_length – Length of data (in bytes).
- \_str – Persistent, raw string.

LOG\_HEXDUMP\_DBG(_data, _length, _str)

Writes a DEBUG level message to the log.

It's meant to write developer oriented information.

Parameters

- \_data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_INST_HEXDUMP_ERR(_log_inst, _data, _length, _str)

Writes an ERROR hexdump message associated with the instance to the log.

Message is associated with specific instance of the module which has independent filtering settings (if runtime filtering is enabled) and message prefix (<module_name>.<instance_name>). It’s meant to report severe errors, such as those from which it’s not possible to recover.

Parameters
• _log_inst – Pointer to the log structure associated with the instance.
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_INST_HEXDUMP_WRN(_log_inst, _data, _length, _str)

Writes a WARNING level hexdump message associated with the instance to the log.

It’s meant to register messages related to unusual situations that are not necessarily errors.

Parameters
• _log_inst – Pointer to the log structure associated with the instance.
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_INST_HEXDUMP_INF(_log_inst, _data, _length, _str)

Writes an INFO level hexdump message associated with the instance to the log.

It’s meant to write generic user oriented messages.

Parameters
• _log_inst – Pointer to the log structure associated with the instance.
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_INST_HEXDUMP_DBG(_log_inst, _data, _length, _str)

Writes a DEBUG level hexdump message associated with the instance to the log.

It’s meant to write developer oriented information.

Parameters
• _log_inst – Pointer to the log structure associated with the instance.
• _data – Pointer to the data to be logged.
• _length – Length of data (in bytes).
• _str – Persistent, raw string.

LOG_MODULE_REGISTER(...)

Create module-specific state and register the module with Logger.

This macro normally must be used after including <zephyr/logging/log.h> to complete the initialization of the module.
Module registration can be skipped in two cases:

- The module consists of more than one file, and another file invokes this macro. \( \text{LOG\_MODULE\_DECLARE()} \) should be used instead in all of the module's other files.
- Instance logging is used and there is no need to create module entry. In that case \( \text{LOG\_LEVEL\_SET()} \) should be used to set log level used within the file.

Macro accepts one or two parameters:

- module name
- optional log level. If not provided then default log level is used in the file.

Example usage:

- \( \text{LOG\_MODULE\_REGISTER(foo, CONFIG\_FOO\_LOG\_LEVEL)} \)
- \( \text{LOG\_MODULE\_REGISTER(foo)} \)

See also:

\( \text{LOG\_MODULE\_DECLARE} \)

Note: The module's state is declared, and the module is registered, only if \( \text{LOG\_LEVEL} \) for the current source file is non-zero or it is not defined and \( \text{CONFIG\_LOG\_DEFAULT\_LEVEL} \) is non-zero. In other cases, this macro has no effect.

\( \text{LOG\_MODULE\_DECLARE(…)} \)

Macro for declaring a log module (not registering it).

Modules which are split up over multiple files must have exactly one file use \( \text{LOG\_MODULE\_REGISTER()} \) to create module-specific state and register the module with the logger core.

The other files in the module should use this macro instead to declare that same state. (Otherwise, \( \text{LOG\_INF()} \) etc. will not be able to refer to module-specific state variables.)

Macro accepts one or two parameters:

- module name
- optional log level. If not provided then default log level is used in the file.

Example usage:

- \( \text{LOG\_MODULE\_DECLARE(foo, CONFIG\_FOO\_LOG\_LEVEL)} \)
- \( \text{LOG\_MODULE\_DECLARE(foo)} \)

See also:

\( \text{LOG\_MODULE\_REGISTER} \)

Note: The module's state is declared only if \( \text{LOG\_LEVEL} \) for the current source file is non-zero or it is not defined and \( \text{CONFIG\_LOG\_DEFAULT\_LEVEL} \) is non-zero. In other cases, this macro has no effect.

\( \text{LOG\_LEVEL\_SET(level)} \)

Macro for setting log level in the file or function where instance logging API is used.

Parameters
• level – Level used in file or in function.

Logger control

Related code samples

• Logging - Output log messages to the console using the logging subsystem.
• Remote syslog - Enable a remote syslog service that sends syslog messages to a remote server

```c

#define LOG_CORE_INIT()
#define LOG_INIT()
#define LOG_PANIC()
#define LOG_PROCESS()

typedef log_timestamp_t (*log_timestamp_get_t)(void)

void log_core_init(void)
    // Function system initialization of the logger.
    // Function is called during start up to allow logging before user can explicitly initialize the logger.

void log_init(void)
    // Function for user initialization of the logger.

void log_thread_set(k_tid_t process_tid)
    // Function for providing thread which is processing logs.
    // See CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD.

Note: Function has asserts and has no effect when CONFIG_LOG_PROCESS_THREAD is set.

Parameters

• process_tid – Process thread id. Used to wake up the thread.
```
int log_set_timestamp_func(log_timestamp_get_t timestamp_getter, uint32_t freq)
Function for providing timestamp function.

Parameters
• timestamp_getter – Timestamp function.
• freq – Timestamping frequency.

Returns
0 on success or error.

void log_panic(void)
Switch the logger subsystem to the panic mode.
Returns immediately if the logger is already in the panic mode.
On panic the logger subsystem informs all backends about panic mode. Backends must switch
to blocking mode or halt. All pending logs are flushed after switching to panic mode. In panic
mode, all log messages must be processed in the context of the call.

bool log_process(void)
Process one pending log message.

Return values
• true – There is more messages pending to be processed.
• false – No messages pending.

uint32_t log_buffered_cnt(void)
Return number of buffered log messages.

Returns
Number of currently buffered log messages.

uint32_t log_src_cnt_get(uint32_t domain_id)
Get number of independent logger sources (modules and instances)

Parameters
• domain_id – Domain ID.

Returns
Number of sources.

const char *log_source_name_get(uint32_t domain_id, uint32_t source_id)
Get name of the source (module or instance).

Parameters
• domain_id – Domain ID.
• source_id – Source ID.

Returns
Source name or NULL if invalid arguments.

static inline uint8_t log_domains_count(void)
Return number of domains present in the system.
There will be at least one local domain.

Returns
Number of domains.
const char *log_domain_name_get(uint32_t domain_id)
Get name of the domain.

Parameters
• domain_id – Domain ID.

Returns
Domain name.

int log_source_id_get(const char *name)
Function for finding source ID based on source name.

Parameters
• name – Source name

Returns
Source ID or negative number when source ID is not found.

uint32_t log_filter_get(struct log_backend const *const backend, uint32_t domain_id, int16_t source_id, bool runtime)
Get source filter for the provided backend.

Parameters
• backend – Backend instance.
• domain_id – ID of the domain.
• source_id – Source (module or instance) ID.
• runtime – True for runtime filter or false for compiled in.

Returns
Severity level.

uint32_t log_filter_set(struct log_backend const *const backend, uint32_t domain_id, int16_t source_id, uint32_t level)
Set filter on given source for the provided backend.

Parameters
• backend – Backend instance. NULL for all backends.
• domain_id – ID of the domain.
• source_id – Source (module or instance) ID.
• level – Severity level.

Returns
Actual level set which may be limited by compiled level. If filter was set for all backends then maximal level that was set is returned.

void log_backend_enable(struct log_backend const *const backend, void *ctx, uint32_t level)
Enable backend with initial maximum filtering level.

Parameters
• backend – Backend instance.
• ctx – User context.
• level – Severity level.

void log_backend_disable(struct log_backend const *const backend)
Disable backend.

Parameters
• backend – Backend instance.

const struct log_backend *log_backend_get_by_name(const char *backend_name)
Get backend by name.

Parameters

• backend_name – [in] Name of the backend as defined by the LOG_BACKEND_DEFINE.

Return values

Pointer – to the backend instance if found, NULL if backend is not found.

const struct log_backend *log_format_set_all_active_backends(size_t log_type)
Sets logging format for all active backends.

Parameters

• log_type – Log format.

Return values

Pointer – to the last backend that failed, NULL for success.

static inline bool log_data_pending(void)
Check if there is pending data to be processed by the logging subsystem.
Function can be used to determine if all logs have been flushed. Function returns false when deferred mode is not enabled.

Return values

• true – There is pending data.
• false – No pending data to process.

int log_set_tag(const char *tag)
Configure tag used to prefix each message.

Parameters

• tag – Tag.

Return values

• 0 – on successful operation.
• -ENOTSUP – if feature is disabled.
• -ENOMEM – if string is longer than the buffer capacity. Tag will be trimmed.

int log_mem_get_usage(uint32_t *buf_size, uint32_t *usage)
Get current memory usage.

Parameters

• buf_size – [out] Capacity of the buffer used for storing log messages.
• usage – [out] Number of bytes currently containing pending log messages.

Return values

• -EINVAL – if logging mode does not use the buffer.
• 0 – successfully collected usage data.

int log_mem_get_max_usage(uint32_t *max)
Get maximum memory usage.
Requires CONFIG_LOG_MEM_UTILIZATION option.

Parameters
• `max` – [out] Maximum number of bytes used for pending log messages.

Return values
• `-EINVAL` – if logging mode does not use the buffer.
• `-ENOTSUP` – if instrumentation is not enabled.
• `0` – successfully collected usage data.

Log message

group log_msg
Log message API.

Defines

`LOG_MSG_GENERIC_HDR`

Functions

static inline uint32_t log_msg_get_total_wlen(const struct log_msg_desc desc)
Get total length (in 32 bit words) of a log message.

Parameters
• `desc` – Log message descriptor.

Returns
Length.

static inline uint32_t log_msg_generic_get_wlen(const union mpsc_pbuf_generic *item)
Get length of the log item.

Parameters
• `item` – Item.

Returns
Length in 32 bit words.

static inline uint8_t log_msg_get_domain(struct log_msg *msg)
Get log message domain ID.

Parameters
• `msg` – Log message.

Returns
Domain ID

static inline uint8_t log_msg_get_level(struct log_msg *msg)
Get log message level.

Parameters
• `msg` – Log message.

Returns
Log level.
static inline const void *
log_msg_get_source(struct log_msg *msg)
Get message source data.

Parameters
• msg – Log message.

Returns
Pointer to the source data.

static inline log_timestamp_t
log_msg_get_timestamp(struct log_msg *msg)
Get timestamp.

Parameters
• msg – Log message.

Returns
Timestamp.

static inline void *
log_msg_get_tid(struct log_msg *msg)
Get Thread ID.

Parameters
• msg – Log message.

Returns
Thread ID.

static inline uint8_t *
log_msg_get_data(struct log_msg *msg, size_t *len)
Get data buffer.

Parameters
• msg – log message.
• len – location where data length is written.

Returns
pointer to the data buffer.

static inline uint8_t *
log_msg_get_package(struct log_msg *msg, size_t *len)
Get string package.

Parameters
• msg – log message.
• len – location where string package length is written.

Returns
pointer to the package.

struct log_msg_desc
#include <log_msg.h>

union log_msg_source
#include <log_msg.h>

Public Members

const struct log_source_const_data *fixed
struct log_source_dynamic_data *dynamic
void *raw

struct log_msg_hdr
#include <log_msg.h>

struct log_msg
#include <log_msg.h>

struct log_msg_generic_hdr
#include <log_msg.h>

union log_msg_generic
#include <log_msg.h>

Public Members

union mpsc_pbuf_generic buf

struct log_msg_generic_hdr generic

struct log_msg log

Logger backend interface

Related code samples

• BLE logging backend - Send log messages over BLE using the BLE logging backend.
• Remote syslog - Enable a remote syslog service that sends syslog messages to a remote server

group log_backend
Logger backend interface.

Defines

LOG_BACKEND_DEFINE(_name, _api, _autostart, ...)
Macro for creating a logger backend instance.

Parameters

• _name – Name of the backend instance.
• _api – Logger backend API.
• _autostart – If true backend is initialized and activated together with the logger subsystem.
• ... – Optional context.
**Enums**

```plaintext
enum log_backend_evt
   Backend events.

Values:

enumerator LOG_BACKEND_EVT_PROCESS_THREAD_DONE
   Event when process thread finishes processing.
   This event is emitted when the process thread finishes processing pending log messages.

Note: This is not emitted when there are no pending log messages being processed.
```

Note: Deferred mode only.

```plaintext
enumerator LOG_BACKEND_EVT_MAX
   Maximum number of backend events.
```

**Functions**

```plaintext
static inline void log_backend_init(const struct log_backend *const backend)
   Initialize or initiate the logging backend.
   If backend initialization takes longer time it could block logging thread if backend is auto-started. That is because all backends are initialized in the context of the logging thread. In that case, backend shall provide function for polling for readiness (log_backend_is_ready).

Parameters
   • backend – [in] Pointer to the backend instance.
```

```plaintext
static inline int log_backend_is_ready(const struct log_backend *const backend)
   Poll for backend readiness.
   If backend is ready immediately after initialization then backend may not provide this function.

Parameters
   • backend – [in] Pointer to the backend instance.

Return values
   • 0 – if backend is ready.
   • -EBUSY – if backend is not yet ready.
```

```plaintext
static inline void log_backend_msg_process(const struct log_backend *const backend, union log_msg_generic *msg)
   Process message.
   Function is used in deferred and immediate mode. On return, message content is processed by the backend and memory can be freed.

Parameters
   • backend – [in] Pointer to the backend instance.
   • msg – [in] Pointer to message with log entry.
```
static inline void log_backend_dropped(const struct log_backend *const backend, uint32_t cnt)
Notify backend about dropped log messages.
Function is optional.

Parameters
- cnt – [in] Number of dropped logs since last notification.

static inline void log_backend_panic(const struct log_backend *const backend)
Reconfigure backend to panic mode.

Parameters

static inline void log_backend_id_set(const struct log_backend *const backend, uint8_t id)
Set backend id.

Note: It is used internally by the logger.

Parameters
- backend – Pointer to the backend instance.
- id – ID.

static inline uint8_t log_backend_id_get(const struct log_backend *const backend)
Get backend id.

Note: It is used internally by the logger.

Parameters

Returns
Id.

static inline const struct log_backend *log_backend_get(uint32_t idx)
Get backend.

Parameters

Returns
Pointer to the backend instance.

static inline int log_backend_count_get(void)
Get number of backends.

Returns
Number of backends.

static inline void log_backend_activate(const struct log_backend *const backend, void *ctx)
Activate backend.

Parameters
• ctx – [in] User context.

static inline void log_backend_deactivate(const struct log_backend *const backend)
  Deactivate backend.

  **Parameters**
  • backend – [in] Pointer to the backend instance.

static inline bool log_backend_is_active(const struct log_backend *const backend)
  Check state of the backend.

  **Parameters**
  • backend – [in] Pointer to the backend instance.

  **Returns**
  True if backend is active, false otherwise.

static inline int log_backend_format_set(const struct log_backend *backend, uint32_t log_type)
  Set logging format.

  **Parameters**
  • backend – Pointer to the backend instance.
  • log_type – Log format.

  **Return values**
  • -ENOTSUP – If the backend does not support changing format types.
  • -EINVAL – If the input is invalid.
  • 0 – for success.

static inline void log_backend_notify(const struct log_backend *const backend, enum log_backend_evt event, union log_backend_evt_arg *arg)
  Notify a backend of an event.

  **Parameters**
  • backend – Pointer to the backend instance.
  • event – Event to be notified.
  • arg – Pointer to the argument(s).

union log_backend_evt_arg
  #include <log_backend.h> Argument(s) for backend events.

  **Public Members**

  void *raw
    Unspecified argument(s).

struct log_backend_api
  #include <log_backend.h> Logger backend API.

struct log_backend_control_block
  #include <log_backend.h> Logger backend control block.

struct log_backend
  #include <log_backend.h> Logger backend structure.
Logger output formatting

**group log_output**

Log output API.

**Unnamed Group**

```c
void log_custom_output_msg_process(const struct log_output *log_output, struct log_msg *msg, uint32_t flags)
```

Custom logging output formatting.

Process log messages from an external output function set with `log_custom_output_msg_set`. Function is using provided context with the buffer and output function to process formatted string and output the data.

**Parameters**

- `log_output` – Pointer to the log output instance.
- `msg` – Log message.
- `flags` – Optional flags.

**Defines**

- `LOG_OUTPUT_TEXT` Supported backend logging format types for use with `log_format_set()` API to switch log format at runtime.
- `LOG_OUTPUT_SYST`
- `LOG_OUTPUT_DICT`
- `LOG_OUTPUT_CUSTOM`

```c
LOG_OUTPUT_DEFINE(_name, _func, _buf, _size)
```

Create `log_output` instance.

**Parameters**

- `_name` – Instance name.
- `_func` – Function for processing output data.
- `_buf` – Pointer to the output buffer.
- `_size` – Size of the output buffer.

**Typedefs**

```c
typedef int (*log_output_func_t)(uint8_t *buf, size_t size, void *ctx)
```

Prototype of the function processing output data.
Note: If the log output function cannot process all of the data, it is its responsibility to mark them as dropped or discarded by returning the corresponding number of bytes dropped or discarded to the caller.

**Param buf**
The buffer data.

**Param size**
The buffer size.

**Param ctx**
User context.

**Return**
Number of bytes processed, dropped or discarded.

typedef void (*log_format_func_t)(const struct log_output *output, struct log_msg *msg, uint32_t flags)

Typedef of the function pointer table "format_table".

**Param output**
Pointer to log_output struct.

**Param msg**
Pointer to log_msg struct.

**Param flags**
Flags used for text formatting options.

**Return**
Function pointer based on Kconfigs defined for backends.

### Functions

**log_format_func_t log_format_func_t_get(uint32_t log_type)**
Declaration of the get routine for function pointer table format_table.

**void log_output_msg_process(const struct log_output *log_output, struct log_msg *msg, uint32_t flags)**
Process log messages v2 to readable strings.
Function is using provided context with the buffer and output function to process formatted string and output the data.

**Parameters**
- log_output – Pointer to the log output instance.
- msg – Log message.
- flags – Optional flags. See Log output formatting flags..

**void log_output_process(const struct log_output *log_output, log_timestamp_t timestamp, const char *domain, const char *source, const k_tid_t tid, uint8_t level, const uint8_t *package, const uint8_t *data, size_t data_len, uint32_t flags)**
Process input data to a readable string.

**Parameters**
- log_output – Pointer to the log output instance.
- timestamp – Timestamp.
- domain – Domain name string. Can be NULL.
- source – Source name string. Can be NULL.
- tid – Thread ID.
- level – Criticality level.
- package – Cbprintf package with a logging message string.
- data – Data passed to hexdump API. Can be NULL.
- data_len – Data length.
- flags – Formatting flags. See Log output formatting flags.

```c
void log_output_msg_syst_process(const struct log_output *log_output, struct log_msg *msg, uint32_t flags)
```

Process log messages v2 to SYS-T format.

Function is using provided context with the buffer and output function to process formatted string and output the data in sys-t log output format.

**Parameters**

- log_output – Pointer to the log output instance.
- msg – Log message.
- flags – Optional flags. See Log output formatting flags.

```c
void log_output_dropped_process(const struct log_output *output, uint32_t cnt)
```

Process dropped messages indication.

Function prints error message indicating lost log messages.

**Parameters**

- output – Pointer to the log output instance.
- cnt – Number of dropped messages.

```c
void log_output_flush(const struct log_output *output)
```

Flush output buffer.

**Parameters**

- output – Pointer to the log output instance.

```c
static inline void log_output_ctx_set(const struct log_output *output, void *ctx)
```

Function for setting user context passed to the output function.

**Parameters**

- output – Pointer to the log output instance.
- ctx – User context.

```c
static inline void log_output_hostname_set(const struct log_output *output, const char *hostname)
```

Function for setting hostname of this device.

**Parameters**

- output – Pointer to the log output instance.
- hostname – Hostname of this device.
void log_output_timestamp_freq_set(uint32_t freq)
    Set timestamp frequency.

    **Parameters**
    - freq – Frequency in Hz.

uint64_t log_output_timestamp_to_us(log_timestamp_t timestamp)
    Convert timestamp of the message to us.

    **Parameters**
    - timestamp – Message timestamp

    **Returns**
    Timestamp value in us.

struct log_output_control_block
    #include <log_output.h>

struct log_output
    #include <log_output.h> Log_output instance structure.

4.12 Tracing

4.12.1 Overview

The tracing feature provides hooks that permits you to collect data from your application and allows tools running on a host to visualize the inner-working of the kernel and various subsystems.

Every system has application-specific events to trace out. Historically, that has implied:

1. Determining the application-specific payload,
2. Choosing suitable serialization-format,
3. Writing the on-target serialization code,
4. Deciding on and writing the I/O transport mechanics,
5. Writing the PC-side deserializer/parser,
6. Writing custom ad-hoc tools for filtering and presentation.

An application can use one of the existing formats or define a custom format by overriding the macros declared in include/zephyr/tracing/tracing.h.

Different formats, transports and host tools are available and supported in Zephyr.

In fact, I/O varies greatly from system to system. Therefore, it is instructive to create a taxonomy for I/O types when we must ensure the interface between payload/format (Top Layer) and the transport mechanics (bottom Layer) is generic and efficient enough to model these. See the I/O taxonomy section below.

4.12.2 Serialization Formats

Common Trace Format (CTF) Support

Common Trace Format, CTF, is an open format and language to describe trace formats. This enables tool reuse, of which line-textual (babeltrace) and graphical (TraceCompass) variants already exist.
CTF should look familiar to C programmers but adds stronger typing. See CTF - A Flexible, High-performance Binary Trace Format.

CTF allows us to formally describe application specific payload and the serialization format, which enables common infrastructure for host tools and parsers and tools for filtering and presentation.

**A Generic Interface** In CTF, an event is serialized to a packet containing one or more fields. As seen from I/O taxonomy section below, a bottom layer may:

- perform actions at transaction-start (e.g. mutex-lock),
- process each field in some way (e.g. sync-push emit, concat, enqueue to thread-bound FIFO),
- perform actions at transaction-stop (e.g. mutex-release, emit of concat buffer).

**CTF Top-Layer Example** The CTF_EVENT macro will serialize each argument to a field:

```c
/* Example for illustration */
static inline void ctf_top_foo(uint32_t thread_id, ctf_bounded_string_t name)
{
    CTF_EVENT(
        CTF_LITERAL(uint8_t, 42),
        thread_id,
        name,
        "hello, I was emitted from function: ",
        __func__ /* __func__ is standard since C99 */
    );
}
```

How to serialize and emit fields as well as handling alignment, can be done internally and statically at compile-time in the bottom-layer.

The CTF top layer is enabled using the configuration option `CONFIG_TRACING_CTF` and can be used with the different transport backends both in synchronous and asynchronous modes.

**SEGGER SystemView Support**

Zephyr provides built-in support for SEGGER SystemView that can be enabled in any application for platforms that have the required hardware support.

The payload and format used with SystemView is custom to the application and relies on RTT as a transport. Newer versions of SystemView support other transports, for example UART or using snapshot mode (both still not supported in Zephyr).

To enable tracing support with SEGGER SystemView add the configuration option `CONFIG_SEGGER_SYSTEMVIEW` to your project configuration file and set it to `y`. For example, this can be added to the synchronization sample to visualize fast switching between threads.

SystemView can also be used for post-mortem tracing, which can be enabled with `CONFIG_SEGGER_SYSVIEW_POST_MORTEM_MODE`. In this mode, a debugger can be attached after the system has crashed using `west attach` after which the latest data from the internal RAM buffer can be loaded into SystemView:

```
CONFIG_STDOUT_CONSOLE=y
# enable to use thread names
CONFIG_THREAD_NAME=y
CONFIG_SEGGER_SYSTEMVIEW=y
CONFIG_USE_SEGGER_RTT=y
CONFIG_TRACING=y
```

(continues on next page)
Recent versions of SEGGER SystemView come with an API translation table for Zephyr which is incomplete and does not match the current level of support available in Zephyr. To use the latest Zephyr API description table, copy the file available in the tree to your local configuration directory to override the builtin table:

```
# On Linux and MacOS
cp $ZEPHYR_BASE/subsys/tracing/sysview/SYSVIEW_Zephyr.txt ~/.config/SEGGER/
```

User-Defined Tracing

This tracing format allows the user to define functions to perform any work desired when a task is switched in or out, when an interrupt is entered or exited, and when the cpu is idle.

Examples include:
- simple toggling of GPIO for external scope tracing while minimizing extra cpu load
- generating/outputting trace data in a non-standard or proprietary format that can not be supported by the other tracing systems

The following functions can be defined by the user:

```c
void sys_trace_thread_create_user(struct k_thread *thread);
void sys_trace_thread_abort_user(struct k_thread *thread);
void sys_trace_thread_suspend_user(struct k_thread *thread);
void sys_trace_thread_resume_user(struct k_thread *thread);
void sys_trace_thread_name_set_user(struct k_thread *thread);
void sys_trace_thread_switched_in_user(struct k_thread *thread);
void sys_trace_thread_switched_out_user(struct k_thread *thread);
void sys_trace_thread_sched_ready_user(struct k_thread *thread);
void sys_trace_thread_pend_user(struct k_thread *thread);
void sys_trace_thread_priority_set_user(struct k_thread *thread);
void sys_trace_isr_enter_user(int nested_interrupts);
void sys_trace_isr_exit_user(int nested_interrupts);
void sys_trace_idle_user();
```
Enable this format with the CONFIG_TRACING_USER option.

### 4.12.3 Transport Backends

The following backends are currently supported:

- UART
- USB
- File (Using native posix port)
- RTT (With SystemView)
- RAM (buffer to be retrieved by a debugger)

### 4.12.4 Using Tracing

The sample `samples/subsys/tracing` demonstrates tracing with different formats and backends.

To get started, the simplest way is to use the CTF format with the `native_posix` port, build the sample as follows:

#### Using west:

```
west build -b native_posix samples/subsys/tracing -- -DCONF_FILE=prj_native_posix_ctf.conf
```

#### Using CMake and ninja:

```
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=native_posix -DCONF_FILE=prj_native_posix_ctf.conf
    samples/subsys/tracing

# Now run ninja on the generated build system:
ninja -Cbuild
```

You can then run the resulting binary with the option `-trace-file` to generate the tracing data:

```
mkdir data
cp $ZEPHYR_BASE/subsys/tracing/ctf/tsdl/metadata data/
./build/zephyr/zephyr.exe -trace-file=data/channel0_0
```

The resulting CTF output can be visualized using babeltrace or TraceCompass by pointing the tool to the data directory with the metadata and trace files.

#### Using RAM backend

For devices that do not have available I/O for tracing such as USB or UART but have enough RAM to collect trace data, the ram backend can be enabled with configuration `CONFIG_TRACING_BACKEND_RAM`.

Adjust `CONFIG_RAM_TRACING_BUFFER_SIZE` to be able to record enough traces for your needs. Then thanks to a runtime debugger such as `gdb` this buffer can be fetched from the target to an host computer:

```
(gdb) dump binary memory data/channel0_0 <ram_tracing_start> <ram_tracing_end>
```

The resulting channel0_0 file have to be placed in a directory with the metadata file like the other backend.
4.12.5 Visualisation Tools

TraceCompass

TraceCompass is an open source tool that visualizes CTF events such as thread scheduling and interrupts, and is helpful to find unintended interactions and resource conflicts on complex systems. See also the presentation by Ericsson, Advanced Trouble-shooting Of Real-time Systems.

4.12.6 Future LTTng Inspiration

Currently, the top-layer provided here is quite simple and bare-bones, and needlessly copied from Zephyr’s Segger SystemView debug module.

For an OS like Zephyr, it would make sense to draw inspiration from Linux’s LTTng and change the top-layer to serialize to the same format. Doing this would enable direct reuse of TraceCompass’ canned analyses for Linux. Alternatively, LTTng-analyses in TraceCompass could be customized to Zephyr. It is ongoing work to enable TraceCompass visibility of Zephyr in a target-agnostic and open source way.

I/O Taxonomy

- Atomic Push/Produce/Write/Enqueue:
  - synchronous:
    means data-transmission has completed with the return of the call.
  - asynchronous:
    means data-transmission is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - buffered:
    means data-transmissions are copied and grouped together to form a larger ones. Usually for amortizing overhead (burst dequeue) or jitter-mitigation (steady dequeue).

Examples:

  - sync unbuffered
    E.g. PIO via GPIOs having steady stream, no extra FIFO memory needed. Low jitter but may be less efficient (can’t amortize the overhead of writing).
  - sync buffered
    E.g. fwrite() or enqueuing into FIFO. Blockingly burst the FIFO when its buffer-waterlevel exceeds threshold. Jitter due to bursts may lead to missed deadlines.
  - async unbuffered
    E.g. DMA, or zero-copying in shared memory. Be careful of data hazards, race conditions, etc!
  - async buffered
    E.g. enqueuing into FIFO.

- Atomic Pull/Consume/Read/Dequeue:
  - synchronous:
    means data-reception has completed with the return of the call.
  - asynchronous:
    means data-reception is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - buffered:
    means data is copied-in in larger chunks than request-size. Usually for amortizing wait-time.
Examples:

- **sync unbuffered**
  E.g. Blocking read-call, `fread()` or SPI-read, zero-copying in shared memory.

- **sync buffered**
  E.g. Blocking read-call with caching applied. Makes sense if read pattern exhibits spatial locality.

- **async unbuffered**
  E.g. zero-copying in shared memory. Be careful of data hazards, race conditions, etc!

- **async buffered**
  E.g. `aio_read()` or DMA.

Unfortunately, I/O may not be atomic and may, therefore, require locking. Locking may not be needed if multiple independent channels are available.

- **The system has non-atomic write and one shared channel**
  E.g. UART. Locking required.

  ```c
  lock(); emit(a); emit(b); emit(c); release();
  ```

- **The system has non-atomic write but many channels**
  E.g. Multi-UART. Lock-free if the bottom-layer maps each Zephyr thread+ISR to its own channel, thus alleviating races as each thread is sequentially consistent with itself.

  ```c
  emit(a,thread_id); emit(b,thread_id); emit(c,thread_id);
  ```

- **The system has atomic write but one shared channel**
  E.g. native_posix or board with DMA. May or may not need locking.

  ```c
  emit(a ## b ## c); /* Concat to buffer */
  lock(); emit(a); emit(b); emit(c); release(); /* No extra mem */
  ```

- **The system has atomic write and many channels**
  E.g. native_posix or board with multi-channel DMA. Lock-free.

  ```c
  emit(a ## b ## c, thread_id);
  ```

### 4.12.7 Object tracking

The kernel can also maintain lists of objects that can be used to track their usage. Currently, the following lists can be enabled:

```c
struct k_timer *_track_list_k_timer;
struct k_mem slab *_track_list_k_mem_slab;
struct k sem *_track_list_k_sem;
struct k mutex *_track_list_k_mutex;
struct k stack *_track_list_k_stack;
struct k msgq *_track_list_k_msgq;
struct k mbox *_track_list_k mbox;
struct k pipe *_track_list_k pipe;
struct k queue *_track_list_k queue;
struct k event *_track_list_k event;
```

Those global variables are the head of each list - they can be traversed with the help of macro `SYS_PORT_TRACK_NEXT`. For instance, to traverse all initialized mutexes, one can write:

```c
struct k_mutex *cur = _track_list_k_mutex;
while (cur != NULL) {
  /* Do something */
  cur = SYS_PORT_TRACK_NEXT(cur);
}
```
To enable object tracking, enable `CONFIG_TRACING_OBJECT_TRACKING`. Note that each list can be enabled or disabled via their tracing configuration. For example, to disable tracking of semaphores, one can disable `CONFIG_TRACING_SEMAPHORE`.

Object tracking is behind tracing configuration as it currently leverages tracing infrastructure to perform the tracking.

### 4.12.8 API

**Common**

```c
cur = SYS_PORT_TRACK_NEXT(cur);
```

void `sys_trace_isr_enter(void)`
Called when entering an ISR.

void `sys_trace_isr_exit(void)`
Called when exiting an ISR.

void `sys_trace_isr_exit_to_scheduler(void)`
Called when exiting an ISR and switching to scheduler.

void `sys_trace_idle(void)`
Called when the cpu enters the idle state.

**Threads**

```c
Functions
```

void `sys_port_trace_k_thread_foreach_enter()`
Called when entering a `k_thread_foreach` call.

void `sys_port_trace_k_thread_foreach_exit()`
Called when exiting a `k_thread_foreach` call.

void `sys_port_trace_k_thread_foreach_unlocked_enter()`
Called when entering a `k_thread_foreach_unlocked`.

void `sys_port_trace_k_thread_foreach_unlocked_exit()`
Called when exiting a `k_thread_foreach_unlocked`.
sys_port_trace_k_thread_create(new_thread)
Trace creating a Thread.

Parameters
• new_thread – Thread object

sys_port_trace_k_thread_user_mode_enter()
Trace Thread entering user mode.

sys_port_trace_k_thread_join_enter(thread, timeout)
Called when entering a k_thread_join.

Parameters
• thread – Thread object
• timeout – Timeout period

sys_port_trace_k_thread_join_blocking(thread, timeout)
Called when k_thread_join blocks.

Parameters
• thread – Thread object
• timeout – Timeout period

sys_port_trace_k_thread_join_exit(thread, timeout, ret)
Called when exiting k_thread_join.

Parameters
• thread – Thread object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_thread_sleep_enter(timeout)
Called when entering k_thread_sleep.

Parameters
• timeout – Timeout period

sys_port_trace_k_thread_sleep_exit(timeout, ret)
Called when exiting k_thread_sleep.

Parameters
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_thread_msleep_enter(ms)
Called when entering k_thread_msleep.

Parameters
• ms – Duration in milliseconds

sys_port_trace_k_thread_msleep_exit(ms, ret)
Called when exiting k_thread_msleep.

Parameters
• ms – Duration in milliseconds
• ret – Return value
sys_port_trace_k_thread_usleep_enter(us)
Called when entering k_thread_usleep.

Parameters
• us – Duration in microseconds

sys_port_trace_k_thread_usleep_exit(us, ret)
Called when exiting k_thread_usleep.

Parameters
• us – Duration in microseconds
• ret – Return value

sys_port_trace_k_thread_busy_wait_enter(usec_to_wait)
Called when entering k_thread_busy_wait.

Parameters
• usec_to_wait – Duration in microseconds

sys_port_trace_k_thread_busy_wait_exit(usec_to_wait)
Called when exiting k_thread_busy_wait.

Parameters
• usec_to_wait – Duration in microseconds

sys_port_trace_k_thread_yield()
Called when a thread yields.

sys_port_trace_k_thread_wakeup(thread)
Called when a thread wakes up.

Parameters
• thread – Thread object

sys_port_trace_k_thread_start(thread)
Called when a thread is started.

Parameters
• thread – Thread object

sys_port_trace_k_thread_abort(thread)
Called when a thread is being aborted.

Parameters
• thread – Thread object

sys_port_trace_k_thread_abort_enter(thread)
Called when a thread enters the k_thread_abort routine.

Parameters
• thread – Thread object

sys_port_trace_k_thread_abort_exit(thread)
Called when a thread exits the k_thread_abort routine.

Parameters
• thread – Thread object
sys_port_trace_k_thread_priority_set(thread)
   Called when setting priority of a thread.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_suspend_enter(thread)
   Called when a thread enters the k_thread_suspend function.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_suspend_exit(thread)
   Called when a thread exits the k_thread_suspend function.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_resume_enter(thread)
   Called when a thread enters the resume from suspension function.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_resume_exit(thread)
   Called when a thread exits the resumed from suspension function.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_sched_lock()
   Called when the thread scheduler is locked.

sys_port_trace_k_thread_sched_unlock()
   Called when the thread scheduler is unlocked.

sys_port_trace_k_thread_name_set(thread, ret)
   Called when a thread name is set.

   Parameters
   • thread – Thread object
   • ret – Return value

sys_port_trace_k_thread_switched_out()
   Called before a thread has been selected to run.

sys_port_trace_k_thread_switched_in()
   Called after a thread has been selected to run.

sys_port_trace_k_thread_ready(thread)
   Called when a thread is ready to run.

   Parameters
   • thread – Thread object

sys_port_trace_k_thread_pend(thread)
   Called when a thread is pending.

   Parameters
   • thread – Thread object
sys_port_trace_k_thread_info(thread)
  Provide information about specific thread.

  Parameters
  • thread – Thread object

sys_port_trace_k_thread_sched_wakeup(thread)
  Trace implicit thread wakeup invocation by the scheduler.

  Parameters
  • thread – Thread object

sys_port_trace_k_thread_sched_abort(thread)
  Trace implicit thread abort invocation by the scheduler.

  Parameters
  • thread – Thread object

sys_port_trace_k_thread_sched_priority_set(thread, prio)
  Trace implicit thread set priority invocation by the scheduler.

  Parameters
  • thread – Thread object
  • prio – Thread priority

sys_port_trace_k_thread_sched_ready(thread)
  Trace implicit thread ready invocation by the scheduler.

  Parameters
  • thread – Thread object

sys_port_trace_k_thread_sched_pend(thread)
  Trace implicit thread pend invocation by the scheduler.

  Parameters
  • thread – Thread object

sys_port_trace_k_thread_sched_resume(thread)
  Trace implicit thread resume invocation by the scheduler.

  Parameters
  • thread – Thread object

sys_port_trace_k_thread_sched_suspend(thread)
  Trace implicit thread suspend invocation by the scheduler.

  Parameters
  • thread – Thread object

Work Queues

  group subsys_tracing_apis_work
  Work Tracing APIs.
Defines

sys_port_trace_k_work_init(work)
Trace initialisation of a Work structure.

Parameters
• work – Work structure

sys_port_trace_k_work_submit_to_queue_enter(queue, work)
Trace submit work to work queue call entry.

Parameters
• queue – Work queue structure
• work – Work structure

sys_port_trace_k_work_submit_to_queue_exit(queue, work, ret)
Trace submit work to work queue call exit.

Parameters
• queue – Work queue structure
• work – Work structure
• ret – Return value

sys_port_trace_k_work_submit_enter(work)
Trace submit work to system work queue call entry.

Parameters
• work – Work structure

sys_port_trace_k_work_submit_exit(work, ret)
Trace submit work to system work queue call exit.

Parameters
• work – Work structure
• ret – Return value

sys_port_trace_k_work_flush_enter(work)
Trace flush work call entry.

Parameters
• work – Work structure

sys_port_trace_k_work_flush_blocking(work, timeout)
Trace flush work call blocking.

Parameters
• work – Work structure
• timeout – Timeout period

sys_port_trace_k_work_flush_exit(work, ret)
Trace flush work call exit.

Parameters
• work – Work structure
• ret – Return value
sys_port_trace_k_work_cancel_enter(work)
Trace cancel work call entry.

Parameters
• work – Work structure

sys_port_trace_k_work_cancel_exit(work, ret)
Trace cancel work call exit.

Parameters
• work – Work structure
• ret – Return value

sys_port_trace_k_work_cancel_sync_enter(work, sync)
Trace cancel sync work call entry.

Parameters
• work – Work structure
• sync – Sync object

sys_port_trace_k_work_cancel_sync_blocking(work, sync)
Trace cancel sync work call blocking.

Parameters
• work – Work structure
• sync – Sync object

sys_port_trace_k_work_cancel_sync_exit(work, sync, ret)
Trace cancel sync work call exit.

Parameters
• work – Work structure
• sync – Sync object
• ret – Return value

Poll

group subsys_tracing_api_poll
Poll Tracing APIs.

Defines

sys_port_trace_k_poll_api_event_init(event)
Trace initialisation of a Poll Event.

Parameters
• event – Poll Event

sys_port_trace_k_poll_api_poll_enter(events)
Trace Polling call start.

Parameters
• events – Poll Events
sys_port_trace_k_poll_api_poll_exit(events, ret)
Trace Polling call outcome.

**Parameters**
- **events** – Poll Events
- **ret** – Return value

sys_port_trace_k_poll_api_signal_init(signal)
Trace initialisation of a Poll Signal.

**Parameters**
- **signal** – Poll Signal

sys_port_trace_k_poll_api_signal_reset(signal)
Trace resetting of Poll Signal.

**Parameters**
- **signal** – Poll Signal

sys_port_trace_k_poll_api_signal_check(signal)
Trace checking of Poll Signal.

**Parameters**
- **signal** – Poll Signal

sys_port_trace_k_poll_api_signal_raise(signal, ret)
Trace raising of Poll Signal.

**Parameters**
- **signal** – Poll Signal
- **ret** – Return value

Semaphore

group subsys_tracing.Apis_sem
Semaphore Tracing APIs.

Defines

sys_port_trace_k_sem_init(sem, ret)
Trace initialisation of a Semaphore.

**Parameters**
- **sem** – Semaphore object
- **ret** – Return value

sys_port_trace_k_sem_give_enter(sem)
Trace giving a Semaphore entry.

**Parameters**
- **sem** – Semaphore object
sys_port_trace_k_sem_give_exit(sem)
  Trace giving a Semaphore exit.

  **Parameters**
  - sem – Semaphore object

sys_port_trace_k_sem_take_enter(sem, timeout)
  Trace taking a Semaphore attempt start.

  **Parameters**
  - sem – Semaphore object
  - timeout – Timeout period

sys_port_trace_k_sem_take_blocking(sem, timeout)
  Trace taking a Semaphore attempt blocking.

  **Parameters**
  - sem – Semaphore object
  - timeout – Timeout period

sys_port_trace_k_sem_take_exit(sem, timeout, ret)
  Trace taking a Semaphore attempt outcome.

  **Parameters**
  - sem – Semaphore object
  - timeout – Timeout period
  - ret – Return value

sys_port_trace_k_sem_reset(sem)
  Trace resetting a Semaphore.

  **Parameters**
  - sem – Semaphore object

**Mutex**

group subsys_tracing/apis_mutex
  Mutex Tracing APIs.

**Defines**

sys_port_trace_k_mutex_init(mutex, ret)
  Trace initialization of Mutex.

  **Parameters**
  - mutex – Mutex object
  - ret – Return value

sys_port_trace_k_mutex_lock_enter(mutex, timeout)
  Trace Mutex lock attempt start.

  **Parameters**
  - mutex – Mutex object
• timeout – Timeout period

sys_port_trace_k_mutex_lock_blocking(mutex, timeout)
Trace Mutex lock attempt blocking.

Parameters
• mutex – Mutex object
• timeout – Timeout period

sys_port_trace_k_mutex_lock_exit(mutex, timeout, ret)
Trace Mutex lock attempt outcome.

Parameters
• mutex – Mutex object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_mutex_unlock_enter(mutex)
Trace Mutex unlock entry.

Parameters
• mutex – Mutex object

sys_port_trace_k_mutex_unlock_exit(mutex, ret)
Trace Mutex unlock exit.

Condition Variables

**group** subsys_tracing_apis_condvar
Conditional Variable Tracing APIs.

Defines

sys_port_trace_k_condvar_init(condvar, ret)
Trace initialization of Conditional Variable.

Parameters
• condvar – Conditional Variable object
• ret – Return value

sys_port_trace_k_condvar_signal_enter(condvar)
Trace Conditional Variable signaling start.

Parameters
• condvar – Conditional Variable object

sys_port_trace_k_condvar_signal_blocking(condvar, timeout)
Trace Conditional Variable signaling blocking.

Parameters
• condvar – Conditional Variable object
• timeout – Timeout period
sys_port_trace_k_condvar_signal_exit(condvar, ret)
Trace Conditional Variable signaling outcome.

Parameters
- condvar – Conditional Variable object
- ret – Return value

sys_port_trace_k_condvar_broadcast_enter(condvar)
Trace Conditional Variable broadcast enter.

Parameters
- condvar – Conditional Variable object

sys_port_trace_k_condvar_broadcast_exit(condvar, ret)
Trace Conditional Variable broadcast exit.

Parameters
- condvar – Conditional Variable object
- ret – Return value

sys_port_trace_k_condvar_wait_enter(condvar)
Trace Conditional Variable wait enter.

Parameters
- condvar – Conditional Variable object

sys_port_trace_k_condvar_wait_exit(condvar, ret)
Trace Conditional Variable wait exit.

Parameters
- condvar – Conditional Variable object
- ret – Return value

Queues

group subsys_tracing.Apis_queue
Queue Tracing APIs.

Defines

sys_port_trace_k_queue_init(queue)
Trace initialization of Queue.

Parameters
- queue – Queue object

sys_port_trace_k_queue_cancel_wait(queue)
Trace Queue cancel wait.

Parameters
- queue – Queue object
sys_port_trace_k_queue_queue_insert_enter(queue, alloc)
  Trace Queue insert attempt entry.
  **Parameters**
  • queue – Queue object  
  • alloc – Allocation flag

sys_port_trace_k_queue_queue_insert_blocking(queue, alloc, timeout)
  Trace Queue insert attempt blocking.
  **Parameters**
  • queue – Queue object  
  • alloc – Allocation flag  
  • timeout – Timeout period

sys_port_trace_k_queue_queue_insert_exit(queue, alloc, ret)
  Trace Queue insert attempt outcome.
  **Parameters**
  • queue – Queue object  
  • alloc – Allocation flag  
  • ret – Return value

sys_port_trace_k_queue_append_enter(queue)
  Trace Queue append enter.
  **Parameters**
  • queue – Queue object

sys_port_trace_k_queue_append_exit(queue)
  Trace Queue append exit.
  **Parameters**
  • queue – Queue object

sys_port_trace_k_queue_alloc_append_enter(queue)
  Trace Queue alloc append enter.
  **Parameters**
  • queue – Queue object

sys_port_trace_k_queue_alloc_append_exit(queue, ret)
  Trace Queue alloc append exit.
  **Parameters**
  • queue – Queue object  
  • ret – Return value

sys_port_trace_k_queue_prepend_enter(queue)
  Trace Queue prepend enter.
  **Parameters**
  • queue – Queue object
sys_port_trace_k_queue_prepend_exit(queue)
   Trace Queue prepend exit.
   **Parameters**
   • queue – Queue object

sys_port_trace_k_queue_alloc_prepend_enter(queue)
   Trace Queue alloc prepend enter.
   **Parameters**
   • queue – Queue object

sys_port_trace_k_queue_alloc_prepend_exit(queue, ret)
   Trace Queue alloc prepend exit.
   **Parameters**
   • queue – Queue object
   • ret – Return value

sys_port_trace_k_queue_insert_enter(queue)
   Trace Queue insert attempt entry.
   **Parameters**
   • queue – Queue object

sys_port_trace_k_queue_insert_blocking(queue, timeout)
   Trace Queue insert attempt blocking.
   **Parameters**
   • queue – Queue object
   • timeout – Timeout period

sys_port_trace_k_queue_insert_exit(queue)
   Trace Queue insert attempt exit.
   **Parameters**
   • queue – Queue object

sys_port_trace_k_queue_append_list_enter(queue)
   Trace Queue append list enter.
   **Parameters**
   • queue – Queue object

sys_port_trace_k_queue_append_list_exit(queue, ret)
   Trace Queue append list exit.
   **Parameters**
   • queue – Queue object
   • ret – Return value

sys_port_trace_k_queue_merge_slist_enter(queue)
   Trace Queue merge slist enter.
   **Parameters**
   • queue – Queue object
sys_port_trace_k_queue_merge_slist_exit(queue, ret)
Trace Queue merge slist exit.

Parameters
• queue – Queue object
• ret – Return value

sys_port_trace_k_queue_get_enter(queue, timeout)
Trace Queue get attempt enter.

Parameters
• queue – Queue object
• timeout – Timeout period

sys_port_trace_k_queue_get_blocking(queue, timeout)
Trace Queue get attempt blockings.

Parameters
• queue – Queue object
• timeout – Timeout period

sys_port_trace_k_queue_get_exit(queue, timeout, ret)
Trace Queue get attempt outcome.

Parameters
• queue – Queue object
• timeout – Timeout period
• ret – Return value

sys_port_trace_k_queue_remove_enter(queue)
Trace Queue remove enter.

Parameters
• queue – Queue object

sys_port_trace_k_queue_remove_exit(queue, ret)
Trace Queue remove exit.

Parameters
• queue – Queue object
• ret – Return value

sys_port_trace_k_queue_unique_append_enter(queue)
Trace Queue unique append enter.

Parameters
• queue – Queue object

sys_port_trace_k_queue_unique_append_exit(queue, ret)
Trace Queue unique append exit.

Parameters
• queue – Queue object
• ret – Return value
sys_port_trace_k_queue.peek.head(queue, ret)
Trace Queue peek head.

Parameters
• queue – Queue object
• ret – Return value

sys_port_trace_k_queue.peek.tail(queue, ret)
Trace Queue peek tail.

Parameters
• queue – Queue object
• ret – Return value

FIFO

group subsys_tracing.apis fifo
FIFO Tracing APIs.

Defines

sys_port_trace_k_fifo_init.enter(fifo)
Trace initialization of FIFO Queue entry.

Parameters
• fifo – FIFO object

sys_port_trace_k_fifo_init.exit(fifo)
Trace initialization of FIFO Queue exit.

Parameters
• fifo – FIFO object

sys_port_trace_k_fifo_cancel_wait.enter(fifo)
Trace FIFO Queue cancel wait entry.

Parameters
• fifo – FIFO object

sys_port_trace_k_fifo_cancel_wait.exit(fifo)
Trace FIFO Queue cancel wait exit.

Parameters
• fifo – FIFO object

sys_port_trace_k_fifo.put.enter(fifo, data)
Trace FIFO Queue put entry.

Parameters
• fifo – FIFO object
• data – Data item
sys_port_trace_k_fifo_put_exit(fifo, data)
  Trace FIFO Queue put exit.
  **Parameters**
  * fifo – FIFO object
  * data – Data item

sys_port_trace_k_fifo_alloc_put_enter(fifo, data)
  Trace FIFO Queue alloc put entry.
  **Parameters**
  * fifo – FIFO object
  * data – Data item

sys_port_trace_k_fifo_alloc_put_exit(fifo, data, ret)
  Trace FIFO Queue alloc put exit.
  **Parameters**
  * fifo – FIFO object
  * data – Data item
  * ret – Return value

sys_port_trace_k_fifo_put_list_enter(fifo, head, tail)
  Trace FIFO Queue put list entry.
  **Parameters**
  * fifo – FIFO object
  * head – First ll-node
  * tail – Last ll-node

sys_port_trace_k_fifo_put_list_exit(fifo, head, tail)
  Trace FIFO Queue put list exit.
  **Parameters**
  * fifo – FIFO object
  * head – First ll-node
  * tail – Last ll-node

sys_port_trace_k_fifo_alloc_put_slist_enter(fifo, list)
  Trace FIFO Queue put slist entry.
  **Parameters**
  * fifo – FIFO object
  * list – Syslist object

sys_port_trace_k_fifo_alloc_put_slist_exit(fifo, list)
  Trace FIFO Queue put slist exit.
  **Parameters**
  * fifo – FIFO object
  * list – Syslist object
sys_port_trace_k_fifo_get_enter(fifo, timeout)
Trace FIFO Queue get entry.

Parameters
- fifo – FIFO object
- timeout – Timeout period

sys_port_trace_k_fifo_get_exit(fifo, timeout, ret)
Trace FIFO Queue get exit.

Parameters
- fifo – FIFO object
- timeout – Timeout period
- ret – Return value

LIFO

group subsys_tracingApis_lifo
LIFO Tracing APIs.

Defines

sys_port_trace_k_lifo_init_enter(lifo)
Trace initialization of LIFO Queue entry.

Parameters
- lifo – LIFO object
sys_port_trace_k_lifo_init_exit(lifo)
Trace initialization of LIFO Queue exit.

Parameters
• lifo – LIFO object

sys_port_trace_k_lifo_put_enter(lifo, data)
Trace LIFO Queue put entry.

Parameters
• lifo – LIFO object
• data – Data item

sys_port_trace_k_lifo_put_exit(lifo, data)
Trace LIFO Queue put exit.

Parameters
• lifo – LIFO object
• data – Data item

sys_port_trace_k_lifo_alloc_put_enter(lifo, data)
Trace LIFO Queue alloc put entry.

Parameters
• lifo – LIFO object
• data – Data item

sys_port_trace_k_lifo_alloc_put_exit(lifo, data, ret)
Trace LIFO Queue alloc put exit.

Parameters
• lifo – LIFO object
• data – Data item
• ret – Return value

sys_port_trace_k_lifo_get_enter(lifo, timeout)
Trace LIFO Queue get entry.

Parameters
• lifo – LIFO object
• timeout – Timeout period

sys_port_trace_k_lifo_get_exit(lifo, timeout, ret)
Trace LIFO Queue get exit.

Parameters
• lifo – LIFO object
• timeout – Timeout period
• ret – Return value

Stacks

group subsys_tracing_apis_stack
Stack Tracing APIs.
Defines

sys_port_trace_k_stack_init(stack)
Trace initialization of Stack.

Parameters
• stack – Stack object

sys_port_trace_k_stack_alloc_init_enter(stack)
Trace Stack alloc init attempt entry.

Parameters
• stack – Stack object

sys_port_trace_k_stack_alloc_init_exit(stack, ret)
Trace Stack alloc init outcome.

Parameters
• stack – Stack object
• ret – Return value

sys_port_trace_k_stack_cleanup_enter(stack)
Trace Stack cleanup attempt entry.

Parameters
• stack – Stack object

sys_port_trace_k_stack_cleanup_exit(stack, ret)
Trace Stack cleanup outcome.

Parameters
• stack – Stack object
• ret – Return value

sys_port_trace_k_stack_push_enter(stack)
Trace Stack push attempt entry.

Parameters
• stack – Stack object

sys_port_trace_k_stack_push_exit(stack, ret)
Trace Stack push attempt outcome.

Parameters
• stack – Stack object
• ret – Return value

sys_port_trace_k_stack_pop_enter(stack, timeout)
Trace Stack pop attempt entry.

Parameters
• stack – Stack object
• timeout – Timeout period
sys_port_trace_k_stack_pop_blocking(stack, timeout)
  Trace Stack pop attempt blocking.
  
  **Parameters**
  • stack – Stack object
  • timeout – Timeout period

sys_port_trace_k_stack_pop_exit(stack, timeout, ret)
  Trace Stack pop attempt outcome.
  
  **Parameters**
  • stack – Stack object
  • timeout – Timeout period
  • ret – Return value

Message Queues

**group** subsys_tracing_apis_msgq
Message Queue Tracing APIs.

**Defines**

sys_port_trace_k_msgq_init(msgq)
  Trace initialization of Message Queue.
  
  **Parameters**
  • msgq – Message Queue object

sys_port_trace_k_msgq_alloc_init_enter(msgq)
  Trace Message Queue alloc init attempt entry.
  
  **Parameters**
  • msgq – Message Queue object

sys_port_trace_k_msgq_alloc_init_exit(msgq, ret)
  Trace Message Queue alloc init attempt outcome.
  
  **Parameters**
  • msgq – Message Queue object
  • ret – Return value

sys_port_trace_k_msgq_cleanup_enter(msgq)
  Trace Message Queue cleanup attempt entry.
  
  **Parameters**
  • msgq – Message Queue object

sys_port_trace_k_msgq_cleanup_exit(msgq, ret)
  Trace Message Queue cleanup attempt outcome.
  
  **Parameters**
  • msgq – Message Queue object
  • ret – Return value
sys_port_trace_k_msgq_put_enter(msgq, timeout)
Trace Message Queue put attempt entry.

Parameters
- msgq – Message Queue object
- timeout – Timeout period

sys_port_trace_k_msgq_put_blocking(msgq, timeout)
Trace Message Queue put attempt blocking.

Parameters
- msgq – Message Queue object
- timeout – Timeout period

sys_port_trace_k_msgq_put_exit(msgq, timeout, ret)
Trace Message Queue put attempt outcome.

Parameters
- msgq – Message Queue object
- timeout – Timeout period
- ret – Return value

sys_port_trace_k_msgq_get_enter(msgq, timeout)
Trace Message Queue get attempt entry.

Parameters
- msgq – Message Queue object
- timeout – Timeout period

sys_port_trace_k_msgq_get_blocking(msgq, timeout)
Trace Message Queue get attempt blockings.

Parameters
- msgq – Message Queue object
- timeout – Timeout period

sys_port_trace_k_msgq_get_exit(msgq, timeout, ret)
Trace Message Queue get attempt outcome.

Parameters
- msgq – Message Queue object
- timeout – Timeout period
- ret – Return value

sys_port_trace_k_msgq_peek(msgq, ret)
Trace Message Queue peek.

Parameters
- msgq – Message Queue object
- ret – Return value

sys_port_trace_k_msgq_purge(msgq)
Trace Message Queue purge.

Parameters
- msgq – Message Queue object
Mailbox

**group** subsys_tracing.Apis_mbox

Mailbox Tracing APIs.

**Defines**

`sys_port_trace_k_mbox_init(mbox)`

Trace initialization of Mailbox.

**Parameters**

- `mbox` – Mailbox object

`sys_port_trace_k_mbox_message_put_enter(mbox, timeout)`

Trace Mailbox message put attempt entry.

**Parameters**

- `mbox` – Mailbox object
- `timeout` – Timeout period

`sys_port_trace_k_mbox_message_put_blocking(mbox, timeout)`

Trace Mailbox message put attempt blocking.

**Parameters**

- `mbox` – Mailbox object
- `timeout` – Timeout period

`sys_port_trace_k_mbox_message_put_exit(mbox, timeout, ret)`

Trace Mailbox message put attempt outcome.

**Parameters**

- `mbox` – Mailbox object
- `timeout` – Timeout period
- `ret` – Return value

`sys_port_trace_k_mbox_put_enter(mbox, timeout)`

Trace Mailbox put attempt entry.

**Parameters**

- `mbox` – Mailbox object
- `timeout` – Timeout period

`sys_port_trace_k_mbox_put_exit(mbox, timeout, ret)`

Trace Mailbox put attempt blocking.

**Parameters**

- `mbox` – Mailbox object
- `timeout` – Timeout period
- `ret` – Return value
sys_port_trace_k_mbox_async_put_enter(mbox, sem)
    Trace Mailbox async put entry.

    **Parameters**
    
    - `mbox` – Mailbox object
    - `sem` – Semaphore object

sys_port_trace_k_mbox_async_put_exit(mbox, sem)
    Trace Mailbox async put exit.

    **Parameters**
    
    - `mbox` – Mailbox object
    - `sem` – Semaphore object

sys_port_trace_k_mbox_get_enter(mbox, timeout)
    Trace Mailbox get attempt entry.

    **Parameters**
    
    - `mbox` – Mailbox entry
    - `timeout` – Timeout period

sys_port_trace_k_mbox_get_blocking(mbox, timeout)
    Trace Mailbox get attempt blocking.

    **Parameters**
    
    - `mbox` – Mailbox entry
    - `timeout` – Timeout period

sys_port_trace_k_mbox_get_exit(mbox, timeout, ret)
    Trace Mailbox get attempt outcome.

    **Parameters**
    
    - `mbox` – Mailbox entry
    - `timeout` – Timeout period
    - `ret` – Return value

sys_port_trace_k_mbox_data_get(rx_msg)
    Trace Mailbox data get.

    **rx_msg** – Receive Message object

---

**Pipes**

`group subsys_tracing apis_pipe`

Pipe Tracing APIs.

---

**Defines**

sys_port_trace_k_pipe_init(pipe)
    Trace initialization of Pipe.

    **Parameters**
    
    - `pipe` – Pipe object
sys_port_trace_k_pipe_cleanup_enter(pipe)
  Trace Pipe cleanup entry.

Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_cleanup_exit(pipe, ret)
  Trace Pipe cleanup exit.

Parameters
  • pipe – Pipe object
  • ret – Return value

sys_port_trace_k_pipe_alloc_init_enter(pipe)
  Trace Pipe alloc init entry.

Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_alloc_init_exit(pipe, ret)
  Trace Pipe alloc init exit.

Parameters
  • pipe – Pipe object
  • ret – Return value

sys_port_trace_k_pipe_flush_enter(pipe)
  Trace Pipe flush entry.

Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_flush_exit(pipe)
  Trace Pipe flush exit.

Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_buffer_flush_enter(pipe)
  Trace Pipe buffer flush entry.

Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_buffer_flush_exit(pipe)
  Trace Pipe buffer flush exit.

Parameters
  • pipe – Pipe object

sys_port_trace_k_pipe_put_enter(pipe, timeout)
  Trace Pipe put attempt entry.

Parameters
  • pipe – Pipe object
  • timeout – Timeout period
sys_port_trace_k_pipe_put_blocking(pipe, timeout)
Trace Pipe put attempt blocking.

Parameters
  • pipe – Pipe object
  • timeout – Timeout period

sys_port_trace_k_pipe_put_exit(pipe, timeout, ret)
Trace Pipe put attempt outcome.

Parameters
  • pipe – Pipe object
  • timeout – Timeout period
  • ret – Return value

sys_port_trace_k_pipe_get_enter(pipe, timeout)
Trace Pipe get attempt entry.

Parameters
  • pipe – Pipe object
  • timeout – Timeout period

sys_port_trace_k_pipe_get_blocking(pipe, timeout)
Trace Pipe get attempt blocking.

Parameters
  • pipe – Pipe object
  • timeout – Timeout period

sys_port_trace_k_pipe_get_exit(pipe, timeout, ret)
Trace Pipe get attempt outcome.

Parameters
  • pipe – Pipe object
  • timeout – Timeout period
  • ret – Return value

Heaps

group subsys_tracing_apis_heap
Heap Tracing APIs.

Defines

sys_port_trace_k_heap_init(h)
Trace initialization of Heap.

Parameters
  • h – Heap object
sys_port_trace_k_heap_aligned_alloc_enter(h, timeout)
  Trace Heap aligned alloc attempt entry.

  **Parameters**
  * h – Heap object
  * timeout – Timeout period

sys_port_trace_k_heap_aligned_alloc_blocking(h, timeout)
  Trace Heap align alloc attempt blocking.

  **Parameters**
  * h – Heap object
  * timeout – Timeout period

sys_port_trace_k_heap_aligned_alloc_exit(h, timeout, ret)
  Trace Heap align alloc attempt outcome.

  **Parameters**
  * h – Heap object
  * timeout – Timeout period
  * ret – Return value

sys_port_trace_k_heap_alloc_enter(h, timeout)
  Trace Heap alloc enter.

  **Parameters**
  * h – Heap object
  * timeout – Timeout period

sys_port_trace_k_heap_alloc_exit(h, timeout, ret)
  Trace Heap alloc exit.

  **Parameters**
  * h – Heap object
  * timeout – Timeout period
  * ret – Return value

sys_port_trace_k_heap_free(h)
  Trace Heap free.

  **Parameters**
  * h – Heap object

sys_port_trace_k_heap_sys_k_aligned_alloc_enter(heap)
  Trace System Heap aligned alloc enter.

  **Parameters**
  * heap – Heap object

sys_port_trace_k_heap_sys_k_aligned_alloc_exit(heap, ret)
  Trace System Heap aligned alloc exit.

  **Parameters**
  * heap – Heap object
  * ret – Return value
sys_port_trace_k_heap_sys_k_malloc_enter(heap)
Trace System Heap aligned alloc enter.

Parameters
• heap – Heap object

sys_port_trace_k_heap_sys_k_malloc_exit(heap, ret)
Trace System Heap aligned alloc exit.

Parameters
• heap – Heap object
• ret – Return value

sys_port_trace_k_heap_sys_k_free_enter(heap, heap_ref)
Trace System Heap free entry.

Parameters
• heap – Heap object
• heap_ref – Heap reference

sys_port_trace_k_heap_sys_k_free_exit(heap, heap_ref)
Trace System Heap free exit.

Parameters
• heap – Heap object
• heap_ref – Heap reference

sys_port_trace_k_heap_sys_k_calloc_enter(heap)
Trace System heap calloc enter.

Parameters
• heap –

sys_port_trace_k_heap_sys_k_calloc_exit(heap, ret)
Trace System heap calloc exit.

Parameters
• heap – Heap object
• ret – Return value

Memory Slabs

group subsys_tracing_apis_mslab
Memory Slab Tracing APIs.

Defines

sys_port_trace_k_mem_slab_init(slab, rc)
Trace initialization of Memory Slab.

Parameters
• slab – Memory Slab object
• rc – Return value
sys_port_trace_k_mem_slab_alloc_enter(slab, timeout)
Trace Memory Slab alloc attempt entry.

Parameters
- slab – Memory Slab object
- timeout – Timeout period

sys_port_trace_k_mem_slab_alloc_blocking(slab, timeout)
Trace Memory Slab alloc attempt blocking.

Parameters
- slab – Memory Slab object
- timeout – Timeout period

sys_port_trace_k_mem_slab_alloc_exit(slab, timeout, ret)
Trace Memory Slab alloc attempt outcome.

Parameters
- slab – Memory Slab object
- timeout – Timeout period
- ret – Return value

sys_port_trace_k_mem_slab_free_enter(slab)
Trace Memory Slab free entry.

Parameters
- slab – Memory Slab object

sys_port_trace_k_mem_slab_free_exit(slab)
Trace Memory Slab free exit.

Parameters
- slab – Memory Slab object

Timers

group subsys_tracing_apis_timer
Timer Tracing APIs.

Defines

sys_port_trace_k_timer_init(timer)
Trace initialization of Timer.

Parameters
- timer – Timer object

sys_port_trace_k_timer_start(timer, duration, period)
Trace Timer start.

Parameters
- timer – Timer object
- duration – Timer duration
• **period** – Timer period

```c
sys_port_trace_k_timer_stop(timer)
```

Trace Timer stop.

**Parameters**

• **timer** – Timer object

```c
sys_port_trace_k_timer_status_sync_enter(timer)
```

Trace Timer status sync entry.

**Parameters**

• **timer** – Timer object

```c
sys_port_trace_k_timer_status_sync_blocking(timer, timeout)
```

Trace Timer Status sync blocking.

**Parameters**

• **timer** – Timer object
  
• **timeout** – Timeout period

```c
sys_port_trace_k_timer_status_sync_exit(timer, result)
```

Trace Time Status sync outcome.

**Parameters**

• **timer** – Timer object
  
• **result** – Return value

---

**Object tracking**

```c
objecttrack group subsys_tracing_object_tracking

Object tracking.
```

Object tracking provides lists to kernel objects, so their existence and current status can be tracked. The following global variables are the heads of available lists:

• `_track_list_k_timer`
  
• `_track_list_k_mem_slab`
  
• `_track_list_k_sem`
  
• `_track_list_k_mutex`
  
• `_track_list_k_stack`
  
• `_track_list_k_msgq`
  
• `_track_list_k_mbox`
  
• `_track_list_k_pipe`
  
• `_track_list_k_queue`
  
• `_track_list_k_event`

---
Defines

SYS_PORT_TRACK_NEXT(list)

Gets node's next element in a object tracking list.

Parameters

• list – Node to get next element from.

Syscalls

group subsys_tracing_apis_syscall

Syscall Tracing APIs.

Defines

sys_port_trace_syscall_enter(id, name, ...)

Trace syscall entry.

Parameters

• id – Syscall ID (as defined in the generated syscall_list.h)
• name – Syscall name as a token (ex: k_thread_create)
• ... – Other parameters passed to the syscall

sys_port_trace_syscall_exit(id, name, ...)

Trace syscall exit.

Parameters

• id – Syscall ID (as defined in the generated syscall_list.h)
• name – Syscall name as a token (ex: k_thread_create)
• ... – Other parameters passed to the syscall, if the syscall has a return, the return value is the last parameter in the list

4.13 Resource Management

There are various situations where it's necessary to coordinate resource use at runtime among multiple clients. These include power rails, clocks, other peripherals, and binary device power management. The complexity of properly managing multiple consumers of a device in a multithreaded system, especially when transitions may be asynchronous, suggests that a shared implementation is desirable.

Zephyr provides managers for several coordination policies. These managers are embedded into services that use them for specific functions.

• On-Off Manager

4.13.1 On-Off Manager

An on-off manager supports an arbitrary number of clients of a service which has a binary state. Example applications are power rails, clocks, and binary device power management.

The manager has the following properties:
• The stable states are off, on, and error. The service always begins in the off state. The service may also be in a transition to a given state.

• The core operations are request (add a dependency) and release (remove a dependency). Supporting operations are reset (to clear an error state) and cancel (to reclaim client data from an in-progress transition). The service manages the state based on calls to functions that initiate these operations.

• The service transitions from off to on when first client request is received.

• The service transitions from on to off when last client release is received.

• Each service configuration provides functions that implement the transition from off to on, from on to off, and optionally from an error state to off. Transitions must be invokable from both thread and interrupt context.

• The request and reset operations are asynchronous using Asynchronous Notifications. Both operations may be cancelled, but cancellation has no effect on the in-progress transition.

• Requests to turn on may be queued while a transition to off is in progress: when the service has turned off successfully it will be immediately turned on again (where context allows) and waiting clients notified when the start completes.

Requests are reference counted, but not tracked. That means clients are responsible for recording whether their requests were accepted, and for initiating a release only if they have previously successfully completed a request. Improper use of the API can cause an active client to be shut out, and the manager does not maintain a record of specific clients that have been granted a request.

Failures in executing a transition are recorded and inhibit further requests or releases until the manager is reset. Pending requests are notified (and cancelled) when errors are discovered.

Transition operation completion notifications are provided through Asynchronous Notifications.

Clients and other components interested in tracking all service state changes, including when a service begins turning off or enters an error state, can be informed of state transitions by registering a monitor with onoff_monitor_register(). Notification of changes are provided before issuing completion notifications associated with the new state.

Note: A generic API may be implemented by multiple drivers where the common case is asynchronous. The on-off client structure may be an appropriate solution for the generic API. Where drivers that can guarantee synchronous context-independent transitions a driver may use onoff_sync_service and its supporting API rather than onoff_manager, with only a small reduction in functionality (primarily no support for the monitor API).

Defines

ONOFF_FLAG_ERROR
Flag indicating an error state.
Error states are cleared using onoff_reset().

ONOFF_STATE_MASK
Mask used to isolate bits defining the service state.
Mask a value with this then test for ONOFF_FLAG_ERROR to determine whether the machine has an unfixed error, or compare against ONOFF_STATE_ON, ONOFF_STATE_OFF, ONOFF_STATE_TO_ON, ONOFF_STATE_TO_OFF, or ONOFF_STATE_RESETTING.
ONOFF_STATE_OFF
Value exposed by ONOFF_STATE_MASK when service is off.

ONOFF_STATE_ON
Value exposed by ONOFF_STATE_MASK when service is on.

ONOFF_STATE_ERROR
Value exposed by ONOFF_STATE_MASK when the service is in an error state (and not in the process of resetting its state).

ONOFF_STATE_TO_ON
Value exposed by ONOFF_STATE_MASK when service is transitioning to on.

ONOFF_STATE_TO_OFF
Value exposed by ONOFF_STATE_MASK when service is transitioning to off.

ONOFF_STATE_RESETTING
Value exposed by ONOFF_STATE_MASK when service is in the process of resetting.

ONOFF_TRANSITIONS_INITIALIZER(_start, _stop, _reset)
Initializer for a onoff_transitions object.

Parameters
• _start – a function used to transition from off to on state.
• _stop – a function used to transition from on to off state.
• _reset – a function used to clear errors and force the service to an off state.
  Can be null.

ONOFF_CLIENT_EXTENSION_POS
Identify region of sys_notify flags available for containing services.
Bits of the flags field of the sys_notify structure contained within the queued_operation structure at and above this position may be used by extensions to the onoff_client structure.

These bits are intended for use by containing service implementations to record client-specific information and are subject to other conditions of use specified on the sys_notify API.

Typedefs

typedef void (*onoff_notify_fn)(struct onoff_manager *mgr, int res)
Signature used to notify an on-off manager that a transition has completed.
Functions of this type are passed to service-specific transition functions to be used to report the completion of the operation. The functions may be invoked from any context.

Param mgr
the manager for which transition was requested.

Param res
the result of the transition. This shall be non-negative on success, or a negative error code. If an error is indicated the service shall enter an error state.
typedef void (*onoff_transition_fn)(struct onoff_manager *mgr, onoff_notify_fn notify)

Signature used by service implementations to effect a transition.

Service definitions use two required function pointers of this type to be notified that a transition is required, and a third optional one to reset the service when it is in an error state.

The start function will be called only from the off state.
The stop function will be called only from the on state.

The reset function (where supported) will be called only when onoff_has_error() returns true.

**Note:** All transitions functions must be isr-ok.

**Param mgr**
the manager for which transition was requested.

**Param notify**
the function to be invoked when the transition has completed. If the transition is synchronous, notify shall be invoked by the implementation before the transition function returns. Otherwise the implementation shall capture this parameter and invoke it when the transition completes.

typedef void (*onoff_client_callback)(struct onoff_manager *mgr, struct onoff_client *cli, uint32_t state, int res)

Signature used to notify an on-off service client of the completion of an operation.

These functions may be invoked from any context including pre-kernel, ISR, or cooperative or pre-emptible threads. Compatible functions must be isr-ok and not sleep.

**Param mgr**
the manager for which the operation was initiated. This may be null if the on-off service uses synchronous transitions.

**Param cli**
the client structure passed to the function that initiated the operation.

**Param state**
the state of the machine at the time of completion, restricted by ONOFF_STATE_MASK. ONOFF_FLAG_ERROR must be checked independently of whether res is negative as a machine error may indicate that all future operations except onoff_reset() will fail.

**Param res**
the result of the operation. Expected values are service-specific, but the value shall be non-negative if the operation succeeded, and negative if the operation failed. If res is negative ONOFF_FLAG_ERROR will be set in state, but if res is non-negative ONOFF_FLAG_ERROR may still be set in state.

typedef void (*onoff_monitor_callback)(struct onoff_manager *mgr, struct onoff_monitor *mon, uint32_t state, int res)

Signature used to notify a monitor of an onoff service of errors or completion of a state transition.

This is similar to onoff_client_callback but provides information about all transitions, not just ones associated with a specific client. Monitor callbacks are invoked before any completion notifications associated with the state change are made.

These functions may be invoked from any context including pre-kernel, ISR, or cooperative or pre-emptible threads. Compatible functions must be isr-ok and not sleep.
The callback is permitted to unregister itself from the manager, but must not register or unregister any other monitors.

**Param mgr**
the manager for which a transition has completed.

**Param mon**
the monitor instance through which this notification arrived.

**Param state**
the state of the machine at the time of completion, restricted by ONOFF_STATE_MASK. All valid states may be observed.

**Param res**
the result of the operation. Expected values are service- and state-specific, but the value shall be non-negative if the operation succeeded, and negative if the operation failed.

### Functions

```c
int onoff_manager_init(struct onoff_manager *mgr, const struct onoff_transitions *transitions)
```
Initialize an on-off service to off state.

This function must be invoked exactly once per service instance, by the infrastructure that provides the service, and before any other on-off service API is invoked on the service.

This function should never be invoked by clients of an on-off service.

**Parameters**

- `mgr` – the manager definition object to be initialized.
- `transitions` – pointer to a structure providing transition functions. The referenced object must persist as long as the manager can be referenced.

**Return values**

- `0` – on success
- `-EINVAL` – if start, stop, or flags are invalid

```c
static inline bool onoff_has_error(const struct onoff_manager *mgr)
```
Test whether an on-off service has recorded an error.

This function can be used to determine whether the service has recorded an error. Errors may be cleared by invoking `onoff_reset()`.

This is an unlocked convenience function suitable for use only when it is known that no other process might invoke an operation that transitions the service between an error and non-error state.

**Returns**

true if and only if the service has an uncleared error.

```c
int onoff_request(struct onoff_manager *mgr, struct onoff_client *cli)
```
Request a reservation to use an on-off service.

The return value indicates the success or failure of an attempt to initiate an operation to request the resource be made available. If initiation of the operation succeeds the result of the request operation is provided through the configured client notification method, possibly before this call returns.

Note that the call to this function may succeed in a case where the actual request fails. Always check the operation completion result.

**Parameters**
• `mgr` – the manager that will be used.

• `cli` – a non-null pointer to client state providing instructions on synchronous expectations and how to notify the client when the request completes. Behavior is undefined if client passes a pointer object associated with an incomplete service operation.

Return values

• `non-negative` – the observed state of the machine at the time the request was processed, if successful.

• `-EIO` – if service has recorded an an error.

• `-EINVAL` – if the parameters are invalid.

• `-EAGAIN` – if the reference count would overflow.

```c
int onoff_release(struct onoff_manager *mgr)
```
Release a reserved use of an on-off service.

This synchronously releases the caller’s previous request. If the last request is released the manager will initiate a transition to off, which can be observed by registering an onoff_monitor.

Note: Behavior is undefined if this is not paired with a preceding onoff_request() call that completed successfully.

Parameters

• `mgr` – the manager for which a request was successful.

Return values

• `non-negative` – the observed state (ONOFF_STATE_ON) of the machine at the time of the release, if the release succeeds.

• `-EIO` – if service has recorded an an error.

• `-ENOTSUP` – if the machine is not in a state that permits release.

```c
int onoff_cancel(struct onoff_manager *mgr, struct onoff_client *cli)
```
Attempt to cancel an in-progress client operation.

It may be that a client has initiated an operation but needs to shut down before the operation has completed. For example, when a request was made and the need is no longer present.

Cancelling is supported only for onoff_request() and onoff_reset() operations, and is a synchronous operation. Be aware that any transition that was initiated on behalf of the client will continue to progress to completion: it is only notification of transition completion that may be eliminated. If there are no active requests when a transition to on completes the manager will initiate a transition to off.

Client notification does not occur for cancelled operations.

Parameters

• `mgr` – the manager for which an operation is to be cancelled.

• `cli` – a pointer to the same client state that was provided when the operation to be cancelled was issued.

Return values

• `non-negative` – the observed state of the machine at the time of the cancellation, if the cancellation succeeds. On successful cancellation ownership of `*cli` reverts to the client.
• -EINVAL – if the parameters are invalid.
• -EALREADY – if cli was not a record of an uncompleted notification at the time
  the cancellation was processed. This likely indicates that the operation and
  client notification had already completed.

static inline int onoff_cancel_or_release(struct onoff_manager *mgr, struct onoff_client *cli)

Helper function to safely cancel a request.

Some applications may want to issue requests on an asynchronous event (such as connection
to a USB bus) and to release on a paired event (such as loss of connection to a USB bus).
Applications cannot precisely determine that an in-progress request is still pending without
using onoff_monitor and carefully avoiding race conditions.

This function is a helper that attempts to cancel the operation and issues a release if cancel-
lation fails because the request was completed. This synchronously ensures that ownership of
the client data reverts to the client so is available for a future request.

Parameters

• mgr – the manager for which an operation is to be cancelled.
• cli – a pointer to the same client state that was provided when onoff_request() was invoked. Behavior is undefined if this is a pointer to client data associated with an onoff_reset() request.

Return values

• ONOFF_STATE_TO_ON – if the cancellation occurred before the transition com-
  pleted.
• ONOFF_STATE_ON – if the cancellation occurred after the transition completed.
• -EINVAL – if the parameters are invalid.
• negative – other errors produced by onoff_release().

int onoff_reset(struct onoff_manager *mgr, struct onoff_client *cli)

Clear errors on an on-off service and reset it to its off state.

A service can only be reset when it is in an error state as indicated by onoff_has_error().

The return value indicates the success or failure of an attempt to initiate an operation to reset
the resource. If initiation of the operation succeeds the result of the reset operation itself is
provided through the configured client notification method, possibly before this call returns.
Multiple clients may request a reset; all are notified when it is complete.

Note that the call to this function may succeed in a case where the actual reset fails. Always
check the operation completion result.

Note: Due to the conditions on state transition all incomplete asynchronous operations will
have been informed of the error when it occurred. There need be no concern about dangling
requests left after a reset completes.

Parameters

• mgr – the manager to be reset.
• cli – pointer to client state, including instructions on how to notify the client
  when reset completes. Behavior is undefined if cli references an object associ-
  ated with an incomplete service operation.

Return values

• non-negative – the observed state of the machine at the time of the reset, if
  the reset succeeds.
• -ENOTSUP – if reset is not supported by the service.
• -EINVAL – if the parameters are invalid.
• -EALREADY – if the service does not have a recorded error.

int onoff_monitor_register(struct onoff_manager *mgr, struct onoff_monitor *mon)
Add a monitor of state changes for a manager.

Parameters
• mgr – the manager for which a state changes are to be monitored.
• mon – a linkable node providing a non-null callback to be invoked on state changes.

Returns
  non-negative on successful addition, or a negative error code.

int onoff_monitor_unregister(struct onoff_manager *mgr, struct onoff_monitor *mon)
Remove a monitor of state changes from a manager.

Parameters
• mgr – the manager for which a state changes are to be monitored.
• mon – a linkable node providing the callback to be invoked on state changes.

Returns
  non-negative on successful removal, or a negative error code.

int onoff_sync_lock(struct onoff_sync_service *srv, k_spinlock_key_t *keyp)
Lock a synchronous onoff service and provide its state.

Note: If an error state is returned it is the caller’s responsibility to decide whether to preserve it (finalize with the same error state) or clear the error (finalize with a non-error result).

Parameters
• srv – pointer to the synchronous service state.
• keyp – pointer to where the lock key should be stored

Returns
  negative if the service is in an error state, otherwise the number of active requests at the time the lock was taken. The lock is held on return regardless of whether a negative state is returned.

int onoff_sync_finalize(struct onoff_sync_service *srv, k_spinlock_key_t key, struct onoff_client *cli, int res, bool on)
Process the completion of a transition in a synchronous service and release lock.

This function updates the service state on the res and on parameters then releases the lock. If cli is not null it finalizes the client notification using res.

If the service was in an error state when locked, and res is non-negative when finalized, the count is reset to zero before completing finalization.

Parameters
• srv – pointer to the synchronous service state
• key – the key returned by the preceding invocation of onoff_sync_lock().
• cli – pointer to the onoff client through which completion information is returned. If a null pointer is passed only the state of the service is updated. For compatibility with the behavior of callbacks used with the manager API cli must be null when on is false (the manager does not support callbacks when turning off devices).

• res – the result of the transition. A negative value places the service into an error state. A non-negative value increments or decrements the reference count as specified by on.

• on – Only when res is non-negative, the service reference count will be incremented if on is true, and decremented if on is false.

Returns
negative if the service is left or put into an error state, otherwise the number of active requests at the time the lock was released.

struct onoff_transitions
#include <onoff.h> On-off service transition functions.

Public Members

onoff_transition_fn start
Function to invoke to transition the service to on.

onoff_transition_fn stop
Function to invoke to transition the service to off.

onoff_transition_fn reset
Function to force the service state to reset, where supported.

struct onoff_manager
#include <onoff.h> State associated with an on-off manager.

No fields in this structure are intended for use by service providers or clients. The state is to be initialized once, using onoff_manager_init(), when the service provider is initialized. In case of error it may be reset through the onoff_reset() API.

Public Members

sys_slist_t clients
List of clients waiting for request or reset completion notifications.

sys_slist_t monitors
List of monitors to be notified of state changes including errors and transition completion.

const struct onoff_transitions *transitions
Transition functions.

struct k_spinlock lock
Mutex protection for other fields.
int last_res
    The result of the last transition.

uint16_t flags
    Flags identifying the service state.

uint16_t refs
    Number of active clients for the service.

struct onoff_client
#include <onoff.h> State associated with a client of an on-off service.
Objects of this type are allocated by a client, which is responsible for zero-initializing the node
field and invoking the appropriate sys_notify init function to configure notification.
Control of the object content transfers to the service provider when a pointer to the object is passed to any on-off manager function. While the service provider controls the object the client must not change any object fields. Control reverts to the client concurrent with release of the owned sys_notify structure, or when indicated by an onoff_cancel() return value.
After control has reverted to the client the notify field must be reinitialized for the next operation.

Public Members

struct sys_notify notify
    Notification configuration.

struct onoff_monitor
#include <onoff.h> Registration state for notifications of onoff service transitions.
Any given onoff_monitor structure can be associated with at most one onoff_manager instance.

Public Members

sys_snode_t node
    Links the client into the set of waiting service users.
    This must be zero-initialized.

onoff_monitor_callback callback
    Callback to be invoked on state change.
    This must not be null.

struct onoff_sync_service
#include <onoff.h> State used when a driver uses the on-off service API for synchronous operations.
This is useful when a subsystem API uses the on-off API to support asynchronous operations but the transitions required by a particular driver are isr-ok and not sleep. It serves as a substitute for onoff_manager, with locking and persisted state updates supported by onoff_sync_lock() and onoff_sync_finalize().

880 Chapter 4. OS Services
Public Members

```c
struct k_spinlock lock
    Mutex protection for other fields.

int32_t count
    Negative is error, non-negative is reference count.
```

## 4.14 Memory Attributes

It is possible in the devicetree to mark the memory regions with attributes by using the `zephyr, memory-attr` property. This property and the related memory region can then be retrieved at run-time by leveraging a provided helper library.

The set of general attributes that can be specified in the property are defined and explained in `include/zephyr/dt-bindings/memory-attr/memory-attr.h`. For example, to mark a memory region in the devicetree as non-volatile, cacheable, out-of-order:

```json
mem: memory@10000000 {
    compatible = "mmio-sram";
    reg = <0x10000000 0x1000>;
    zephyr,memory-attr = <( DT_MEM_NON_VOLATILE | DT_MEM_CACHEABLE | DT_MEM_OOO )>;
};
```

**Note:** The `zephyr,memory-attr` usage does not result in any memory region actually created. When it is needed to create an actual section out of the devicetree defined memory region, it is possible to use the compatible `zephyr,memory-region` that will result (only when supported by the architecture) in a new linker section and region.

The `zephyr,memory-attr` property can also be used to set architecture-specific and software-specific custom attributes that can be interpreted at run time. This is leveraged, among other things, to create MPU regions out of devicetree defined memory regions, for example:

```json
mem: memory@10000000 {
    compatible = "mmio-sram";
    reg = <0x10000000 0x1000>;
    zephyr,memory-region = "NOCACHE_REGION";
    zephyr,memory-attr = <( DT_MEM_ARM(ATTR_MPU_RAM_NOCACHE) )>;
};
```

See `include/zephyr/dt-bindings/memory-attr/memory-attr-arm.h` and *Arm Cortex-M Developer Guide* for more details about MPU usage.

The conventional and recommended way to deal and manage with memory regions marked with attributes is by using the provided `mem-attr` helper library by enabling `CONFIG_MEM_ATTR`. When this option is enabled the list of memory regions and their attributes are compiled in a user-accessible array and a set of functions is made available that can be used to query, probe and act on regions and attributes (see next section for more details).

**Note:** The `zephyr,memory-attr` property is only a descriptive property of the capabilities of the associated memory region, but it does not result in any actual setting for the memory to be set. The user, code or subsystem willing to use this information to do some work (for example creating an MPU region...
out of the property) must use either the provided mem-attr library or the usual devicetree helpers to perform the required work / setting.

A test for the mem-attr library and its usage is provided in tests/subsys/mem_mgmt/mem_attr/.

### 4.14.1 Migration guide from zephyr,memory-region-mpu

When the zephyr,memory-attr property was introduced, the zephyr,memory-region-mpu property was removed and deprecated.

The developers that are still using the deprecated property can move to the new one by renaming the property and changing its value according to the following list:

<table>
<thead>
<tr>
<th>Old Property</th>
<th>New Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;RAM&quot;</td>
<td>&lt;( DT_ARM_MPU(ATTR_MPU_RAM) )&gt;</td>
</tr>
<tr>
<td>&quot;RAM_NOCACHE&quot;</td>
<td>&lt;( DT_ARM_MPU(ATTR_MPU_RAM_NOCACHE) )&gt;</td>
</tr>
<tr>
<td>&quot;FLASH&quot;</td>
<td>&lt;( DT_ARM_MPU(ATTR_MPU_FLASH) )&gt;</td>
</tr>
<tr>
<td>&quot;PPB&quot;</td>
<td>&lt;( DT_ARM_MPU(ATTR_MPU_PPB) )&gt;</td>
</tr>
<tr>
<td>&quot;IO&quot;</td>
<td>&lt;( DT_ARM_MPU(ATTR_MPU_IO) )&gt;</td>
</tr>
<tr>
<td>&quot;EXTMEM&quot;</td>
<td>&lt;( DT_ARM_MPU(ATTR_MPU_EXTMEM) )&gt;</td>
</tr>
</tbody>
</table>

### 4.14.2 API Reference

**group memory_attr_interface**

Memory-Attr Interface.

**Defines**

```
DT_MEMORY_ATTR_FOREACH_STATUS_OKAY_NODE(fn)
```

Invokes fn for every status okay node in the tree with property zephyr,memory-attr

The macro fn must take one parameter, which will be a node identifier with the zephyr,memory-attr property. The macro is expanded once for each node in the tree with status okay. The order that nodes are visited in is not specified.

**Parameters**

- fn – macro to invoke

**Functions**

```
size_t mem_attr_get_regions(const struct mem_attr_region_t **region)
```

Get the list of memory regions.

Get the list of enabled memory regions with their memory-attribute as gathered by DT.

**Parameters**

- region – Pointer to pointer to the list of memory regions.

**Return values**

Number – of memory regions returned in the parameter.
int mem_attr_check_buf (void *addr, size_t size, uint32_t attr)
Check if a buffer has correct size and attributes.
This function is used to check if a given buffer with a given set of attributes fully match a
memory region in terms of size and attributes.
This is usually used to verify that a buffer has the expected attributes (for example the buffer
is cacheable / non-cacheable or belongs to RAM / FLASH, etc...) and it has been correctly
allocated.
The expected set of attributes for the buffer is and-matched against the full set of attributes
for the memory region it belongs to (bitmask). So the buffer is considered matching when at
least that set of attributes are valid for the memory region (but the region can be marked also
with other attributes besides the one passed as parameter).

Parameters
• addr – Virtual address of the user buffer.
• size – Size of the user buffer.
• attr – Expected / desired attribute for the buffer.

Return values
• 0 – if the buffer has the correct size and attribute.
• -ENOSYS – if the operation is not supported (for example if the MMU is en-
abled).
• -ENOTSUP – if the wrong parameters were passed.
• -EINVAL – if the buffer has the wrong set of attributes.
• -ENOSPC – if the buffer is too big for the region it belongs to.
• -ENOBUFS – if the buffer is entirely allocated outside a memory region.

struct mem_attr_region_t
#include <mem_attr.h> memory-attr region structure.
This structure represents the data gathered from DT about a memory-region marked with
memory attributes.

Public Members

const char *dt_name
    Memory node full name.

uintptr_t dt_addr
    Memory region physical address.

size_t dt_size
    Memory region size.

uint32_t dt_attr
    Memory region attributes.
4.15 Modbus

Modbus is an industrial messaging protocol. The protocol is specified for different types of networks or buses. Zephyr OS implementation supports communication over serial line and may be used with different physical interfaces, like RS485 or RS232. TCP support is not implemented directly, but there are helper functions to realize TCP support according to the application's needs.

Modbus communication is based on client/server model. Only one client may be present on the bus. Client can communicate with several server devices. Server devices themselves are passive and must not send requests or unsolicited responses. Services requested by the client are specified by function codes (FCxx), and can be found in the specification or documentation of the API below.

Zephyr RTOS implementation supports both client and server roles.

More information about Modbus and Modbus RTU can be found on the website MODBUS Protocol Specifications.

4.15.1 Samples

- modbus-rtu-server and modbus-rtu-client samples give the possibility to try out RTU server and RTU client implementation with an evaluation board.
- modbus-tcp-server sample is a simple Modbus TCP server.
- modbus-gateway sample shows how to build a TCP to serial line gateway with Zephyr OS.

4.15.2 API Reference

Related code samples

- Modbus RTU client - Communicate with a Modbus RTU server.
- Modbus RTU server - Implement a Modbus RTU server exposing Modbus commands to control LEDs.
- Modbus TCP server - Implement a Modbus TCP server exposing Modbus commands to control LEDs.
- Modbus TCP-to-serial gateway - Implement a gateway between an Ethernet TCP-IP network and a Modbus serial line.

\begin{verbatim}
$ modbus

MODBUS transport protocol API.

Modbus exception codes

MODBUS_EXC_NONE

MODBUS_EXC_ILLEGAL_FC

MODBUS_EXC_ILLEGAL_DATA_ADDR

MODBUS_EXC_ILLEGAL_DATA_VAL
\end{verbatim}
MODBUS_EXC_SERVER_DEVICE_FAILURE

MODBUS_EXC_ACK

MODBUS_EXC_SERVER_DEVICE_BUSY

MODBUS_EXC_MEM_PARITY_ERROR

MODBUS_EXC_GW_PATH_UNAVAILABLE

MODBUS_EXC_GW_TARGET_FAILED_TO_RESP

Defines

MODBUS_MBAP_LENGTH
   Length of MBAP Header.

MODBUS_MBAP_AND_FC_LENGTH
   Length of MBAP Header plus function code.

MODBUS_CUSTOM_FC_DEFINE(name, user_cb, user_fc, userdata)
   INTERNAL_HIDDEN.
   Helper macro for initializing custom function code structs

Typedefs

typedef int (*modbus_raw_cb_t)(const int iface, const struct modbus_adu *adu, void *user_data)
   ADU raw callback function signature.

   Param iface
      Modbus RTU interface index

   Param adu
      Pointer to the RAW ADU struct to send

   Param user_data
      Pointer to the user data

   Retval 0
      If transfer was successful

typedef bool (*modbus_custom_cb_t)(const int iface, const struct modbus_adu *const rx_adu,
   struct modbus_adu *const tx_adu, uint8_t *const excep_code, void *const user_data)
   Custom function code handler function signature.
   Modbus allows user defined function codes which can be used to extend the base protocol. These
   callbacks can also be used to implement function codes currently not supported by Zephyr's Modbus
   subsystem.

   If an error occurs during the handling of the request, the handler should signal this by setting
   excep_code to a modbus exception code.

   User data pointer can be used to pass state between subsequent calls to the handler.
**Param iface**
Modbus interface index

**Param rx_adu**
Pointer to the received ADU struct

**Param tx_adu**
Pointer to the outgoing ADU struct

**Param excep_code**
Pointer to possible exception code

**Param user_data**
Pointer to user data

**Retval true**
If response should be sent, false otherwise

---

**Enums**

```cpp
class modbus_mode
{
    Modbus interface mode.
    
    Values:
    
    enumerator MODBUS_MODE_RTU
        Modbus over serial line RTU mode.
    
    enumerator MODBUS_MODE_ASCII
        Modbus over serial line ASCII mode.
    
    enumerator MODBUS_MODE_RAW
        Modbus raw ADU mode.
}
```

---

**Functions**

```cpp
int modbus_read_coils(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint8_t *const coil_tbl, const uint16_t num_coils)
```

Sends a Modbus message to read the status of coils from a server.

**Parameters**

- `iface` – Modbus interface index
- `unit_id` – Modbus unit ID of the server
- `start_addr` – Coil starting address
- `coil_tbl` – Pointer to an array of bytes containing the value of the coils read. The format is:

```plaintext
<table>
<thead>
<tr>
<th>MSB</th>
</tr>
</thead>
<tbody>
<tr>
<td>B7</td>
</tr>
<tr>
<td>B6</td>
</tr>
<tr>
<td>B5</td>
</tr>
<tr>
<td>B4</td>
</tr>
<tr>
<td>B3</td>
</tr>
<tr>
<td>B2</td>
</tr>
<tr>
<td>B1</td>
</tr>
<tr>
<td>B0</td>
</tr>
</tbody>
</table>
```

- `coil_tbl[0]` – `#8 #7` #1
- `coil_tbl[1]` – `#16 #15` #9
- `...`
Note that the array that will be receiving the coil values must be greater than or equal to: \((\text{num}_{\text{coils}} - 1) / 8 + 1\)

- \text{num}_{\text{coils}} – Quantity of coils to read

**Return values**

\(0\) – If the function was successful

```c
int modbus_read_di(inputs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint8_t *const di_tbl, const uint16_t num_di)
```

Read discrete inputs (FC02)

Sends a Modbus message to read the status of discrete inputs from a server.

**Parameters**

- \text{iface} – Modbus interface index
- \text{unit_id} – Modbus unit ID of the server
- \text{start_addr} – Discrete input starting address
- \text{di_tbl} – Pointer to an array that will receive the state of the discrete inputs.
  The format of the array is as follows:

<table>
<thead>
<tr>
<th>MSB</th>
<th>LSB</th>
</tr>
</thead>
<tbody>
<tr>
<td>B7</td>
<td>B0</td>
</tr>
<tr>
<td>B6</td>
<td>B1</td>
</tr>
<tr>
<td>B5</td>
<td>B2</td>
</tr>
<tr>
<td>B4</td>
<td>B3</td>
</tr>
</tbody>
</table>

```
di_tbl[0]
#8  #7  #1
```

```
di_tbl[1]
#16 #15 #9
```

Note that the array that will be receiving the discrete input values must be greater than or equal to: \((\text{num}_{\text{di}} - 1) / 8 + 1\)

- \text{num}_{\text{di}} – Quantity of discrete inputs to read

**Return values**

\(0\) – If the function was successful

```c
int modbus_read_holding_regs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint16_t *const reg_buf, const uint16_t num_regs)
```

Read holding registers (FC03)

Sends a Modbus message to read the value of holding registers from a server.

**Parameters**

- \text{iface} – Modbus interface index
- \text{unit_id} – Modbus unit ID of the server
- \text{start_addr} – Register starting address
- \text{reg_buf} – Is a pointer to an array that will receive the current values of the holding registers from the server. The array pointed to by \text{reg_buf} needs to be able to hold at least \text{num_regs} entries.
- \text{num_regs} – Quantity of registers to read

**Return values**

\(0\) – If the function was successful

```c
int modbus_read_input_regs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint16_t *const reg_buf, const uint16_t num_regs)
```

Read input registers (FC04)

Sends a Modbus message to read the value of input registers from a server.
Parameters

- **iface** – Modbus interface index
- **unit_id** – Modbus unit ID of the server
- **start_addr** – Register starting address
- **reg_buf** – Is a pointer to an array that will receive the current value of the holding registers from the server. The array pointed to by 'reg_buf' needs to be able to hold at least 'num_regs' entries.
- **num_regs** – Quantity of registers to read

Return values

0 – If the function was successful

```c
int modbus_write_coil(const int iface, const uint8_t unit_id, const uint16_t coil_addr, const bool coil_state)
```

Write single coil (FC05)

Sends a Modbus message to write the value of single coil to a server.

Parameters

- **iface** – Modbus interface index
- **unit_id** – Modbus unit ID of the server
- **coil_addr** – Coils starting address
- **coil_state** – Is the desired state of the coil

Return values

0 – If the function was successful

```c
int modbus_write_holding_reg(const int iface, const uint8_t unit_id, const uint16_t start_addr, const uint16_t reg_val)
```

Write single holding register (FC06)

Sends a Modbus message to write the value of single holding register to a server unit.

Parameters

- **iface** – Modbus interface index
- **unit_id** – Modbus unit ID of the server
- **start_addr** – Coils starting address
- **reg_val** – Desired value of the holding register

Return values

0 – If the function was successful

```c
int modbus_request_diagnostic(const int iface, const uint8_t unit_id, const uint16_t sfunc, const uint16_t data, uint16_t *const data_out)
```

Read diagnostic (FC08)

Sends a Modbus message to perform a diagnostic function of a server unit.

Parameters

- **iface** – Modbus interface index
- **unit_id** – Modbus unit ID of the server
- **sfunc** – Diagnostic sub-function code
- **data** – Sub-function data
- **data_out** – Pointer to the data value
Return values
0 – If the function was successful

int modbus_write_coils(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint8_t *const coil_tbl, const uint16_t num_coils)

Write coils (FC15)
Sends a Modbus message to write to coils on a server unit.

Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Coils starting address
• coil_tbl – Pointer to an array of bytes containing the value of the coils to write. The format is:

<table>
<thead>
<tr>
<th>MSB</th>
<th>B7</th>
<th>B6</th>
<th>B5</th>
<th>B4</th>
<th>B3</th>
<th>B2</th>
<th>B1</th>
<th>LSB</th>
<th>B0</th>
</tr>
</thead>
<tbody>
<tr>
<td>coil_tbl[0]</td>
<td>#8</td>
<td>#7</td>
<td>#1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>coil_tbl[1]</td>
<td>#16</td>
<td>#15</td>
<td>#9</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>:</td>
<td>:</td>
<td>:</td>
<td>:</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note that the array that will be receiving the coil values must be greater than or equal to: \((\text{num}_\text{coils} - 1) / 8 + 1\)

• num_coils – Quantity of coils to write

Return values
0 – If the function was successful

int modbus_write_holding_regs(const int iface, const uint8_t unit_id, const uint16_t start_addr, uint16_t *const reg_buf, const uint16_t num_regs)

Write holding registers (FC16)
Sends a Modbus message to write to integer holding registers to a server unit.

Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Register starting address
• reg_buf – Is a pointer to an array containing the value of the holding registers to write. Note that the array containing the register values must be greater than or equal to ‘num_regs’
• num_regs – Quantity of registers to write

Return values
0 – If the function was successful

int modbus_read_holding_regs_fp(const int iface, const uint8_t unit_id, const uint16_t start_addr, float *const reg_buf, const uint16_t num_regs)

Read floating-point holding registers (FC03)
Sends a Modbus message to read the value of floating-point holding registers from a server unit.

Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Register starting address
• reg_buf – Is a pointer to an array that will receive the current values of the holding registers from the server. The array pointed to by ‘reg_buf’ needs to be able to hold at least ‘num_regs’ entries.
• num_regs – Quantity of registers to read

Return values
0 – If the function was successful

int modbus_write_holding_regs_fp(const int iface, const uint8_t unit_id, const uint16_t start_addr, float *const reg_buf, const uint16_t num_regs)

Write floating-point holding registers (FC16)
Sends a Modbus message to write to floating-point holding registers to a server unit.

Parameters
• iface – Modbus interface index
• unit_id – Modbus unit ID of the server
• start_addr – Register starting address
• reg_buf – Is a pointer to an array containing the value of the holding registers to write. Note that the array containing the register values must be greater than or equal to ‘num_regs’
• num_regs – Quantity of registers to write

Return values
0 – If the function was successful

int modbus_iface_get_by_name(const char *iface_name)

Get Modbus interface index according to interface name.
If there is more than one interface, it can be used to clearly identify interfaces in the application.

Parameters
• iface_name – Modbus interface name

Return values
Modbus – interface index or negative error value.

int modbus_init_server(const int iface, struct modbus_iface_param param)
Configure Modbus Interface as raw ADU server.

Parameters
• iface – Modbus RTU interface index
• param – Configuration parameter of the server interface

Return values
0 – If the function was successful

int modbus_init_client(const int iface, struct modbus_iface_param param)
Configure Modbus Interface as raw ADU client.

Parameters
• iface – Modbus RTU interface index
• param – Configuration parameter of the client interface
**Return values**
0 – If the function was successful

```c
text modbus_disable(const uint8_t iface)
```
Disable Modbus Interface.

This function is called to disable Modbus interface.

**Parameters**
- iface – Modbus interface index

**Return values**
0 – If the function was successful

```c
text modbus_raw_submit_rx(const int iface, const struct modbus_adu *adu)
```
Submit raw ADU.

**Parameters**
- iface – Modbus RTU interface index
- adu – Pointer to the RAW ADU struct that is received

**Return values**
0 – If transfer was successful

```c
text modbus_raw_put_header(const struct modbus_adu *adu, uint8_t *header)
```
Put MBAP header into a buffer.

**Parameters**
- adu – Pointer to the RAW ADU struct
- header – Pointer to the buffer in which MBAP header will be placed.

```c
text modbus_raw_get_header(struct modbus_adu *adu, const uint8_t *header)
```
Get MBAP header from a buffer.

**Parameters**
- adu – Pointer to the RAW ADU struct
- header – Pointer to the buffer containing MBAP header

```c
text modbus_raw_set_server_failure(struct modbus_adu *adu)
```
Set Server Device Failure exception.

This function modifies ADU passed by the pointer.

**Parameters**
- adu – Pointer to the RAW ADU struct

```c
text modbus_raw_backend_txn(const int iface, struct modbus_adu *adu)
```
Use interface as backend to send and receive ADU.

This function overwrites ADU passed by the pointer and generates exception responses if backend interface is misconfigured or target device is unreachable.

**Parameters**
- iface – Modbus client interface index
- adu – Pointer to the RAW ADU struct

**Return values**
0 – If transfer was successful
int modbus_register_user_fc(const int iface, struct modbus_custom_fc *custom_fc)

Register a user-defined function code handler.

The Modbus specification allows users to define standard function codes missing from Zephyr's Modbus implementation as well as add non-standard function codes in the ranges 65 to 72 and 100 to 110 (decimal), as per specification.

This function registers a new handler at runtime for the given function code.

**Parameters**

- `iface` – Modbus client interface index
- `custom_fc` – User defined function code and callback pair

**Return values**

0 – on success

```c
struct modbus_adu
```

#include `<modbus.h>` Frame struct used internally and for raw ADU support.

**Public Members**

- `uint16_t trans_id`  
  Transaction Identifier.
- `uint16_t proto_id`  
  Protocol Identifier.
- `uint16_t length`  
  Length of the data only (not the length of unit ID + PDU)
- `uint8_t unit_id`  
  Unit Identifier.
- `uint8_t fc`  
  Function Code.
- `uint8_t data[CONFIG_MODBUS_BUFFER_SIZE - 4]`  
  Transaction Data.
- `uint16_t crc`  
  RTU CRC.

```c
struct modbus_user_callbacks
```

#include `<modbus.h>` Modbus Server User Callback structure.

**Public Members**

- `int (*coil_rd)(uint16_t addr, bool *state)`  
  Coil read callback.
int (*coil_wr)(uint16_t addr, bool state)
    Coil write callback.

int (*discrete_input_rd)(uint16_t addr, bool *state)
    Discrete Input read callback.

int (*input_reg_rd)(uint16_t addr, uint16_t *reg)
    Input Register read callback.

int (*input_reg_rd.fp)(uint16_t addr, float *reg)
    Floating Point Input Register read callback.

int (*holding_reg_rd)(uint16_t addr, uint16_t *reg)
    Holding Register read callback.

int (*holding_reg_wr)(uint16_t addr, uint16_t reg)
    Holding Register write callback.

int (*holding_reg_rd.fp)(uint16_t addr, float *reg)
    Floating Point Holding Register read callback.

int (*holding_reg_wr.fp)(uint16_t addr, float reg)
    Floating Point Holding Register write callback.

struct modbus_serial_param
    #include <modbus.h> Modbus serial line parameter.

Public Members

uint32_t baud
    Baudrate of the serial line.

enum uart_config_parity parity
    parity UART's parity setting: UART_CFG_PARITY_NONE, UART_CFG_PARITY_EVEN, UART_CFG_PARITY_ODD

enum uart_config_stop_bits stop_bits_client
    stop_bits_client UART's stop bits setting if in client mode: UART_CFG_STOP_BITS_0_5, UART_CFG_STOP_BITS_1, UART_CFG_STOP_BITS_1_5, UART_CFG_STOP_BITS_2,

struct modbus_server_param
    #include <modbus.h> Modbus server parameter.

Public Members

struct modbus_user_callbacks *user_cb
    Pointer to the User Callback structure.
uint8_t unit_id
    Modbus unit ID of the server.

struct modbus_raw_cb
    #include <modbus.h>

struct modbus_iface_param
    #include <modbus.h> User parameter structure to configure Modbus interface as client or server.

**Public Members**

eenum modbus_mode mode
    Mode of the interface.

uint32_t rx_timeout
    Amount of time client will wait for a response from the server.

struct modbus_serial_param serial
    Serial support parameter of the interface.

struct modbus_raw_cb rawcb
    Pointer to raw ADU callback function.

## 4.16 Asynchronous Notifications

Zephyr APIs often include *async* functions where an operation is initiated and the application needs to be informed when it completes, and whether it succeeded. Using *k_poll()* is often a good method, but some application architectures may be more suited to a callback notification, and operations like enabling clocks and power rails may need to be invoked before kernel functions are available so a busy-wait for completion may be needed.

This API is intended to be embedded within specific subsystems such as *On-Off Manager* and other APIs that support async transactions. The subsystem wrappers are responsible for extracting operation-specific data from requests that include a notification element, and for invoking callbacks with the parameters required by the API.

A limitation is that this API is not suitable for *System Calls* because:

- *sys_notify* is not a kernel object;
- copying the notification content from userspace will break use of *CONTAINER_OF* in the implementing function;
- neither the spin-wait nor callback notification methods can be accepted from userspace callers.

Where a notification is required for an asynchronous operation invoked from a user mode thread the subsystem or driver should provide a syscall API that uses *k_poll_signal* for notification.

### 4.16.1 API Reference

group sys_notify_apis
### Typedefs

typedef void (*sys_notify_generic_callback)()

Generic signature used to notify of result completion by callback.

Functions with this role may be invoked from any context including pre-kernel, ISR, or cooperative or pre-emptible threads. Compatible functions must be isr-ok and not sleep.

Parameters that should generally be passed to such functions include:

- a pointer to a specific client request structure, i.e. the one that contains the `sys_notify` structure.
- the result of the operation, either as passed to `sys_notify_finalize()` or extracted afterwards using `sys_notify_fetch_result()`. Expected values are service-specific, but the value shall be non-negative if the operation succeeded, and negative if the operation failed.

### Functions

```c
static inline uint32_t sys_notify_get_method(const struct sys_notify *notify)
```

```c
int sys_notify_validate(struct sys_notify *notify)
```

Validate and initialize the notify structure.

This should be invoked at the start of any service-specific configuration validation. It ensures that the basic asynchronous notification configuration is consistent, and clears the result.

Note that this function does not validate extension bits (zeroed by async notify API init functions like `sys_notify_init_callback()`). It may fail to recognize that an uninitialized structure has been passed because only method bits of flags are tested against method settings. To reduce the chance of accepting an uninitialized operation service validation of structures that contain an `sys_notify` instance should confirm that the extension bits are set or cleared as expected.

**Return values**

- `0` – on successful validation and reinitialization
- `-EINVAL` – if the configuration is not valid.

```c
sys_notify_generic_callback sys_notify_finalize(struct sys_notify *notify, int res)
```

Record and signal the operation completion.

**Parameters**

- `notify` – pointer to the notification state structure.
- `res` – the result of the operation. Expected values are service-specific, but the value shall be non-negative if the operation succeeded, and negative if the operation failed.

**Returns**

If the notification is to be done by callback this returns the generic version of the function to be invoked. The caller must immediately invoke that function with whatever arguments are expected by the callback. If notification is by spin-wait or signal, the notification has been completed by the point this function returns, and a null pointer is returned.

```c
static inline int sys_notify_fetch_result(const struct sys_notify *notify, int *result)
```

Check for and read the result of an asynchronous operation.

**Parameters**
• notify – pointer to the object used to specify asynchronous function behavior and store completion information.
• result – pointer to storage for the result of the operation. The result is stored only if the operation has completed.

**Return values**
• 0 – if the operation has completed.
• -EAGAIN – if the operation has not completed.

static inline void sys_notify_init_spinwait(struct sys_notify *notify)
Initialize a notify object for spin-wait notification.
Clients that use this initialization receive no asynchronous notification, and instead must periodically check for completion using `sys_notify_fetch_result()`.
On completion of the operation the client object must be reinitialized before it can be re-used.

**Parameters**
• notify – pointer to the notification configuration object.

static inline void sys_notify_init_signal(struct sys_notify *notify, struct k_poll_signal *sigp)
Initialize a notify object for (k_poll) signal notification.
Clients that use this initialization will be notified of the completion of operations through the provided signal.
On completion of the operation the client object must be reinitialized before it can be re-used.

**Note:** This capability is available only when CONFIG_POLL is selected.

**Parameters**
• notify – pointer to the notification configuration object.
  • sigp – pointer to the signal to use for notification. The value must not be null. The signal must be reset before the client object is passed to the on-off service API.

static inline void sys_notify_init_callback(struct sys_notify *notify, sys_notify_generic_callback handler)
Initialize a notify object for callback notification.
Clients that use this initialization will be notified of the completion of operations through the provided callback. Note that callbacks may be invoked from various contexts depending on the specific service; see `sys_notify_generic_callback`.
On completion of the operation the client object must be reinitialized before it can be re-used.

**Parameters**
• notify – pointer to the notification configuration object.
  • handler – a function pointer to use for notification.

static inline bool sys_notify_uses_callback(const struct sys_notify *notify)
Detect whether a particular notification uses a callback.
The generic handler does not capture the signature expected by the callback, and the translation to a service-specific callback must be provided by the service. This check allows abstracted services to reject callback notification requests when the service doesn’t provide a translation function.
 Returns
true if and only if a callback is to be used for notification.

struct sys_notify
#include <notify.h> State associated with notification for an asynchronous operation.

Objects of this type are allocated by a client, which must use an initialization function (e.g. sys_notify_init_signal()) to configure them. Generally the structure is a member of a service-specific client structure, such as onoff_client.

Control of the containing object transfers to the service provider when a pointer to the object is passed to a service function that is documented to take control of the object, such as onoff_service_request(). While the service provider controls the object the client must not change any object fields. Control reverts to the client:

• if the call to the service API returns an error;
• when operation completion is posted. This may occur before the call to the service API returns.

Operation completion is technically posted when the flags field is updated so that sys_notify_fetch_result() returns success. This will happen before the signal is posted or callback is invoked. Note that although the manager will no longer reference the sys_notify object past this point, the containing object may have state that will be referenced within the callback. Where callbacks are used control of the containing object does not revert to the client until the callback has been invoked. (Re-use within the callback is explicitly permitted.)

After control has reverted to the client the notify object must be reinitialized for the next operation.

The content of this structure is not public API to clients: all configuration and inspection should be done with functions like sys_notify_init_callback() and sys_notify_fetch_result(). However, services that use this structure may access certain fields directly.

4.17 Power Management

Zephyr RTOS power management subsystem provides several means for a system integrator to implement power management support that can take full advantage of the power saving features of SOCs.

4.17.1 Overview

The interfaces and APIs provided by the power management subsystem are designed to be architecture and SOC independent. This enables power management implementations to be easily adapted to different SOCs and architectures.
The architecture and SOC independence is achieved by separating the core infrastructure and the SOC specific implementations. The SOC specific implementations are abstracted to the application and the OS using hardware abstraction layers.

The power management features are classified into the following categories.

- System Power Management
- Device Power Management

### 4.17.2 System Power Management

The kernel enters the idle state when it has nothing to schedule. If enabled via the `CONFIG_PM` Kconfig option, the Power Management Subsystem can put an idle system in one of the supported power states, based on the selected power management policy and the duration of the idle time allotted by the kernel.

It is an application responsibility to set up a wake up event. A wake up event will typically be an interrupt triggered by one of the SoC peripheral modules such as a SysTick, RTC, counter, or GPIO. Depending on the power mode entered, only some SoC peripheral modules may be active and can be used as a wake up source.

The following diagram describes system power management:
4.17. Power Management
Some handful examples using different power management features:

- samples/boards/stm32/power_mgmt/blinky/
- samples/boards/nrf/system_off/
- samples/boards/esp32/deep_sleep/
- samples/subsys/pm/device_pm/
- tests/subsys/pm/power_mgmt/
- tests/subsys/pm/power_mgmt_soc/
- tests/subsys/pm/power_states_api/

### Power States

The power management subsystem contains a set of states based on power consumption and context retention.

The list of available power states is defined by \texttt{pm\_state}. In general power states with higher indexes will offer greater power savings and have higher wake latencies.

### Power Management Policies

The power management subsystem supports the following power management policies:

- Residency based
- Application defined

The policy manager is responsible for informing the power subsystem which power state the system should transition to based on states defined by the platform and other constraints such as a list of allowed states.

More details on the states definition can be found in the \texttt{zephyr,power-state} binding documentation.

#### Residency

The power management system enters the power state which offers the highest power savings, and with a minimum residency value (see \texttt{zephyr,power-state}) less than or equal to the scheduled system idle time duration.

This policy also accounts for the time necessary to become active again. The core logic used by this policy to select the best power state is:

```c
if (time_to_next_scheduled_event >= (state.min_residency_us + state.exit_latency))) {
    return state
}
```

#### Application

The application defines the power management policy by implementing the \texttt{pm\_policy\_next\_state()} function. In this policy the application is free to decide which power state the system should transition to based on the remaining time for the next scheduled timeout.

An example of an application that defines its own policy can be found in \texttt{tests/subsys/pm/power_mgmt/}.

#### Policy and Power States

The power management subsystem allows different Zephyr components and applications to configure the policy manager to block system from transitioning into certain power states. This can be used by devices when executing tasks in background to prevent the system from going to a specific state where it would lose context.
4.17.3 Device Power Management

Introduction

Device power management (PM) on Zephyr is a feature that enables devices to save energy when they are not being used. This feature can be enabled by setting CONFIG_PM_DEVICE to y. When this option is selected, device drivers implementing power management will be able to take advantage of the device power management subsystem.

Zephyr supports two types of device power management:

- **Device Runtime Power Management**
- **System Power Management**

Device Runtime Power Management

In this method, the application or any component that deals with devices directly and has the best knowledge of their use, performs the device power management. This saves power if some devices that are not in use can be turned off or put in power saving mode. This method allows saving power even when the CPU is active. The components that use the devices need to be power aware and should be able to make decisions related to managing device power.

When using this type of device power management, the kernel can change CPU power states quickly when pm_system_suspend() gets called. This is because it does not need to spend time doing device power management if the devices are already put in the appropriate power state by the application or component managing the devices.

For more information, see *Device Runtime Power Management*.

System Power Management

When using this type, device power management is mostly done inside pm_system_suspend() along with entering a CPU or SOC power state.

If a decision to enter a CPU lower power state is made, the power management subsystem will suspend devices before changing state. The subsystem takes care of suspending devices following their initialization order, ensuring that possible dependencies between them are satisfied. As soon as the CPU wakes up from a sleep state, devices are resumed in the opposite order that they were suspended.

**Note:** When using *System Power Management*, device transitions can be run from the idle thread. As functions in this context cannot block, transitions that intend to use blocking APIs **must** check whether they can do so with k_can_yield().

This type of device power management can be useful when the application is not power aware and does not implement runtime device power management. Though, *Device Runtime Power Management* is the preferred option for device power management.

**Note:** When using this type of device power management, the CPU will only enter a low power state only if no device is in the middle of a hardware transaction that cannot be interrupted.

**Note:** This type of device power management is disabled when CONFIG_PM_DEVICE_RUNTIME_EXCLUSIVE is set to y (that is the default value when CONFIG_PM_DEVICE_RUNTIME is enabled).
**Note:** Devices are suspended only when the last active core is entering a low power state and devices are resumed by the first core that becomes active.

### Device Power Management States

The power management subsystem defines device states in `pm_device_state`. This type is used to track power states of a particular device. It is important to emphasize that, although the state is tracked by the subsystem, it is the responsibility of each device driver to handle device actions(`pm_device_action`) which change device state.

Each `pm_device_action` have a direct an unambiguous relationship with a `pm_device_state`.

![Device Actions x States Diagram](image)

As mentioned above, device drivers do not directly change between these states. This is entirely done by the power management subsystem. Instead, drivers are responsible for implementing any hardware-specific tasks needed to handle state changes.

### Device Model with Power Management Support

Drivers initialize devices using macros. See *Device Driver Model* for details on how these macros are used. A driver which implements device power management support must provide these macros with arguments that describe its power management implementation.

Use `PM_DEVICE_DEFINE` or `PM_DEVICE_DT_DEFINE` to define the power management resources required by a driver. These macros allocate the driver-specific state which is required by the power management subsystem.

Drivers can use `PM_DEVICE_GET` or `PM_DEVICE_DT_GET` to get a pointer to this state. These pointers should be passed to `DEVICE_DEFINE` or `DEVICE_DT_DEFINE` to initialize the power management field in each `device`.

Here is some example code showing how to implement device power management support in a device driver.
```c
#define DT_DRV_COMPAT dummy_device

static int dummy_driver_pm_action(const struct device *dev,
                              enum pm_device_action *action)
{
    switch (action) {
        case PM_DEVICE_ACTION_SUSPEND:
            /* suspend the device */
            ...
            break;
        case PM_DEVICE_ACTION_RESUME:
            /* resume the device */
            ...
            break;
        case PM_DEVICE_ACTION_TURN_ON:
            /*
             * powered on the device, used when the power
             * domain this device belongs is resumed.
             */
            ...
            break;
        case PM_DEVICE_ACTION_TURN_OFF:
            /*
             * power off the device, used when the power
             * domain this device belongs is suspended.
             */
            ...
            break;
        default:
            return -ENOTSUP;
    }
    return 0;
}

PM_DEVICE_DT_INST_DEFINE(0, dummy_driver_pm_action);

DEVICE_DT_INST_DEFINE(0, &dummy_init,
    PM_DEVICE_DT_INST_GET(0), NULL, NULL, POST_KERNEL,
    CONFIG_KERNEL_INIT_PRIORITY_DEFAULT, NULL);
```

**Busy Status Indication**

When the system is idle and the SoC is going to sleep, the power management subsystem can suspend
devices, as described in *System Power Management*. This can cause device hardware to lose some states.
Suspending a device which is in the middle of a hardware transaction, such as writing to a flash memory,
may lead to undefined behavior or inconsistent states. This API guards such transactions by indicating
to the kernel that the device is in the middle of an operation and should not be suspended.

When `pm_device_busy_set()` is called, the device is marked as busy and the system will not do power
management on it. After the device is no longer doing an operation and can be suspended, it should call
`pm_device_busy_clear()`.
Wakeup capability

Some devices are capable of waking the system up from a sleep state. When a device has such capability, applications can enable or disable this feature on a device dynamically using `pm_device_wakeup_enable()`.

This property can be set on device declaring the property `wakeup-source` in the device node in device-tree. For example, this devicetree fragment sets the `gpio0` device as a “wakeup” source:

```markdown
gpio0: gpio@40022000 {
    compatible = "ti,cc13xx-cc26xx-gpio";
    reg = <0x40022000 0x400>
    interrupts = <0 0>
    status = "disabled"
    label = "GPIO_0"
    gpio-controller;
    wakeup-source;
    #gpio-cells = <2>
};
```

By default, “wakeup” capable devices do not have this functionality enabled during the device initialization. Applications can enable this functionality later calling `pm_device_wakeup_enable()`.

Note: This property is only used by the system power management to identify devices that should not be suspended. It is responsibility of driver or the application to do any additional configuration required by the device to support it.

Power Domain

Power domain on Zephyr is represented as a regular device. The power management subsystem ensures that a domain is resumed before and suspended after devices using it. For more details, see Power Domain.

4.17.4 Device Runtime Power Management

Introduction

The device runtime power management (PM) framework is an active power management mechanism which reduces the overall system power consumption by suspending the devices which are idle or not used independently of the system state. It can be enabled by setting `CONFIG_PM_DEVICE_RUNTIME`. In this model the device driver is responsible to indicate when it needs the device and when it does not. This information is used to determine when to suspend or resume a device based on usage count.

When device runtime power management is enabled on a device, its state will be initially set to a `PM_DEVICE_STATE_SUSPENDED` indicating it is not used. On the first device request, it will be resumed and so put into the `PM_DEVICE_STATE_ACTIVE` state. The device will remain in this state until it is no longer used. At this point, the device will be suspended until the next device request. If the suspension is performed synchronously the device will be immediately put into the `PM_DEVICE_STATE_SUSPENDED` state, whereas if it is performed asynchronously, it will be put into the `PM_DEVICE_STATE_SUSPENDING` state first and then into the `PM_DEVICE_STATE_SUSPENDED` state when the action is run.

For devices on a power domain (via the devicetree ‘power-domain' property), device runtime power management automatically attempts to request and release the dependent domain in response to `pm_device_runtime_get()` and `pm_device_runtime_put()` calls on the child device.
For the previous to automatically control the power domain state, device runtime PM must be enabled on the power domain device (either through the `zephyr:pm-device-runtime-auto` devicetree property or `pm_device_runtime_enable()`).

![Device states and transitions](image)

**PM_DEVICE_STATE_SUSPENDED**

**PM_DEVICE_STATE_SUSPENDING**

**PM_DEVICE_STATE_ACTIVE**

**Fig. 4: Device states and transitions**

The device runtime power management framework has been designed to minimize devices power consumption with minimal application work. Device drivers are responsible for indicating when they need the device to be operational and when they do not. Therefore, applications can not manually suspend or resume a device. An application can, however, decide when to disable or enable runtime power management for a device. This can be useful, for example, if an application wants a particular device to be always active.

**Design principles**

When runtime PM is enabled on a device it will no longer be resumed or suspended during system power transitions. Instead, the device is fully responsible to indicate when it needs a device and when it does not. The device runtime PM API uses reference counting to keep track of device's usage. This allows the API to determine when a device needs to be resumed or suspended. The API uses the `get` and `put` terminology to indicate when a device is needed or not, respectively. This mechanism plays a key role when we account for device dependencies. For example, if a bus device is used by multiple sensors, we can keep the bus active until the last sensor has finished using it.

**Note:** As of today, the device runtime power management API does not manage device dependencies. This effectively means that, if a device depends on other devices to operate (e.g. a sensor may depend on a bus device), the bus will be resumed and suspended on every transaction. In general, it is more efficient to keep parent devices active when their children are used, since the children may perform multiple transactions in a short period of time. Until this feature is added, devices can manually `get` or `put` their dependencies.

The `pm_device_runtime_get()` function can be used by a device driver to indicate it needs the device to be active or operational. This function will increase device usage count and resume the device if necessary. Similarly, the `pm_device_runtime_put()` function can be used to indicate that the device is...
no longer needed. This function will decrease the device usage count and suspend the device if necessary. It is worth to note that in both cases, the operation is carried out synchronously. The sequence diagram shown below illustrates how a device can use this API and the expected sequence of events.

The synchronous model is as simple as it gets. However, it may introduce unnecessary delays since the application will not get the operation result until the device is suspended (in case device is no longer used). It will likely not be a problem if the operation is fast, e.g. a register toggle. However, the situation will not be the same if suspension involves sending packets through a slow bus. For this reason the device drivers can also make use of the `pm_device_runtime_put_async()` function. This function will schedule the suspend operation, again, if device is no longer used. The suspension will then be carried out when the system work queue gets the chance to run. The sequence diagram shown below illustrates this scenario.

**Implementation guidelines**

In a first place, a device driver needs to implement the PM action callback used by the PM subsystem to suspend or resume devices.
Fig. 6: Asynchronous operation on a single device
The PM action callback calls are serialized by the PM subsystem, therefore, no special synchronization is required.

To enable device runtime power management on a device, the driver needs to call `pm_device_runtime_enable()` at initialization time. Note that this function will suspend the device if its state is `PM_DEVICE_STATE_ACTIVE`. In case the device is physically suspended, the init function should call `pm_device_init_suspended()` before calling `pm_device_runtime_enable()`.

```
/* device driver initialization function */
static int mydev_init(const struct device *dev)
{
    int ret;
    ...

    /* OPTIONAL: mark device as suspended if it is physically suspended */
    pm_device_init_suspended(dev);

    /* enable device runtime power management */
    ret = pm_device_runtime_enable(dev);
    if ((ret < 0) && (ret != -ENOSYS)) {
        return ret;
    }
}
```

Device runtime power management can also be automatically enabled on a device instance by adding the `zephyr.pm-device-runtime-auto` flag onto the corresponding devicetree node. If enabled, `pm_device_runtime_enable()` is called immediately after the init function of the device runs and returns successfully.

```
foo {
    /* ... */
    zephyr.pm-device-runtime-auto;
};
```

Assuming an example device driver that implements an operation API call, the `get` and `put` operations could be carried out as follows:

```
static int mydev_operation(const struct device *dev)
{
    int ret;

    /* "get" device (increases usage count, resumes device if suspended) */
    ret = pm_device_runtime_get(dev);
```
if (ret < 0) {
    return ret;
}

/* do something with the device */
...

/* "put" device (decreases usage count, suspends device if no more users) */
return pm_device_runtime_put(dev);

In case the suspend operation is slow, the device driver can use the asynchronous API:

```c
static int mydev_operation(const struct device *dev)
{
    int ret;

    /* "get" device (increases usage count, resumes device if suspended) */
    ret = pm_device_runtime_get(dev);
    if (ret < 0) {
        return ret;
    }

    /* do something with the device */
    ...

    /* "put" device (decreases usage count, schedule suspend if no more users) */
    return pm_device_runtime_put_async(dev);
}
```

4.17.5 Power Domain

Introduction

The Zephyr power domain abstraction is designed to support groupings of devices powered by a common source to be notified of power source state changes in a generic fashion. Application code that is using device A does not need to know that device B is on the same power domain and should also be configured into a low power state.

Power domains are optional on Zephyr, to enable this feature the option CONFIG_PM_DEVICE_POWER_DOMAIN has to be set.

When a power domain turns itself on or off, it is the responsibility of the power domain to notify all devices using it through their power management callback called with PM_DEVICE_ACTION_TURN_ON or PM_DEVICE_ACTION_TURN_OFF respectively. This work flow is illustrated in the diagram below.

**Internal Power Domains**  Most of the devices in an SoC have independent power control that can be turned on or off to reduce power consumption. But there is a significant amount of static current leakage that can't be controlled only using device power management. To solve this problem, SoCs normally are divided into several regions grouping devices that are generally used together, so that an unused region can be completely powered off to eliminate this leakage. These regions are called “power domains”, can be present in a hierarchy and can be nested.

**External Power Domains**  Devices external to a SoC can be powered from sources other than the main power source of the SoC. These external sources are typically a switch, a regulator, or a dedicated power
IC. Multiple devices can be powered from the same source, and this grouping of devices is typically called a "power domain".

Placing devices on power domains can be done for a variety of reasons, including to enable devices with high power consumption in low power mode to be completely turned off when not in use.

**Implementation guidelines**

In a first place, a device that acts as a power domain needs to declare compatible with `power-domain`.

Taking the **Power domain work flow** as example, the following code defines a domain called `gpio_domain`.

```c
gpio_domain: gpio_domain@4 {
    compatible = "power-domain";
    ...
};
```

A power domain needs to implement the PM action callback used by the PM subsystem to turn devices on and off.

```c
static int mydomain_pm_action(const struct device *dev,
    enum pm_device_action *action)
{
    switch (action) {
    case PM_DEVICE_ACTION_RESUME:
        /* resume the domain */
        ...
        /* notify children domain is now powered */
        pm_device_children_action_run(dev, PM_DEVICE_ACTION_TURN_ON, NULL);
        break;
    case PM_DEVICE_ACTION_SUSPEND:
        /* notify children domain is going down */
        pm_device_children_action_run(dev, PM_DEVICE_ACTION_TURN_OFF, NULL);
        /* suspend the domain */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_ON:
        /* turn on the domain (e.g. setup control pins to disabled) */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_OFF:
        /* turn off the domain (e.g. reset control pins to default state) */
```

(continues on next page)
Devices belonging to this device can be declared referring it in the power-domain node's property. The example below declares devices gpio0 and gpio1 belonging to domain gpio_domain:

```c
&gpio0 {
    compatible = "zephyr,gpio-emul";
    gpio-controller;
    power-domain = <&gpio_domain>;
};

&gpio1 {
    compatible = "zephyr,gpio-emul";
    gpio-controller;
    power-domain = <&gpio_domain>;
};
```

All devices under a domain will be notified when the domain changes state. These notifications are sent as actions in the device PM action callback and can be used by them to do any additional work required. They can safely be ignored though.

```c
static int mydev_pm_action(const struct device *dev,
        enum pm_device_action *action)
{
    switch (action) {
        case PM_DEVICE_ACTION_SUSPEND:
            /* suspend the device */
            ... break;
        case PM_DEVICE_ACTION_RESUME:
            /* resume the device */
            ... break;
        case PM_DEVICE_ACTION_TURN_ON:
            /* configure the device into low power mode */
            ... break;
        case PM_DEVICE_ACTION_TURN_OFF:
            /* prepare the device for power down */
            ... break;
        default:
            return -ENOTSUP;
    }

    return 0;
}
```

**Note:** It is responsibility of driver or the application to set the domain as “wakeup” source if a device
depending on it is used as “wakeup” source.

4.17.6 Power Management

System PM APIs

*group* subsys_pm_sys

System Power Management API.

*Functions*

`bool pm_state_force(uint8_t cpu, const struct pm_state_info *info)`

Force usage of given power state.

This function overrides decision made by PM policy forcing usage of given power state upon next entry of the idle thread.

**Note:** This function can only run in thread context

**Parameters**

- `cpu` – CPU index.
- `info` – Power state which should be used in the ongoing suspend operation.

`void pm_notifier_register(struct pm_notifier *notifier)`

Register a power management notifier.

Register the given notifier from the power management notification list.

**Parameters**

- `notifier` – `pm_notifier` object to be registered.

`int pm_notifier_unregister(struct pm_notifier *notifier)`

Unregister a power management notifier.

Remove the given notifier from the power management notification list. After that this object callbacks will not be called.

**Parameters**

- `notifier` – `pm_notifier` object to be unregistered.

**Returns**

0 if the notifier was successfully removed, a negative value otherwise.

`const struct pm_state_info *pm_state_next_get(uint8_t cpu)`

Gets the next power state that will be used.

This function returns the next power state that will be used by the SoC.

**Parameters**

- `cpu` – CPU index.

**Returns**

next `pm_state_info` that will be used
struct pm_notifier

#include <pm.h>  Power management notifier struct.

This struct contains callbacks that are called when the target enters and exits power states.
As currently implemented the entry callback is invoked when transitioning from
PM_STATE_ACTIVE to another state, and the exit callback is invoked when transitioning from
a non-active state to PM_STATE_ACTIVE. This behavior may change in the future.

Note: These callbacks can be called from the ISR of the event that caused the kernel exit
from idling.

Note: It is not allowed to call pm_notifier_unregister or pm_notifier_register from these call-
backs because they are called with the spin locked in those functions.

Public Members

void (*state_entry)(enum pm_state state)
  Application defined function for doing any target specific operations for power state entry.

void (*state_exit)(enum pm_state state)
  Application defined function for doing any target specific operations for power state exit.

States

group subsys_pm_states
  System Power Management States.

Defines

PM_STATE_INFO_DT_INIT(node_id)
  Initializer for struct pm_state_info given a DT node identifier with zephyr,power-state compatible.
  Parameters
    • node_id – A node identifier with compatible zephyr,power-state

PM_STATE_DT_INIT(node_id)
  Initializer for enum pm_state given a DT node identifier with zephyr,power-state compatible.
  Parameters
    • node_id – A node identifier with compatible zephyr,power-state

DT_NUM_CPU_POWER_STATES(node_id)
  Obtain number of CPU power states supported and enabled by the given CPU node identifier.
  Parameters
    • node_id – A CPU node identifier.

  Returns
    Number of supported and enabled CPU power states.
PM_STATE_INFO_LIST_FROM_DT_CPU(node_id)

Initialize an array of struct pm_state_info with information from all the states present and enabled in the given CPU node identifier.

Example devicetree fragment:

```c
const struct pm_state_info states[] =
PM_STATE_INFO_LIST_FROM_DT_CPU(DT_NODELABEL(cpu0));
```

**Parameters**

- **node_id** – A CPU node identifier.

PM_STATE_LIST_FROM_DT_CPU(node_id)

Initialize an array of struct pm_state with information from all the states present and enabled in the given CPU node identifier.

Example devicetree fragment:

```c
const struct pm_state_info states[] =
PM_STATE_LIST_FROM_DT_CPU(DT_NODELABEL(cpu0));
```
Example usage:

```c
const enum pm_state states[] = PM_STATE_LIST_FROM_DT_CPU(DT_NODELABEL(cpu0));
```

### Parameters

- **node_id** – A CPU node identifier.

### Enums

**enum pm_state**

Power management state.

**Values:**

- **enumerator PM_STATE_ACTIVE**
  
  Runtime active state.
  
  The system is fully powered and active.

  **Note:** This state is correlated with ACPI G0/S0 state

- **enumerator PM_STATE_RUNTIME_IDLE**
  
  Runtime idle state.
  
  Runtime idle is a system sleep state in which all of the cores enter deepest possible idle state and wait for interrupts, no requirements for the devices, leaving them at the states where they are.

  **Note:** This state is correlated with ACPI S0ix state

- **enumerator PM_STATE_SUSPEND_TO_IDLE**
  
  Suspend to idle state.
  
  The system goes through a normal platform suspend where it puts all of the cores in deepest possible idle state and may puts peripherals into low-power states. No operating state is lost (ie. the cpu core does not lose execution context), so the system can go back to where it left off easily enough.

  **Note:** This state is correlated with ACPI S1 state
enumerator PM_STATE_STANDBY

Standby state.

In addition to putting peripherals into low-power states all non-boot CPUs are powered off. It should allow more energy to be saved relative to suspend to idle, but the resume latency will generally be greater than for that state. But it should be the same state with suspend to idle state on uniprocessor system.

**Note:** This state is correlated with ACPI S2 state

enumerator PM_STATE_SUSPEND_TO_RAM

Suspend to ram state.

This state offers significant energy savings by powering off as much of the system as possible, where memory should be placed into the self-refresh mode to retain its contents. The state of devices and CPUs is saved and held in memory, and it may require some boot-strapping code in ROM to resume the system from it.

**Note:** This state is correlated with ACPI S3 state

enumerator PM_STATE_SUSPEND_TO_DISK

Suspend to disk state.

This state offers significant energy savings by powering off as much of the system as possible, including the memory. The contents of memory are written to disk or other non-volatile storage, and on resume it’s read back into memory with the help of boot-strapping code, restores the system to the same point of execution where it went to suspend to disk.

**Note:** This state is correlated with ACPI S4 state

enumerator PM_STATE_SOFT_OFF

Soft off state.

This state consumes a minimal amount of power and requires a large latency in order to return to runtime active state. The contents of system(CPU and memory) will not be preserved, so the system will be restarted as if from initial power-up and kernel boot.

**Note:** This state is correlated with ACPI G2/S5 state

enumerator PM_STATE_COUNT

Number of power management states (internal use)

**Functions**

```c
uint8_t pm_state_cpu_get_all(uint8_t cpu, const struct pm_state_info **states)
```

Obtain information about all supported states by a CPU.

**Parameters**

- `cpu` – CPU index.
states – Where to store the list of supported states.

Returns
Number of supported states.

```c
#include <state.h> Information about a power management state.
```

Public Members

```c
struct pm_state_info
```

```c
uint8_t substate_id
```

Some platforms have multiple states that map to one Zephyr power state. This property allows the platform to distinguish them. e.g:

```c
power-states {
  state0: state0 {
    compatible = "zephyr,power-state";
    power-state-name = "suspend-to-idle";
    substate-id = <1>;
    min-residency-us = <10000>;
    exit-latency-us = <100>;
  }
  state1: state1 {
    compatible = "zephyr,power-state";
    power-state-name = "suspend-to-idle";
    substate-id = <2>;
    min-residency-us = <20000>;
    exit-latency-us = <200>;
  }
}
```

```c
uint32_t min_residency_us
```

Minimum residency duration in microseconds. It is the minimum time for a given idle state to be worthwhile energywise.

**Note:** 0 means that this property is not available for this state.

```c
uint32_t exit_latency_us
```

Worst case latency in microseconds required to exit the idle state.

**Note:** 0 means that this property is not available for this state.

Policy

```c
group subsys_pm_sys_policy
```

System Power Management Policy API.

**Defines**
PM_ALL_SUBSTATES
Special value for ‘all substates’.

Typedefs

typedef void (*pm_policy_latency_changed_cb_t)(int32_t latency)
Callback to notify when maximum latency changes.

Param latency
New maximum latency. Positive value represents latency in microseconds. SYS_FOREVER_US value lifts the latency constraint. Other values are forbidden.

Functions

void pm_policy_state_lock_get(enum pm_state state, uint8_t substate_id)
Increase a power state lock counter.

A power state will not be allowed on the first call of pm_policy_state_lock_get(). Subsequent calls will just increase a reference count, thus meaning this API can be safely used concurrently. A state will be allowed again after pm_policy_state_lock_put() is called as many times as pm_policy_state_lock_get().

Note that the PM_STATE_ACTIVE state is always allowed, so calling this API with PM_STATE_ACTIVE will have no effect.

See also:

pm_policy_state_lock_put()

Parameters

• state – Power state.
• substate_id – Power substate ID. Use PM_ALL_SUBSTATES to affect all the substates in the given power state.

void pm_policy_state_lock_put(enum pm_state state, uint8_t substate_id)
Decrease a power state lock counter.

See also:

pm_policy_state_lock_get()

Parameters

• state – Power state.
• substate_id – Power substate ID. Use PM_ALL_SUBSTATES to affect all the substates in the given power state.

bool pm_policy_state_lock_is_active(enum pm_state state, uint8_t substate_id)
Check if a power state lock is active (not allowed).

Parameters

• state – Power state.
• substate_id – Power substate ID. Use PM_ALL_SUBSTATES to affect all the
substates in the given power state.

Return values
• true – if power state lock is active.
• false – if power state lock is not active.

void pm_policy_latency_request_add(struct pm_policy_latency_request *req, uint32_t value_us)

Add a new latency requirement.
The system will not enter any power state that would make the system to exceed the given latency value.

Parameters
• req – Latency request.
• value_us – Maximum allowed latency in microseconds.

void pm_policy_latency_request_update(struct pm_policy_latency_request *req, uint32_t value_us)

Update a latency requirement.

Parameters
• req – Latency request.
• value_us – New maximum allowed latency in microseconds.

void pm_policy_latency_request_remove(struct pm_policy_latency_request *req)

Remove a latency requirement.

Parameters
• req – Latency request.

void pm_policy_latency_changed_subscribe(struct pm_policy_latency_subscription *req,
  pm_policy_latency_changed_cb_t cb)

Subscribe to maximum latency changes.

Parameters
• req – Subscription request.
• cb – Callback function (NULL to disable).

void pm_policy_latency_changed_unsubscribe(struct pm_policy_latency_subscription *req)

Unsubscribe to maximum latency changes.

Parameters
• req – Subscription request.

void pm_policy_event_register(struct pm_policy_event *evt, uint32_t time_us)

Register an event.

Events in the power-management policy context are defined as any source that will wake up the system at a known time in the future. By registering such event, the policy manager will be able to decide whether certain power states are worth entering or not.

See also:

pm_policy_event_unregister
Note: It is mandatory to unregister events once they have happened by using `pm_policy_event_unregister()`. Not doing so is an API contract violation, because the system would continue to consider them as valid events in the far future, that is, after the cycle counter rollover.

### Parameters

- `evt` - Event.
- `time_us` - When the event will occur, in microseconds from now.

```c
void pm_policy_event_update(struct pm_policy_event *evt, uint32_t time_us)
```

Update an event.

See also:

- `pm_policy_event_register`

### Parameters

- `evt` - Event.
- `time_us` - When the event will occur, in microseconds from now.

```c
void pm_policy_event_unregister(struct pm_policy_event *evt)
```

Unregister an event.

See also:

- `pm_policy_event_register`

### Parameters

- `evt` - Event.

```c
struct pm_policy_latency_subscription
#include <policy.h> Latency change subscription.
```

Note: All fields in this structure are meant for private usage.

```c
struct pm_policy_latency_request
#include <policy.h> Latency request.
```

Note: All fields in this structure are meant for private usage.

```c
struct pm_policy_event
#include <policy.h> Event.
```

Note: All fields in this structure are meant for private usage.
Hooks

**group subsys_pm_sys_hooks**

System Power Management Hooks.

Functions

```c
void pm_state_set(enum pm_state state, uint8_t substate_id)
```

Put processor into a power state.

This function implements the SoC specific details necessary to put the processor into available power states.

**Parameters**

- **state** – Power state.
- **substate_id** – Power substate id.

```c
void pm_state_exit_post_ops(enum pm_state state, uint8_t substate_id)
```

Do any SoC or architecture specific post ops after sleep state exits.

This function is a place holder to do any operations that may be needed to be done after sleep state exits. Currently it enables interrupts after resuming from sleep state. In future, the enabling of interrupts may be moved into the kernel.

**Parameters**

- **state** – Power state.
- **substate_id** – Power substate id.

Device PM APIs

**group subsys_pm_device**

Device Power Management API.

Defines

```c
PM_DEVICE_DEFINE(dev_id, pm_action_cb)
```

Define device PM resources for the given device name.

**See also:**

`PM_DEVICE_DT_DEFINE, PM_DEVICE_DT_INST_DEFINE`

**Note:** This macro is a no-op if CONFIG_PM_DEVICE is not enabled.

**Parameters**

- **dev_id** – Device id.
- **pm_action_cb** – PM control callback.
PM_DEVICE_DT_DEFINE(node_id, pm_action_cb)
Define device PM resources for the given node identifier.

See also:
PM_DEVICE_DT_INST_DEFINE, PM_DEVICE_DEFINE

Note: This macro is a no-op if CONFIG_PM_DEVICE is not enabled.

Parameters
• node_id – Node identifier.
• pm_action_cb – PM control callback.

PM_DEVICE_DT_INST_DEFINE(idx, pm_action_cb)
Define device PM resources for the given instance.

See also:
PM_DEVICE_DT_DEFINE, PM_DEVICE_DEFINE

Note: This macro is a no-op if CONFIG_PM_DEVICE is not enabled.

Parameters
• idx – Instance index.
• pm_action_cb – PM control callback.

PM_DEVICE_GET(dev_id)
Obtain a reference to the device PM resources for the given device.

Parameters
• dev_id – Device id.

Returns
Reference to the device PM resources (NULL if device CONFIG_PM_DEVICE is disabled).

PM_DEVICE_DT_GET(node_id)
Obtain a reference to the device PM resources for the given node.

Parameters
• node_id – Node identifier.

Returns
Reference to the device PM resources (NULL if device CONFIG_PM_DEVICE is disabled).

PM_DEVICE_DT_INST_GET(idx)
Obtain a reference to the device PM resources for the given instance.

Parameters
• idx – Instance index.
Returns
Reference to the device PM resources (NULL if device CONFIG_PM_DEVICE is disabled).

Typedefs

typedef int (*pm_device_action_cb_t)(const struct device *dev, enum pm_device_action action)
Device PM action callback.

Param dev
Device instance.

Param action
Requested action.

Retval 0
If successful.

Retval -ENOTSUP
If the requested action is not supported.

Retval Errno
Other negative errno on failure.

typedef bool (*pm_device_action_failed_cb_t)(const struct device *dev, int err)
Device PM action failed callback.

Param dev
Device that failed the action.

Param err
Return code of action failure.

Return
True to continue iteration, false to halt iteration.

Enums

enum pm_device_state
Device power states.

Values:

enumerator PM_DEVICE_STATE_ACTIVE
Device is in active or regular state.

enumerator PM_DEVICE_STATE_SUSPENDED
Device is suspended.

Note: Device context may be lost.

enumerator PM_DEVICE_STATE_SUSPENDING
Device is being suspended.
enumerator PM_DEVICE_STATE_OFF
    Device is turned off (power removed).

    **Note:** Device context is lost.

enum pm_device_action
    Device PM actions.

**Values:**

enumerator PM_DEVICE_ACTION_SUSPEND
    Suspend.

enumerator PM_DEVICE_ACTION_RESUME
    Resume.

enumerator PM_DEVICE_ACTION_TURN_OFF
    Turn off.

    **Note:** Action triggered only by a power domain.

enumerator PM_DEVICE_ACTION_TURN_ON
    Turn on.

    **Note:** Action triggered only by a power domain.

**Functions**

const char *pm_device_state_str(enum pm_device_state state)
    Get name of device PM state.

**Parameters**

- `state` – State id which name should be returned

int pm_device_action_run(const struct device *dev, enum pm_device_action action)
    Run a pm action on a device.

    This function calls the device PM control callback so that the device does the necessary operations to execute the given action.

**Parameters**

- `dev` – Device instance.
- `action` – Device pm action.

**Return values**

- 0 – If successful.
- -ENOTSUP – If requested state is not supported.
- -EALREADY – If device is already at the requested state.
-EBUSY – If device is changing its state.
-ENOSYS – If device does not support PM.
-EPERM – If device has power state locked.
Errno – Other negative errno on failure.

`void pm_device_children_action_run(const struct device *dev, enum pm_device_action action, pm_device_action_failed_cb_t failure_cb)`

Run a pm action on all children of a device.
This function calls all child devices PM control callback so that the device does the necessary
operations to execute the given action.

**Parameters**
- `dev` – Device instance.
- `action` – Device pm action.
- `failure_cb` – Function to call if a child fails the action, can be NULL.

`int pm_device_state_get(const struct device *dev, enum pm_device_state *state)`

Obtain the power state of a device.

**Parameters**
- `dev` – Device instance.
- `state` – Pointer where device power state will be stored.

**Return values**
- 0 – If successful.
- -ENOSYS – If device does not implement power management.

`static inline void pm_device_init_suspended(const struct device *dev)`

Initialize a device state to `PM_DEVICE_STATE_SUSPENDED`.

By default device state is initialized to `PM_DEVICE_STATE_ACTIVE`. However in order to save
power some drivers may choose to only initialize the device to the suspended state, or actively
put the device into the suspended state. This function can therefore be used to notify the PM
subsystem that the device is in `PM_DEVICE_STATE_SUSPENDED` instead of the default.

**Parameters**
- `dev` – Device instance.

`static inline void pm_device_init_off(const struct device *dev)`

Initialize a device state to `PM_DEVICE_STATE_OFF`.

By default device state is initialized to `PM_DEVICE_STATE_ACTIVE`. In general, this makes
sense because the device initialization function will resume and configure a device, leaving
it operational. However, when power domains are enabled, the device may be connected to
a switchable power source, in which case it won’t be powered at boot. This function can
therefore be used to notify the PM subsystem that the device is in `PM_DEVICE_STATE_OFF`
instead of the default.

**Parameters**
- `dev` – Device instance.

`void pm_device_busy_set(const struct device *dev)`

Mark a device as busy.

Devices marked as busy will not be suspended when the system goes into low-power states.
This can be useful if, for example, the device is in the middle of a transaction.
See also:

**pm_device_busy_clear()**

Parameters

- **dev** – Device instance.

```c
void pm_device_busy_clear(const struct device *dev)
```

Clear a device busy status.

See also:

**pm_device_busy_set()**

Parameters

- **dev** – Device instance.

```c
bool pm_device_is_any_busy(void)
```

Check if any device is busy.

**Return values**

- **false** – If no device is busy
- **true** – If one or more devices are busy

```c
bool pm_device_is_busy(const struct device *dev)
```

Check if a device is busy.

**Parameters**

- **dev** – Device instance.

**Return values**

- **false** – If the device is not busy
- **true** – If the device is busy

```c
bool pm_device_wakeup_enable(const struct device *dev, bool enable)
```

Enable or disable a device as a wake up source.

A device marked as a wake up source will not be suspended when the system goes into low-power modes, thus allowing to use it as a wake up source for the system.

**Parameters**

- **dev** – Device instance.
- **enable** – **true** to enable or **false** to disable

**Return values**

- **true** – If the wakeup source was successfully enabled.
- **false** – If the wakeup source was not successfully enabled.

```c
bool pm_device_wakeup_is_enabled(const struct device *dev)
```

Check if a device is enabled as a wake up source.

**Parameters**

- **dev** – Device instance.

**Return values**
• `true` – if the wakeup source is enabled.
• `false` – if the wakeup source is not enabled.

```c
bool pm_device_wakeup_is_capable(const struct device *dev)
```

Check if a device is wake up capable.

**Parameters**

• `dev` – Device instance.

**Return values**

• `true` – If the device is wake up capable.
• `false` – If the device is not wake up capable.

```c
void pm_device_state_lock(const struct device *dev)
```

Lock current device state.

This function locks the current device power state. Once locked the device power state will not be changed by system power management or device runtime power management until unlocked.

**See also:**

`pm_device_state_unlock`

**Note:** The given device should not have device runtime enabled.

```c
void pm_device_state_unlock(const struct device *dev)
```

Unlock the current device state.

Unlocks a previously locked device pm.

**See also:**

`pm_device_state_lock`

```c
bool pm_device_state_is_locked(const struct device *dev)
```

Check if the device pm is locked.

**Parameters**

• `dev` – Device instance.

**Return values**

• `true` – If device is locked.
• `false` – If device is not locked.
bool pm_device_on_power_domain(const struct device *dev)
Check if the device is on a switchable power domain.

Parameters
• dev – Device instance.

Return values
• true – If device is on a switchable power domain.
• false – If device is not on a switchable power domain.

int pm_device_power_domain_add(const struct device *dev, const struct device *domain)
Add a device to a power domain.
This function adds a device to a given power domain.

Parameters
• dev – Device to be added to the power domain.
• domain – Power domain.

Return values
• 0 – If successful.
• -EALREADY – If device is already part of the power domain.
• -ENOSYS – If the application was built without power domain support.
• -ENOSPC – If there is no space available in the power domain to add the device.

int pm_device_power_domain_remove(const struct device *dev, const struct device *domain)
Remove a device from a power domain.
This function removes a device from a given power domain.

Parameters
• dev – Device to be removed from the power domain.
• domain – Power domain.

Return values
• 0 – If successful.
• -ENOSYS – If the application was built without power domain support.
• -ENOENT – If device is not in the given domain.

bool pm_device_is_powered(const struct device *dev)
Check if the device is currently powered.

Parameters
• dev – Device instance.

Return values
• true – If device is currently powered, or is assumed to be powered (i.e. it does not support PM or is not under a PM domain)
• false – If device is not currently powered

int pm_device_driver_init(const struct device *dev, pm_device_action_cb_t action_cb)
Setup a device driver into the lowest valid power mode.
This helper function is intended to be called at the end of a driver init function to automatically setup the device into the lowest power mode. It assumes that the device has been configured as if it is in PM_DEVICE_STATE_OFF.
Parameters

- `dev` – Device instance.
- `action_cb` – Device PM control callback function.

Return values

- `0` – On success.
- `-errno` – Error code from `action_cb` on failure.

```c
struct pm_device
#include <device.h> Device PM info.
```

Public Members

```c
const struct device *dev
  Pointer to the device.

struct k_sem lock
  Lock to synchronize the get/put operations.

struct k_event event
  Event var to listen to the sync request events.

uint32_t usage
  Device usage count.

struct k_work_delayable work
  Work object for asynchronous calls.

enum pm_device_state state
  Device power state.

pm_device_action_cb_t action_cb
  Device PM action callback.
```

Device Runtime PM APIs

```c
group subsys_pm_device_runtime
  Device Runtime Power Management API.
```

Functions

```c
int pm_device_runtime_auto_enable(const struct device *dev)
  Automatically enable device runtime based on devicetree properties.
```

Note: Must not be called from application code. See the zephyr,pm-device-runtime-auto property in pm.yaml and z_sys_init_run_level.
Parameters
  • dev – Device instance.

Return values
  • 0 – If the device runtime PM is enabled successfully or it has not been requested for this device in devicetree.
  • -errno – Other negative errno, result of enabled device runtime PM.

int pm_device_runtime_enable(const struct device *dev)
Enable device runtime PM.
This function will enable runtime PM on the given device. If the device is in
PM_DEVICE_STATE_ACTIVE state, the device will be suspended.

See also:
  pm_device_init_suspended()

Function properties (list may not be complete)
  pre-kernel-ok

Parameters
  • dev – Device instance.

Return values
  • 0 – If the device runtime PM is enabled successfully.
  • -EPERM – If device has power state locked.
  • -ENOTSUP – If the device does not support PM.
  • -errno – Other negative errno, result of suspending the device.

int pm_device_runtime_disable(const struct device *dev)
Disable device runtime PM.
If the device is currently suspended it will be resumed.

Function properties (list may not be complete)
  pre-kernel-ok

Parameters
  • dev – Device instance.

Return values
  • 0 – If the device runtime PM is disabled successfully.
  • -ENOTSUP – If the device does not support PM.
  • -errno – Other negative errno, result of resuming the device.

int pm_device_runtime_get(const struct device *dev)
Resume a device based on usage count.
This function will resume the device if the device is suspended (usage count equal to 0). In case of a resume failure, usage count and device state will be left unchanged. In all other cases, usage count will be incremented.
If the device is still being suspended as a result of calling `pm_device_runtime_put_async()`, this function will wait for the operation to finish to then resume the device.

**Function properties (list may not be complete)**

* pre-kernel-ok

**Note:** It is safe to use this function in contexts where blocking is not allowed, e.g. ISR, provided the device PM implementation does not block.

**Parameters**

- `dev` – Device instance.

**Return values**

- 0 – If it succeeds. In case device runtime PM is not enabled or not available this function will be a no-op and will also return 0.
- -EWOULDBLOCK – If call would block but it is not allowed (e.g. in ISR).
- -errno – Other negative errno, result of the PM action callback.

```c
int pm_device_runtime_put(const struct device *dev)
```

Suspend a device based on usage count.

This function will suspend the device if the device is no longer required (usage count equal to 0). In case of suspend failure, usage count and device state will be left unchanged. In all other cases, usage count will be decremented (down to 0).

**See also:**

`pm_device_runtime_put_async()`

**Function properties (list may not be complete)**

* pre-kernel-ok

**Parameters**

- `dev` – Device instance.

**Return values**

- 0 – If it succeeds. In case device runtime PM is not enabled or not available this function will be a no-op and will also return 0.
- -EALREADY – If device is already suspended (can only happen if get/put calls are unbalanced).
- -errno – Other negative errno, result of the action callback.

```c
int pm_device_runtime_put_async(const struct device *dev)
```

Suspend a device based on usage count (asynchronously).

This function will schedule the device suspension if the device is no longer required (usage count equal to 0). In all other cases, usage count will be decremented (down to 0).

**See also:**

`pm_device_runtime_put()`

4.17. Power Management
Function properties (list may not be complete)
  pre-kernel-ok, async, isr-ok

Note: Asynchronous operations are not supported when in pre-kernel mode. In this case, the function will be blocking (equivalent to `pm_device_runtime_put()`).

Parameters
  • dev – Device instance.

Return values
  • 0 – If it succeeds. In case device runtime PM is not enabled or not available this function will be a no-op and will also return 0.
  • -EBUSY – If the device is busy.
  • -EALREADY – If device is already suspended (can only happen if get/put calls are unbalanced).

```
bool pm_device_runtime_is_enabled(const struct device *dev)
```
Check if device runtime is enabled for a given device.

See also:
  `pm_device_runtime_enable()`

Function properties (list may not be complete)
  pre-kernel-ok

Parameters
  • dev – Device instance.

Return values
  • true – If device has device runtime PM enabled.
  • false – If the device has device runtime PM disabled.

4.18 OS Abstraction

OS abstraction layers (OSAL) provide wrapper function APIs that encapsulate common system functions offered by any operating system. These APIs make it easier and quicker to develop for, and port code to multiple software and hardware platforms.

These sections describe the software and hardware abstraction layers supported by the Zephyr RTOS.

4.18.1 POSIX Support

The Portable Operating System Interface (POSIX) is a family of standards specified by the IEEE Computer Society for maintaining compatibility between operating systems. Zephyr implements a subset of the embedded profiles PSE51 and PSE52, and BSD Sockets API.

With the POSIX support available in Zephyr, an existing POSIX compliant application can be ported to run on the Zephyr kernel, and therefore leverage Zephyr features and functionality. Additionally, a library designed for use with POSIX threading compatible operating systems can be ported to Zephyr kernel based applications with minimal or no changes.
The POSIX API subset is an increasingly popular OSAL (operating system abstraction layer) for IoT and embedded applications, as can be seen in Zephyr, AWS:FreeRTOS, TI-RTOS, and NuttX.

Benefits of POSIX support in Zephyr include:

- Offering a familiar API to non-embedded programmers, especially from Linux
- Enabling reuse (portability) of existing libraries based on POSIX APIs
- Providing an efficient API subset appropriate for small (MCU) embedded systems

### System Overview

**Units of Functionality** The system profile is defined in terms of component profiles that specify Units of Functionality that can be combined to realize the application platform. A Unit of Functionality is a defined set of services which can be implemented. If implemented, the standard prescribes that all services in the Unit must be implemented.

A Minimal Realtime System Profile implementation must support the following Units of Functionality as defined in IEEE Std. 1003.1 (also referred to as POSIX.1-2017).

**Table 4: Units of Functionality**

4.18. OS Abstraction 933
Option Requirements  An implementation supporting the Minimal Realtime System Profile must support the POSIX.1 Option Requirements which are defined in the standard. Options Requirements are used for further sub-profiling within the units of functionality: they further define the functional behavior of the system service (normally adding extra functionality). Depending on the profile to which the POSIX implementation complies, parameters and/or the precise functionality of certain services may differ.

The following list shows the option requirements that are implemented in Zephyr.

<table>
<thead>
<tr>
<th>Requirements</th>
<th>Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>_POSIX_BARRIERS</td>
<td>yes</td>
</tr>
<tr>
<td>_POSIX_CLOCK_SELECTION</td>
<td></td>
</tr>
<tr>
<td>_POSIX_FSYNC</td>
<td></td>
</tr>
<tr>
<td>_POSIX_MEMLOCK</td>
<td></td>
</tr>
<tr>
<td>_POSIX_MEMLOCK_RANGE</td>
<td></td>
</tr>
<tr>
<td>_POSIX_MONOTONIC_CLOCK</td>
<td></td>
</tr>
<tr>
<td>_POSIX_NO_TRUNC</td>
<td></td>
</tr>
<tr>
<td>_POSIX_REALTIME_SIGNALS</td>
<td></td>
</tr>
<tr>
<td>_POSIX_SEMAPHORES</td>
<td>yes</td>
</tr>
<tr>
<td>_POSIX_SHARED_MEMORY_OBJECTS</td>
<td></td>
</tr>
<tr>
<td>_POSIX_SPIN_LOCKS</td>
<td>yes</td>
</tr>
<tr>
<td>_POSIX_SYNCHRONIZED_IO</td>
<td></td>
</tr>
<tr>
<td>_POSIX_THREAD_ATTR_STACKADDR</td>
<td></td>
</tr>
<tr>
<td>_POSIX_THREAD_ATTR_STACKSIZE</td>
<td>yes</td>
</tr>
<tr>
<td>_POSIX_THREAD_CPUETIME</td>
<td></td>
</tr>
<tr>
<td>_POSIX_THREAD_PRIO_INHERIT</td>
<td></td>
</tr>
<tr>
<td>_POSIX_THREAD_PRIO_PROTECT</td>
<td></td>
</tr>
<tr>
<td>_POSIX_THREAD_PRIORITY_SCHEDULING</td>
<td>yes</td>
</tr>
<tr>
<td>_POSIX_THREAD_SPORADIC_SERVER</td>
<td></td>
</tr>
<tr>
<td>_POSIX_TIMEOUTS</td>
<td></td>
</tr>
<tr>
<td>_POSIX_TIMERS</td>
<td></td>
</tr>
<tr>
<td>POSIX2_C_DEV</td>
<td></td>
</tr>
<tr>
<td>POSIX2_SW_DEV</td>
<td></td>
</tr>
</tbody>
</table>

Units of Functionality

This section describes the Units of Functionality (fixed sets of interfaces) which are implemented (partially or completely) in Zephyr. Please refer to the standard for a full description of each listed interface.

POSIX_THREADS_BASE  The basic assumption in this profile is that the system consists of a single (implicit) process with multiple threads. Therefore, the standard requires all basic thread services, except those related to multiple processes.

<table>
<thead>
<tr>
<th>API</th>
<th>Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>pthread_atfork()</td>
<td></td>
</tr>
<tr>
<td>pthread_attr_destroy()</td>
<td>yes</td>
</tr>
<tr>
<td>pthread_attr_getdetachstate()</td>
<td>yes</td>
</tr>
<tr>
<td>pthread_attr_getschedparam()</td>
<td>yes</td>
</tr>
<tr>
<td>pthread_attr_init()</td>
<td>yes</td>
</tr>
<tr>
<td>pthread_attr_setdetachstate()</td>
<td>yes</td>
</tr>
<tr>
<td>pthread_attr_setschedparam()</td>
<td>yes</td>
</tr>
</tbody>
</table>

continues on next page
The XSI_THREADS_EXT Unit of Functionality is required because it provides functions to control a thread's stack. This is considered useful for any real-time application.

This table lists service support status in Zephyr:
Table 7: XSI_THREAD_EXT

<table>
<thead>
<tr>
<th>API</th>
<th>Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>pthread_attr_getguardsize()</td>
<td></td>
</tr>
<tr>
<td>pthread_attr_getstack()</td>
<td>yes</td>
</tr>
<tr>
<td>pthread_attr_setguardsize()</td>
<td></td>
</tr>
<tr>
<td>pthread_attr_setstack()</td>
<td>yes</td>
</tr>
<tr>
<td>pthread_getconcurrency()</td>
<td></td>
</tr>
<tr>
<td>pthread_setconcurrency()</td>
<td></td>
</tr>
</tbody>
</table>

**XSI_THREAD_MUTEX_EXT**  The XSI_THREAD_MUTEX_EXT Unit of Functionality is required because it has options for controlling the behavior of mutexes under erroneous application use.

This table lists service support status in Zephyr:

Table 8: XSI_THREAD_MUTEX_EXT

<table>
<thead>
<tr>
<th>API</th>
<th>Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>pthread_mutexattr_gettype()</td>
<td>yes</td>
</tr>
<tr>
<td>pthread_mutexattr_settype()</td>
<td>yes</td>
</tr>
</tbody>
</table>

**POSIX_C_LANG_SUPPORT**  The POSIX_C_LANG_SUPPORT Unit of Functionality contains the general ISO C Library.

This is implemented as part of the minimal C library available in Zephyr.

Table 9: POSIX_C_LANG_SUPPORT

### 4.18.2 CMSIS RTOS v1

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v1, please refer to [CMSIS-RTOS v1 Documentation](http://www.keil.com/pack/doc/CMSIS/RTOS/html/index.html).

### 4.18.3 CMSIS RTOS v2

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v2, please refer to the CMSIS-RTOS2 Documentation.

**Features not supported in Zephyr implementation**

**Kernel**

- `osKernelGetState`, `osKernelSuspend`, `osKernelResume`, `osKernelInitialize` and `osKernelStart` are not supported.
Mutex

- `osMutexPrioInherit` is supported by default and is not configurable, you cannot select/unselect this attribute.
- `osMutexRecursive` is also supported by default. If this attribute is not set, an error is thrown when the same thread tries to acquire it the second time.
- `osMutexRobust` is not supported in Zephyr.

Return values not supported in the Zephyr implementation

- `osKernelUnlock`, `osKernelLock`, `osKernelRestoreLock`
  - `osError (Unspecified error)` is not supported.
- `osSemaphoreDelete`
  - `osErrorResource` (the semaphore specified by parameter semaphore_id is in an invalid semaphore state) is not supported.
- `osMutexDelete`
  - `osErrorResource` (mutex specified by parameter mutex_id is in an invalid mutex state) is not supported.
- `osTimerDelete`
  - `osErrorResource` (the timer specified by parameter timer_id is in an invalid timer state) is not supported.
- `osMessageQueueReset`
  - `osErrorResource` (the message queue specified by parameter msgq_id is in an invalid message queue state) is not supported.
- `osMessageQueueDelete`
  - `osErrorResource` (the message queue specified by parameter msgq_id is in an invalid message queue state) is not supported.
- `osMemoryPoolFree`
  - `osErrorResource` (the memory pool specified by parameter mp_id is in an invalid memory pool state) is not supported.
- `osMemoryPoolDelete`
  - `osErrorResource` (the memory pool specified by parameter mp_id is in an invalid memory pool state) is not supported.
- `osEventFlagsSet`, `osEventFlagsClear`
  - `osFlagsErrorUnknown (Unspecified error)` and `osFlagsErrorResource` (Event flags object specified by parameter ef_id is not ready to be used) are not supported.
- `osEventFlagsDelete`
  - `osErrorParameter` (the value of the parameter ef_id is incorrect) is not supported.
- `osThreadFlagsSet`
  - `osFlagsErrorUnknown (Unspecified error)` and `osFlagsErrorResource` (Thread specified by parameter thread_id is not active to receive flags) are not supported.
- `osThreadFlagsClear`
  - `osFlagsErrorResource` (Running thread is not active to receive flags) is not supported.
- `osDelayUntil`
  - `osParameter` (the time cannot be handled) is not supported.

4.19 Power off

group sys_poweroff
Functions

FUNC_NORETURN void sys_poweroff(void)
Perform a system power off.

This function will perform an immediate power off of the system. It is the responsibility of
the caller to ensure that the system is in a safe state to be powered off. Any required wake up
sources must be enabled before calling this function.

CONFIG_POWEROFF needs to be enabled to use this API.

4.20 Shell

4.20.1 Overview

This module allows you to create and handle a shell with a user-defined command set. You can use it in
examples where more than simple button or LED user interaction is required. This module is a Unix-like
shell with these features:

- Support for multiple instances.
- Advanced cooperation with the Logging.
- Support for static and dynamic commands.
- Support for dictionary commands.
- Smart command completion with the Tab key.
- Built-in commands: clear, shell, colors, echo, history and resize.
• Viewing recently executed commands using keys: ↑ ↓ or meta keys.
• Text edition using keys: ← → Backspace, Delete, Home, Insert.
• Support for ANSI escape codes: VT100 and ESC[~ for cursor control and color printing.
• Support for editing multiline commands.
• Built-in handler to display help for the commands.
• Support for wildcards: * and ?.
• Support for meta keys.
• Support for getopt and getopt_long.
• Kconfig configuration to optimize memory usage.

Note: Some of these features have a significant impact on RAM and flash usage, but many can be disabled when not needed. To default to options which favor reduced RAM and flash requirements instead of features, you should enable CONFIG_SHELL_MINIMAL and selectively enable just the features you want.

The module can be connected to any transport for command input and output. At this point, the following transport layers are implemented:

• Segger RTT
• SMP
• Telnet
• UART
• USB
• DUMMY - not a physical transport layer.

Connecting to Segger RTT via TCP (on macOS, for example)

On macOS JLinkRTTClient won’t let you enter input. Instead, please use following procedure:

• Open up a first Terminal window and enter:
  
  JLinkRTTLogger -Device NRF52840_XXAA -RTTChannel 1 -if SWD -Speed 4000 ~/rtt.log

  (change device if required)

• Open up a second Terminal window and enter:

  nc localhost 19021

• Now you should have a network connection to RTT that will let you enter input to the shell.

4.20.2 Commands

Shell commands are organized in a tree structure and grouped into the following types:

• Root command (level 0): Gathered and alphabetically sorted in a dedicated memory section.
• Static subcommand (level > 0): Number and syntax must be known during compile time. Created in the software module.
• Dynamic subcommand (level > 0): Number and syntax does not need to be known during compile time. Created in the software module.
Creating commands

Use the following macros for adding shell commands:

- **SHELL_CMD_REGISTER** - Create root command. All root commands must have different name.
- **SHELL_COND_CMD_REGISTER** - Conditionally (if compile time flag is set) create root command. All root commands must have different name.
- **SHELL_CMD_ARG_REGISTER** - Create root command with arguments. All root commands must have different name.
- **SHELL_COND_CMD_ARG_REGISTER** - Conditionally (if compile time flag is set) create root command with arguments. All root commands must have different name.
- **SHELL_CMD** - Initialize a command.
- **SHELL_COND_CMD** - Initialize a command if compile time flag is set.
- **SHELL_EXPR_CMD** - Initialize a command if compile time expression is non-zero.
- **SHELL_CMD_ARG** - Initialize a command with arguments.
- **SHELL_COND_CMD_ARG** - Initialize a command with arguments if compile time flag is set.
- **SHELL_EXPR_CMD_ARG** - Initialize a command with arguments if compile time expression is non-zero.
- **SHELL_STATIC_SUBCMD_SET_CREATE** - Create a static subcommands array.
- **SHELL_SUBCMD_DICT_SET_CREATE** - Create a dictionary subcommands array.
- **SHELL_DYNAMIC_CMD_CREATE** - Create a dynamic subcommands array.

Commands can be created in any file in the system that includes include/zephyr/shell/shell.h. All created commands are available for all shell instances.

**Static commands** Example code demonstrating how to create a root command with static subcommands.

```c
/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
        SHELL_CMD(params, NULL, "Print params command.", cmd_demo_params),
        SHELL_CMD(ping, NULL, "Ping command.", cmd_demo_ping),
        SHELL_SUBCMD_SET_END);
/* Creating root (level 0) command "demo" */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);
```

Example implementation can be found under following location: samples/subsys/shell/shell_module/src/main.c.
Dictionary commands

This is a special kind of static commands. Dictionary commands can be used every time you want to use a pair: (string <-> corresponding data) in a command handler. The string is usually a verbal description of a given data. The idea is to use the string as a command syntax that can be prompted by the shell and corresponding data can be used to process the command.

Let's use an example. Suppose you created a command to set an ADC gain. It is a perfect place where a dictionary can be used. The dictionary would be a set of pairs: (string: gain_value, int: value) where int value could be used with the ADC driver API.

Abstract code for this task would look like this:

```c
static int gain_cmd_handler(const struct shell *sh, size_t argc, char **argv, void *data)
{
    int gain;

    /* data is a value corresponding to called command syntax */
    gain = (int)data;
    adc_set_gain(gain);

    shell_print(sh, "ADC gain set to: %s\n"
               "Value send to ADC driver: %d",
               argv[0],
               gain);

    return 0;
}
```

SHELL_SUBCMD_DICT_SET_CREATE(sub_gain, gain_cmd_handler, (gain_1, 1, "gain 1"), (gain_2, 2, "gain 2"), (gain_1_2, 3, "gain 1/2"), (gain_1_4, 4, "gain 1/4"));
SHELL_CMD_REGISTER(gain, &sub_gain, "Set ADC gain", NULL);

This is how it would look like in the shell:

```
uart:-$ gain ga
    gain_1 gain_2 gain_1_2 gain_1_4
uart:-$ gain gain_1
    ADC gain set to: gain_1
    Value send to ADC driver: 1
uart:-$ gain gain_2
    ADC gain set to: gain_2
    Value send to ADC driver: 2
uart:-$ gain gain_1_2
    ADC gain set to: gain_1_2
    Value send to ADC driver: 3
uart:-$ gain gain_1_4
    ADC gain set to: gain_1_4
    Value send to ADC driver: 4
uart:-$ 
```

Dynamic commands

Example code demonstrating how to create a root command with static and dynamic subcommands. At the beginning dynamic command list is empty. New commands can be added...
by typing:

```
dynamic add <new_dynamic_command>
```

Newly added commands can be prompted or autocompleted with the Tab key.

```
/* Buffer for 10 dynamic commands */
static char dynamic_cmd_buffer[10][50];

/* commands counter */
static uint8_t dynamic_cmd_cnt;

/* Function returning command dynamically created
* in dynamic_cmd_buffer.
*/
static void dynamic_cmd_get(size_t idx,

    struct shell_static_entry *entry)
{
    if (idx < dynamic_cmd_cnt) {
        entry->syntax = dynamic_cmd_buffer[idx];
        entry->handler = NULL;
        entry->subcmd = NULL;
        entry->help = "Show dynamic command name.";
    } else {
        /* if there are no more dynamic commands available
         * syntax must be set to NULL.
         */
        entry->syntax = NULL;
    }
}
```

SHELL_DYNAMIC_CMD_CREATE(m_sub_dynamic_set, dynamic_cmd_get);
SHELL_STATIC_SUBCMD_SET_CREATE(m_sub_dynamic,
    SHELL_CMD(add, NULL,"Add new command to dynamic_cmd_buffer and"
              " sort them alphabetically.",
              cmd_dynamic_add),
    SHELL_CMD(execute, &m_sub_dynamic_set,
              "Execute a command.", cmd_dynamic_execute),
    SHELL_CMD(remove, &m_sub_dynamic_set,
              "Remove a command from dynamic_cmd_buffer.",
              cmd_dynamic_remove),
    SHELL_CMD(show, NULL,
              "Show all commands in dynamic_cmd_buffer."),
```
Example implementation can be found under following location: samples/subsys/shell/shell_module/src/dynamic_cmd.c.

Commands execution

Each command or subcommand may have a handler. The shell executes the handler that is found deepest in the command tree and further subcommands (without a handler) are passed as arguments. Characters within parentheses are treated as one argument. If shell won't find a handler it will display an error message.

Commands can be also executed from a user application using any active backend and a function shell_execute_cmd(), as shown in this example:

```c
int main(void)
{
    /* Below code will execute "clear" command on a DUMMY backend */
    shell_execute_cmd(NULL, "clear");

    /* Below code will execute "shell colors off" command on
     * an UART backend
     */
    shell_execute_cmd(shell_backend_uart_get_ptr(),
                      "shell colors off");
}
```

Enable the DUMMY backend by setting the Kconfig CONFIG_SHELL_BACKEND_DUMMY option.

Commands execution example  Let's assume a command structure as in the following figure, where:

- root_cmd - root command without a handler
- cmd_xxx_h - command has a handler
- cmd_xxx - command does not have a handler
Example 1  Sequence: root_cmd cmd_1_h cmd_12_h cmd_121_h parameter will execute command cmd_121_h and parameter will be passed as an argument.

Example 2  Sequence: root_cmd cmd_2 cmd_22_h parameter1 parameter2 will execute command cmd_22_h and parameter1 parameter2 will be passed as an arguments.

Example 3  Sequence: root_cmd cmd_1_h parameter1 cmd_121_h parameter2 will execute command cmd_1_h and parameter1, cmd_121_h and parameter2 will be passed as an arguments.

Example 4  Sequence: root_cmd parameter cmd_121_h parameter2 will not execute any command.

Command handler  Simple command handler implementation:

```c
static int cmd_handler(const struct shell *sh, size_t argc, char **argv)
{
    ARG_UNUSED(argc);
    ARG_UNUSED(argv);

    shell_fprintf(shell, SHELL_INFO, "Print info message\n");
    shell_print(sh, "Print simple text.");
    shell_warn(sh, "Print warning text.");
    shell_error(sh, "Print error text.");
    return 0;
}
```
Function `shell_fprintf()` or the shell print macros: `shell_print`, `shell_info`, `shell_warn` and `shell_error` can be used from the command handler or from threads, but not from an interrupt context. Instead, interrupt handlers should use Logging for printing.

**Command help** Every user-defined command or subcommand can have its own help description. The help for commands and subcommands can be created with respective macros: `SHELL_CMD_REGISTER`, `SHELL_CMD_ARG_REGISTER`, `SHELL_CMD`, and `SHELL_CMD_ARG`. Shell prints this help message when you call a command or subcommand with `-h` or `--help` parameter.

**Parent commands** In the subcommand handler, you can access both the parameters passed to commands or the parent commands, depending on how you index `argv`.

- When indexing `argv` with positive numbers, you can access the parameters.
- When indexing `argv` with negative numbers, you can access the parent commands.
- The subcommand to which the handler belongs has the `argv` index of 0.

```c
static int cmd_handler(const struct shell *sh, size_t argc, char **argv)
{
    ARG_UNUSED(argc);

    /* If it is a subcommand handler parent command syntax
     * can be found using argv[-1].
     */
    shell_print(sh, "This command has a parent command: %s",
                argv[-1]);

    /* Print this command syntax */
    shell_print(sh, "This command syntax is: %s", argv[0]);

    /* Print first argument */
    shell_print(sh, "%s", argv[1]);

    return 0;
}
```

**Built-in commands**

These commands are activated by `CONFIG_SHELL_CMDS` set to `y`.

- **clear** - Clears the screen.
- **history** - Shows the recently entered commands.
- **resize** - Must be executed when terminal width is different than 80 characters or after each change of terminal width. It ensures proper multilime text display and ←, →, End, Home keys handling. Currently this command works only with UART flow control switched on. It can be also called with a subcommand:
  - **default** - Shell will send terminal width = 80 to the terminal and assume successful delivery. These command needs extra activation: `CONFIG_SHELL_CMDS_RESIZE` set to `y`.
- **select** - It can be used to set new root command. Exit to main command tree is with alt+r. This command needs extra activation: `CONFIG_SHELL_CMDS_SELECT` set to `y`.
- **shell** - Root command with useful shell-related subcommands like:
– echo - Toggles shell echo.
– colors - Toggles colored syntax. This might be helpful in case of Bluetooth shell to limit the amount of transferred bytes.
– stats - Shows shell statistics.

4.20.3 Tab Feature

The Tab button can be used to suggest commands or subcommands. This feature is enabled by CONFIG_SHELL_TAB set to y. It can also be used for partial or complete auto-completion of commands. This feature is activated by CONFIG_SHELL_TAB_AUTOCOMPLETION set to y. When user starts writing a command and presses the Tab button then the shell will do one of 3 possible things:

• Autocomplete the command.
• Prompts available commands and if possible partly completes the command.
• Will not do anything if there are no available or matching commands.

4.20.4 History Feature

This feature enables commands history in the shell. It is activated by: CONFIG_SHELL_HISTORY set to y. History can be accessed using keys: ↑ ↓ or Ctrl+n and Ctrl+p if meta keys are active. Number of commands that can be stored depends on size of CONFIG_SHELL_HISTORY_BUFFER parameter.

4.20.5 Wildcards Feature

The shell module can handle wildcards. Wildcards are interpreted correctly when expanded command and its subcommands do not have a handler. For example, if you want to set logging level to err for the app and app_test modules you can execute the following command:

```
log enable err a*
```
This feature is activated by CONFIG_SHELL_WILDCARD set to y.

4.20.6 Meta Keys Feature

The shell module supports the following meta keys:

<table>
<thead>
<tr>
<th>Meta keys</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl+a</td>
<td>Moves the cursor to the beginning of the line.</td>
</tr>
<tr>
<td>Ctrl+b</td>
<td>Moves the cursor backward one character.</td>
</tr>
<tr>
<td>Ctrl+c</td>
<td>Preserves the last command on the screen and starts a new command in a new line.</td>
</tr>
<tr>
<td>Ctrl+d</td>
<td>Deletes the character under the cursor.</td>
</tr>
<tr>
<td>Ctrl+e</td>
<td>Moves the cursor to the end of the line.</td>
</tr>
<tr>
<td>Ctrl+f</td>
<td>Moves the cursor forward one character.</td>
</tr>
<tr>
<td>Ctrl+k</td>
<td>Deletes from the cursor to the end of the line.</td>
</tr>
<tr>
<td>Ctrl+l</td>
<td>Clears the screen and leaves the currently typed command at the top of the screen.</td>
</tr>
<tr>
<td>Ctrl+n</td>
<td>Moves in history to next entry.</td>
</tr>
<tr>
<td>Ctrl+p</td>
<td>Moves in history to previous entry.</td>
</tr>
<tr>
<td>Ctrl+u</td>
<td>Clears the currently typed command.</td>
</tr>
<tr>
<td>Ctrl+w</td>
<td>Removes the word or part of the word to the left of the cursor. Words separated by period instead of space are treated as one word.</td>
</tr>
<tr>
<td>Alt+b</td>
<td>Moves the cursor backward one word.</td>
</tr>
<tr>
<td>Alt+f</td>
<td>Moves the cursor forward one word.</td>
</tr>
</tbody>
</table>

This feature is activated by CONFIG_SHELL_METAKEYS set to y.

4.20.7 Getopt Feature

Some shell users apart from subcommands might need to use options as well, the arguments string, looking for supported options. Typically, this task is accomplished by the getopt family functions.

For this purpose shell supports the getopt and getopt_long libraries available in the FreeBSD project. This feature is activated by: CONFIG_GETOPT set to y and CONFIG_GETOPT_LONG set to y.

This feature can be used in thread safe as well as non thread safe manner. The former is full compatible with regular getopt usage while the latter a bit differs.

An example non-thread safe usage:
An example thread safe usage:

```c
char *cvalue = NULL;
while ((char c = getopt(argc, argv, "abhc:")) != -1) {
    state = getopt_state_get();
    switch (c) {
    case 'c':
        cvalue = state->optarg;
        break;
    default:
        break;
    }
}
```

Thread safe getopt functionality is activated by `CONFIG_SHELL_GETOPT` set to `y`.

### 4.20.8 Obscured Input Feature

With the obscured input feature, the shell can be used for implementing a login prompt or other user interaction whereby the characters the user types should not be revealed on screen, such as when entering a password.

Once the obscured input has been accepted, it is normally desired to return the shell to normal operation. Such runtime control is possible with the `shell_obscure_set` function.

An example of login and logout commands using this feature is located in `samples/subsys/shell/shell_module/src/main.c` and the config file `samples/subsys/shell/shell_module/prj_login.conf`.

This feature is activated upon startup by `CONFIG_SHELL_START_OBSCURED` set to `y`. With this set either way, the option can still be controlled later at runtime. `CONFIG_SHELL_CMDS_SELECT` is useful to prevent entry of any other command besides a login command, by means of the `shell_set_root_cmd` function. Likewise, `CONFIG_SHELL_PROMPT_UART` allows you to set the prompt upon startup, but it can be changed later with the `shell_prompt_change` function.

### 4.20.9 Shell Logger Backend Feature

Shell instance can act as the Logging backend. Shell ensures that log messages are correctly multiplexed with shell output. Log messages from logger thread are enqueued and processed in the shell thread. Logger thread will block for configurable amount of time if queue is full, blocking logger thread context for that time. Oldest log message is removed from the queue after timeout and new message is enqueued. Use the `shell stats show` command to retrieve number of log messages dropped by the shell instance. Log queue size and timeout are `SHELL_DEFINE` arguments.

This feature is activated by: `CONFIG_SHELL_LOG_BACKEND` set to `y`. 

952 Chapter 4. OS Services
**Warning:** Enqueuing timeout must be set carefully when multiple backends are used in the system. The shell instance could have a slow transport or could block, for example, by a UART with hardware flow control. If timeout is set too high, the logger thread could be blocked and impact other logger backends.

**Warning:** As the shell is a complex logger backend, it cannot output logs if the application crashes before the shell thread is running. In this situation, you can enable one of the simple logging backends instead, such as UART (CONFIG_LOG_BACKEND_UART) or RTT (CONFIG_LOG_BACKEND_RTT), which are available earlier during system initialization.

### 4.20.10 RTT Backend Channel Selection

Instead of using the shell as a logger backend, RTT shell backend and RTT log backend can also be used simultaneously, but over different channels. By separating them, the log can be captured or monitored without shell output or the shell may be scripted without log interference. Enabling both the Shell RTT backend and the Log RTT backend does not work by default, because both default to channel 0. There are two options:

1. The Shell buffer can use an alternate channel, for example using SHELL_BACKEND_RTT_BUFFER set to 1. This allows monitoring the log using JLinkRTTViewer while a script interfaces over channel 1.
2. The Log buffer can use an alternate channel, for example using LOG_BACKEND_RTT_BUFFER set to 1. This allows interactive use of the shell through JLinkRTTViewer, while the log is written to file.

**Warning:** Regardless of the channel selection, the RTT log backend must be explicitly enabled using LOG_BACKEND_RTT set to y, because it defaults to n when the Shell RTT backend is also enabled using SHELL_BACKEND_RTT being set to y.

### 4.20.11 Usage

To create a new shell instance, the user needs to activate requested backend using menuconfig.

The following code shows a simple use case of this library:

```c
int main(void)
{
}

static int cmd_demo_ping(const struct shell *sh, size_t argc, char **argv)
{
    ARG_UNUSED(argc);
    ARG_UNUSED(argv);
    shell_print(sh, "pong");
    return 0;
}

static int cmd_demo_params(const struct shell *sh, size_t argc, char **argv)
{
    (continues on next page)
```
int cnt;

shell_print(sh, "argc = %d", argc);
for (cnt = 0; cnt < argc; cnt++) {
    shell_print(sh, "%argv[%d] = %s", cnt, argv[cnt]);
}
return 0;

/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
    SHELL_CMD(params, NULL, "Print params command.", cmd_demo_params),
    SHELL_CMD(ping, NULL, "Ping command.", cmd_demo_ping),
    SHELL_SUBCMD_SET_END);

/* Creating root (level 0) command "demo" without a handler */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);

/* Creating root (level 0) command "version" */
SHELL_CMD_REGISTER(version, NULL, "Show kernel version", cmd_version);

Users may use the Tab key to complete a command/subcommand or to see the available subcommands for the currently entered command level. For example, when the cursor is positioned at the beginning of the command line and the Tab key is pressed, the user will see all root (level 0) commands:

```
clear  demo  shell  history  log  resize  version
```

**Note:** To view the subcommands that are available for a specific command, you must first type a space after this command and then hit Tab.

These commands are registered by various modules, for example:

- clear, shell, history, and resize are built-in commands which have been registered by `subsys/shell/shell.c`
- demo and version have been registered in example code above by `main.c`
- log has been registered by `subsys/logging/log_cmds.c`

Then, if a user types a demo command and presses the Tab key, the shell will only print the subcommands registered for this command:

```
params  ping
```

**4.20.12 API Reference**

**Related code samples**

- Telnet console - Access Zephyr shell over telnet.
Defines

SHELL_CMD_ARG_REGISTER(syntax, subcmd, help, handler, mandatory, optional)
Macro for defining and adding a root command (level 0) with required number of arguments.

Note: Each root command shall have unique syntax. If a command will be called with wrong number of arguments shell will print an error message and command handler will not be called.

Parameters

- mandatory – [in] Number of mandatory arguments including command name.

SHELL_COND_CMD_ARG_REGISTER(flag, syntax, subcmd, help, handler, mandatory, optional)
Macro for defining and adding a conditional root command (level 0) with required number of arguments.

Macro can be used to create a command which can be conditionally present. It is an alternative to #ifdefs around command registration and command handler. If command is disabled handler and subcommands are removed from the application.

See also:
SHELL_CMD_ARG_REGISTER for details.

Parameters

- flag – [in] Compile time flag. Command is present only if flag exists and equals 1.
- mandatory – [in] Number of mandatory arguments including command name.

SHELL_CMD_REGISTER(syntax, subcmd, help, handler)
Macro for defining and adding a root command (level 0) with arguments.

Note: All root commands must have different name.

Parameters

• help – [in] Pointer to a command help string.
• handler – [in] Pointer to a function handler.

SHELL_COND_CMD_REGISTER(flag, syntax, subcmd, help, handler)
Macro for defining and adding a conditional root command (level 0) with arguments.

See also:
SHELL_COND_CMD_ARG_REGISTER.

Parameters
• flag – [in] Compile time flag. Command is present only if flag exists and equals 1.
• syntax – [in] Command syntax (for example: history).
• subcmd – [in] Pointer to a subcommands array.
• help – [in] Pointer to a command help string.
• handler – [in] Pointer to a function handler.

SHELL_STATIC_SUBCMD_SET_CREATE(name, ...)
Macro for creating a subcommand set.
It must be used outside of any function body.
Example usage:

SHELL_STATIC_SUBCMD_SET_CREATE(
    foo,
    SHELL_CMD(abc, ...),
    SHELL_CMD(def, ...),
    SHELL_SUBCMD_SET_END
)

Parameters
• name – [in] Name of the subcommand set.
• ... – [in] List of commands created with SHELL_CMD_ARG or or SHELL_CMD

SHELL_SUBCMD_SET_CREATE(_name, _parent)
Create set of subcommands.
Commands to this set are added using SHELL_SUBCMD_ADD and SHELL_SUBCMD_COND_ADD. Commands can be added from multiple files.

Parameters
• _name – [in] Name of the set. _name is used to refer the set in the parent command.
• _parent – [in] Set of comma separated parent commands in parenthesis, e.g. (foo_cmd) if subcommands are for the root command “foo_cmd”.

SHELL_SUBCMD_COND_ADD(_flag, _parent, _syntax, _subcmd, _help, _handler, _mand, _opt)
Conditionally add command to the set of subcommands.
Add command to the set created with SHELL_SUBCMD_SET_CREATE.
Parameters

- **flag** – [in] Compile time flag. Command is present only if flag exists and equals 1.
- **syntax** – [in] Command syntax (for example: history).
- **subcmd** – [in] Pointer to a subcommands array.
- **help** – [in] Pointer to a command help string.
- **handler** – [in] Pointer to a function handler.
- **mand** – [in] Number of mandatory arguments including command name.
- **opt** – [in] Number of optional arguments.

SHELL_SUBCMD_ADD(_parent, _syntax, _subcmd, _help, _handler, _mand, _opt)
Add command to the set of subcommands.

Add command to the set created with SHELL_SUBCMD_SET_CREATE.

Parameters

- **syntax** – [in] Command syntax (for example: history).
- **subcmd** – [in] Pointer to a subcommands array.
- **help** – [in] Pointer to a command help string.
- **handler** – [in] Pointer to a function handler.
- **mand** – [in] Number of mandatory arguments including command name.
- **opt** – [in] Number of optional arguments.

SHELL_SUBCMD_SET_END
Define ending subcommands set.

SHELL_DYNAMIC_CMD_CREATE(name, get)
Macro for creating a dynamic entry.

Parameters

- **name** – [in] Name of the dynamic entry.
- **get** – [in] Pointer to the function returning dynamic commands array

SHELL_CMD_ARG(syntax, subcmd, help, handler, mand, opt)
Initializes a shell command with arguments.

**Note:** If a command will be called with wrong number of arguments shell will print an error message and command handler will not be called.
• **syntax** – [in] Command syntax (for example: history).
• **subcmd** – [in] Pointer to a subcommands array.
• **help** – [in] Pointer to a command help string.
• **handler** – [in] Pointer to a function handler.
• **mand** – [in] Number of mandatory arguments including command name.
• **opt** – [in] Number of optional arguments.

`SHELL_COND_CMD_ARG(flag, syntax, subcmd, help, handler, mand, opt)`

Initializes a conditional shell command with arguments.

**See also:**

`SHELL_CMD_ARG`. Based on the flag, creates a valid entry or an empty command which is ignored by the `shell`. It is an alternative to `#if`defs around command registration and command handler. However, empty structure is present in the flash even if command is disabled (subcommands and handler are removed). Macro internally handles case if flag is not defined so flag must be provided without any wrapper, e.g.: `SHELL_COND_CMD_ARG(CONFIG_FOO, ...)`

**Parameters**

- **flag** – [in] Compile time flag. Command is present only if flag exists and equals 1.
- **syntax** – [in] Command syntax (for example: history).
- **subcmd** – [in] Pointer to a subcommands array.
- **help** – [in] Pointer to a command help string.
- **handler** – [in] Pointer to a function handler.
- **mand** – [in] Number of mandatory arguments including command name.
- **opt** – [in] Number of optional arguments.

`SHELL_EXPR_CMD_ARG(_expr, _syntax, _subcmd, _help, _handler, _mand, _opt)`

Initializes a conditional shell command with arguments if expression gives non-zero result at compile time.

**See also:**

`SHELL_CMD_ARG`. Based on the expression, creates a valid entry or an empty command which is ignored by the `shell`. It should be used instead of `SHELL_COND_CMD_ARG` if condition is not a single configuration flag, e.g.: `SHELL_EXPR_CMD_ARG(IS_ENABLED(CONFIG_FOO) && IS_ENABLED(CONFIG_FOO_SETTING_1), ...)`

**Parameters**

- **_syntax** – [in] Command syntax (for example: history).
- **_subcmd** – [in] Pointer to a subcommands array.
- **_help** – [in] Pointer to a command help string.
- **_handler** – [in] Pointer to a function handler.
- **_mand** – [in] Number of mandatory arguments including command name.
• _opt – [in] Number of optional arguments.

SHELL_CMD(_syntax, _subcmd, _help, _handler)

Initializes a shell command.

**Parameters**

• _syntax – [in] Command syntax (for example: history).
• _subcmd – [in] Pointer to a subcommands array.
• _help – [in] Pointer to a command help string.
• _handler – [in] Pointer to a function handler.

SHELL_COND_CMD(_flag, _syntax, _subcmd, _help, _handler)

Initializes a conditional shell command.

**See also:**

*SHELL_COND_CMD_ARG.*

**Parameters**

• _flag – [in] Compile time flag. Command is present only if flag exists and equals 1.
• _syntax – [in] Command syntax (for example: history).
• _subcmd – [in] Pointer to a subcommands array.
• _help – [in] Pointer to a command help string.
• _handler – [in] Pointer to a function handler.

SHELL_EXPR_CMD(_expr, _syntax, _subcmd, _help, _handler)

Initializes shell command if expression gives non-zero result at compile time.

**See also:**

*SHELL_EXPR_CMD_ARG.*

**Parameters**

• _expr – [in] Compile time expression. Command is present only if expression is non-zero.
• _syntax – [in] Command syntax (for example: history).
• _subcmd – [in] Pointer to a subcommands array.
• _help – [in] Pointer to a command help string.
• _handler – [in] Pointer to a function handler.

SHELL_CMD_DICT_CREATE(_data, _handler)

SHELL_SUBCMD_DICT_SET_CREATE(_name, _handler, ...)

Initializes shell dictionary commands.

This is a special kind of static commands. Dictionary commands can be used every time you want to use a pair: (string <-> corresponding data) in a command handler. The string is usually a verbal description of a given data. The idea is to use the string as a command syntax that can be prompted by the shell and corresponding data can be used to process the command.
Example usage:

```c
static int my_handler(const struct shell *sh,
                      size_t argc, char **argv, void *data)
{
    int val = (int)data;

    shell_print(sh, "(syntax, value) : (%s, %d)", argv[0], val);
    return 0;
}
```

SHELL_SUBCMD_DICT_SET_CREATE(sub_dict_cmds, my_handler,
    (value_0, 0, "value 0"), (value_1, 1, "value 1"),
    (value_2, 2, "value 2"), (value_3, 3, "value 3")
);

SHELL_CMD_REGISTER(dictionary, &sub_dict_cmds, NULL, NULL);

See also:

shell_dict_cmd_handler

Parameters

- _name – [in] Name of the dictionary subcommand set
- ... – [in] Dictionary triplets: (command_syntax, value, helper). Value will be passed to the _handler as user data.

SHELL_DEFAULT_BACKEND_CONFIG_FLAGS

SHELL_DEFINE(_name, _prompt, _transport_iface, _log_queue_size, _log_timeout, _shell_flag)

Macro for defining a shell instance.

Parameters

- _name – [in] Instance name.
- _log_timeout – [in] Logger thread timeout in milliseconds on full log queue. If queue is full logger thread is blocked for given amount of time before log message is dropped.

SHELL_NORMAL

Terminal default text color for shell_fprintf function.

SHELL_INFO

Green text color for shell_fprintf function.

SHELL_OPTION

Cyan text color for shell_fprintf function.
SHELL_WARNING

Yellow text color for shell_fprintf function.

SHELL_ERROR

Red text color for shell_fprintf function.

shell_info(_sh, _ft, ...)

Print info message to the shell.

See shell_fprintf.

Parameters

• _sh – [in] Pointer to the shell instance.
• ... – [in] List of parameters to print.

shell_print(_sh, _ft, ...)

Print normal message to the shell.

See shell_fprintf.

Parameters

• _sh – [in] Pointer to the shell instance.
• ... – [in] List of parameters to print.

shell_warn(_sh, _ft, ...)

Print warning message to the shell.

See shell_fprintf.

Parameters

• _sh – [in] Pointer to the shell instance.
• ... – [in] List of parameters to print.

shell_error(_sh, _ft, ...)

Print error message to the shell.

See shell_fprintf.

Parameters

• _sh – [in] Pointer to the shell instance.
• ... – [in] List of parameters to print.

SHELL_CMD_HELP_PRINTED

Command's help has been printed.

Typedefs
typedef void (*shell_dynamic_get)(size_t idx, struct shell_static_entry *entry)

Shell dynamic command descriptor.

Function shall fill the received shell static entry structure with requested (idx) dynamic subcommand data. If there is more than one dynamic subcommand available, the function shall ensure that the returned commands: entry->syntax are sorted in alphabetical order. If idx exceeds the available dynamic subcommands, the function must write to entry->syntax NULL value. This will indicate to the shell module that there are no more dynamic commands to read.

typedef int (*shell_cmd_handler)(const struct shell *sh, size_t argc, char **argv)

Shell command handler prototype.

Param sh
   Shell instance.

Param argc
   Arguments count.

Param argv
   Arguments.

Retval 0
   Successful command execution.

Retval 1
   Help printed and command not executed.

Retval -EINVAL
   Argument validation failed.

Retval -ENOEXEC
   Command not executed.

typedef int (*shell_dict_cmd_handler)(const struct shell *sh, size_t argc, char **argv, void *data)

Shell dictionary command handler prototype.

Param sh
   Shell instance.

Param argc
   Arguments count.

Param argv
   Arguments.

Param data
   Pointer to the user data.

Retval 0
   Successful command execution.

Retval 1
   Help printed and command not executed.

Retval -EINVAL
   Argument validation failed.

Retval -ENOEXEC
   Command not executed.

typedef void (*shell_transport_handler_t)(enum shell_transport_evt evt, void *context)
typedef void (*shell_uninit_cb_t)(const struct shell *sh, int res)

typedef void (*shell_bypass_cb_t)(const struct shell *sh, uint8_t *data, size_t len)

Bypass callback.

**Param sh**
Shell instance.

**Param data**
Raw data from transport.

**Param len**
Data length.

** Enums **

** enum shell_receive_state **

Values:

enumerator SHELL_RECEIVE_DEFAULT

enumerator SHELL_RECEIVE_ESC

enumerator SHELL_RECEIVE_ESC_SEQ

enumerator SHELL_RECEIVE_TILDE_EXP

** enum shell_state **

Values:

enumerator SHELL_STATE_UNINITIALIZED

enumerator SHELL_STATE_INITIALIZED

enumerator SHELL_STATE_ACTIVE

enumerator SHELL_STATE_PANIC_MODE_ACTIVE
Panic activated.

enumerator SHELL_STATE_PANIC_MODE_INACTIVE
Panic requested, not supported.

** enum shell_transport_evt **
Shell transport event.

Values:

enumerator SHELL_TRANSPORT_EVT_RX_RDY
enumerator SHELL_TRANSPORT_EVT_TX_RDY

enum shell_signal

Values:

enumerator SHELL_SIGNAL_RXRDY

enumerator SHELL_SIGNAL_LOG_MSG

enumerator SHELL_SIGNAL_KILL

enumerator SHELL_SIGNAL_TXDONE

enumerator SHELL_SIGNALS

enum shell_flag

Flags for setting shell output newline sequence.

Values:

enumerator SHELL_FLAG_CRLF_DEFAULT = (1 << 0)
  Do not map CR or LF.

enumerator SHELL_FLAG_OLF_CRLF = (1 << 1)
  Map LF to CRLF on output.

Functions

const struct device *shell_device_lookup(size_t idx, const char *prefix)
  Get by index a device that matches.
  This can be used, for example, to identify I2C_1 as the second I2C device.
  Devices that failed to initialize or do not have a non-empty name are excluded from the candidates for a match.

Parameters

• idx – the device number starting from zero.
• prefix – optional name prefix used to restrict candidate devices. Indexing is done relative to devices with names that start with this text. Pass null if no prefix match is required.

int shell_init(const struct shell *sh, const void *transport_config, struct shell_backend_config_flags cfg_flags, bool log_backend, uint32_t init_log_level)
  Function for initializing a transport layer and internal shell state.

Parameters

• sh – [in] Pointer to shell instance.
• cfg_flags – [in] Initial backend configuration flags. Shell will copy this data.
• log_backend – If true, the console will be used as logger backend.
• init_log_level – [in] Default severity level for the logger.

Returns
Standard error code.

void shell_uninit(const struct shell *sh, shell_uninit_cb_t cb)
Uninitializes the transport layer and the internal shell state.

Parameters
• sh – Pointer to shell instance.
• cb – Callback called when uninitialization is completed.

int shell_start(const struct shell *sh)
Function for starting shell processing.

Parameters
• sh – Pointer to the shell instance.

Returns
Standard error code.

int shell_stop(const struct shell *sh)
Function for stopping shell processing.

Parameters
• sh – Pointer to shell instance.

Returns
Standard error code.

void shell_fprintf(const struct shell *sh, enum shell_vt100_color color, const char *fmt, ...)
printf-like function which sends formatted data stream to the shell.
This function can be used from the command handler or from threads, but not from an interrupt context.

Parameters
• sh – [in] Pointer to the shell instance.
• color – [in] Printed text color.
• ... – [in] List of parameters to print.

void shell_vfprintf(const struct shell *sh, enum shell_vt100_color color, const char *fmt, va_list args)
vprintf-like function which sends formatted data stream to the shell.
This function can be used from the command handler or from threads, but not from an interrupt context. It is similar to shell_fprintf() but takes a va_list instead of variable arguments.

Parameters
• sh – [in] Pointer to the shell instance.
• color – [in] Printed text color.
• args – [in] List of parameters to print.
void shell_hexdump_line(const struct shell *sh, unsigned int offset, const uint8_t *data, size_t len)
Print a line of data in hexadecimal format.
Each line shows the offset, bytes and then ASCII representation.
For example:
00008010: 20 25 00 20 2f 48 00 08 80 05 00 20 af 46 00 | %. /H... . . . .F. |

Parameters
• sh – [in] Pointer to the shell instance.
• offset – [in] Offset to show for this line.
• data – [in] Pointer to data.
• len – [in] Length of data.

void shell_hexdump(const struct shell *sh, const uint8_t *data, size_t len)
Print data in hexadecimal format.

Parameters
• sh – [in] Pointer to the shell instance.
• data – [in] Pointer to data.
• len – [in] Length of data.

void shell_process(const struct shell *sh)
Process function, which should be executed when data is ready in the transport interface.
To be used if shell thread is disabled.

Parameters
• sh – [in] Pointer to the shell instance.

int shell_prompt_change(const struct shell *sh, const char *prompt)
Change displayed shell prompt.

Parameters
• sh – [in] Pointer to the shell instance.

Returns
0 Success.
Returns
-EINVAL Pointer to new prompt is not correct.

void shell_help(const struct shell *sh)
Prints the current command help.
Function will print a help string with: the currently entered command and subcommands (if they exist).

Parameters
• sh – [in] Pointer to the shell instance.

int shell_execute_cmd(const struct shell *sh, const char *cmd)
Execute command.
Pass command line to shell to execute.
Note: This by no means makes any of the commands a stable interface, so this function should only be used for debugging/diagnostic.
This function must not be called from shell command context!

**Parameters**

- `sh` — [in] Pointer to the shell instance. It can be NULL when the `CONFIG_SHELL_BACKEND_DUMMY` option is enabled.
- `cmd` — [in] Command to be executed.

**Returns**

Result of the execution

```c
int shell_set_root_cmd(const char *cmd)
```

Set root command for all shell instances.

It allows setting from the code the root command. It is an equivalent of calling select command with one of the root commands as the argument (e.g. “select log”) except it sets command for all shell instances.

**Parameters**

- `cmd` — String with one of the root commands or null pointer to reset.

**Return values**

- 0 — if root command is set.
- -EINVAL — if invalid root command is provided.

```c
void shell_set_bypass(const struct shell *sh, shell_bypass_cb_t bypass)
```

Set bypass callback.

Bypass callback is called whenever data is received. Shell is bypassed and data is passed directly to the callback. Use null to disable bypass functionality.

**Parameters**

- `sh` — [in] Pointer to the shell instance.
- `bypass` — [in] Bypass callback or null to disable.

```c
bool shell_ready(const struct shell *sh)
```

Get shell readiness to execute commands.

**Parameters**

- `sh` — [in] Pointer to the shell instance.

**Return values**

- `true` — Shell backend is ready to execute commands.
- `false` — Shell backend is not initialized or not started.

```c
int shell_insert_mode_set(const struct shell *sh, bool val)
```

Allow application to control text insert mode.

Value is modified atomically and the previous value is returned.

**Parameters**

- `sh` — [in] Pointer to the shell instance.
- `val` — [in] Insert mode.

**Return values**

- 0 — or 1: previous value
- -EINVAL — if shell is NULL.
int shell_use_colors_set(const struct shell *sh, bool val)
Allow application to control whether terminal output uses colored syntax.
Value is modified atomically and the previous value is returned.

Parameters
• sh – [in] Pointer to the shell instance.
• val – [in] Color mode.

Return values
• 0 – or 1: previous value
• -EINVAL – if shell is NULL.

int shell_use_vt100_set(const struct shell *sh, bool val)
Allow application to control whether terminal is using vt100 commands.
Value is modified atomically and the previous value is returned.

Parameters
• sh – [in] Pointer to the shell instance.
• val – [in] vt100 mode.

Return values
• 0 – or 1: previous value
• -EINVAL – if shell is NULL.

int shell_echo_set(const struct shell *sh, bool val)
Allow application to control whether user input is echoed back.
Value is modified atomically and the previous value is returned.

Parameters
• sh – [in] Pointer to the shell instance.
• val – [in] Echo mode.

Return values
• 0 – or 1: previous value
• -EINVAL – if shell is NULL.

int shell_obscure_set(const struct shell *sh, bool obscure)
Allow application to control whether user input is obscured with asterisks \\#8212; useful for implementing passwords.
Value is modified atomically and the previous value is returned.

Parameters
• sh – [in] Pointer to the shell instance.
• obscure – [in] Obscure mode.

Return values
• 0 – or 1: previous value.
• -EINVAL – if shell is NULL.

int shell_mode_delete_set(const struct shell *sh, bool val)
Allow application to control whether the delete key backspaces or deletes.
Value is modified atomically and the previous value is returned.
Parameters

Return values

- 0 – or 1: previous value
- -EINVAL – if shell is NULL.

```c
int shell_get_return_value(const struct shell *sh)
```

Retrieve return value of most recently executed shell command.

Parameters

- `sh` – [in] Pointer to the shell instance

Return values

- `return` – value of previous command

Variables

```c
const struct log_backend_api log_backend_shell_api
```

union shell_cmd_entry

```
#include <shell.h> Shell command descriptor.
```

Public Members

```c
shell_dynamic_get dynamic_get
```

Pointer to function returning dynamic commands.

```c
const struct shell_static_entry *entry
```

Pointer to array of static commands.

```c
struct shell_static_args
```

```
#include <shell.h>
```

Public Members

```c
uint8_t mandatory
```

Number of mandatory arguments.

```c
uint8_t optional
```

Number of optional arguments.

```c
struct shell_static_entry
```

```
#include <shell.h>
```
Public Members

const char *syntax
    Command syntax strings.

const char *help
    Command help string.

const union shell_cmd_entry *subcmd
    Pointer to subcommand.

    shell_cmd_handler handler
    Command handler.

    struct shell_static_args args
    Command arguments.

struct shell_transport_api
    #include <shell.h> Unified shell transport interface.

Public Members

int (*init)(const struct shell_transport *transport, const void *config,
            shell_transport_handler_t evt_handler, void *context)
    Function for initializing the shell transport interface.

    Param transport
        [in] Pointer to the transfer instance.

    Param config
        [in] Pointer to instance configuration.

    Param evt_handler

    Param context
        [in] Pointer to the context passed to event handler.

    Return
        Standard error code.

int (*uninit)(const struct shell_transport *transport)
    Function for uninitializing the shell transport interface.

    Param transport
        [in] Pointer to the transfer instance.

    Return
        Standard error code.

int (*enable)(const struct shell_transport *transport, bool blocking_tx)
    Function for enabling transport in given TX mode.

    Function can be used to reconfigure TX to work in blocking mode.

    Param transport
        Pointer to the transfer instance.

    Param blocking_tx
        If true, the transport TX is enabled in blocking mode.
Return
NRF_SUCCESS on successful enabling, error otherwise (also if not supported).

int (*write)(const struct shell_transport *transport, const void *data, size_t length, size_t *cnt)
Function for writing data to the transport interface.
    Param transport
        [in] Pointer to the transfer instance.
    Param data
        [in] Pointer to the source buffer.
    Param length
        [in] Source buffer length.
    Param cnt
        [out] Pointer to the sent bytes counter.
Return
    Standard error code.

int (*read)(const struct shell_transport *transport, void *data, size_t length, size_t *cnt)
Function for reading data from the transport interface.
    Param transport
        [in] Pointer to the transfer instance.
    Param data
        [in] Pointer to the destination buffer.
    Param length
        [in] Destination buffer length.
    Param cnt
        [out] Pointer to the received bytes counter.
Return
    Standard error code.

void (*update)(const struct shell_transport *transport)
Function called in shell thread loop.
Can be used for backend operations that require longer execution time
    Param transport
        [in] Pointer to the transfer instance.

struct shell_transport
#include <shell.h>

struct shell_stats
#include <shell.h> Shell statistics structure.

Public Members

atomic_t log_lost_cnt
Lost log counter.

struct shell_backend_config_flags
#include <shell.h>

Public Members

4.20. Shell
# Public Members

- **insert_mode**
  Controls insert mode for text introduction.

- **echo**
  Controls shell echo.

- **obscure**
  If echo on, print asterisk instead.

- **mode_delete**
  Operation mode of backspace key.

- **use_colors**
  Controls colored syntax.

- **use_vt100**
  Controls VT100 commands usage in shell.

## Public Members

- **processing**
  Shell is executing process function.

- **history_exit**
  Request to exit history mode.

- **last_nl**
  Last received new line character.

- **cmd_ctx**
  Shell is executing command.

- **print_noinit**
  Print request from not initialized shell.

- **sync_mode**
  Shell in synchronous mode.
struct shell_backend_config_flags flags

union shell_backend_ctx
    #include <shell.h>

Public Members

uint32_t value

struct shell_backend_ctx_flags flags

struct shell_ctx
    #include <shell.h> Shell instance context.

Public Members

const char *prompt
    shell current prompt.

denum shell_state state
    Internal module state.

denum shell_receive_state receive_state
    Escape sequence indicator.

struct shell_static_entry active_cmd
    Currently executed command.

dconst struct shell_static_entry *selected_cmd
    New root command.
    If NULL shell uses default root commands.

struct shell_vt100_ctx vt100_ctx
    VT100 color and cursor position, terminal width.

shell_uninit_cb_t uninit_cb
    Callback called from shell thread context when uninitialization is completed just before aborting shell thread.

shell_bypass_cb_t bypass
    When bypass is set, all incoming data is passed to the callback.

uint16_t cmd_buff_len
    Command length.
uint16_t cmd_buff_pos
   Command buffer cursor position.

uint16_t cmd_tmp_buff_len
   Command length in tmp buffer.

char cmd_buff[0]
   Command input buffer.

char temp_buff[0]
   Command temporary buffer.

char printf_buff[0]
   Printf buffer size.

struct k_poll_event events[SHELL_SIGNALS]
   Events that should be used only internally by shell thread.
   Event for SHELL_SIGNAL_TXDONE is initialized but unused.

struct shell
   #include <shell.h> Shell instance internals.

Public Members

const char *default_prompt
   shell default prompt.

const struct shell_transport *iface
   Transport interface.

struct shell_ctx *ctx
   Internal context.

4.21 Settings

The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. A variety of storage implementations are provided behind a common API using FCB, NVS, or a file system. These different implementations give the application developer flexibility to select an appropriate storage medium, and even change it later as needs change. This subsystem is used by various Zephyr components and can be used simultaneously by user applications.

Settings items are stored as key-value pair strings. By convention, the keys can be organized by the package and subtree defining the key, for example the key id/serial would define the serial configuration element for the package id.

Convenience routines are provided for converting a key value to and from a string type.

For an example of the settings subsystem refer to settings sample.
4.21.1 Handlers

Settings handlers for subtree implement a set of handler functions. These are registered using a call to `settings_register()`.

h_get
This gets called when asking for a settings element value by its name using `settings_runtime_get()` from the runtime backend.

h_set
This gets called when the value is loaded from persisted storage with `settings_load()`, or when using `settings_runtime_set()` from the runtime backend.

h_commit
This gets called after the settings have been loaded in full. Sometimes you don’t want an individual setting value to take effect right away, for example if there are multiple settings which are interdependent.

h_export
This gets called to write all current settings. This happens when `settings_save()` tries to save the settings or transfer to any user-implemented back-end.

4.21.2 Backends

Backends are meant to load and save data to/from setting handlers, and implement a set of handler functions. These are registered using a call to `settings_src_register()` for backends that can load data, and/or `settings_dst_register()` for backends that can save data. The current implementation allows for multiple source backends but only a single destination backend.

csi_load
This gets called when loading values from persistent storage using `settings_load()`.

csi_save
This gets called when saving a single setting to persistent storage using `settings_save_one()`.

csi_save_start
This gets called when starting a save of all current settings using `settings_save()`.

csi_save_end
This gets called after having saved all current settings using `settings_save()`.

4.21.3 Zephyr Storage Backends

Zephyr has three storage backends: a Flash Circular Buffer (CONFIG_SETTINGS_FCB), a file in the filesystem (CONFIG_SETTINGS_FILE), or non-volatile storage (CONFIG_SETTINGS_NVS).

You can declare multiple sources for settings; settings from all of these are restored when `settings_load()` is called.

There can be only one target for writing settings; this is where data is stored when you call `settings_save()`, or `settings_save_one()`.

FCB read target is registered using `settings_fcb_src()`, and write target using `settings_fcb_dst()`. As a side-effect, `settings_fcb_src()` initializes the FCB area, so it must be called before calling `settings_fcb_dst()`. File read target is registered using `settings_file_src()`, and write target by using `settings_file_dst()`. Non-volatile storage read target is registered using `settings_nvs_src()`, and write target by using `settings_nvs_dst()`.

Note: As of Zephyr release 2.1 the recommended backend for non-filesystem storage is NVS.
4.21.4 Storage Location

The FCB and non-volatile storage (NVS) backends both look for a fixed partition with label “storage” by default. A different partition can be selected by setting the `zephyr.settings-partition` property of the chosen node in the devicetree.

The file path used by the file backend to store settings is selected via the option `CONFIG_SETTINGS_FILE_PATH`.

4.21.5 Loading data from persisted storage

A call to `settings_load()` uses an `h_set` implementation to load settings data from storage to volatile memory. After all data is loaded, the `h_commit` handler is issued, signalling the application that the settings were successfully retrieved.

Technically FCB and file backends may store some history of the entities. This means that the newest data entity is stored after any older existing data entities. Starting with Zephyr 2.1, the back-end must filter out all old entities and call the callback with only the newest entity.

4.21.6 Storing data to persistent storage

A call to `settings_save_one()` uses a backend implementation to store settings data to the storage medium. A call to `settings_save()` uses an `h_export` implementation to store different data in one operation using `settings_save_one()`. A key need to be covered by a `h_export` only if it is supposed to be stored by `settings_save()` call.

For both FCB and file back-end only storage requests with data which changes most actual key’s value are stored, therefore there is no need to check whether a value changed by the application. Such a storage mechanism implies that storage can contain multiple value assignments for a key, while only the last is the current value for the key.

Garbage collection

When storage becomes full (FCB) or consumes too much space (file), the backend removes non-recent key-value pairs records and unnecessary key-delete records.

4.21.7 Secure domain settings

Currently settings doesn’t provide scheme of being secure, and non-secure configuration storage simultaneously for the same instance. It is recommended that secure domain uses its own settings instance and it might provide data for non-secure domain using dedicated interface if needed (case dependent).

4.21.8 Example: Device Configuration

This is a simple example, where the settings handler only implements `h_set` and `h_export`. `h_set` is called when the value is restored from storage (or when set initially), and `h_export` is used to write the value to storage thanks to `storage_func()`. The user can also implement some other export functionality, for example, writing to the shell console.

```
#define DEFAULT_FOO_VAL_VALUE 1

static int8 foo_val = DEFAULT_FOO_VAL_VALUE;

static int foo_settings_set(const char *name, size_t len,
```

(continues on next page)
settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) & !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }
        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            /* key-value pair was properly read.
             * rc contains value length.
             */
            return 0;
        }
        /* read-out error */
        return rc;
    }
    return -ENOENT;
}

static int foo_settings_export(int (*storage_func)(const char *name,
    const void *value,
    size_t val_len))
{
    return storage_func("foo/bar", &foo_val, sizeof(foo_val));
}

struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set,
    .h_export = foo_settings_export
};

4.21.9 Example: Persist Runtime State

This is a simple example showing how to persist runtime state. In this example, only h_set is defined, which is used when restoring value from persisted storage.

In this example, the main function increments foo_val, and then persists the latest number. When the system restarts, the application calls settings_load() while initializing, and foo_val will continue counting up from where it was before restart.

#include <zephyr/kernel.h>
#include <zephyr/sys/reboot.h>
#include <zephyr/settings/settings.h>
#include <zephyr/sys/printk.h>
#include <inttypes.h>

#define DEFAULT_FOO_VAL_VALUE 0

static uint8_t foo_val = DEFAULT_FOO_VAL_VALUE;
static int foo_settings_set(const char *name, size_t len,
            settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) && !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }
        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            return 0;
        }
    }
    return rc;
}

return -ENOENT;
}

struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set
};

int main(void)
{
    settings_subsys_init();
    settings_register(&my_conf);
    settings_load();

    foo_val++;
    settings_save_one("foo/bar", &foo_val, sizeof(foo_val));

    printk("foo: %d\n", foo_val);
    k_msleep(1000);
    sys_reboot(SYS_REBOOT_COLD);
}

### 4.21.10 Example: Custom Backend Implementation

This is a simple example showing how to register a simple custom backend handler (CONFIG_SETTINGS_CUSTOM).

```c
static int settings_custom_load(struct settings_store *cs,
            const struct settings_load_arg *arg)
{
    //...
}
```
static int settings_custom_save(struct settings_store *cs, const char *name, const char *value, size_t val_len)
{
    //...
}

/* custom backend interface */
static struct settings_store_itf settings_custom_itf = {
    .csi_load = settings_custom_load,
    .csi_save = settings_custom_save,
};

/* custom backend node */
static struct settings_store settings_custom_store = {
    .cs_itf = &settings_custom_itf
};

int settings_backend_init(void)
{
    /* register custom backend */
    settings_dst_register(&settings_custom_store);
    settings_src_register(&settings_custom_store);
    return 0;
}

4.21.11 API Reference

The Settings subsystem APIs are provided by settings.h:

API for general settings usage

Related code samples

- Settings API - Load and save configuration values using the settings API.

group settings

Defines

SETTINGS_MAX_DIR_DEPTH

SETTINGS_MAX_NAME_LEN

SETTINGS_MAX_VAL_LEN

SETTINGS_NAME_SEPARATOR

SETTINGS_NAME_END
Define a static handler for settings items.

This creates a variable *hname prepended by* settings_handler.

**Parameters**
- `_hname` – handler name
- `_tree` – subtree name
- `_get` – get routine (can be NULL)
- `_set` – set routine (can be NULL)
- `_commit` – commit routine (can be NULL)
- `_export` – export routine (can be NULL)

**Typedefs**

typedef ssize_t (*settings_read_cb)(void *cb_arg, void *data, size_t len)

Function used to read the data from the settings storage in h_set handler implementations.

**Param cb_arg**
[in] arguments for the read function. Appropriate cb_arg is transferred to h_set handler implementation by the backend.

**Param data**
[ out] the destination buffer

**Param len**
[in] length of read

**Return**
positive: Number of bytes read, 0: key-value pair is deleted. On error returns -ERRNO code.

typedef int (*settings_load_direct_cb)(const char *key, size_t len, settings_read_cb read_cb, void *cb_arg, void *param)

Callback function used for direct loading.

Used by settings_load_subtree_direct function.

**Param key**
[in] the name with skipped part that was used as name in handler registration

**Param len**
[in] the size of the data found in the backend.

**Param read_cb**
[in] function provided to read the data from the backend.

**Param cb_arg**
[inout] arguments for the read function provided by the backend.

**Param param**
[inout] parameter given to the settings_load_subtree_direct function.

**Return**
When nonzero value is returned, further subtree searching is stopped.
Functions

int settings_subsys_init(void)
Initialization of settings and backend.
Can be called at application startup. In case the backend is a FS Remember to call it after the FS was mounted. For FCB backend it can be called without such a restriction.

Returns
0 on success, non-zero on failure.

int settings_register(struct settings_handler *cf)
Register a handler for settings items stored in RAM.

Parameters
• cf – Structure containing registration info.

Returns
0 on success, non-zero on failure.

int settings_load(void)
Load serialized items from registered persistence sources.
Handlers for serialized item subtrees registered earlier will be called for encountered values.

Returns
0 on success, non-zero on failure.

int settings_load_subtree(const char *subtree)
Load limited set of serialized items from registered persistence sources.
Handlers for serialized item subtrees registered earlier will be called for encountered values that belong to the subtree.

Parameters
• subtree – [in] name of the subtree to be loaded.

Returns
0 on success, non-zero on failure.

int settings_load_subtree_direct(const char *subtree, settings_load_direct_cb cb, void *param)
Load limited set of serialized items using given callback.
This function bypasses the normal data workflow in settings module. All the settings values that are found are passed to the given callback.

Note: This function does not call commit function. It works as a blocking function, so it is up to the user to call any kind of commit function when this operation ends.

Parameters
• subtree – [in] subtree name of the subtree to be loaded.
• cb – [in] pointer to the callback function.
• param – [inout] parameter to be passed when callback function is called.

Returns
0 on success, non-zero on failure.
int settings_save(void)
  Save currently running serialized items.
  All serialized items which are different from currently persisted values will be saved.

  **Returns**
  0 on success, non-zero on failure.

int settings_save_one(const char *name, const void *value, size_t val_len)
  Write a single serialized value to persisted storage (if it has changed value).

  **Parameters**
  - **name** – Name/key of the settings item.
  - **value** – Pointer to the value of the settings item. This value will be transferred to the `settings_handler::h_export` handler implementation.
  - **val_len** – Length of the value.

  **Returns**
  0 on success, non-zero on failure.

int settings_delete(const char *name)
  Delete a single serialized in persisted storage.
  Deleting an existing key-value pair in the settings mean to set its value to NULL.

  **Parameters**
  - **name** – Name/key of the settings item.

  **Returns**
  0 on success, non-zero on failure.

int settings_commit(void)
  Call commit for all settings handler.
  This should apply all settings which has been set, but not applied yet.

  **Returns**
  0 on success, non-zero on failure.

int settings_commit_subtree(const char *subtree)
  Call commit for settings handler that belong to subtree.
  This should apply all settings which has been set, but not applied yet.

  **Parameters**
  - **subtree** – [in] name of the subtree to be committed.

  **Returns**
  0 on success, non-zero on failure.

struct settings_handler
  #include <settings.h> Config handlers for subtree implement a set of handler functions.
  These are registered using a call to `settings_register`.

  **Public Members**

  const char *name
  Name of subtree.
int (*h_get)(const char *key, char *val, int val_len_max)
Get values handler of settings items identified by keyword names.
Parameters:
- key[in] the name with skipped part that was used as name in handler registration
- val[out] buffer to receive value.
- val_len_max[in] size of that buffer.
Return: length of data read on success, negative on failure.

int (*h_set)(const char *key, size_t len, settings_read_cb read_cb, void *cb_arg)
Set value handler of settings items identified by keyword names.
Parameters:
- key[in] the name with skipped part that was used as name in handler registration
- len[in] the size of the data found in the backend.
- read_cb[in] function provided to read the data from the backend.
- cb_arg[in] arguments for the read function provided by the backend.
Return: 0 on success, non-zero on failure.

int (*h_commit)(void)
This handler gets called after settings has been loaded in full.
User might use it to apply setting to the application.
Return: 0 on success, non-zero on failure.

int (*h_export)(int (*export_func)(const char *name, const void *val, size_t val_len))
This gets called to dump all current settings items.
This happens when settings_save tries to save the settings. Parameters:
- export_func: the pointer to the internal function which appends a single key-value pair to persisted settings. Don't store duplicated value. The name is subtree/key string, val is the string with value.
Return: 0 on success, non-zero on failure.

**Remark**
The User might limit a implementations of handler to serving only one keyword at one call - what will impose limit to get/set values using full subtree/key name.

*sys_snnode_t node*
Linked list node info for module internal usage.

*struct settings_handler_static*
#include <settings.h> Config handlers without the node element, used for static handlers.
These are registered using a call to SETTINGS_STATIC_HANDLER_DEFINE().

**Public Members**

- const char *name
  Name of subtree.
int (*h_get)(const char *key, char *val, int val_len_max)
Get values handler of settings items identified by keyword names.
Parameters:
• key[in] the name with skipped part that was used as name in handler registration
• val[out] buffer to receive value.
• val_len_max[in] size of that buffer.
Return: length of data read on success, negative on failure.

int (*h_set)(const char *key, size_t len, settings_read_cb read_cb, void *cb_arg)
Set value handler of settings items identified by keyword names.
Parameters:
• key[in] the name with skipped part that was used as name in handler registration
• len[in] the size of the data found in the backend.
• read_cb[in] function provided to read the data from the backend.
• cb_arg[in] arguments for the read function provided by the backend.
Return: 0 on success, non-zero on failure.

int (*h_commit)(void)
This handler gets called after settings has been loaded in full.
User might use it to apply setting to the application.

int (*h_export)(int (*export_func)(const char *name, const void *val, size_t val_len))
This gets called to dump all current settings items.
This happens when settings_save tries to save the settings. Parameters:
• export_func: the pointer to the internal function which appends a single key-value pair to persisted settings. Don't store duplicated value. The name is subtree/key string, val is the string with value.
Return: 0 on success, non-zero on failure.

Remark
The User might limit a implementations of handler to serving only one keyword at one call - what will impose limit to get/set values using full subtree/key name.

API for key-name processing

Related code samples
• Settings API - Load and save configuration values using the settings API.

group settings_name_proc
API for const name processing.

Functions
int settings_name_steq(const char *name, const char *key, const char **next)

Compares the start of name with a key.

Some examples: settings_name_steq("bt/btmesh/iv", "b", &next) returns 1, next="t/btmesh/iv" settings_name_steq("bt/btmesh/iv", "bt", &next) returns 1, next="btmesh/iv" settings_name_steq("bt/btmesh/iv", "bt/", &next) returns 0, next=NULL settings_name_steq("bt/btmesh/iv", "bta", &next) returns 0, next=NULL

REMARK: This routine could be simplified if the settings_handler names would include a separator at the end.

Parameters
- name – [in] in string format
- key – [in] comparison string
- next – [out] pointer to remaining of name, when the remaining part starts with a separator the separator is removed from next

Returns
0: no match 1: match, next can be used to check if match is full

int settings_name_next(const char *name, const char **next)

determine the number of characters before the first separator

Parameters
- name – [in] in string format
- next – [out] pointer to remaining of name (excluding separator)

Returns
index of the first separator, in case no separator was found this is the size of name

API for runtime settings manipulation

Related code samples
- Settings API - Load and save configuration values using the settings API.

API for runtime settings manipulation

Functions

int settings_runtime_set(const char *name, const void *data, size_t len)

Set a value with a specific key to a module handler.

Parameters
- name – Key in string format.
- data – Binary value.
- len – Value length in bytes.

Returns
0 on success, non-zero on failure.
int settings_runtime_get(const char *name, void *data, size_t len)
Get a value corresponding to a key from a module handler.

**Parameters**
- name – Key in string format.
- data – Returned binary value.
- len – requested value length in bytes.

**Returns**
length of data read on success, negative on failure.

int settings_runtime_commit(const char *name)
Apply settings in a module handler.

**Parameters**
- name – Key in string format.

**Returns**
0 on success, non-zero on failure.

**API of backend interface**

**group** settings_backend

**settings**

**Functions**

void settings_src_register(struct settings_store *cs)
Register a backend handler acting as source.

**Parameters**
- cs – Backend handler node containing handler information.

void settings_dst_register(struct settings_store *cs)
Register a backend handler acting as destination.

**Parameters**
- cs – Backend handler node containing handler information.

struct settings_handler_* settings_parse_and_lookup(const char *name, const char **next)
Parses a key to an array of elements and locate corresponding module handler.

**Parameters**
- name – [in] in string format
- next – [out] remaining of name after matched handler

**Returns**
settings_handler_static on success, NULL on failure.

int settings_call_set_handler(const char *name, size_t len, settings_read_cb read_cb, void *read_cb_arg, const struct settings_load_arg *load_arg)
Calls settings handler.

**Parameters**
- name – [in] The name of the data found in the backend.
• len – [in] The size of the data found in the backend.
• read_cb – [in] Function provided to read the data from the backend.
• read_cb_arg – [inout] Arguments for the read function provided by the backend.

Returns
0 or negative error code

struct settings_store
#include <settings.h> Backend handler node for storage handling.

Public Members

sys_snode_t cs_next
Linked list node info for internal usage.

const struct settings_store_itf *cs_itf
Backend handler structure.

struct settings_load_arg
#include <settings.h> Arguments for data loading.
Holds all parameters that changes the way data should be loaded from backend.

Public Members

const char *subtree
Name of the subtree to be loaded.
If NULL, all values would be loaded.

settings_load_direct_cb cb
Pointer to the callback function.
If NULL then matching registered function would be used.

void *param
Parameter for callback function.
Parameter to be passed to the callback function.

struct settings_store_itf
#include <settings.h> Backend handler functions.
Sources are registered using a call to settings_src_register. Destinations are registered using a call to settings_dst_register.
Public Members

int (*csi_load)(struct settings_store *cs, const struct settings_load_arg *arg)
Loads values from storage limited to subtree defined by subtree.
Parameters:
• cs - Corresponding backend handler node,
• arg - Structure that holds additional data for data loading.

Note: Backend is expected not to provide duplicates of the entities. It means that if the backend does not contain any functionality to really delete old keys, it has to filter out old entities and call load callback only on the final entity.

int (*csi_save_start)(struct settings_store *cs)
Handler called before an export operation.
Parameters:
• cs - Corresponding backend handler node

int (*csi_save)(struct settings_store *cs, const char *name, const char *value, size_t val_len)
Save a single key-value pair to storage.
Parameters:
• cs - Corresponding backend handler node
• name - Key in string format
• value - Binary value
• val_len - Length of value in bytes.

int (*csi_save_end)(struct settings_store *cs)
Handler called after an export operation.
Parameters:
• cs - Corresponding backend handler node

Get pointer to the storage instance used by the backend.

Parameters:
• cs - Corresponding backend handler node

4.22 State Machine Framework

4.22.1 Overview

The State Machine Framework (SMF) is an application agnostic framework that provides an easy way for developers to integrate state machines into their application. The framework can be added to any project by enabling the CONFIG_SMF option.

4.22.2 State Creation

A state is represented by three functions, where one function implements the Entry actions, another function implements the Run actions, and the last function implements the Exit actions. The prototype for these functions is as follows: void funct(void *obj), where the obj parameter is a user defined structure that has the state machine context, struct smf_ctx, as its first member. For example:
The `struct smf_ctx` member must be first because the state machine framework's functions cast the user defined object to the `struct smf_ctx` type with the following macro: \texttt{SMF_CTX(o)}.

For example instead of doing this `(struct smf_ctx *)&user_obj`, you could use `SMF_CTX(&user_obj)`. By default, a state can have no ancestor states, resulting in a flat state machine. But to enable the creation of a hierarchical state machine, the `CONFIG_SMF_ANCESTOR_SUPPORT` option must be enabled.

The following macro can be used for easy state creation:

- \texttt{SMF_CREATE_STATE} Create a state

\textbf{NOTE:} The \texttt{SMF_CREATE_STATE} macro takes an additional parameter when \texttt{CONFIG_SMF_ANCESTOR_SUPPORT} is enabled.

### 4.22.3 State Machine Creation

A state machine is created by defining a table of states that's indexed by an enum. For example, the following creates three flat states:

```c
enum demo_state { S0, S1, S2 };

const struct smf_state demo_states[] = {
    [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit),
    [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit),
    [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit)
};
```

And this example creates three hierarchical states:

```c
enum demo_state { S0, S1, S2 };

const struct smf_state demo_states[] = {
    [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, parent_s0),
    [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit, parent_s12),
    [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit, parent_s12)
};
```

To set the initial state, the `smf_set_initial` function should be called. It has the following prototype:

```c
void smf_set_initial(smf_ctx *ctx, smf_state *state)
```

To transition from one state to another, the `smf_set_state` function is used and it has the following prototype:

```c
void smf_set_state(smf_ctx *ctx, smf_state *state)
```

\textbf{NOTE:} While the state machine is running, `smf_set_state` should only be called from the Entry and Run functions. Calling `smf_set_state` from the Exit functions doesn't make sense and will generate a warning.

### 4.22.4 State Machine Execution

To run the state machine, the `smf_run_state` function should be called in some application dependent way. An application should cease calling `smf_run_state` if it returns a non-zero value. The function has the following prototype:

```c
int32_t smf_run_state(smf_ctx *ctx)
```
4.22.5 State Machine Termination

To terminate the state machine, the \texttt{smf\_terminate} function should be called. It can be called from the entry, run, or exit action. The function takes a non-zero user defined value that's returned by the \texttt{smf\_run\_state} function. The function has the following prototype: \texttt{void smf\_terminate(smf\_ctx *ctx, int32\_t val)}

4.22.6 Flat State Machine Example

This example turns the following state diagram into code using the SMF, where the initial state is S0.

Fig. 9: Flat state machine diagram

Code:

```c
#include <zephyr/smf.h>

/* Forward declaration of state table */
static const struct smf\_state demo\_states[];

/* List of demo states */
enum demo\_state { S0, S1, S2 };

/* User defined object */
struct s\_object {
    /* This must be first */
    struct smf\_ctx ctx;

    /* Other state specific data add here */
} s\_obj;
```

(continues on next page)
/* State S0 */
static void s0_entry(void *o)
{
    /* Do something */
}
static void s0_run(void *o)
{
    smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
}
static void s0_exit(void *o)
{
    /* Do something */
}

/* State S1 */
static void s1_run(void *o)
{
    smf_set_state(SMF_CTX(&s_obj), &demo_states[S2]);
}
static void s1_exit(void *o)
{
    /* Do something */
}

/* State S2 */
static void s2_entry(void *o)
{
    /* Do something */
}
static void s2_run(void *o)
{
    smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
}

/* Populate state table */
static const struct smf_state demo_states[] = {
    [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit),
    /* State S1 does not have an entry action */
    [S1] = SMF_CREATE_STATE(NULL, s1_run, s1_exit),
    /* State S2 does not have an exit action */
    [S2] = SMF_CREATE_STATE(s2_entry, s2_run, NULL),
};

int main(void)
{
    int32_t ret;

    /* Set initial state */
    smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

    /* Run the state machine */
    while(1) {
        /* State machine terminates if a non-zero value is returned */
        ret = smf_run_state(SMF_CTX(&s_obj));
        if (ret) {
            (continues on next page)
4.22.7 Hierarchical State Machine Example

This example turns the following state diagram into code using the SMF, where S0 and S1 share a parent state and S0 is the initial state.

![Hierarchical state machine diagram](image)

**Fig. 10: Hierarchical state machine diagram**

**Code:**

```c
#include <zephyr/smf.h>

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
enum demo_state { PARENT, S0, S1, S2 };

/* User defined object */
struct s_object {
    /* This must be first */
    struct smf_ctx ctx;
```

(continues on next page)
Zephyr Project Documentation, Release 3.5.0-rc1

(continued from previous page)

    /* Other state specific data add here */
} s_obj;

/* Parent State */
static void parent_entry(void *o)
{
    /* Do something */
}
static void parent_exit(void *o)
{
    /* Do something */
}

/* State S0 */
static void s0_run(void *o)
{
    smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
}

/* State S1 */
static void s1_run(void *o)
{
    smf_set_state(SMF_CTX(&s_obj), &demo_states[S2]);
}

/* State S2 */
static void s2_run(void *o)
{
    smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
}

/* Populate state table */
static const struct smf_state demo_states[] = {
    /* Parent state does not have a run action */
    [PARENT] = SMF_CREATE_STATE(parent_entry, NULL, parent_exit, NULL),
    /* Child states do not have entry or exit actions */
    [S0] = SMF_CREATE_STATE(NULL, s0_run, NULL, &demo_states[PARENT]),
    [S1] = SMF_CREATE_STATE(NULL, s1_run, NULL, &demo_states[PARENT]),
    /* State S2 do ot have entry or exit actions and no parent */
    [S2] = SMF_CREATE_STATE(NULL, s2_run, NULL, NULL),
};

int main(void)
{
    int32_t ret;

    /* Set initial state */
    smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

    /* Run the state machine */
    while(1) {
        /* State machine terminates if a non-zero value is returned */
        ret = smf_run_state(SMF_CTX(&s_obj));
        if (ret) {
            /* handle return code and terminate state machine */
            break;
    
    (continues on next page)
When designing hierarchical state machines, the following should be considered:

- Ancestor entry actions are executed before the sibling entry actions. For example, the parent_entry function is called before the s0_entry function.
- Transitioning from one sibling to another with a shared ancestry does not re-execute the ancestor’s entry action or execute the exit action. For example, the parent_entry function is not called when transitioning from S0 to S1, nor is the parent_exit function called.
- Ancestor exit actions are executed after the sibling exit actions. For example, the s1_exit function is called before the parent_exit function is called.
- The parent_run function only executes if the child_run function returns without transitioning to another state, i.e. calling smf_set_state.

### 4.22.8 Event Driven State Machine Example

Events are not explicitly part of the State Machine Framework but an event driven state machine can be implemented using Zephyr *Events*.

![Event driven state machine diagram](image)

**Fig. 11: Event driven state machine diagram**

**Code:**

```c
#include <zephyr/kernel.h>
#include <zephyr/drivers/gpio.h>
#include <zephyr/smf.h>

#define SW0_NODE DT_ALIAS(sw0)

/* List of events */
```

(continues on next page)
#define EVENT_BTN_PRESS BIT(0)

static const struct gpio_dt_spec button =
    GPIO_DT_SPEC_GET_OR(SW0_NODE, gpios, {0});

static struct gpio_callback button_cb_data;

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
enum demo_state { S0, S1 };

/* User defined object */
struct s_object {
    /* This must be first */
    struct smf_ctx ctx;

    /* Events */
    struct k_event smf_event;
    int32_t events;

    /* Other state specific data add here */
} s_obj;

/* State S0 */
static void s0_entry(void *o)
{
    printk("STATE0\n");
}

static void s0_run(void *o)
{
    struct s_object *s = (struct s_object *)o;

    /* Change states on Button Press Event */
    if (s->events & EVENT_BTN_PRESS) {
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
    }
}

/* State S1 */
static void s1_entry(void *o)
{
    printk("STATE1\n");
}

static void s1_run(void *o)
{
    struct s_object *s = (struct s_object *)o;

    /* Change states on Button Press Event */
    if (s->events & EVENT_BTN_PRESS) {
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
    }
}
static const struct smf_state demo_states[] = {
    [S0] = SMF_CREATE_STATE(s0_entry, s0_run, NULL),
    [S1] = SMF_CREATE_STATE(s1_entry, s1_run, NULL),
};

void button_pressed(const struct device *dev,
    struct gpio_callback *cb, uint32_t pins)
{
    /* Generate Button Press Event */
    k_event_post(&s_obj.smf_event, EVENT_BTN_PRESS);
}

int main(void)
{
    int ret;

    if (!gpio_is_ready_dt(&button)) {
        printk("Error: button device %s is not ready\n", 
            button.port->name);
        return;
    }

    ret = gpio_pin_configure_dt(&button, GPIO_INPUT);
    if (ret != 0) {
        printk("Error %d: failed to configure %s pin %d\n", 
            ret, button.port->name, button.pin);
        return;
    }

    ret = gpio_pin_interrupt_configure_dt(&button, 
        GPIO_INT_EDGE_TO_ACTIVE);
    if (ret != 0) {
        printk("Error %d: failed to configure interrupt on %s pin %d\n", 
            ret, button.port->name, button.pin);
        return;
    }

    gpio_init_callback(&button_cb_data, button_pressed, BIT(button.pin));
    gpio_add_callback(button.port, &button_cb_data);

    /* Initialize the event */
    k_event_init(&s_obj.smf_event);

    /* Set initial state */
    smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

    /* Run the state machine */
    while(1) {
        /* Block until an event is detected */
        s_obj.events = k_event_wait(&s_obj.smf_event, 
            EVENT_BTN_PRESS, true, K_FOREVER);

        /* State machine terminates if a non-zero value is returned */
        ret = smf_run_state(SMF_CTX(&s_obj));
    }
if (ret) {
    /* handle return code and terminate state machine */
    break;
}
}

4.23 Storage

4.23.1 Non-Volatile Storage (NVS)

Elements, represented as id-data pairs, are stored in flash using a FIFO-managed circular buffer. The flash area is divided into sectors. Elements are appended to a sector until storage space in the sector is exhausted. Then a new sector in the flash area is prepared for use (erased). Before erasing the sector it is checked that identifier - data pairs exist in the sectors in use, if not the id-data pair is copied.

The id is a 16-bit unsigned number. NVS ensures that for each used id there is at least one id-data pair stored in flash at all time.

NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Each element is stored in flash as metadata (8 byte) and data. The metadata is written in a table starting from the end of a nvs sector, the data is written one after the other from the start of the sector. The metadata consists of: id, data offset in sector, data length, part (unused) and a crc.

A write of data to nvs always starts with writing the data, followed by a write of the metadata. Data that is written in flash without metadata is ignored during initialization.

During initialization NVS will verify the data stored in flash, if it encounters an error it will ignore any data with missing/incorrect metadata.

NVS checks the id-data pair before writing data to flash. If the id-data pair is unchanged no write to flash is performed.

To protect the flash area against frequent erases it is important that there is sufficient free space. NVS has a protection mechanism to avoid getting in a endless loop of flash page erases when there is limited free space. When such a loop is detected NVS returns that there is no more space available.

For NVS the file system is declared as:

```c
static struct nvs_fs fs = {
    .flash_device = NVS_FLASH_DEVICE,
    .sector_size = NVS_SECTOR_SIZE,
    .sector_count = NVS_SECTOR_COUNT,
    .offset = NVS_STORAGE_OFFSET,
};
```

where

- **NVS_FLASH_DEVICE** is a reference to the flash device that will be used. The device needs to be operational.
- **NVS_SECTOR_SIZE** is the sector size, it has to be a multiple of the flash erase page size and a power of 2.
- **NVS_SECTOR_COUNT** is the number of sectors, it is at least 2, one sector is always kept empty to allow copying of existing data.
- **NVS_STORAGE_OFFSET** is the offset of the storage area in flash.
Flash wear

When writing data to flash a study of the flash wear is important. Flash has a limited life which is determined by the number of times flash can be erased. Flash is erased one page at a time and the pagesize is determined by the hardware. As an example a nRF51822 device has a pagesize of 1024 bytes and each page can be erased about 20,000 times.

Calculating expected device lifetime Suppose we use a 4 bytes state variable that is changed every minute and needs to be restored after reboot. NVS has been defined with a sector_size equal to the pagesize (1024 bytes) and 2 sectors have been defined.

Each write of the state variable requires 12 bytes of flash storage: 8 bytes for the metadata and 4 bytes for the data. When storing the data the first sector will be full after 1024/12 = 85.33 minutes. After another 85.33 minutes, the second sector is full. When this happens, because we're using only two sectors, the first sector will be used for storage and will be erased after 171 minutes of system time. With the expected device life of 20,000 writes, with two sectors writing every 171 minutes, the device should last about 171 * 20,000 minutes, or about 6.5 years.

More generally then, with
• NS as the number of storage requests per minute,
• DS as the data size in bytes,
• SECTOR_SIZE in bytes, and
• PAGE_ERASES as the number of times the page can be erased,
the expected device life (in minutes) can be calculated as:

\[
\text{SECTOR\_COUNT} \times \text{SECTOR\_SIZE} \times \text{PAGE\_ERASES} / (\text{NS} \times (\text{DS}+8)) \text{ minutes}
\]

From this formula it is also clear what to do in case the expected life is too short: increase SECTOR\_COUNT or SECTOR\_SIZE.

Flash write block size migration

It is possible that during a DFU process, the flash driver used by the NVS changes the supported minimal write block size. The NVS in-flash image will stay compatible unless the physical ATE size changes. Especially, migration between 1,2,4,8-bytes write block sizes is allowed.

Sample

A sample of how NVS can be used is supplied in samples/subsys/nvs.

Troubleshooting

MPU fault while using NVS, or -ETIMEDOUT error returned

NVS can use the internal flash of the SoC. While the MPU is enabled, the flash driver requires MPU RWX access to flash memory, configured using CONFIG_MPU_ALLOW_FLASH_WRITE. If this option is disabled, the NVS application will get an MPU fault if it references the internal SoC flash and it's the only thread running. In a multi-threaded application, another thread might intercept the fault and the NVS API will return an -ETIMEDOUT error.
API Reference

The NVS subsystem APIs are provided by nvs.h:

```c
#include <nvs.h>
```

Non-volatile Storage Data Structures.

```c
struct nvs_fs
```

Non-volatile Storage File system structure.
