This is simple, but crucial: if this is not implemented correctly, the kernel will not function as intended and will experience bizarre crashes, mostly due to stack corruption.

**Note:** If running a coop-only system, i.e. if `CONFIG_NUM_PREEMPT_PRIORITIES` is 0, no preemptive context switch ever happens. The interrupt code can be optimized to not take any scheduling decision when this is the case.

### Thread Creation and Termination

To start a new thread, a stack frame must be constructed so that the context switch can pop it the same way it would pop one from a thread that had been context switched out. This is to be implemented in an architecture-specific `_new_thread` internal routine.

The thread entry point is also not to be called directly, i.e. it should not be set as the PC (program counter) for the new thread. Rather it must be wrapped in `_thread_entry`. This means that the PC in the stack frame shall be set to `_thread_entry`, and the thread entry point shall be passed as the first parameter to `_thread_entry`. The specifics of this depend on the ABI.

The need for an architecture-specific thread termination implementation depends on the architecture. There is a generic implementation, but it might not work for a given architecture.

One reason that has been encountered for having an architecture-specific implementation of thread termination is that aborting a thread might be different if aborting because of a graceful exit or because of an exception. This is the case for ARM Cortex-M, where the CPU has to be taken out of handler mode if the thread triggered a fatal exception, but not if the thread gracefully exits its entry point function.

This means implementing an architecture-specific version of `k_thread_abort()`, and setting the Kconfig option `CONFIG_ARCH_HAS_THREAD_ABORT` as needed for the architecture (e.g. see `arch/arm/core/cortex_m/Kconfig`).

### Thread Local Storage

To enable thread local storage on a new architecture:

1. Implement `arch_tls_stack_setup()` to setup the TLS storage area in stack. Refer to the toolchain documentation on how the storage area needs to be structured. Some helper functions can be used:
   - Function `z_tls_data_size()` returns the size needed for thread local variables (excluding any extra data required by toolchain and architecture).
   - Function `z_tls_copy()` prepares the TLS storage area for thread local variables. This only copies the variable themselves and does not do architecture and/or toolchain specific data.

2. In the context switching, grab the `tls` field inside the new thread's `struct k_thread` and put it into an appropriate register (or some other variable) for access to the TLS storage area. Refer to toolchain and architecture documentation on which registers to use.

3. In kconfig, add select `CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE` to kconfig related to the new architecture.

4. Run the `tests/kernel/threads/tls` to make sure the new code works.
Device Drivers

The kernel requires very few hardware devices to function. In theory, the only required device is the interrupt controller, since the kernel can run without a system clock. In practice, to get access to most, if not all, of the sanity check test suite, a system clock is needed as well. Since these two are usually tied to the architecture, they are part of the architecture port.

Interrupt Controllers

There can be significant differences between the interrupt controllers and the interrupt concepts across architectures.

For example, x86 has the concept of an IDT and different interrupt controllers. The position of an interrupt in the IDT determines its priority.

On the other hand, the ARM Cortex-M has the NVIC (Nested Vectored Interrupt Controller) as part of the architecture definition. There is no need for an IDT-like table that is separate from the NVIC vector table. The position in the table has nothing to do with priority of an IRQ: priorities are programmable per-entry.

The ARCv2 has its interrupt unit as part of the architecture definition, which is somewhat similar to the NVIC. However, where ARC defines interrupts as having a one-to-one mapping between exception and interrupt numbers (i.e., exception 1 is IRQ1, and device IRQs start at 16), ARM has IRQ0 being equivalent to exception 16 (and weirdly enough, exception 1 can be seen as IRQ-15).

All these differences mean that very little, if anything, can be shared between architectures with regards to interrupt controllers.

System Clock

x86 has APIC timers and the HPET as part of its architecture definition. ARM Cortex-M has the SYSTICK exception. Finally, ARCv2 has the timer0/1 device.

Kernel timeouts are handled in the context of the system clock timer driver's interrupt handler.

Console Over Serial Line

There is one other device that is almost a requirement for an architecture port, since it is so useful for debugging. It is a simple polling, output-only, serial port driver on which to send the console (printk, printf) output.

It is not required, and a RAM console (CONFIG_RAM_CONSOLE) can be used to send all output to a circular buffer that can be read by a debugger instead.

Utility Libraries

The kernel depends on a few functions that can be implemented with very few instructions or in a lock-less manner in modern processors. Those are thus expected to be implemented as part of an architecture port.

- Atomic operators.
  - If instructions do exist for a given architecture, the implementation is configured using the CONFIG_ATOMIC_OPERATIONS_ARCH Kconfig option.
  - If instructions do not exist for a given architecture, a generic version that wraps irq_lock() or irq_unlock() around non-atomic operations exists. It is configured using the CONFIG_ATOMIC_OPERATIONS_C Kconfig option.

- Find-least-significant-bit-set and find-most-significant-bit-set.
  - If instructions do not exist for a given architecture, it is always possible to implement these functions as generic C functions.

It is possible to use compiler built-ins to implement these, but be careful they use the required compiler barriers.
CPU Idling/Power Management

The kernel provides support for CPU power management with two functions: `arch_cpu_idle()` and `arch_cpu_atomic_idle()`.

`arch_cpu_idle()` can be as simple as calling the power saving instruction for the architecture with interrupts unlocked, for example `hlt` on x86, `wfi` or `wfe` on ARM, `sleep` on ARC. This function can be called in a loop within a context that does not care if it gets interrupted or not by an interrupt before going to sleep. There are basically two scenarios when it is correct to use this function:

- In a single-threaded system, in the only thread when the thread is not used for doing real work after initialization, i.e. it is sitting in a loop doing nothing for the duration of the application.
- In the idle thread.

`arch_cpu_atomic_idle()`, on the other hand, must be able to atomically re-enable interrupts and invoke the power saving instruction. It can thus be used in real application code, again in single-threaded systems.

Normally, idling the CPU should be left to the idle thread, but in some very special scenarios, these APIs can be used by applications.

Both functions must exist for a given architecture. However, the implementation can be simply the following steps, if desired:

1. unlock interrupts
2. NOP

However, a real implementation is strongly recommended.

Fault Management

In the event of an unhandled CPU exception, the architecture code must call into `z_fatal_error()`. This function dumps out architecture-agnostic information and makes a policy decision on what to do next by invoking `k_sys_fatal_error()`. This function can be overridden to implement application-specific policies that could include locking interrupts and spinning forever (the default implementation) or even powering off the system (if supported).

Toolchain and Linking

Toolchain support has to be added to the build system.

Some architecture-specific definitions are needed in `include/zephyr/toolchain/gcc.h`. See what exists in that file for currently supported architectures.

Each architecture also needs its own linker script, even if most sections can be derived from the linker scripts of other architectures. Some sections might be specific to the new architecture, for example the SCB section on ARM and the IDT section on x86.

Memory Management and Memory Mapping

If the target platform enables paging and requires drivers to memory-map their I/O regions, `CONFIG_MMU` needs to be enabled and the following API implemented:

- `arch_mem_map()`
- `arch_mem_unmap()`
- `arch_page_phys_get()`
Stack Objects

The presence of memory protection hardware affects how stack objects are created. All architecture ports must specify the required alignment of the stack pointer, which is some combination of CPU and ABI requirements. This is defined in architecture headers with ARCH_STACK_PTR_ALIGN and is typically something small like 4, 8, or 16 bytes.

Two types of thread stacks exist:

- “kernel” stacks defined with K_KERNEL_STACK_DEFINE() and related APIs, which can host kernel threads running in supervisor mode or used as the stack for interrupt/exception handling. These have significantly relaxed alignment requirements and use less reserved data. No memory is reserved for privilege elevation stacks.
- “thread” stacks which typically use more memory, but are capable of hosting thread running in user mode, as well as any use-cases for kernel stacks.

If CONFIG_USERSPACE is not enabled, “thread” and “kernel” stacks are equivalent.

Additional macros may be defined in the architecture layer to specify the alignment of the base of stack objects, any reserved data inside the stack object not used for the thread’s stack buffer, and how to round up stack sizes to support user mode threads. In the absence of definitions some defaults are assumed:

- ARCH_KERNEL_STACK_RESERVED: default no reserved space
- ARCH_THREAD_STACK_RESERVED: default no reserved space
- ARCH_KERNEL_STACK_OBJ_ALIGN: default align to ARCH_STACK_PTR_ALIGN
- ARCH_THREAD_STACK_OBJ_ALIGN: default align to ARCH_STACK_PTR_ALIGN
- ARCH_THREAD_STACK_SIZE_ALIGN: default round up to ARCH_STACK_PTR_ALIGN

All stack creation macros are defined in terms of these.

Stack objects all have the following layout, with some regions potentially zero-sized depending on configuration. There are always two main parts: reserved memory at the beginning, and then the stack buffer itself. The bounds of some areas can only be determined at runtime in the context of its associated thread object. Other areas are entirely computable at build time.

Some architectures may need to carve-out reserved memory at runtime from the stack buffer, instead of unconditionally reserving it at build time, or to supplement an existing reserved area (as is the case with the ARM FPU). Such carve-outs will always be tracked in thread.stack_info.start. The region specified by thread.stack_info.start and thread.stack_info.size is always fully accessible by a user mode thread. thread.stack_info.delta denotes an offset which can be used to compute the initial stack pointer from the very end of the stack object, taking into account storage for TLS and ASLR random offsets.

At present, Zephyr does not support stacks that grow upward.
No Memory Protection  If no memory protection is in use, then the defaults are sufficient.

HW-based stack overflow detection  This option uses hardware features to generate a fatal error if a thread in supervisor mode overflows its stack. This is useful for debugging, although for a couple reasons, you can’t reliably make any assertions about the state of the system after this happens:

- The kernel could have been inside a critical section when the overflow occurs, leaving important global data structures in a corrupted state.
- For systems that implement stack protection using a guard memory region, it’s possible to overshoot the guard and corrupt adjacent data structures before the hardware detects this situation.

To enable the CONFIG_HW_STACK_PROTECTION feature, the system must provide some kind of hardware-based stack overflow protection, and enable the CONFIG_ARCH_HAS_STACK_PROTECTION option.

Two forms of HW-based stack overflow detection are supported: dedicated CPU features for this purpose, or special read-only guard regions immediately preceding stack buffers.

CONFIG_HW_STACK_PROTECTION only catches stack overflows for supervisor threads. This is not required to catch stack overflow from user threads; CONFIG_USERSPACE is orthogonal.

This feature only detects supervisor mode stack overflows, including stack overflows when handling system calls. It doesn’t guarantee that the kernel has not been corrupted. Any stack overflow in supervisor mode should be treated as a fatal error, with no assertions about the integrity of the overall system possible.

Stack overflows in user mode are recoverable (from the kernel’s perspective) and require no special configuration; CONFIG_HW_STACK_PROTECTION only applies to catching overflows when the CPU is in supervisor mode.

CPU-based stack overflow detection  If we are detecting stack overflows in supervisor mode via special CPU registers (like ARM’s SPLIM), then the defaults are sufficient.

Guard-based stack overflow detection  We are detecting supervisor mode stack overflows via special memory protection region located immediately before the stack buffer that generates an exception on write. Reserved memory will be used for the guard region.

ARCH_KERNEL_STACK_RESERVED should be defined to the minimum size of a memory protection region. On most ARM CPUs this is 32 bytes. ARCH_KERNEL_STACK_OBJ_ALIGN should also be set to the required alignment for this region.

MMU-based systems should not reserve RAM for the guard region and instead simply leave an non-present virtual page below every stack when it is mapped into the address space. The stack object will still need to be properly aligned and sized to page granularity.

Guard carve-outs for kernel stacks are uncommon and should be avoided if possible. They tend to be needed for two situations:
• The same stack may be re-purposed to host a user thread, in which case the guard is unne-
necessary and shouldn’t be unconditionally reserved. This is the case when privilege elevation
stacks are not inside the stack object.

• The required guard size is variable and depends on context. For example, some ARM CPUs
have lazy floating point stacking during exceptions and may decrement the stack pointer by
a large value without writing anything, completely overshooting a minimally-sized guard
and corrupting adjacent memory. Rather than unconditionally reserving a larger guard,
the extra memory is carved out if the thread uses floating point.

User mode enabled  Enabling user mode activates two new requirements:

• A separate fixed-sized privilege mode stack, specified by CONFIG_PRIVILEGED_STACK_SIZE,
must be allocated that the user thread cannot access. It is used as the stack by the kernel
when handling system calls. If stack guards are implemented, a stack guard region must
be able to be placed before it, with support for carve-outs if necessary.

• The memory protection hardware must be able to program a region that exactly
covers the thread’s stack buffer, tracked in thread.stack_info. This implies that
ARCH_THREAD_STACK_SIZE_ADJUST() will need to round up the requested stack size so that
a region may cover it, and that ARCH_THREAD_STACK_OBJ_ALIGN() is also specified per the
granularity of the memory protection hardware.

This becomes more complicated if the memory protection hardware requires that all memory
regions be sized to a power of two, and aligned to their own size. This is common on older MPUs
and is known with CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT.

thread.stack_info always tracks the user-accessible part of the stack object, it must always be
correct to program a memory protection region with user access using the range stored within.

Non power-of-two memory region requirements On systems without power-of-
two region requirements, the reserved memory area for threads stacks defined by
K_THREAD_STACK_RESERVED may be used to contain the privilege mode stack. The layout
could be something like:

```
+------------------------------+ <- thread.stack_obj
| Other platform data |
+------------------------+
| Guard region (if enabled) |
+------------------------+
| Guard carve-out (if needed) |
|..............................|
| Privilege elevation stack |
+-------------------------------| <- thread.stack_obj +
| Stack buffer |
.                         K_THREAD_STACK_RESERVED =
thread.stack_info.start
```

The guard region, and any carve-out (if needed) would be configured as a read-only region when
the thread is created.

• If the thread is a supervisor thread, the privilege elevation region is just extra stack memory.
  An overflow will eventually crash into the guard region.

• If the thread is running in user mode, a memory protection region will be configured to
  allow user threads access to the stack buffer, but nothing before or after it. An overflow in
  user mode will crash into the privilege elevation stack, which the user thread has no access
to. An overflow when handling a system call will crash into the guard region.

On an MMU system there should be no physical guards; the privilege mode stack will be mapped
into kernel memory, and the stack buffer in the user part of memory, each with non-present
virtual guard pages below them to catch runtime stack overflows.
Other platform data may be stored before the guard region, but this is highly discouraged if such data could be stored in thread.arch somewhere.

ARCH_THREAD_STACK_RESERVED will need to be defined to capture the size of the reserved region containing platform data, privilege elevation stacks, and guards. It must be appropriately sized such that an MPU region to grant user mode access to the stack buffer can be placed immediately after it.

**Power-of-two memory region requirements**

Thread stack objects must be sized and aligned to the same power of two, without any reserved memory to allow efficient packing in memory. Thus, any guards in the thread stack must be completely carved out, and the privilege elevation stack must be allocated elsewhere.

ARCH_THREAD_STACK_SIZE_ADJUST() and ARCH_THREAD_STACK_OBJ_ALIGN() should both be defined to Z_POW2_CEIL(). K_THREAD_STACK_RESERVED must be 0.

For the privilege stacks, the CONFIG_GEN_PRIV_STACKS must be enabled. For every thread stack found in the system, a corresponding fixed-size kernel stack used for handling system calls is generated. The address of the privilege stacks can be looked up quickly at runtime based on the thread stack address using z_priv_stack_find(). These stacks are laid out the same way as other kernel-only stacks.

![Thread Stack Alignment Diagram]

The guard carve-out in the thread stack object is only used if the thread is running in supervisor mode. If the thread drops to user mode, there is no guard and the entire object is used as the stack buffer, with full access to the associated user mode thread and thread.stack_info updated appropriately.

**User Mode Threads**

To support user mode threads, several kernel-to-arch APIs need to be implemented, and the system must enable the CONFIG_ARCH_HAS_USERSPACE option. Please see the documentation for each of these functions for more details:

- `arch_buffer_validate()` to test whether the current thread has access permissions to a particular memory region
- `arch_user_mode_enter()` which will irreversibly drop a supervisor thread to user mode privileges. The stack must be wiped.
- `arch_syscall_oops()` which generates a kernel oops when system call parameters can’t be validated, in such a way that the oops appears to be generated from where the system call was invoked in the user thread
• `arch_syscall_invoke0()` through `arch_syscall_invoke6()` invoke a system call with the appropriate number of arguments which must all be passed in during the privilege elevation via registers.

• `arch_is_user_context()` return nonzero if the CPU is currently running in user mode

• `arch_mem_domain_max_partitions_get()` which indicates the max number of regions for a memory domain. MMU systems have an unlimited amount, MPU systems have constraints on this.

Some architectures may need to update software memory management structures or modify hardware registers on another CPU when memory domain APIs are invoked. If so, CONFIG_ARCH_MEM_DOMAIN_SYNCHRONOUS_API must be selected by the architecture and some additional APIs must be implemented. This is common on MMU systems and uncommon on MPU systems:

• `arch_mem_domain_thread_add()`

• `arch_mem_domain_thread_remove()`

• `arch_mem_domain_partition_add()`

• `arch_mem_domain_partition_remove()`

Please see the doxygen documentation of these APIs for details.

In addition to implementing these APIs, there are some other tasks as well:

• `_new_thread()` needs to spawn threads with `K_USER` in user mode

• On context switch, the outgoing thread's stack memory should be marked inaccessible to user mode by making the appropriate configuration changes in the memory management hardware. The incoming thread's stack memory should likewise be marked as accessible. This ensures that threads can't mess with other thread stacks.

• On context switch, the system needs to switch between memory domains for the incoming and outgoing threads.

• Thread stack areas must include a kernel stack region. This should be inaccessible to user threads at all times. This stack will be used when system calls are made. This should be fixed size for all threads, and must be large enough to handle any system call.

• A software interrupt or some kind of privilege elevation mechanism needs to be established. This is closely tied to how the _arch_syscall_invoke macros are implemented. On system call, the appropriate handler function needs to be looked up in _k_syscall_table. Bad system call IDs should jump to the K_SYSCALL_BAD handler. Upon completion of the system call, care must be taken not to leak any register state back to user mode.

GDB Stub

To enable GDB stub for remote debugging on a new architecture:

1. Create a new gdbstub.h header file under appropriate architecture include directory (include/arch/<arch>/gdbstub.h).
   
   • Create a new struct struct gdb_ctx as the GDB context.
     
     – Must define a member named exception of type `unsigned int` to store the GDB exception reason. This value needs to be set before entering `z_gdb_main_loop()`.
     
     – Architecture can define as many members as needed for GDB stub to function.
     
     – Pointer to this struct needs to be passed to `z_gdb_main_loop()`, where this pointer will be passed to other GDB stub functions.

2. Functions for entering and exiting GDB stub main loop.
• If the architecture relies on interrupts to service breakpoints, interrupt service routines (ISR) need to be implemented, which will serve as the entry point to GDB stub main loop.

• These functions need to save and restore context so code execution can continue as if no breakpoints have been encountered.

• These functions need to call `z_gdb_main_loop()` after saving execution context to go into the GDB stub main loop to receive commands from GDB.

• Before calling `z_gdb_main_loop()`, `gdb_ctx.exception` must be set to specify the exception reason.

3. Implement necessary functions to support GDB stub functionality:

• `arch_gdb_init()`
  – This needs to initialize necessary bits to support GDB stub functionality, for example, setting up the GDB context and connecting debug interrupts.
  – This must stop code execution via architecture specific method (e.g. raising debug interrupts). This allows GDB to connect during boot.

• `arch_gdb_continue()`
  – This function is called when GDB sends a `c` or `continue` command to continue code execution.

• `arch_gdb_step()`
  – This function is called when GDB sends a `si` or `stepi` command to execute one machine instruction, before returning to GDB prompt.

• Hardware register read/write functions:
  – Since the GDB stub is running on the target, manipulation of hardware registers need to cached to avoid affecting the execution of GDB stub. Think of it as context switching, where the execution context is changed to the GDB stub. So that the register values of the running thread before context switch need to be stored. Manipulation of register values must only be done to this cached copy. The updated values will then be written to hardware registers before switching back to the previous running thread.

  – `arch_gdb_reg_readall()`
    * This collects all hardware register values that would appear in a `g/G` packets which will be sent back to GDB. The format of the G-packet is architecture specific. Consult GDB on what is expected.
    * Note that, for most architectures, a valid G-packet must be returned and sent to GDB. If a packet without incorrect length is sent to GDB, GDB will abort the debugging session.

  – `arch_gdb_reg_writeall()`
    * This takes a G-packet sent by GDB and populates the hardware registers with values from the G-packet.

  – `arch_gdb_reg_readone()`
    * This reads the value of one hardware register and sends the result to GDB.

  – `arch_gdb_reg_writeone()`
    * This writes the value of one hardware register received from GDB.

• Breakpoints:

  – `arch_gdb_add_breakpoint()` and `arch_gdb_remove_breakpoint()`
– GDB may decide to use software breakpoints which modifies the memory at the breakpoint locations to replace the instruction with software breakpoint or trap instructions. GDB will then restore the memory content once execution reaches the breakpoints. GDB supports this by default and there is usually no need to handle software breakpoints in the architecture code (where breakpoint type is 0).

– Hardware breakpoints (type 1) are required if the code is in ROM or flash that cannot be modified at runtime. Consult the architecture datasheet on how to enable hardware breakpoints.

– If hardware breakpoints are not supported by the architecture, there is no need to implement these in architecture code. GDB will then rely on software breakpoints.

4. For architecture where certain memory regions are not accessible, an array named `gdb_mem_region_array` of type `gdb_mem_region` needs to be defined to specify regions that are accessible. For each array item:
   - `gdb_mem_region.start` specifies the start of a memory region.
   - `gdb_mem_region.end` specifies the end of a memory region.
   - `gdb_mem_region.attributes` specifies the permission of a memory region.
     - `GDB_MEM_REGION_RO`: region is read-only.
     - `GDB_MEM_REGION_RW`: region is read-write.
   - `gdb_mem_region.alignment` specifies read/write alignment of a memory region. Use 0 if there is no alignment requirement and read/write can be done byte-by-byte.

API Reference

Timing

`group arch-timing`

Functions

```c
void arch_busy_wait(uint32_t usec_to_wait)
```

Architecture-specific implementation of busy-waiting.

**Parameters**

- `usec_to_wait` – Wait period, in microseconds

```c
static inline uint32_t arch_k_cycle_get_32(void)
```

Obtain the current cycle count, in units specified by `CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC`.

While this is historically specified as part of the architecture API, in practice virtually all platforms forward it to the `sys_clock_cycle_get_32()` API provided by the timer driver.

**See also:**

`k_cycle_get_32()`

**Returns**

The current cycle time. This should count up monotonically through the full 32 bit space, wrapping at 0xffffffff. Hardware with fewer bits of precision in the timer is expected to synthesize a 32 bit count.
static inline uint64_t arch_k_cycle_get_64(void)
    As for arch_k_cycle_get_32(), but with a 64 bit return value.
    Not all timer hardware has a 64 bit timer; this needs to be implemented only if CONFIG_TIMER_HAS_64BIT_CYCLE_COUNTER is set.

See also:
arch_k_cycle_get_32()

Returns
The current cycle time. This should count up monotonically through the full 64 bit space, wrapping at 2^64-1. Hardware with fewer bits of precision in the timer is generally not expected to implement this API.

Threads
group arch-threads

Functions
void arch_new_thread(struct k_thread *thread, k_thread_stack_t *stack, char *stack_ptr,
    k_thread_entry_t entry, void *p1, void *p2, void *p3)
  Handle arch-specific logic for setting up new threads.
  The stack and arch-specific thread state variables must be set up such that a later attempt to switch to this thread will succeed and we will enter z_thread_entry with the requested thread and arguments as its parameters.
  At some point in this function's implementation, z_setup_new_thread() must be called with the true bounds of the available stack buffer within the thread's stack object.
  The provided stack pointer is guaranteed to be properly aligned with respect to the CPU and ABI requirements. There may be space reserved between the stack pointer and the bounds of the stack buffer for initial stack pointer randomization and thread-local storage.
  Fields in thread->base will be initialized when this is called.

Parameters
  • thread – Pointer to uninitialized struct k_thread
  • stack – Pointer to the stack object
  • stack_ptr – Aligned initial stack pointer
  • entry – Thread entry function
  • p1 – 1st entry point parameter
  • p2 – 2nd entry point parameter
  • p3 – 3rd entry point parameter

static inline void arch_switch(void *switch_to, void **switched_from)
  Cooperative context switch primitive.
  The action of arch_switch() should be to switch to a new context passed in the first argument, and save a pointer to the current context into the address passed in the second argument.
The actual type and interpretation of the switch handle is specified by the architecture. It is the same data structure stored in the “switch_handle” field of a newly-created thread in `arch_new_thread()`, and passed to the kernel as the “interrupted” argument to `z_get_next_switch_handle()`.

Note that on SMP systems, the kernel uses the store through the second pointer as a synchronization point to detect when a thread context is completely saved (so another CPU can know when it is safe to switch). This store must be done AFTER all relevant state is saved, and must include whatever memory barriers or cache management code is required to be sure another CPU will see the result correctly.

The simplest implementation of `arch_switch()` is generally to push state onto the thread stack and use the resulting stack pointer as the switch handle. Some architectures may instead decide to use a pointer into the thread struct as the “switch handle” type. These can legally assume that the second argument to `arch_switch()` is the address of the switch_handle field of struct thread_base and can use an offset on this value to find other parts of the thread struct. For example a (C pseudocode) implementation of `arch_switch()` might look like:

```c
void arch_switch(void *switch_to, void **switched_from) { struct k_thread *new = switch_to; struct k_thread *old = CONTAINER_OF(switched_from, struct k_thread, switch_handle);
  // save old context... *switched_from = old; // restore new context... }
```

Note that the kernel manages the switch_handle field for synchronization as described above. So it is not legal for architecture code to assume that it has any particular value at any other time. In particular it is not legal to read the field from the address passed in the second argument.

**Parameters**

- `switch_to` – Incoming thread’s switch handle
- `switched_from` – Pointer to outgoing thread’s switch handle storage location, which must be updated.

```c
void arch_switch_to_main_thread(struct k_thread *main_thread, char *stack_ptr, k_thread_entry_t _main)
```

Custom logic for entering main thread context at early boot.

Used by architectures where the typical trick of setting up a dummy thread in early boot context to “switch out” of isn’t workable.

**Parameters**

- `main_thread` – main thread object
- `stack_ptr` – Initial stack pointer
- `_main` – Entry point for application main function.

```c
int arch_float_disable(struct k_thread *thread)
```

Disable floating point context preservation.

The function is used to disable the preservation of floating point context information for a particular thread.

**Note:** For ARM architecture, disabling floating point preservation may only be requested for the current thread and cannot be requested in ISRs.

**Return values**

- `0` – On success.
• -EINVAL – If the floating point disabling could not be performed.
• -ENOTSUP – If the operation is not supported

int arch_float_enable(struct k_thread *thread, unsigned int options)

Enable floating point context preservation.

The function is used to enable the preservation of floating point context information for a particular thread. This API depends on each architecture implementation. If the architecture does not support enabling, this API will always be failed.

The options parameter indicates which floating point register sets will be used by the specified thread. Currently it is used by x86 only.

Parameters
• thread – ID of thread.
• options – architecture dependent options

Return values
• 0 – On success.
• -EINVAL – If the floating point enabling could not be performed.
• -ENOTSUP – If the operation is not supported

group arch-tls

Functions

size_t arch_tls_stack_setup(struct k_thread *new_thread, char *stack_ptr)

Setup Architecture-specific TLS area in stack.

This sets up the stack area for thread local storage. The structure inside TLS area is architecture specific.

Parameters
• new_thread – New thread object
• stack_ptr – Stack pointer

Returns
Number of bytes taken by the TLS area

Power Management
group arch-pm

Functions

FUNC_NORETURN void arch_system_halt(unsigned int reason)

Halt the system, optionally propagating a reason code.
void arch_cpu_idle(void)
   Power save idle routine.

   This function will be called by the kernel idle loop or possibly within an implemen-
   tation of z_pm_save_idle in the kernel when the '_pm_save_flag' variable is non-zero.

   Architectures that do not implement power management instructions may immediately
   return, otherwise a power-saving instruction should be issued to wait for an in-
   terrupt.

   See also:
   k_cpu_idle()

   Note: The function is expected to return after the interrupt that has caused the CPU
   to exit power-saving mode has been serviced, although this is not a firm requirement.

void arch_cpu_atomic_idle(unsigned int key)
   Atomically re-enable interrupts and enter low power mode.
   The requirements for arch_cpu_atomic_idle() are as follows:

   a. Enabling interrupts and entering a low-power mode needs to be atomic, i.e. there
      should be no period of time where interrupts are enabled before the processor
      enters a low-power mode. See the comments in k_lifo_get(), for example, of the
      race condition that occurs if this requirement is not met.

   b. After waking up from the low-power mode, the interrupt lockout state must be
      restored as indicated in the 'key' input parameter.

   See also:
   k_cpu_atomic_idle()

   Parameters
   • key – Lockout key returned by previous invocation of arch_irq_lock()

Symmetric Multi-Processing

   group arch-smp

   Typedefs

typedef void (*arch_cpustart_t)(void *data)
   Per-cpu entry function.

   Param data
   context parameter, implementation specific
Functions

void arch_start_cpu(int cpu_num, k_thread_stack_t *stack, int sz, arch_cpustart_t fn, void *arg)

Start a numbered CPU on a MP-capable system.
This starts and initializes a specific CPU. The main thread on startup is running on
CPU zero, other processors are numbered sequentially. On return from this function,
the CPU is known to have begun operating and will enter the provided function. Its
interrupts will be initialized but disabled such that irq_unlock() with the provided key
will work to enable them.

Normally, in SMP mode this function will be called by the kernel initialization and
should not be used as a user API. But it is defined here for special-purpose apps which
want Zephyr running on one core and to use others for design-specific processing.

Parameters

• cpu_num – Integer number of the CPU
• stack – Stack memory for the CPU
• sz – Stack buffer size, in bytes
• fn – Function to begin running on the CPU.
• arg – Untyped argument to be passed to “fn”

bool arch_cpu_active(int cpu_num)

Return CPU power status.

Parameters

• cpu_num – Integer number of the CPU

static inline struct _cpu *arch_curr_cpu(void)

Return the CPU struct for the currently executing CPU.

static inline uint32_t arch_proc_id(void)

Processor hardware ID.

Most multiprocessor architectures have a low-level unique ID value associated with
the current CPU that can be retrieved rapidly and efficiently in kernel context. Note
that while the numbering of the CPUs is guaranteed to be unique, the values are
platform-defined. In particular, they are not guaranteed to match Zephyr’s own se-
quential CPU IDs (even though on some platforms they do).

Note: There is an inherent race with this API: the system may preempt the current
thread and migrate it to another CPU before the value is used. Safe usage requires
knowing the migration is impossible (e.g. because the code is in interrupt context,
holds a spinlock, or cannot migrate due to k_cpu_mask state).

Returns

Unique ID for currently-executing CPU

void arch_sched_ipi(void)

Broadcast an interrupt to all CPUs.

This will invoke z_sched_ipi() on other CPUs in the system.

int arch_smp_init(void)
static inline unsigned int arch_num_cpus(void)
    Returns the number of CPUs.
    For most systems this will be the same as CONFIG_MP_MAX_NUM_CPUS, however
    some systems may determine this at runtime instead.

    Returns
    the number of CPUs

**Interrupts**

*group arch-irq*

**Functions**

static inline bool arch_is_in_isr(void)
    Test if the current context is in interrupt context.
    XXX: This is inconsistently handled among arches wrt exception context See: #17656

    Returns
    true if we are in interrupt context

static inline unsigned int arch_irq_lock(void)
    Lock interrupts on the current CPU.

    See also:
    *irq_lock()*

static inline void arch_irq_unlock(unsigned int key)
    Unlock interrupts on the current CPU.

    See also:
    *irq_unlock()*

static inline bool arch_irq_unlocked(unsigned int key)
    Test if calling *arch_irq_unlock()* with this key would unlock irqs.

    Parameters
    • key – value returned by *arch_irq_lock()*

    Returns
    true if interrupts were unlocked prior to the *arch_irq_lock()* call that pro-
    duced the key argument.

void arch_irq_disable(unsigned int irq)
    Disable the specified interrupt line.

    See also:
    *irq_disable()*

**Note:** The behavior of interrupts that arrive after this call returns and before the cor-
responding call to *arch_irq_enable()* is undefined. The hardware is not required to latch
and deliver such an interrupt, though on some architectures that may work. Other archi-

tectures will simply lose such an interrupt and never deliver it. Many drivers and

subsystems are not tolerant of such dropped interrupts and it is the job of the applica-
tion layer to ensure that behavior remains correct.

```c
void arch_irq_enable(unsigned int irq)
```

Enable the specified interrupt line.

**See also:**

`irq_enable()`

```c
int arch_irq_is_enabled(unsigned int irq)
```

Test if an interrupt line is enabled.

**See also:**

`irq_is_enabled()`

```c
int arch_irq_connect_dynamic(unsigned int irq, unsigned int priority, void (*routine)(const void *parameter), const void *parameter, uint32_t flags)
```

Arch-specific hook to install a dynamic interrupt.

**Parameters**

- `irq` – IRQ line number
- `priority` – Interrupt priority
- `routine` – Interrupt service routine
- `parameter` – ISR parameter
- `flags` – Arch-specific IRQ configuration flag

**Returns**

The vector assigned to this interrupt

```c
int arch_irq_disconnect_dynamic(unsigned int irq, unsigned int priority, void (*routine)(const void *parameter), const void *parameter, uint32_t flags)
```

Arch-specific hook to dynamically uninstall a shared interrupt.

If the interrupt is not being shared, then the associated `_sw_isr_table` entry will be

replaced by (NULL, `z_irq_spurious`) (default entry).

**Parameters**

- `irq` – IRQ line number
- `priority` – Interrupt priority
- `routine` – Interrupt service routine
- `parameter` – ISR parameter
- `flags` – Arch-specific IRQ configuration flag

**Returns**

0 in case of success, negative value otherwise
unsigned int arch_irq_allocate(void)
Arch-specific hook for allocating IRQs.

Note: disable/enable IRQ relevantly inside the implementation of such function to avoid concurrency issues. Also, an allocated IRQ is assumed to be used thus a following

See also:
arch_irq_is_used() should return true.

Returns
The newly allocated IRQ or UINT_MAX on error.

void arch_irq_set_used(unsigned int irq)
Arch-specific hook for declaring an IRQ being used.

Note: disable/enable IRQ relevantly inside the implementation of such function to avoid concurrency issues.

Parameters
• irq – the IRQ to declare being used

bool arch_irq_is_used(unsigned int irq)
Arch-specific hook for checking if an IRQ is being used already.

Parameters
• irq – the IRQ to check

Returns
truer if being, false otherwise

Userspace
group arch-userspace

Functions

static inline uintptr_t arch_syscall_invoke0(uintptr_t call_id)
Invoke a system call with 0 arguments.

No general-purpose register state other than return value may be preserved when transitioning from supervisor mode back down to user mode for security reasons.

It is required that all arguments be stored in registers when elevating privileges from user to supervisor mode.

Processing of the syscall takes place on a separate kernel stack. Interrupts should be enabled when invoking the system call marshellers from the dispatch table. Thread preemption may occur when handling system calls.

Call IDs are untrusted and must be bounds-checked, as the value is used to index the system call dispatch table, containing function pointers to the specific system call code.

Parameters
• call_id – System call ID

Returns
Return value of the system call. Void system calls return 0 here.
static inline uintptr_t arch_syscall_invoke1(uintptr_t arg1, uintptr_t call_id)
   Invoke a system call with 1 argument.

See also:
arch_syscall_invoke0()

Parameters
• arg1 – First argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

Returns
Return value of the system call. Void system calls return 0 here.

static inline uintptr_t arch_syscall_invoke2(uintptr_t arg1, uintptr_t arg2, uintptr_t call_id)
   Invoke a system call with 2 arguments.

See also:
arch_syscall_invoke0()

Parameters
• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

Returns
Return value of the system call. Void system calls return 0 here.

static inline uintptr_t arch_syscall_invoke3(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3, uintptr_t call_id)
   Invoke a system call with 3 arguments.

See also:
arch_syscall_invoke0()

Parameters
• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• arg3 – Third argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

Returns
Return value of the system call. Void system calls return 0 here.
static inline uintptr_t arch_syscall_invoke4(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3, uintptr_t arg4, uintptr_t call_id)

Invoke a system call with 4 arguments.

See also:
arch_syscall_invoke0()

Parameters

• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• arg3 – Third argument to the system call.
• arg4 – Fourth argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

Returns
Return value of the system call. Void system calls return 0 here.

static inline uintptr_t arch_syscall_invoke5(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3, uintptr_t arg4, uintptr_t arg5, uintptr_t call_id)

Invoke a system call with 5 arguments.

See also:
arch_syscall_invoke0()

Parameters

• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• arg3 – Third argument to the system call.
• arg4 – Fourth argument to the system call.
• arg5 – Fifth argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

Returns
Return value of the system call. Void system calls return 0 here.

static inline uintptr_t arch_syscall_invoke6(uintptr_t arg1, uintptr_t arg2, uintptr_t arg3, uintptr_t arg4, uintptr_t arg5, uintptr_t arg6, uintptr_t call_id)

Invoke a system call with 6 arguments.

See also:
arch_syscall_invoke0()

Parameters

• arg1 – First argument to the system call.
• arg2 – Second argument to the system call.
• arg3 – Third argument to the system call.
• arg4 – Fourth argument to the system call.
• arg5 – Fifth argument to the system call.
• arg6 – Sixth argument to the system call.
• call_id – System call ID, will be bounds-checked and used to reference kernel-side dispatch table

Returns
Return value of the system call. Void system calls return 0 here.

static inline bool arch_is_user_context(void)
Indicate whether we are currently running in user mode.

Returns
True if the CPU is currently running with user permissions

int arch_mem_domain_max_partitions_get(void)
Get the maximum number of partitions for a memory domain.

Returns
Max number of partitions, or -1 if there is no limit

int arch_buffer_validate(void *addr, size_t size, int write)
Check memory region permissions.
Given a memory region, return whether the current memory management hardware configuration would allow a user thread to read/write that region. Used by system calls to validate buffers coming in from userspace.
Notes: The function is guaranteed to never return validation success, if the entire buffer area is not user accessible.
The function is guaranteed to correctly validate the permissions of the supplied buffer, if the user access permissions of the entire buffer are enforced by a single, enabled memory management region.
In some architectures the validation will always return failure if the supplied memory buffer spans multiple enabled memory management regions (even if all such regions permit user access).

Warning: Buffer of size zero (0) has undefined behavior.

Parameters
• addr – start address of the buffer
• size – the size of the buffer
• write – If non-zero, additionally check if the area is writable. Otherwise, just check if the memory can be read.

Returns
nonzero if the permissions don’t match.

size_t arch_virt_region_align(uintptr_t phys, size_t size)
Get the optimal virtual region alignment to optimize the MMU table layout.
Some MMU HW requires some region to be aligned to some of the intermediate block alignment in order to reduce table usage. This call returns the optimal virtual address alignment in order to permit such optimization in the following MMU mapping call.

**Parameters**

- **phys** – [in] Physical address of region to be mapped, aligned to CONFIG_MMU_PAGE_SIZE
- **size** – [in] Size of region to be mapped, aligned to CONFIG_MMU_PAGE_SIZE

**Returns**

Alignment to apply on the virtual address of this region

```c
FUNC_NORETURN void arch_user_mode_enter(k_thread_entry_t user_entry, void *p1, void *p2, void *p3)
```

Perform a one-way transition from supervisor to user mode.

Implementations of this function must do the following:

- Reset the thread's stack pointer to a suitable initial value. We do not need any prior context since this is a one-way operation.
- Set up any kernel stack region for the CPU to use during privilege elevation
- Put the CPU in whatever its equivalent of user mode is
- Transfer execution to `arch_new_thread()` passing along all the supplied arguments, in user mode.

**Parameters**

- **user_entry** – Entry point to start executing as a user thread
- **p1** – 1st parameter to user thread
- **p2** – 2nd parameter to user thread
- **p3** – 3rd parameter to user thread

```c
FUNC_NORETURN void arch_syscall_oops(void *ssf)
```

Induce a kernel oops that appears to come from a specific location.

Normally, `k_oops()` generates an exception that appears to come from the call site of the `k_oops()` itself.

However, when validating arguments to a system call, if there are problems we want the oops to appear to come from where the system call was invoked and not inside the validation function.

**Parameters**

- **ssf** – System call stack frame pointer. This gets passed as an argument to `_k_syscall_handler_t` functions and its contents are completely architecture specific.

```c
size_t arch_user_string_nlen(const char *s, size_t maxsize, int *err)
```

Safely take the length of a potentially bad string.

This must not fault, instead the `err` parameter must have -1 written to it. This function otherwise should work exactly like libc `strnlen()`. On success `err` should be set to 0.

**Parameters**

- **s** – String to measure
- **maxsize** – Max length of the string
• err – Error value to write

**Returns**
Length of the string, not counting NULL byte, up to maxsize

static inline bool arch_mem_coherent(void *ptr)
Detect memory coherence type.

Required when ARCH_HAS_COHERENCE is true. This function returns true if the byte
pointed to lies within an architecture-defined “coherence region” (typically imple-
mented with uncached memory) and can safely be used in multiprocessor code with-
out explicit flush or invalidate operations.

**Note:** The result is for only the single byte at the specified address, this API is not
required to check region boundaries or to expect aligned pointers. The expectation is
that the code above will have queried the appropriate address(es).

static inline void arch_coher_stacks(struct k_thread *old_thread, void *
*old_switch_handle, struct k_thread *new_thread)
Ensure cache coherence prior to context switch.

Required when ARCH_HAS_COHERENCE is true. On cache-incoherent multiprocessor
architectures, thread stacks are cached by default for performance reasons. They must
therefore be flushed appropriately on context switch. The rules are:

a. The region containing live data in the old stack (generally the bytes between the
current stack pointer and the top of the stack memory) must be flushed to under-
lying storage so a new CPU that runs the same thread sees the correct data. This
must happen before the assignment of the switch_handle field in the thread struct
which signals the completion of context switch.

b. Any data areas to be read from the new stack (generally the same as the live region
when it was saved) should be invalidated (and NOT flushed!) in the data cache.
This is because another CPU may have run or re-initialized the thread since this
CPU suspended it, and any data present in cache will be stale.

**Note:** The kernel will call this function during interrupt exit when a new thread has
been chosen to run, and also immediately before entering arch_switch() to effect a
code-driven context switch. In the latter case, it is very likely that more data will be
written to the old_thread stack region after this function returns but before the comple-
tion of the switch. Simply flushing naively here is not sufficient on many architectures
and coordination with the arch_switch() implementation is likely required.

**Parameters**

• old_thread – The old thread to be flushed before being allowed to run
on other CPUs.

• old_switch_handle – The switch handle to be stored into old_thread (it
will not be valid until the cache is flushed so is not present yet). This will
be NULL if inside z_swap() (because the arch_switch() has not saved it
yet).

• new_thread – The new thread to be invalidated before it runs locally.

**Memory Management**

**group arch-mmu**

**Defines**

**ARCH_DATA_PAGE_ACCESSSED**

Bit indicating the data page was accessed since the value was last cleared.
Used by marking eviction algorithms. Safe to set this if uncertain.
This bit is undefined if ARCH_DATA_PAGE_LOADED is not set.

**ARCH_DATA_PAGE_DIRTY**

Bit indicating the data page, if evicted, will need to be paged out.
Set if the data page was modified since it was last paged out, or if it has never been paged out before. Safe to set this if uncertain.
This bit is undefined if ARCH_DATA_PAGE_LOADED is not set.

**ARCH_DATA_PAGE_LOADED**

Bit indicating that the data page is loaded into a physical page frame.
If un-set, the data page is paged out or not mapped.

**ARCH_DATA_PAGE_NOT_MAPPED**

If ARCH_DATA_PAGE_LOADED is un-set, this will indicate that the page is not mapped at all.
This bit is undefined if ARCH_DATA_PAGE_LOADED is set.

**Enums**

**enum arch_page_location**

Status of a particular page location.

**Values:**

enumerator **ARCH_PAGE_LOCATION_PAGED_OUT**

The page has been evicted to the backing store.

enumerator **ARCH_PAGE_LOCATION_PAGED_IN**

The page is resident in memory.

enumerator **ARCH_PAGE_LOCATION_BAD**

The page is not mapped.

**Functions**
void arch_mem_map(void *virt, uintptr_t phys, size_t size, uint32_t flags)
Map physical memory into the virtual address space.

This is a low-level interface to mapping pages into the address space. Behavior when providing unaligned addresses/sizes is undefined, these are assumed to be aligned to CONFIG_MMU_PAGE_SIZE.

The core kernel handles all management of the virtual address space; by the time we invoke this function, we know exactly where this mapping will be established. If the page tables already had mappings installed for the virtual memory region, these will be overwritten.

If the target architecture supports multiple page sizes, currently only the smallest page size will be used.

The memory range itself is never accessed by this operation.

This API must be safe to call in ISRs or exception handlers. Calls to this API are assumed to be serialized, and indeed all usage will originate from kernel/mm.c which handles virtual memory management.

Architectures are expected to pre-allocate page tables for the entire address space, as defined by CONFIG_KERNEL_VM_BASE and CONFIG_KERNEL_VM_SIZE. This operation should never require any kind of allocation for paging structures.

Validation of arguments should be done via assertions.

This API is part of infrastructure still under development and may change.

Parameters
- virt – Page-aligned Destination virtual address to map
- phys – Page-aligned Source physical address to map
- size – Page-aligned size of the mapped memory region in bytes
- flags – Caching, access and control flags, see K_MAP_* macros

void arch_mem_unmap(void *addr, size_t size)
Remove mappings for a provided virtual address range.

This is a low-level interface for un-mapping pages from the address space. When this completes, the relevant page table entries will be updated as if no mapping was ever made for that memory range. No previous context needs to be preserved. This function must update mappings in all active page tables.

Behavior when providing unaligned addresses/sizes is undefined, these are assumed to be aligned to CONFIG_MMU_PAGE_SIZE.

Behavior when providing an address range that is not already mapped is undefined.

This function should never require memory allocations for paging structures, and it is not necessary to free any paging structures. Empty page tables due to all contained entries being un-mapped may remain in place.

Implementations must invalidate TLBs as necessary.

This API is part of infrastructure still under development and may change.

Parameters
- addr – Page-aligned base virtual address to un-map
- size – Page-aligned region size
int arch_page_phys_get(void *virt, uintptr_t *phys)

Get the mapped physical memory address from virtual address.

The function only needs to query the current set of page tables as the information it reports must be common to all of them if multiple page tables are in use. If multiple page tables are active it is unnecessary to iterate over all of them.

Unless otherwise specified, virtual pages have the same mappings across all page tables. Calling this function on data pages that are exceptions to this rule (such as the scratch page) is undefined behavior. Just check the currently installed page tables and return the information in that.

**Parameters**

- **virt** – Page-aligned virtual address
- **phys** – [out] Mapped physical address (can be NULL if only checking if virtual address is mapped)

**Return values**

- **0** – if mapping is found and valid
- **EFAULT** – if virtual address is not mapped

void arch_reserved_pages_update(void)

Update page frame database with reserved pages.

Some page frames within system RAM may not be available for use. A good example of this is reserved regions in the first megabyte on PC-like systems.

Implementations of this function should mark all relevant entries in z_page_frames with K_PAGE_FRAME_RESERVED. This function is called at early system initialization with mm_lock held.

void arch_mem_page_out(void *addr, uintptr_t location)

Update all page tables for a paged-out data page.

This function:

- Sets the data page virtual address to trigger a fault if accessed that can be distinguished from access violations or un-mapped pages.
- Saves the provided location value so that it can retrieved for that data page in the page fault handler.
- The location value semantics are undefined here but the value will be always be page-aligned. It could be 0.

If multiple page tables are in use, this must update all page tables. This function is called with interrupts locked.

Calling this function on data pages which are already paged out is undefined behavior.

This API is part of infrastructure still under development and may change.

void arch_mem_page_in(void *addr, uintptr_t phys)

Update all page tables for a paged-in data page.

This function:

- Maps the specified virtual data page address to the provided physical page frame address, such that future memory accesses will function as expected. Access and caching attributes are undisturbed.
- Clears any accounting for “accessed” and “dirty” states.
If multiple page tables are in use, this must update all page tables. This function is called with interrupts locked.

Calling this function on data pages which are already paged in is undefined behavior.

This API is part of infrastructure still under development and may change.

```c
void arch_mem_scratch(uintptr_t phys)
```

Update current page tables for a temporary mapping.

Map a physical page frame address to a special virtual address Z_SCRATCH_PAGE, with read/write access to supervisor mode, such that when this function returns, the calling context can read/write the page frame’s contents from the Z_SCRATCH_PAGE address.

This mapping only needs to be done on the current set of page tables, as it is only used for a short period of time exclusively by the caller. This function is called with interrupts locked.

This API is part of infrastructure still under development and may change.

```c
enum arch_page_location arch_page_location_get(void *addr, uintptr_t *location)
```

Fetch location information about a page at a particular address.

The function only needs to query the current set of page tables as the information it reports must be common to all of them if multiple page tables are in use. If multiple page tables are active it is unnecessary to iterate over all of them. This may allow certain types of optimizations (such as reverse page table mapping on x86).

This function is called with interrupts locked, so that the reported information can’t become stale while decisions are being made based on it.

Unless otherwise specified, virtual data pages have the same mappings across all page tables. Calling this function on data pages that are exceptions to this rule (such as the scratch page) is undefined behavior. Just check the currently installed page tables and return the information in that.

**Parameters**

- `addr` – Virtual data page address that took the page fault
- `location` – [out] In the case of ARCH_PAGE_FAULT_PAGED_OUT, the backing store location value used to retrieve the data page. In the case of ARCH_PAGE_FAULT_PAGED_IN, the physical address the page is mapped to.

**Return values**

- `ARCH_PAGE_FAULT_PAGED_OUT` – The page was evicted to the backing store.
- `ARCH_PAGE_FAULT_PAGED_IN` – The data page is resident in memory.
- `ARCH_PAGE_FAULT_BAD` – The page is un-mapped or otherwise has had invalid access

```c
uintptr_t arch_page_info_get(void *addr, uintptr_t *location, bool clear_accessed)
```

Retrieve page characteristics from the page table(s)

The architecture is responsible for maintaining “accessed” and “dirty” states of data pages to support marking eviction algorithms. This can either be directly supported by hardware or emulated by modifying protection policy to generate faults on reads or writes. In all cases the architecture must maintain this information in some way.

For the provided virtual address, report the logical OR of the accessed and dirty states for the relevant entries in all active page tables in the system if the page is mapped and not paged out.
If clear_accessed is true, the ARCH_DATA_PAGE_ACCESSED flag will be reset. This function will report its prior state. If multiple page tables are in use, this function clears accessed state in all of them.

This function is called with interrupts locked, so that the reported information can't become stale while decisions are being made based on it.

The return value may have other bits set which the caller must ignore.

Clearing accessed state for data pages that are not ARCH_DATA_PAGE_LOADED is undefined behavior.

ARCH_DATA_PAGE_DIRTY and ARCH_DATA_PAGE_ACCESSED bits in the return value are only significant if ARCH_DATA_PAGE_LOADED is set, otherwise ignore them.

ARCH_DATA_PAGE_NOT_MAPPED bit in the return value is only significant if ARCH_DATA_PAGE_LOADED is un-set, otherwise ignore it.

Unless otherwise specified, virtual data pages have the same mappings across all page tables. Calling this function on data pages that are exceptions to this rule (such as the scratch page) is undefined behavior.

This API is part of infrastructure still under development and may change.

**Parameters**

- **addr** – Virtual address to look up in page tables
- **location** – [out] If non-NULL, updated with either physical page frame address or backing store location depending on ARCH_DATA_PAGE_LOADED state. This is not touched if ARCH_DATA_PAGE_NOT_MAPPED.
- **clear_accessed** – Whether to clear ARCH_DATA_PAGE_ACCESSED state

**Return values**

Value – with ARCH_DATA_PAGE_* bits set reflecting the data page configuration

---

**Miscellaneous Architecture APIs**

*group* arch-misc

**Functions**

int *arch_printk_char_out*(int c)

Early boot console output hook.

Definition of this function is optional. If implemented, any invocation of printk() (or logging calls with CONFIG_LOG_MODE_MINIMAL which are backed by printk) will default to sending characters to this function. It is useful for early boot debugging before main serial or console drivers come up.

This can be overridden at runtime with __printk_hook_install().

The default __weak implementation of this does nothing.

**Parameters**

- **c** – Character to print

**Returns**

The character printed
static inline void arch_kernel_init(void)
    Architecture-specific kernel initialization hook.
    This function is invoked near the top of z_cstart, for additional architecture-specific
    setup before the rest of the kernel is brought up.

static inline void arch_nop(void)
    Do nothing and return.
    Yawn.

GDB Stub APIs

*group arch-gdbstub*

**Functions**

void arch_gdb_init(void)
    Architecture layer debug start.
    This function is called by gdb_init()

void arch_gdb_continue(void)
    Continue running program.
    Continue software execution.

void arch_gdb_step(void)
    Continue with one step.
    Continue software execution until reaches the next statement.

size_t arch_gdb_reg_readall(struct gdb_ctx *ctx, uint8_t *buf, size_t buflen)
    Read all registers, and outputs as hexadecimal string.
    This reads all CPU registers and outputs as hexadecimal string. The output string must
    be parsable by GDB.

    **Parameters**
    • ctx – GDB context
    • buf – Buffer to output hexadecimal string.
    • buflen – Length of buffer.

    **Returns**
    Length of hexadecimal string written. Return 0 if error or not supported.

size_t arch_gdb_reg_writeall(struct gdb_ctx *ctx, uint8_t *hex, size_t hexlen)
    Take a hexadecimal string and update all registers.
    This takes in a hexadecimal string as presented from GDB, and updates all CPU regis-
    ters with new values.

    **Parameters**
    • ctx – GDB context
    • hex – Input hexadecimal string.
    • hexlen – Length of hexadecimal string.

    **Returns**
    Length of hexadecimal string parsed. Return 0 if error or not supported.
size_t arch_gdb_reg_readone(struct gdb_ctx *ctx, uint8_t *buf, size_t buflen, uint32_t regno)

Read one register, and outputs as hexadecimal string.
This reads one CPU register and outputs as hexadecimal string. The output string must be parsable by GDB.

Parameters
- ctx – GDB context
- buf – Buffer to output hexadecimal string.
- buflen – Length of buffer.
- regno – Register number

Returns
Length of hexadecimal string written. Return 0 if error or not supported.

size_t arch_gdb_reg_writeone(struct gdb_ctx *ctx, uint8_t *hex, size_t hexlen, uint32_t regno)

Take a hexadecimal string and update one register.
This takes in a hexadecimal string as presented from GDB, and updates one CPU registers with new value.

Parameters
- ctx – GDB context
- hex – Input hexadecimal string.
- hexlen – Length of hexadecimal string.
- regno – Register number

Returns
Length of hexadecimal string parsed. Return 0 if error or not supported.

int arch_gdb_add_breakpoint(struct gdb_ctx *ctx, uint8_t type, uintptr_t addr, uint32_t kind)

Add breakpoint or watchpoint.

Parameters
- ctx – GDB context
- type – Breakpoint or watchpoint type
- addr – Address of breakpoint or watchpoint
- kind – Size of breakpoint/watchpoint in bytes

Return values
- 0 – Operation successful
- -1 – Error encountered
- -2 – Not supported

int arch_gdb_remove_breakpoint(struct gdb_ctx *ctx, uint8_t type, uintptr_t addr, uint32_t kind)

Remove breakpoint or watchpoint.

Parameters
- ctx – GDB context
- type – Breakpoint or watchpoint type
• `addr` – Address of breakpoint or watchpoint
• `kind` – Size of breakpoint/watchpoint in bytes

**Return values**
• 0 – Operation successful
• -1 – Error encountered
• -2 – Not supported

### 7.8.2 Board Porting Guide

To add Zephyr support for a new board, you at least need a board directory with various files in it. Files in the board directory inherit support for at least one SoC and all of its features. Therefore, Zephyr must support your SoC as well.

**Boards, SoCs, etc.**

Zephyr's hardware support hierarchy has these layers, from most to least specific:
• Board: a particular CPU instance and its peripherals in a concrete hardware specification
• SoC: the exact system on a chip the board's CPU is part of
• SoC series: a smaller group of tightly related SoCs
• SoC family: a wider group of SoCs with similar characteristics
• CPU core: a particular CPU in an architecture
• Architecture: an instruction set architecture

You can visualize the hierarchy like this:

![Fig. 5: Configuration Hierarchy](image-url)
Here are some examples. Notice how the SoC series and family levels are not always used.

<table>
<thead>
<tr>
<th>Board</th>
<th>SoC</th>
<th>SoC series</th>
<th>SoC family</th>
<th>CPU core</th>
<th>Architecture</th>

</table>

Make sure your SoC is supported

Start by making sure your SoC is supported by Zephyr. If it is, it's time to Create your board directory. If you don't know, try:

- checking boards for names that look relevant, and reading individual board documentation to find out for sure.
- asking your SoC vendor

If you need to add SoC, CPU core, or even architecture support, this is the wrong page, but here is some general advice.

Architecture  See Architecture Porting Guide.

CPU Core  CPU core support files go in core subdirectories under arch, e.g. arch/x86/core.

See Install a Toolchain for information about toolchains (compiler, linker, etc.) supported by Zephyr. If you need to support a new toolchain, Build and Configuration Systems is a good place to start learning about the build system. Please reach out to the community if you are looking for advice or want to collaborate on toolchain support.

SoC  Zephyr SoC support files are in architecture-specific subdirectories of soc. They are generally grouped by SoC family.

When adding a new SoC family or series for a vendor that already has SoC support within Zephyr, please try to extract common functionality into shared files to avoid duplication. If there is no support for your vendor yet, you can add it in a new directory zephyr/soc/<YOUR-ARCH>/ <YOUR-SOC>; please use self-explanatory directory names.

Create your board directory

Once you've found an existing board that uses your SoC, you can usually start by copy/pasting its board directory and changing its contents for your hardware.

You need to give your board a unique name. Run west boards for a list of names that are already taken, and pick something new. Let's say your board is called plank (please don't actually use that name).

Start by creating the board directory zephyr/boards/<ARCH>/plank, where <ARCH> is your SoC's architecture subdirectory. (You don't have to put your board directory in the zephyr repository, but it's the easiest way to get started. See Custom Board, Devicetree and SOC Definitions for documentation on moving your board directory to a separate repository once it's working.)
**Note:** The board directory name does not need to match the name of the board. Multiple boards can even be defined in one directory. For example, for boards with multi-core SoC, a logical board might be created for each core following the naming scheme `<board>_<soc-core>`, with definitions for all of these different boards defined inside the same directory. This and similar schemes are common for upstream vendor boards.

Your board directory should look like this:

```
boards/<ARCH>/plank
├── board.cmake
├── CMakeLists.txt
├── doc
│   └── plank.png
│   └── index.rst
├── Kconfig.board
├── Kconfig.defconfig
├── plank_defconfig
├── plank.dts
└── plank.yaml
```

Replace `plank` with your board's name, of course.

The mandatory files are:

1. `plank.dts`: a hardware description in *devicetree* format. This declares your SoC, connectors, and any other hardware components such as LEDs, buttons, sensors, or communication peripherals (USB, BLE controller, etc).

2. `Kconfig.board`, `Kconfig.defconfig`, `plank_defconfig`: software configuration in *Configuration System (Kconfig)* formats. This provides default settings for software features and peripheral drivers.

The optional files are:

- `board.cmake`: used for Flash and debug support
- `CMakeLists.txt`: if you need to add additional source files to your build.
- `doc/index.rst`, `doc/plank.png`: documentation for and a picture of your board. You only need this if you're Contributing your board to Zephyr.
- `plank.yaml`: a YAML file with miscellaneous metadata used by the Test Runner (Twister).

**Write your devicetree**

The devicetree file `boards/<ARCH>/plank/plank.dts` describes your board hardware in the DeviceTree Source (DTS) format (as usual, change `plank` to your board's name). If you're new to devicetree, see *Introduction to devicetree*.

In general, `plank.dts` should look like this:

```
/dts-v1/;
#include <your_soc_vendor/your_soc.dtsi>
/
{
  model = "A human readable name";
  compatible = "yourcompany,plank";

  chosen {
    zephyr,console = &your_uart_console;
    zephyr,sram = &your_memory_node;
  }
```

(continues on next page)
/* other chosen settings for your hardware */

/* Your board-specific hardware: buttons, LEDs, sensors, etc. */

leds {
    compatible = "gpio-leds";
    led0: led_0 {
        gpios = </* GPIO your LED is hooked up to */ >;
        label = "LED 0";
    }
    /* ... other LEDs ... */
};

buttons {
    compatible = "gpio-keys";
    /* ... your button definitions ... */
};

/* These aliases are provided for compatibility with samples */
aliases {
    led0 = &led0; /* now you support the blinky sample! */
    /* other aliases go here */
};

&some_peripheral_you_want_to_enable { /* like a GPIO or SPI controller */
    status = "okay";
};

&another_peripheral_you_want {
    status = "okay";
};

If you're in a hurry, simple hardware can usually be supported by copy/paste followed by trial and error. If you want to understand details, you will need to read the rest of the devicetree documentation and the devicetree specification.

**Example: FRDM-K64F and Hexiwear K64**  This section contains concrete examples related to writing your board's devicetree.

The FRDM-K64F and Hexiwear K64 board devicetrees are defined in frdm_k64fs.dts and hexiwear_k64.dts respectively. Both boards have NXP SoCs from the same Kinetis SoC family, the K6X.

Common devicetree definitions for K6X are stored in nxp_k6x.dtsi, which is included by both board .dts files. nxp_k6x.dtsi in turn includes armv7-m.dtsi, which has common definitions for Arm v7-M cores.

Since nxp_k6x.dtsi is meant to be generic across K6X-based boards, it leaves many devices disabled by default using status properties. For example, there is a CAN controller defined as follows (with unimportant parts skipped):

can0: can@40024000 {
    ... status = "disabled";
    ...
It is up to the board .dts or application overlay files to enable these devices as desired, by setting status = "okay". The board .dts files are also responsible for any board-specific configuration of the device, such as adding nodes for on-board sensors, LEDs, buttons, etc.

For example, FRDM-K64 (but not Hexiwear K64) .dts enables the CAN controller and sets the bus speed:

```c
&can0 {
    status = "okay";
    bus-speed = <125000>;
};
```

The &can0 { ... }; syntax adds/overrides properties on the node with label can0, i.e. the can@4002400 node defined in the .dti file.

Other examples of board-specific customization is pointing properties in aliases and chosen to the right nodes (see Aliases and chosen nodes), and making GPIO/pinmux assignments.

### Write Kconfig files

Zephyr uses the Kconfig language to configure software features. Your board needs to provide some Kconfig settings before you can compile a Zephyr application for it.

Setting Kconfig configuration values is documented in detail in Setting Kconfig configuration values.

There are three mandatory Kconfig files in the board directory for a board named plank:

```
boards/<ARCH>/plank
├── Kconfig.board
├── Kconfig.defconfig
└── plank_defconfig
```

**Kconfig.board**

Included by boards/Kconfig to include your board in the list of options.

This should at least contain a definition for a BOARD_PLANK option, which looks something like this:

```c
config BOARD_PLANK
    bool "Plank board"
    depends on SOC_SERIES_YOUR_SOC_SERIES_HERE
    select SOC_PART_NUMBER_ABCDEFGH
```

**Kconfig.defconfig**

Board-specific default values for Kconfig options.

The entire file should be inside an if BOARD_PLANK / endif pair of lines, like this:

```
if BOARD_PLANK

# Always set CONFIG_BOARD here. This isn't meant to be customized,
# but is set as a "default" due to Kconfig language restrictions.
config BOARD
    default "plank"

# Other options you want enabled by default go next. Examples:

config FOO
    default y

if NETWORKING
```

(continues on next page)
plank_defconfig
A Kconfig fragment that is merged as-is into the final build directory .config whenever an application is compiled for your board.

You should at least select your board’s SOC and do any mandatory settings for your system clock, console, etc. The results are architecture-specific, but typically look something like this:

```c
CONFIG_SOC_${VENDOR_XYZ3000}=y # select your SoC
CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC=12000000 # set up your clock, etc
CONFIG_SERIAL=y
```

plank_x_y_z.conf
A Kconfig fragment that is merged as-is into the final build directory .config whenever an application is compiled for your board revision x.y.z.

Build, test, and fix

Now it’s time to build and test the application(s) you want to run on your board until you’re satisfied.

For example:

```bash
west build -b plank samples/hello_world
west flash
```

For `west flash` to work, see *Flash and debug support* below. You can also just flash build/zephyr/zephyr.elf, zephyr.hex, or zephyr.bin with any other tools you prefer.

General recommendations

For consistency and to make it easier for users to build generic applications that are not board specific for your board, please follow these guidelines while porting.

- Unless explicitly recommended otherwise by this section, leave peripherals and their drivers disabled by default.
- Configure and enable a system clock, along with a tick source.
- Provide pin and driver configuration that matches the board’s valuable components such as sensors, buttons or LEDs, and communication interfaces such as USB, Ethernet connector, or Bluetooth/Wi-Fi chip.
- If your board uses a well-known connector standard (like Arduino, Mikrobus, Grove, or 96Boards connectors), add connector nodes to your DTS and configure pin muxes accordingly.
- Configure components that enable the use of these pins, such as configuring an SPI instance to use the usual Arduino SPI pins.
- If available, configure and enable a serial output for the console using the `zephyr,console` chosen node in the devicetree.
- If your board supports networking, configure a default interface.
• Enable all GPIO ports connected to peripherals or expansion connectors.

• If available, enable pinmux and interrupt controller drivers.

• It is recommended to enable the MPU by default, if there is support for it in hardware. For boards with limited memory resources it is acceptable to disable it. When the MPU is enabled, it is recommended to also enable hardware stack protection (CONFIG_HW_STACK_PROTECTION=y) and, thus, allow the kernel to detect stack overflows when the system is running in privileged mode.

Flash and debug support

Zephyr supports Building, Flashing and Debugging via west extension commands.

To add west flash and west debug support for your board, you need to create a board.cmake file in your board directory. This file's job is to configure a “runner” for your board. (There's nothing special you need to do to get west build support for your board.)

“Runners” are Zephyr-specific Python classes that wrap flash and debug host tools and integrate with west and the zephyr build system to support west flash and related commands. Each runner supports flashing, debugging, or both. You need to configure the arguments to these Python scripts in your board.cmake to support those commands like this example board.cmake:

```python
board_runner_args(jlink "--device=nrf52" "--speed=4000"
board_runner_args(pyocd "--target=nrf52" "--frequency=4000000"
include(${ZEPHYR_BASE}/boards/common/nrfjprog.board.cmake)
include(${ZEPHYR_BASE}/boards/common/jlink.board.cmake)
include(${ZEPHYR_BASE}/boards/common/pyocd.board.cmake)
```

This example configures the nrfjprog, jlink, and pyocd runners.

**Warning:** Runners usually have names which match the tools they wrap, so the jlink runner wraps Segger's J-Link tools, and so on. But the runner command line options like --speed etc. are specific to the Python scripts.

**Note:** Runners and board configuration should be created without being targeted to a single operating system if the tool supports multiple operating systems, nor should it rely upon special system setup/configuration. For example: do not assume that a user will have prior knowledge/configuration or (if using Linux) special udev rules installed, do not assume one specific /dev/X device for all platforms as this will not be compatible with Windows or macOS, and allow for overriding of the selected device so that multiple boards can be connected to a single system and flashed/debugged at the choice of the user.

For more details:

• Run west flash --context to see a list of available runners which support flashing, and west flash --context -r <RUNNER> to view the specific options available for an individual runner.

• Run west debug --context and west debug --context <RUNNER> to get the same output for runners which support debugging.

• Run west flash --help and west debug --help for top-level options for flashing and debugging.

• See Flash and debug runners for Python APIs.

• Look for board.cmake files for other boards similar to your own for more examples.
To see what a `west flash` or `west debug` command is doing exactly, run it in verbose mode:

```
west --verbose flash
west --verbose debug
```

Verbose mode prints any host tool commands the runner uses.

The order of the `include()` calls in your `board.cmake` matters. The first `include` sets the default runner if it's not already set. For example, including `nrfjprog.board.cmake` first means that `nrfjprog` is the default flash runner for this board. Since `nrfjprog` does not support debugging, `jlink` is the default debug runner.

**Multiple board revisions**

See [Building for a board revision](#) for basics on this feature from the user perspective.

To create a new board revision for the `plank` board, create these additional files in the board folder:

```
boards/<ARCH>/plank
│   └── plank_<revision>.conf    # optional
│   │    plank_<revision>.overlay # optional
│   └── revision.cmake
```

When the user builds for board `plank@<revision>`:

- The optional Kconfig settings specified in the file `plank_<revision>.conf` will be merged into the board's default Kconfig configuration.

- The optional devicetree overlay `plank_<revision>.overlay` will be added to the common `plank.dts` devicetree file

- The `revision.cmake` file controls how the Zephyr build system matches the `<board>@<revision>` string specified by the user when building an application for the board.

Currently, `<revision>` can be either a numeric `MAJOR.MINOR.PATCH` style revision like `1.5.0`, an integer number like `1`, or single letter like `A`, `B`, etc. Zephyr provides a CMake board extension function, `board_check_revision()`, to make it easy to match either style from `revision.cmake`.

Valid board revisions may be specified as arguments to the `board_check_revision()` function, like:

```
board_check_revision(
    FORMAT   MAJOR.MINOR.PATCH
    VALID_REVISIONS   0.1.0   0.3.0   ...
)
```

**Note:** `VALID_REVISIONS` can be omitted if all valid revisions have specific Kconfig fragments, such as `<board>_0_1_0.conf`, `<board>_0_3_0.conf`. This allows you to just place Kconfig revision fragments in the board folder and not have to keep the corresponding `VALID_REVISIONS` in sync.

The following sections describe how to support these styles of revision numbers.

**MAJOR.MINOR.PATCH revisions**  Let's say you want to add support for revisions `0.5.0`, `1.0.0`, and `1.5.0` of the `plank` board with both Kconfig fragments and devicetree overlays. Create `revision.cmake` with `board_check_revision(FORMAT MAJOR.MINOR.PATCH)`, and create the following additional files in the board directory:
Notice how the board files have changed periods (".") in the revision number to underscores ("_").

**Fuzzy revision matching** To support "fuzzy" MAJOR.MINOR.PATCH revision matching for the plank board, use the following code in revision.cmake:

```c
board_check_revision(FORMAT MAJOR.MINOR.PATCH)
```

If the user selects a revision between those available, the closest revision number that is not larger than the user's choice is used. For example, if the user builds for plank@0.7.0, the build system will target revision 0.5.0.

The build system will print this at CMake configuration time:

```
-- Board: plank, Revision: 0.7.0 (Active: 0.5.0)
```

This allows you to only create revision configuration files for board revision numbers that introduce incompatible changes.

Any revision less than the minimum defined will be treated as an error.

You may use 0.0.0 as a minimum revision to build for by creating the file plank_0_0_0.conf in the board directory. This will be used for any revision lower than 0.5.0, for example if the user builds for plank@0.1.0.

**Exact revision matching** Alternatively, the EXACT keyword can be given to board_check_revision() in revision.cmake to allow exact matches only, like this:

```c
board_check_revision(FORMAT MAJOR.MINOR.PATCH EXACT)
```

With this revision.cmake, building for plank@0.7.0 in the above example will result in the following error message:

```
Board revision `0.7.0` not found. Please specify a valid board revision.
```

**Letter revision matching** Let's say instead that you need to support revisions A, B, and C of the plank board. Create the following additional files in the board directory:

And add the following to revision.cmake:
Let's say instead that you need to support revisions 1, 2, and 3 of the plank board. Create the following additional files in the board directory:

```
boards/<ARCH>/plank
  └── plank_1.conf
  └── plank_1.overlay
  └── plank_2.conf
  └── plank_2.overlay
  └── plank_3.conf
  └── plank_3.overlay
  └── revision.cmake
```

And add the following to revision.cmake:

```c
board_check_revision(FORMAT NUMBER)
```

### board_check_revision() details

This function supports the following arguments:

- **FORMAT LETTER**: matches single letter revisions from A to Z only
- **FORMAT NUMBER**: matches integer revisions
- **FORMAT MAJOR.MINOR.PATCH**: matches exactly three digits. The command line allows for loose typing, that is `-DBOARD=<board>@1` and `-DBOARD=<board>@1.0` will be handled as `-DBOARD=<board>@1.0.0`. Kconfig fragment and devicetree overlay files must use full numbering to avoid ambiguity, so only `<board>_1_0_0.conf` and `<board>_1_0_0.overlay` are allowed.
- **OPTIONAL**: if given, a revision is not required to be specified. If the revision is not supplied, the base board is used with no overlays. Can be combined with EXACT, in which case providing the revision is optional, but if given the EXACT rules apply. Mutually exclusive with DEFAULT_REVISION.
- **EXACT**: if given, the revision is required to be an exact match. Otherwise, the closest matching revision not greater than the user's choice will be selected.
- **DEFAULT_REVISION <revision>**: if given, `<revision>` is the default revision to use when user has not selected a revision number. If not given, the build system prints an error when the user does not specify a board revision.
- **HIGHEST_REVISION <revision>**: if given, specifies the highest valid revision for a board. This can be used to ensure that a newer board cannot be used with an older Zephyr. For example, if the current board directory supports revisions 0.x.0-0.99.99 and 1.0.0-1.99.99, and it is expected that the implementation will not work with board revision 2.0.0, then giving HIGHEST_REVISION 1.99.99 causes an error if the user builds using `<board>@2.0.0`.
- **VALID_REVISIONS <revision> [ <revision> ...]**: if given, specifies a list of revisions that are valid for this board. If this argument is not given, then each Kconfig fragment of the form `<board>_<revision>.conf` in the board folder will be used as a valid revision for the board.
Custom revision.cmake files

Some boards may not use board revisions supported by board_check_revision(). To support revisions of any type, the file revision.cmake can implement custom revision matching without calling board_check_revision().

To signal to the build system that it should use a different revision than the one specified by the user, revision.cmake can set the variable ACTIVE_BOARD_REVISION to the revision to use instead. The corresponding Kconfig files and devicetree overlays must be named <board>_<ACTIVE_BOARD_REVISION>.conf and <board>_<ACTIVE_BOARD_REVISION>.overlay.

For example, if the user builds for plank@zero, revision.cmake can set ACTIVE_BOARD_REVISION to one to use the files plank_one.conf and plank_one.overlay.

Contributing your board

If you want to contribute your board to Zephyr, first – thanks!

There are some extra things you'll need to do:

1. Make sure you’ve followed all the General recommendations. They are requirements for boards included with Zephyr.
2. Add documentation for your board using the template file doc/templates/board.tmpl. See Documentation Generation for information on how to build your documentation before submitting your pull request.
3. Prepare a pull request adding your board which follows the Contribution Guidelines.

Board extensions

Boards already supported by Zephyr can be extended by downstream users, such as example-application or vendor SDKs. In some situations, certain hardware description or choices can not be added in the upstream Zephyr repository, but they can be in a downstream project, where custom bindings or driver classes can also be created. This feature may also be useful in development phases, when the board skeleton lives upstream, but other features are developed in a downstream module.

Board extensions are board fragments that can be present in an out-of-tree board root folder, under `${BOARD_ROOT}/boards/extensions`. Here is an example structure of an extension for the plank board and its revisions:

```
boards/extensions/plank
├── plank.conf # optional
├── plank_<revision>.conf # optional
├── plank.overlay # optional
└── plank_<revision>.overlay # optional
```

A board extension directory must follow the naming structure of the original board it extends. It may contain Kconfig fragments and/or devicetree overlays. Extensions are, by default, automatically loaded and applied on top of board files, before anything else. There is no guarantee on which order extensions are applied, in case multiple exist. This feature can be disabled by passing -DBOARD_EXTENSIONS=OFF when building.

Note that board extensions need to follow the same guidelines as regular boards. For example, it is wrong to enable extra peripherals or subsystems in a board extension.

**Warning:** Board extensions are not allowed in any module referenced in Zephyr's `west.yml` manifest file. Any board changes are required to be submitted to the main Zephyr repository.
7.8.3 Shields

Shields, also known as “add-on” or “daughter boards”, attach to a board to extend its features and services for easier and modularized prototyping. In Zephyr, the shield feature provides Zephyr-formatted shield descriptions for easier compatibility with applications.

Shield porting and configuration

Shield configuration files are available in the board directory under /boards/shields:

```
boards/shields/<shield>
├── <shield>.overlay
├── Kconfig.shield
└── Kconfig.defconfig
```

These files provide shield configuration as follows:

- **<shield>.overlay**: This file provides a shield description in devicetree format that is merged with the board’s devicetree before compilation.
- **Kconfig.shield**: This file defines shield Kconfig symbols that will be used for default shield configuration. To ease use with applications, the default shield configuration here should be consistent with those in the Write your devicetree.
- **Kconfig.defconfig**: This file defines the default shield configuration. It is made to be consistent with the Write your devicetree. Hence, shield configuration should be done by keeping in mind that features activation is application responsibility.

Besides, in order to avoid name conflicts with devices that may be defined at board level, it is advised, specifically for shields devicetree descriptions, to provide a device nodelabel in the form <device>_<shield>, for instance:

```
sdhc_mystone: sdhc@1 { 
    reg = <1>;
    ...
};
```

Board compatibility

Hardware shield-to-board compatibility depends on the use of well-known connectors used on popular boards (such as Arduino and 96boards). For software compatibility, boards must also provide a configuration matching their supported connectors.

This should be done at two different levels:

- **Pinmux**: Connector pins should be correctly configured to match shield pins
- **Devicetree**: A board devicetree file, BOARD.dts should define an alternate nodelabel for each connector interface. For example, for Arduino I2C:

```
arduino_i2c: &i2c1 {
};
```

Board specific shield configuration If modifications are needed to fit a shield to a particular board or board revision, you can override a shield description for a specific board by adding board or board revision overriding files to a shield, as follows:
boards/shields/<shield>
    └── boards
        ├── <board>_<revision>.overlay
        ├── <board>.overlay
        ├── <board>.defconfig
        └── <board>_<revision>.conf
        └── <board>.conf

Shield activation

Activate support for one or more shields by adding the matching -DSHIELD arg to CMake command

```bash
# From the root of the zephyr repository
west build -b None your_app -- -DSHIELD="x_nucleo_idb05a1 x_nucleo_iks01a1"
```

Alternatively, it could be set by default in a project’s CMakeLists.txt:

```bash
set(SHIELD x_nucleo_iks01a1)
```

Shield variants

Some shields may support several variants or revisions. In that case, it is possible to provide multiple version of the shields description:

boards/shields/<shield>
    ├── <shield_v1>.overlay
    │    ├── <shield_v1>.defconfig
    │    └── <shield_v2>.overlay
    │        └── <shield_v2>.defconfig
    └── boards
        └── <shield_v2>
            └── <board>.overlay
            └── <board>.defconfig

In this case, a shield-particular revision name can be used:

```bash
# From the root of the zephyr repository
west build -b None your_app -- -DSHIELD=shield_v2
```

You can also provide a board-specific configuration to a specific shield revision:

boards/shields/<shield>
    ├── <shield_v1>.overlay
    │    ├── <shield_v1>.defconfig
    │    └── <shield_v2>.overlay
    │        └── <shield_v2>.defconfig
    └── boards
        └── <shield_v2>
            └── <board>.overlay
            └── <board>.defconfig

GPIO nexus nodes

GPIOs accessed by the shield peripherals must be identified using the shield GPIO abstraction, for example from the arduino-header-r3 compatible. Boards that provide the header must map the header pins to SOC-specific pins. This is accomplished by including a nexus node that looks like the following into the board devicetree file:
This specifies how Arduino pin references like `<&arduino_header 11 0>` are converted to SOC gpio pin references like `<&gpiob 4 0>`.

In Zephyr GPIO specifiers generally have two parameters (indicated by `#gpio-cells = <2>`): the pin number and a set of flags. The low 6 bits of the flags correspond to features that can be configured in devicetree. In some cases it’s necessary to use a non-zero flag value to tell the driver how a particular pin behaves, as with:

```plaintext
drdy-gpios = `<&arduino_header 11 GPIO_ACTIVE_LOW>;
```

After preprocessing this becomes `<&arduino_header 11 1>`. Normally the presence of such a flag would cause the map lookup to fail, because there is no map entry with a non-zero flags value. The `gpio-map-mask` property specifies that, for lookup, all bits of the pin and all but the low 6 bits of the flags are used to identify the specifier. Then the `gpio-map-pass-thru` specifies that the low 6 bits of the flags are copied over, so the SOC GPIO reference becomes `<&gpiob 4 1>` as intended.

See [nexus node](#) for more information about this capability.
Chapter 8

Contributing to Zephyr

Contributions from the community are the backbone of the project. Whether it is by submitting code, improving documentation, or proposing new features, your efforts are highly appreciated. This page lists useful resources and guidelines to help you in your contribution journey.

8.1 General Guidelines

8.1.1 Contribution Guidelines

As an open-source project, we welcome and encourage the community to submit patches directly to the project. In our collaborative open source environment, standards and methods for submitting changes help reduce the chaos that can result from an active development community.

This document explains how to participate in project conversations, log bugs and enhancement requests, and submit patches to the project so your patch will be accepted quickly in the code-base.

Licensing

Licensing is very important to open source projects. It helps ensure the software continues to be available under the terms that the author desired.

Zephyr uses the Apache 2.0 license (as found in the LICENSE file in the project's GitHub repo) to strike a balance between open contribution and allowing you to use the software however you would like to. The Apache 2.0 license is a permissive open source license that allows you to freely use, modify, distribute and sell your own products that include Apache 2.0 licensed software. (For more information about this, check out articles such as Why choose Apache 2.0 licensing and Top 10 Apache License Questions Answered).

A license tells you what rights you have as a developer, as provided by the copyright holder. It is important that the contributor fully understands the licensing rights and agrees to them. Sometimes the copyright holder isn't the contributor, such as when the contributor is doing work on behalf of a company.

Components using other Licenses

There are some imported or reused components of the Zephyr project that use other licensing, as described in Licensing of Zephyr Project components.

Importing code into the Zephyr OS from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board.
By carefully reviewing potential contributions and also enforcing a Developer Certification of Origin (DCO) for contributed code, we can ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

See Contributing External Components for more information about this contributing and review process for imported components.

Licensing of Zephyr Project components The Zephyr kernel tree imports or reuses packages, scripts and other files that are not covered by the Apache 2.0 License. In some places there is no LICENSE file or way to put a LICENSE file there, so we describe the licensing in this document.

 scripts/{checkpatch.pl,checkstack.pl,spelling.txt}
  Origin: Linux Kernel
  Licensing: GPLv2 License

Copyrights Notices

Please follow this Community Best Practice for Copyright Notices from the Linux Foundation.

Developer Certification of Origin (DCO)

To make a good faith effort to ensure licensing criteria are met, the Zephyr project requires the Developer Certificate of Origin (DCO) process to be followed.

The DCO is an attestation attached to every contribution made by every developer. In the commit message of the contribution, (described more fully later in this document), the developer simply adds a Signed-off-by statement and thereby agrees to the DCO.

When a developer submits a patch, it is a commitment that the contributor has the right to submit the patch per the license. The DCO agreement is shown below and at http://developercertificate.org/.

<table>
<thead>
<tr>
<th>Developer's Certificate of Origin 1.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>By making a contribution to this project, I certify that:</td>
</tr>
<tr>
<td>(a) The contribution was created in whole or in part by me and I have the right to submit it under the open source license indicated in the file; or</td>
</tr>
<tr>
<td>(b) The contribution is based upon previous work that, to the best of my knowledge, is covered under an appropriate open source license and I have the right under that license to submit that work with modifications, whether created in whole or in part by me, under the same open source license (unless I am permitted to submit under a different license), as indicated in the file; or</td>
</tr>
<tr>
<td>(c) The contribution was provided directly to me by some other person who certified (a), (b) or (c) and I have not modified it.</td>
</tr>
<tr>
<td>(d) I understand and agree that this project and the contribution are public and that a record of the contribution (including all personal information I submit with it, including my sign-off) is maintained indefinitely and may be redistributed consistent with this project or the open source license(s) involved.</td>
</tr>
</tbody>
</table>
DCO Sign-Off  The “sign-off” in the DCO is a “Signed-off-by:” line in each commit’s log message. The Signed-off-by: line must be in the following format:

Signed-off-by: Your Name <your.email@example.com>

For your commits, replace:

- Your Name with your legal name (pseudonyms, hacker handles, and the names of groups are not allowed)
- your.email@example.com with the same email address you are using to author the commit (CI will fail if there is no match)

You can automatically add the Signed-off-by: line to your commit body using `git commit -s`. Use other commits in the zephyr git history as examples.

Additional requirements:

- If you are altering an existing commit created by someone else, you must add your Signed-off-by: line without removing the existing one.
- If you forget to add the Signed-off-by: line, you can add it to your previous commit by running `git commit --amend -s`.
- If you've pushed your changes to GitHub already you'll need to force push your branch after this with `git push -f`.

Notes  Any contributions made as part of submitted pull requests are considered free for the Project to use. Developers are permitted to cherry-pick patches that are included in pull requests submitted by other contributors. It is expected that

- the content of the patches will not be substantially modified,
- the cherry-picked commits or portions of a commit shall preserve the original sign-off messages and the author identity.

Modifying Contributions made by other developers describes additional recommended policies around working with contributions submitted by other developers.

Prerequisites

As a contributor, you'll want to be familiar with the Zephyr project, how to configure, install, and use it as explained in the Zephyr Project website and how to set up your development environment as introduced in the Zephyr Getting Started Guide.

You should be familiar with common developer tools such as Git and CMake, and platforms such as GitHub.

If you haven't already done so, you'll need to create a (free) GitHub account on https://github.com and have Git tools available on your development system.

Note:  The Zephyr development workflow supports all 3 major operating systems (Linux, macOS, and Windows) but some of the tools used in the sections below are only available on Linux and macOS. On Windows, instead of running these tools yourself, you will need to rely on the Continuous Integration (CI) service using Github Actions, which runs automatically on GitHub when you submit your Pull Request (PR). You can see any failure results in the workflow details link near the end of the PR conversation list. See Continuous Integration for more information.
Source Tree Structure

To clone the main Zephyr Project repository use the instructions in *Get Zephyr and install Python dependencies*.

This section describes the main repository’s source tree. In addition to the Zephyr kernel itself, you’ll also find the sources for technical documentation, sample code, supported board configurations, and a collection of subsystem tests. All of these are available for developers to contribute to and enhance.

Understanding the Zephyr source tree can help locate the code associated with a particular Zephyr feature.

At the top of the tree, several files are of importance:

- **CMakeLists.txt**
  - The top-level file for the CMake build system, containing a lot of the logic required to build Zephyr.

- **Kconfig**
  - The top-level Kconfig file, which refers to the file `Kconfig.zephyr` also found in the top-level directory.
  - See the *Kconfig section of the manual* for detailed Kconfig documentation.

- **west.yml**
  - The *West (Zephyr’s meta-tool)* manifest, listing the external repositories managed by the west command-line tool.

The Zephyr source tree also contains the following top-level directories, each of which may have one or more additional levels of subdirectories not described here.

- **arch**
  - Architecture-specific kernel and system-on-chip (SoC) code. Each supported architecture (for example, x86 and ARM) has its own subdirectory, which contains additional subdirectories for the following areas:
    - architecture-specific kernel source files
    - architecture-specific kernel include files for private APIs

- **soc**
  - SoC related code and configuration files.

- **boards**
  - Board related code and configuration files.

- **doc**
  - Zephyr technical documentation source files and tools used to generate the [https://docs.zephyrproject.org](https://docs.zephyrproject.org) web content.

- **drivers**
  - Device driver code.

- **dts**
  - *devicetree* source files used to describe non-discoverable board-specific hardware details.

- **include**
  - Include files for all public APIs, except those defined under `lib`.

- **kernel**
  - Architecture-independent kernel code.

- **lib**
  - Library code, including the minimal standard C library.

- **misc**
  - Miscellaneous code that doesn’t belong to any of the other top-level directories.
samples
Sample applications that demonstrate the use of Zephyr features.

scripts
Various programs and other files used to build and test Zephyr applications.

cmake
Additional build scripts needed to build Zephyr.

subsys
Subsystems of Zephyr, including:

- USB device stack code
- Networking code, including the Bluetooth stack and networking stacks
- File system code
- Bluetooth host and controller

tests
Test code and benchmarks for Zephyr features.

share
Additional architecture independent data. It currently contains Zephyr's CMake package.

Pull Requests and Issues

Before starting on a patch, first check in our issues Zephyr Project Issues system to see what's been reported on the issue you'd like to address. Have a conversation on the Zephyr devel mailing list (or the Zephyr Discord Server) to see what others think of your issue (and proposed solution). You may find others that have encountered the issue you're finding, or that have similar ideas for changes or additions. Send a message to the Zephyr devel mailing list to introduce and discuss your idea with the development community.

It's always a good practice to search for existing or related issues before submitting your own. When you submit an issue (bug or feature request), the triage team will review and comment on the submission, typically within a few business days.

You can find all open pull requests on GitHub and open Zephyr Project Issues in Github issues.

Tools and Git Setup

Name and email  We need to know who you are, and how to contact you. To add this information to your Git installation, set the Git configuration variables user.name to your full name, and user.email to your email address.

For example, if your name is Zephyr Developer and your email address is z.developer@example.com:

```
git config --global user.name "Zephyr Developer"
git config --global user.email "z.developer@example.com"
```

gitlint  When you submit a pull request to the project, a series of checks are performed to verify your commit messages meet the requirements. The same step done during the CI process can be performed locally using the gitlint command.

Run gitlint locally in your tree and branch where your patches have been committed:
Note, gitlint only checks HEAD (the most recent commit), so you should run it after each commit, or use the `--commits` option to specify a commit range covering all the development patches to be submitted.

**twister**  
**Note:** twister support on windows is limited and execution of tests is not supported, only building.

To verify that your changes did not break any tests or samples, please run the `twister` script locally before submitting your pull request to GitHub.

Twister allows limiting the scope of the tests built and run by pointing it to the tests related to the code or the platform you have modified. For example, to limit tests to a single platform and an area in the kernel:

```
source zephyr-env.sh
west twister -p qemu_x86 -T tests/kernel/sched
```

Running tests on connected devices is also supported using the `--device-testing` options. Please consult with the [Twister](#) documentation for more details.

To run the same tests the CI system runs, follow these steps from within your local Zephyr source working directory:

```
source zephyr-env.sh
west twister --integration
```

The above will execute the basic twister script, which will run various tests using the QEMU emulator and other simulators supported in Zephyr. It will also do some build tests on various samples with advanced features that can't run in a simulator or QEMU.

We highly recommend you run these tests locally to avoid any CI failures. However, note that building and executing tests using twister requires significant computing resources. When running locally and to get results in a reasonable time, limit the scope to the areas and platforms you have modified. In case of major changes to the kernel, build or configuration infrastructures of Zephyr, it is advised to use twister for verifying majority the changes before handing over to the dedicated CI resources provided by the Zephyr project.

### clang-format

The `clang-format` tool can be helpful to quickly reformat large amounts of new source code to our [Coding Style](#) standards together with the `.clang-format` configuration file provided in the repository. `clang-format` is well integrated into most editors, but you can also run it manually like this:

```
clang-format -i my_source_file.c
```

`clang-format` is part of LLVM, which can be downloaded from the project releases page [here](https://github.com/llvm/llvm-project/releases). Note that if you are a Linux user, `clang-format` will likely be available as a package in your distribution repositories.

## Coding Style

Use these coding guidelines to ensure that your development complies with the project's style and naming conventions.

In general, follow the [Linux kernel coding style](#), with the following exceptions:
• The line length is 100 columns or fewer. In the documentation, longer lines for URL references are an allowed exception.
• Add braces to every if, else, do, while, for and switch body, even for single-line code blocks. Use the --ignore BRACES flag to make checkpatch stop complaining.
• Use spaces instead of tabs to align comments after declarations, as needed.
• Use C89-style single line comments, /* */. The C99-style single line comment, //, is not allowed.
• Use /** */ for doxygen comments that need to appear in the documentation.
• Avoid using binary literals (constants starting with 0b).

When there are differences between the guidelines above and the formatting generated by code formatting tools, the guidelines above take precedence.

The Linux kernel GPL-licensed tool checkpatch is used to check coding style conformity.

**Note:** checkpatch does not currently run on Windows.

Checkpatch is available in the scripts directory. To invoke it when committing code, make the file $ZEPHYR_BASE/.git/hooks/pre-commit executable and edit it to contain:

```
#!/bin/sh
set -e exec
exec git diff --cached | ${ZEPHYR_BASE}/scripts/checkpatch.pl -
```

Instead of running checkpatch at each commit, you may prefer to run it only before pushing on zephyr repo. To do this, make the file $ZEPHYR_BASE/.git/hooks/pre-push executable and edit it to contain:

```
#!/bin/sh
remote="$1"
url="$2"

z40=0000000000000000000000000000000000000000

echo "Run push hook"
while read local_ref local_sha remote_ref remote_sha
do
  args="$remote $url $local_ref $local_sha $remote_ref $remote_sha"
  exec ${ZEPHYR_BASE}/scripts/series-push-hook.sh $args
done

exit 0
```

If you want to override checkpatch verdict and push you branch despite reported issues, you can add option –no-verify to the git push command.

A more complete alternative to this is using check_compliance.py script from ci-tools repo.

**Static Code Analysis**

Coverity Scan is a free service for static code analysis of Open Source projects. It is based on Coverity's commercial product and is able to analyze C, C++ and Java code.

Coverity's static code analysis doesn't run the code. Instead of that it uses abstract interpretation to gain information about the code's control flow and data flow. It's able to follow all possible code paths that a program may take. For example the analyzer understands that malloc() returns
a memory that must be freed with free() later. It follows all branches and function calls to see if all possible combinations free the memory. The analyzer is able to detect all sorts of issues like resource leaks (memory, file descriptors), NULL dereferencing, use after free, unchecked return values, dead code, buffer overflows, integer overflows, uninitialized variables, and many more.

The results are available on the Coverity Scan website. In order to access the results you have to create an account yourself. From the Zephyr project page, you may select “Add me to project” to be added to the project. New members must be approved by an admin.

Static analysis of the Zephyr codebase is conducted on a bi-weekly basis. GitHub issues are automatically created for any issues detected by static analysis tools. These issues will have the same (or equivalent) priority initially defined by the tool.

To ensure accountability and efficient issue resolution, they are assigned to the respective maintainer who is responsible for the affected code.

A dedicated team comprising members with expertise in static analysis, code quality, and software security ensures the effectiveness of the static analysis process and verifies that identified issues are properly triaged and resolved in a timely manner.

**Workflow**  If after analyzing the Coverity report it is concluded that it is a false positive please set the classification to either “False positive” or “Intentional”, the action to “Ignore”, owner to your own account and add a comment why the issue is considered false positive or intentional.

Update the related Github issue in the zephyr project with the details, and only close it after completing the steps above on scan service website. Any issues closed without a fix or without ignoring the entry in the scan service will be automatically reopened if the issue continues to be present in the code.

**Contribution Workflow**

One general practice we encourage, is to make small, controlled changes. This practice simplifies review, makes merging and rebasing easier, and keeps the change history clear and clean.

When contributing to the Zephyr Project, it is also important you provide as much information as you can about your change, update appropriate documentation, and test your changes thoroughly before submitting.

The general GitHub workflow used by Zephyr developers uses a combination of command line Git commands and browser interaction with GitHub. As it is with Git, there are multiple ways of getting a task done. We’ll describe a typical workflow here:

1. **Create a Fork of Zephyr** to your personal account on GitHub. (Click on the fork button in the top right corner of the Zephyr project repo page in GitHub.)

2. On your development computer, change into the zephyr folder that was created when you obtained the code:

   ````
cd zephyr
```

   Rename the default remote pointing to the upstream repository from origin to upstream:

   ````
git remote rename origin upstream
```

   Let Git know about the fork you just created, naming it origin:

   ````
git remote add origin https://github.com/<your github id>/zephyr
```

   and verify the remote repos:

   ````
git remote -v
```

---

Chapter 8. Contributing to Zephyr
3. Create a topic branch (off of main) for your work (if you’re addressing an issue, we suggest including the issue number in the branch name):

```bash
git checkout main
git checkout -b fix_comment_typo
```

Some Zephyr subsystems do development work on a separate branch from main so you may need to indicate this in your checkout:

```bash
git checkout -b fix_out_of_date_patch origin/net
```

4. Make changes, test locally, change, test, test again, … (Check out the prior chapter on twister as well).

5. When things look good, start the pull request process by adding your changed files:

```bash
git add [file(s) that changed, add -p if you want to be more specific]
```

You can see files that are not yet staged using:

```bash
git status
```

6. Verify changes to be committed look as you expected:

```bash
git diff --cached
```

7. Commit your changes to your local repo:

```bash
git commit -s
```

The -s option automatically adds your Signed-off-by: to your commit message. Your commit will be rejected without this line that indicates your agreement with the Developer Certification of Origin (DCO). See the Commit Message Guidelines section for specific guidelines for writing your commit messages.

8. Push your topic branch with your changes to your fork in your personal GitHub account:

```bash
git push origin fix_comment_typo
```

9. In your web browser, go to your forked repo and click on the Compare & pull request button for the branch you just worked on and you want to open a pull request with.

10. Review the pull request changes, and verify that you are opening a pull request for the main branch. The title and message from your commit message should appear as well.

11. A bot will assign one or more suggested reviewers (based on the MAINTAINERS file in the repo). If you are a project member, you can select additional reviewers now too.

12. Click on the submit button and your pull request is sent and awaits review. Email will be sent as review comments are made, or you can check on your pull request at https://github.com/zephyrproject-rtos/zephyr/pulls.

**Note:** As more commits are merged upstream, the GitHub PR page will show a This branch is out-of-date with the base branch message and a Update branch button on the PR page. That message should be ignored, as the commits will be rebased as part of merging
anyway, and triggering a branch update from the GitHub UI will cause the PR approvals to be dropped.

13. While you're waiting for your pull request to be accepted and merged, you can create another branch to work on another issue. (Be sure to make your new branch off of main and not the previous branch.):

- `git checkout main`
- `git checkout -b fix_another_issue`

and use the same process described above to work on this new topic branch.

14. If reviewers do request changes to your patch, you can interactively rebase commit(s) to fix review issues. In your development repo:

- `git fetch --all`
- `git rebase --ignore-whitespace upstream/main`

The `--ignore-whitespace` option stops `git apply` (called by rebase) from changing any whitespace. Continuing:

- `git rebase -i <offending-commit-id>^`

In the interactive rebase editor, replace `pick` with `edit` to select a specific commit (if there's more than one in your pull request), or remove the line to delete a commit entirely. Then edit files to fix the issues in the review.

As before, inspect and test your changes. When ready, continue the patch submission:

- `git add [file(s)]`
- `git rebase --continue`

Update commit comment if needed, and continue:

- `git push --force origin fix_comment_typo`

By force pushing your update, your original pull request will be updated with your changes so you won't need to resubmit the pull request.

**Note:** While amending commits and force pushing is a common review model outside GitHub, and the one recommended by Zephyr, it's not the main model supported by GitHub. Forced pushes can cause unexpected behavior, such as not being able to use “View Changes” buttons except for the last one - GitHub complains it can’t find older commits. You're also not always able to compare the latest reviewed version with the latest submitted version. When rewriting history GitHub only guarantees access to the latest version.

15. If the CI run fails, you will need to make changes to your code in order to fix the issues and amend your commits by rebasing as described above. Additional information about the CI system can be found in Continuous Integration.

**Commit Message Guidelines**

Changes are submitted as Git commits. Each commit has a commit message describing the change. Acceptable commit messages look like this:

```
[area]: [summary of change]
[Commit message body (must be non-empty)]
```

(continues on next page)
Signed-off-by: [Your Full Name] <[your.email@address]>

You need to change text in square brackets ([like this]) above to fit your commit. Examples and more details follow.

**Example** Here is an example of a good commit message.

```
drivers: sensor: abcd1234: fix bus I/O error handling
```

The abcd1234 sensor driver is failing to check the flags field in the response packet from the device which signals that an error occurred. This can lead to reading invalid data from the response buffer. Fix it by checking the flag and adding an error path.

Signed-off-by: Zephyr Developer <z.developer@example.com>

**[area]: [summary of change]** This line is called the commit's **title**. Titles must be:

- one line
- less than 72 characters long
- followed by a completely blank line

**[area]**

The [area] prefix usually identifies the area of code being changed. It can also identify the change's wider context if multiple areas are affected. Here are some examples:

- doc: ... for documentation changes
- drivers: foo: for foo driver changes
- Bluetooth: Shell: for changes to the Bluetooth shell
- net: ethernet: for Ethernet-related networking changes
- dts: for treewide devicetree changes
- style: for code style changes

If you're not sure what to use, try running `git log FILE`, where `FILE` is a file you are changing, and using previous commits that changed the same file as inspiration.

**[summary of change]**

The [summary of change] part should be a quick description of what you've done. Here are some examples:

- doc: update wiki references to new site
- drivers: sensor: sensor_shell: fix channel name collision

**Warning**: An empty commit message body is not permitted. Even for trivial changes, please include a descriptive commit message body. Your pull request will fail CI checks if you do not.

**Commit Message Body** This part of the commit should explain what your change does, and why it's needed. Be specific. A body that says "Fixes stuff" will be rejected. Be sure to include the following as relevant:
• **what** the change does,
• **why** you chose that approach,
• **what** assumptions were made, and
• **how** you know it works – for example, which tests you ran.

Each line in your commit message should usually be 75 characters or less. Use newlines to wrap longer lines. Exceptions include lines with long URLs, email addresses, etc.

For examples of accepted commit messages, you can refer to the Zephyr GitHub changelog.

If the change addresses a GitHub issue, include a line of the form:

```
Fixes #[issue number]
```

Where `[issue number]` is the relevant GitHub issue's number. For example:

```
Fixes: #1234
```

**Signed-off-by:** ...

**Tip:** You should have set your *Name and email* already. Create your commit with `git commit -s` to add the Signed-off-by: line automatically using this information.

For open source licensing reasons, your commit must include a Signed-off-by: line that looks like this:

```
Signed-off-by: [Your Full Name] <[your.email@address]>
```

For example, if your full name is Zephyr Developer and your email address is z.developer@example.com:

```
Signed-off-by: Zephyr Developer <z.developer@example.com>
```

This means that you have personally made sure your change complies with the *Developer Certification of Origin (DCO)*. For this reason, you must use your legal name. Pseudonyms or “hacker aliases” are not permitted.

Your name and the email address you use must match the name and email in the Git commit’s Author: field.

**Other Commit Expectations**  See the *Contributor Expectations* for a more complete discussion of contributor and reviewer expectations.

**Submitting Proposals**  You can request a new feature or submit a proposal by submitting an issue to our GitHub Repository. If you would like to implement a new feature, please submit an issue with a proposal (RFC) for your work first, to be sure that we can use it. Please consider what kind of change it is:

• For a Major Feature, first open an issue and outline your proposal so that it can be discussed. This will also allow us to better coordinate our efforts, prevent duplication of work, and help you to craft the change so that it is successfully accepted into the project. Providing the following information will increase the chances of your issue being dealt with quickly:
  – Overview of the Proposal
  – Motivation for or Use Case
  – Design Details
  – Alternatives

Chapter 8. Contributing to Zephyr
Test Strategy

- Small Features can be crafted and directly submitted as a Pull Request.

**Identifying Contribution Origin** When adding a new file to the tree, it is important to detail the source of origin on the file, provide attributions, and detail the intended usage. In cases where the file is an original to Zephyr, the commit message should include the following (“Original” is the assumption if no Origin tag is present):

<table>
<thead>
<tr>
<th>Origin: Original</th>
</tr>
</thead>
</table>

In cases where the file is *imported from an external project*, the commit message shall contain details regarding the original project, the location of the project, the SHA-id of the origin commit for the file and the intended purpose.

For example, a copy of a locally maintained import:

<table>
<thead>
<tr>
<th>Origin: Contiki OS</th>
</tr>
</thead>
<tbody>
<tr>
<td>License: BSD 3-Clause</td>
</tr>
<tr>
<td>URL: <a href="http://www.contiki-os.org/">http://www.contiki-os.org/</a></td>
</tr>
<tr>
<td>commit: 853207acfd6549b10eb3e44504b1a75ae1ad63a</td>
</tr>
<tr>
<td>Purpose: Introduction of networking stack.</td>
</tr>
</tbody>
</table>

For example, a copy of an externally maintained import in a module repository:

<table>
<thead>
<tr>
<th>Origin: Tiny Crypt</th>
</tr>
</thead>
<tbody>
<tr>
<td>License: BSD 3-Clause</td>
</tr>
<tr>
<td>URL: <a href="https://github.com/01org/tinycrypt">https://github.com/01org/tinycrypt</a></td>
</tr>
<tr>

**Continuous Integration (CI)**

The Zephyr Project operates a Continuous Integration (CI) system that runs on every Pull Request (PR) in order to verify several aspects of the PR:

- Git commit formatting
- Coding Style
- Twister builds for multiple architectures and boards
- Documentation build to verify any doc changes

CI is run on Github Actions and it uses the same tools described in the Contribution Tools section. The CI results must be green indicating “All checks have passed” before the Pull Request can be merged. CI is run when the PR is created, and again every time the PR is modified with a commit.

The current status of the CI run can always be found at the bottom of the GitHub PR page, below the review status. Depending on the success or failure of the run you will see:

- “All checks have passed”
- “All checks have failed”

In case of failure you can click on the “Details” link presented below the failure message in order to navigate to Github Actions and inspect the results. Once you click on the link you will be taken to the Github Actions summary results page where a table with all the different builds will be shown. To see what build or test failed click on the row that contains the failed (i.e. non-green) build.
Contributions to External Modules

Follow the guidelines in the Modules (External projects) section for contributing new modules and submitting changes to existing modules.

Treewide Changes

This section describes contributions that are treewide changes and some additional associated requirements that apply to them. These requirements exist to try to give such changes increased review and user visibility due to their large impact.

Definition and Decision Making

A treewide change is defined as any change to Zephyr APIs, coding practices, or other development requirements that either implies required changes throughout the zephyr source code repository or can reasonably be expected to do so for a wide class of external Zephyr-based source code.

This definition is informal by necessity. This is because the decision on whether any particular change is treewide can be subjective and may depend on additional context.

Project maintainers should use good judgement and prioritize the Zephyr developer experience when deciding when a proposed change is treewide. Protracted disagreements can be resolved by the Zephyr Project's Technical Steering Committee (TSC), but please avoid premature escalation to the TSC.

Requirements for Treewide Changes

- The zephyr repository must apply the ‘treewide’ GitHub label to any issues or pull requests that are treewide changes
- The person proposing a treewide change must create an RFC issue describing the change, its rationale and impact, etc. before any pull requests related to the change can be merged
- The project's Architecture Working Group (WG) must include the issue on the agenda and discuss whether the project will accept or reject the change before any pull requests related to the change can be merged (with escalation to the TSC if consensus is not reached at the WG)
- The Architecture WG must specify the procedure for merging any PRs associated with each individual treewide change, including any required approvals for pull requests affecting specific subsystems or extra review time requirements
- The person proposing a treewide change must email devel@lists.zephyrproject.org about the RFC if it is accepted by the Architecture WG before any pull requests related to the change can be merged

Examples

Some example past treewide changes are:

- the deprecation of version 1 of the Logging API in favor of version 2 (see commit 262cc55609)
- the removal of support for a legacy Devicetree bindings syntax (6bf761fc0a)

Note that adding a new version of a widely used API while maintaining support for the old one is not a treewide change. Deprecation and removal of such APIs, however, are treewide changes.
Specialized driver requirements

Drivers for standalone devices should use the Zephyr bus APIs (SPI, I2C...) whenever possible so that the device can be used with any SoC from any vendor implementing a compatible bus.

If it is not technically possible to achieve full performance using the Zephyr APIs due to specialized accelerators in a particular SoC family, one could extend the support for an external device by providing a specialized path for that SoC family. However, the driver must still provide a regular path (via Zephyr APIs) for all other SoCs. Every exception must be approved by the Architecture WG in order to be validated and potentially to be learned/improved from.

8.1.2 Coding Guidelines

The project TSC and the Safety Committee of the project agreed to implement a staged and incremental approach for complying with a set of coding rules (AKA Coding Guidelines) to improve quality and consistency of the code base. Below are the agreed upon stages and the approximate timelines:

Stage I
Coding guideline rules are available to be followed and referenced, but not enforced. Rules are not yet enforced in CI and pull-requests cannot be blocked by reviewers/approvers due to violations.

Stage II
Begin enforcement on a limited scope of the code base. Initially, this would be the safety certification scope. For rules easily applied across codebase, we should not limit compliance to initial scope. This step requires tooling, CI setup and an enforcement strategy.

Stage III
Revisit the coding guideline rules and based on experience from previous stages, refine/iterate on selected rules.

Stage IV
Expand enforcement to the wider codebase. Exceptions may be granted on some areas of the codebase with a proper justification. Exception would require TSC approval.

Note: Coding guideline rules may be removed/changed at any time by filing a GH issue/RFC.

Main rules

The coding guideline rules are based on MISRA-C 2012 and are a subset of MISRA-C. The subset is listed in the table below with a summary of the rules, its severity and the equivalent rules from other standards for reference.

Note: For existing Zephyr maintainers and collaborators, if you are unable to obtain a copy through your employer, a limited number of copies will be made available through the project. If you need a copy of MISRA-C 2012, please send email to safety@lists.zephyrproject.org and provide details on reason why you can’t obtain one through other options and expected contributions once you have one. The safety committee will review all requests.

**Additional rules**

**Rule A.1: Conditional Compilation**

**Severity** Required

**Description** Do not conditionally compile function declarations in header files. Do not conditionally compile structure declarations in header files. You may conditionally exclude fields within structure definitions to avoid wasting memory when the feature they support is not enabled.

**Rationale** Excluding declarations from the header based on compile-time options may prevent their documentation from being generated. Their absence also prevents use of `if`
(IS_ENABLED(CONFIG_FOO)) {} as an alternative to preprocessor conditionals when the code path should change based on the selected options.

Rule A.2: Inclusive Language

Severity Required

Description Do not introduce new usage of offensive terms listed below. This rule applies but is not limited to source code, comments, documentation, and branch names. Replacement terms may vary by area or subsystem, but should aim to follow updated industry standards when possible.

Exceptions are allowed for maintaining existing implementations or adding new implementations of industry standard specifications governed externally to the Zephyr Project.

Existing usage is recommended to change as soon as updated industry standard specifications become available or new terms are publicly announced by the governing body, or immediately if no specifications apply.

<table>
<thead>
<tr>
<th>Offensive Terms</th>
<th>Recommended Replacements</th>
</tr>
</thead>
<tbody>
<tr>
<td>{master,leader} / slave</td>
<td>• {primary,main} / {secondary, replica}</td>
</tr>
<tr>
<td></td>
<td>• {initiator,requester} / {target, responder}</td>
</tr>
<tr>
<td></td>
<td>• {controller,host} / {device,worker, proxy,target}</td>
</tr>
<tr>
<td></td>
<td>• director / performer</td>
</tr>
<tr>
<td></td>
<td>• central / peripheral</td>
</tr>
<tr>
<td>blacklist / whitelist</td>
<td>• denylist / allowlist</td>
</tr>
<tr>
<td></td>
<td>• blocklist / allowlist</td>
</tr>
<tr>
<td></td>
<td>• rejectlist / acceptlist</td>
</tr>
<tr>
<td>grandfather policy</td>
<td>• legacy</td>
</tr>
<tr>
<td>sanity</td>
<td>• coherence</td>
</tr>
<tr>
<td></td>
<td>• confidence</td>
</tr>
</tbody>
</table>

Rationale Offensive terms do not create an inclusive community environment and therefore violate the Zephyr Project Code of Conduct. This coding rule was inspired by a similar rule in Linux.

Status Related GitHub Issues and Pull Requests are tagged with the Inclusive Language Label.

**Rule A.3: Macro name collisions**

**Severity**  Required

**Description**  Macros with commonly used names such as MIN, MAX, ARRAY_SIZE, must not be modified or protected to avoid name collisions with other implementations. In particular, they must not be prefixed to place them in a Zephyr-specific namespace, re-defined using #undef, or conditionally excluded from compilation using #ifndef. Instead, if a conflict arises with an existing definition originating from a module, the module's code itself needs to be modified (ideally upstream, alternatively via a change in Zephyr's own fork). This rule applies to Zephyr as
a project in general, regardless of the time of introduction of the macro or its current name in the tree. If a macro name is commonly used in several other well-known open source projects then the implementation in Zephyr should use that name. While there is a subjective and non-measurable component to what “commonly used” means, the ultimate goal is to offer users familiar macros. Finally, this rule applies to inter-module name collisions as well: in that case both modules, prior to their inclusion, should be modified to use module-specific versions of the macro name that collides.

**Rationale** Zephyr is an RTOS that comes with additional functionality and dependencies in the form of modules. Those modules are typically independent projects that may use macro names that can conflict with other modules or with Zephyr itself. Since, in the context of this documentation, Zephyr is considered the central or main project, it should implement the non-namespaced versions of the macros. Given that Zephyr uses a fork of the corresponding upstream for each module, it is always possible to patch the macro implementation in each module to avoid collisions.

**Rule A.4: C Standard Library Usage Restrictions in Zephyr Kernel**

**Severity** Required

**Description** The use of the C standard library functions and macros in the Zephyr kernel shall be limited to the following functions and macros from the ISO/IEC 9899:2011 standard, also known as C11, and their extensions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>

continues on next page
All of the functions listed above must be implemented by the *minimal libc* to ensure that the Zephyr kernel can build with the minimal libc.

In addition, any functions from the above list that are not part of the ISO/IEC 9899:2011 standard must be implemented by the *common libc* to ensure their availability across multiple C standard libraries.

Introducing new C standard library functions to the Zephyr kernel is allowed with justification given that the above requirements are satisfied.

Note that the use of the functions listed above are subject to secure and safe coding practices and it should not be assumed that their use in the Zephyr kernel is unconditionally permitted by
being listed in this rule. The “Zephyr kernel” in this context consists of the following components:

- Kernel (kernel)
- OS Library (lib/os)
- Architecture Port (arch)
- Logging Subsystem (subsys/logging)

**Rationale**  Zephyr kernel must be able to build with the *minimal libc*, a limited C standard library implementation that is part of the Zephyr RTOS and maintained by the Zephyr Project, to allow self-contained testing and verification of the kernel and core OS services.

In order to ensure that the Zephyr kernel can build with the minimal libc, it is necessary to restrict the use of the C standard library functions and macros in the Zephyr kernel to the functions and macros that are available as part of the minimal libc.

**Rule A.5: C Standard Library Usage Restrictions in Zephyr Codebase**

**Severity**  Required

**Description**  The use of the C standard library functions and macros in the Zephyr codebase shall be limited to the functions, excluding the Annex K “Bounds-checking interfaces”, from the ISO/IEC 9899:2011 standard, also known as C11, unless exempted by this rule.

The “Zephyr codebase” in this context refers to all embedded source code files committed to the main Zephyr repository, except the Zephyr kernel as defined by the Rule A.4: C Standard Library Usage Restrictions in Zephyr Kernel. With embedded source code we refer to code which is meant to be executed in embedded targets, and therefore excludes host tooling, and code specific for the native test targets.

The following non-ISO 9899:2011, hereinafter referred to as non-standard, functions and macros are exempt from this rule and allowed to be used in the Zephyr codebase:

<table>
<thead>
<tr>
<th>Function</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>strlen()</td>
<td>POSIX.1-2008</td>
</tr>
<tr>
<td>strtok_r()</td>
<td>POSIX.1-2001</td>
</tr>
</tbody>
</table>

All non-standard functions and macros listed above must be implemented by the *common libc* in order to make sure that these functions can be made available when using a C standard library that does not implement these functions.

Adding a new non-standard function from common C standard libraries to the above list is allowed with justification, given that the above requirement is satisfied. However, when there exists a standard function that is functionally equivalent, the standard function shall be used.

**Rationale**  Some C standard libraries, such as Newlib and Picolibc, include additional functions and macros that are defined by the standards and de-facto standards that extend the ISO C standard (e.g. POSIX, Linux).

The ISO/IEC 9899:2011 standard does not require C compiler toolchains to include the support for these non-standard functions, and therefore using these functions can lead to compatibility issues with the third-party toolchains that come with their own C standard libraries.
8.1.3 Proposals and RFCs

Many changes, including bug fixes and documentation improvements can be implemented and reviewed via the normal GitHub pull request workflow.

Many changes however are “substantial” and need to go through a design process and produce a consensus among the project stakeholders.

The “RFC” (request for comments) process is intended to provide a consistent and controlled path for new features to enter the project.

Contributors and project stakeholders should consider using this process if they intend to make “substantial” changes to Zephyr or its documentation. Some examples that would benefit from an RFC are:

- A new feature that creates new API surface area, and would require a feature flag if introduced.
- The modification of an existing stable API.
- The removal of features that already shipped as part of Zephyr.
- The introduction of new idiomatic usage or conventions, even if they do not include code changes to Zephyr itself.

The RFC process is a great opportunity to get more eyeballs on proposals coming from contributors before it becomes a part of Zephyr. Quite often, even proposals that seem “obvious” can be significantly improved once a wider group of interested people have a chance to weigh in.

The RFC process can also be helpful to encourage discussions about a proposed feature as it is being designed, and incorporate important constraints into the design while it’s easier to change, before the design has been fully implemented.

Some changes do not require an RFC:

- Rephrasing, reorganizing or refactoring
- Addition or removal of warnings
- Addition of new boards, SoCs or drivers to existing subsystems
- ...

The process in itself consists in creating a GitHub issue with the RFC label that documents the proposal thoroughly. There is an RFC template included in the main Zephyr GitHub repository that serves as a guideline to write a new RFC.

As with Pull Requests, RFCs might require discussion in the context of one of the Zephyr meetings in order to move it forward in cases where there is either disagreement or not enough voiced opinions in order to proceed. Make sure to either label it appropriately or include it in the corresponding GitHub project in order for it to be examined during the next meeting.

8.1.4 Contributor Expectations

The Zephyr project encourages contributors to submit changes as smaller pull requests. Smaller pull requests (PRs) have the following benefits:

- Reviewed more quickly and reviewed more thoroughly. It’s easier for reviewers to set aside a few minutes to review smaller changes several times than it is to allocate large blocks of time to review a large PR.
- Less wasted work if reviewers or maintainers reject the direction of the change.
- Easier to rebase and merge. Smaller PRs are less likely to conflict with other changes in the tree.
- Easier to revert if the PR breaks functionality.
Note: This page does not apply to draft PRs which can have any size, any number of commits and any combination of smaller PRs for testing and preview purposes. Draft PRs have no review expectation and PRs created as drafts from the start do not notify anyone by default.

Defining Smaller PRs

- Smaller PRs should encompass one self-contained logical change.
- When adding a new large feature or API, the PR should address only one part of the feature. In this case create an RFC proposal to describe the additional parts of the feature for reviewers.
- PRs should include tests or samples under the following conditions:
  - Adding new features or functionality.
  - Modifying a feature, especially for API behavior contract changes.
  - Fixing a hardware agnostic bug. The test should fail without the bug fixed and pass with the fix applied.
- PRs must update any documentation affected by a functional code change.
- If introducing a new API, the PR must include an example usage of the API. This provides context to the reviewer and prevents submitting PRs with unused APIs.

Multiple Commits on a Single PR

Contributors are further encouraged to break up PRs into multiple commits. Keep in mind each commit in the PR must still build cleanly and pass all the CI tests.

For example, when introducing an extension to an API, contributors can break up the PR into multiple commits targeting these specific changes:

1. Introduce the new APIs, including shared devicetree bindings
2. Update driver implementation X, with driver specific devicetree bindings
3. Update driver implementation Y
4. Add tests for the new API
5. Add a sample using the API
6. Update the documentation

Large Changes

Large changes to the Zephyr project must submit an RFC proposal describing the full scope of change and future work. The RFC proposal provides the required context to reviewers, but allows for smaller, incremental, PRs to get reviewed and merged into the project. The RFC should also define the minimum viable implementation.

Changes which require an RFC proposal include:

- Submitting a new feature.
- Submitting a new API.
- Treewide Changes.
- Other large changes that can benefit from the RFC proposal process.
Maintainers have the discretion to request that contributors create an RFC for PRs that are too large or complicated.

**PR Requirements**

- Each commit in the PR must provide a commit message following the [Commit Message Guidelines](#).
- All files in the PR must comply with [Licensing Requirements](#).
- Follow the Zephyr [Coding Style](#) and [Coding Guidelines](#).
- PRs must pass all CI checks. This is a requirement to merge the PR. Contributors may mark a PR as draft and explicitly request reviewers to provide early feedback, even with failing CI checks.
- When breaking a PR into multiple commits, each commit must build cleanly. The CI system does not enforce this policy, so it is the PR author's responsibility to verify.
- When major new functionality is added, tests for the new functionality shall be added to the automated test suite. All API functions should have test cases and there should be tests for the behavior contracts of the API. Maintainers and reviewers have the discretion to determine if the provided tests are sufficient. The examples below demonstrate best practices on how to test APIs effectively.
  - Kernel timer tests provide around 85% test coverage for the kernel timer, measured by lines of code.
  - Emulators for off-chip peripherals are an effective way to test driver APIs. The fuel gauge tests use the smart battery emulator, providing test coverage for the fuel gauge API and the smart battery driver.
  - Code coverage reports for the Zephyr project are available on Codecov.
- Incompatible changes to APIs must also update the release notes for the next release detailing the change. APIs marked as experimental are excluded from this requirement.
- Changes to APIs must increment the API version number according to the API version rules.
- PRs must also satisfy all [Merge Criteria](#) before a member of the release engineering team merges the PR into the zephyr tree.

Maintainers may request that contributors break up a PR into smaller PRs and may request that they create an [RFC proposal](#).

**Workflow Suggestions That Help Reviewers**

- Unless they applied the reviewer’s recommendation exactly, authors must not resolve and hide comments, they must let the initial reviewer do it. The Zephyr project does not require all comments to be resolved before merge. Leaving some completed discussions open can sometimes be useful to understand the greater picture.
- Respond to comments using the “Start Review” and “Add Review” green buttons in the “Files changed” view. This allows responding to multiple comments and publishing the responses in bulk. This reduces the number of emails sent to reviewers.
- As GitHub does not implement `git range-diff`, try to minimize rebases in the middle of a review. If a rebase is required, push this as a separate update with no other changes since the last push of the PR. When pushing a rebase only, add a comment to the PR indicating which commit is the rebase.
**PR Review Escalation** The Zephyr community is a diverse group of individuals, with different levels of commitment and priorities. As such, reviewers and maintainers may not get to a PR right away.

The Zephyr Dev Meeting performs a triage of PRs missing reviewer approval, following this process:

1. Identify and update PRs missing an Assignee.
2. Identify PRs without any comments or reviews, ping the PR Assignee to start a review or assign to a different maintainer.
3. For PRs that have otherwise stalled, the Zephyr Dev Meeting pings the Assignee and any reviewers that have left comments on the PR.

Contributors may escalate PRs outside of the Zephyr Dev Meeting triage process as follows:

- After 1 week of inactivity, ping the Assignee or reviewers on the PR by adding a comment to the PR.
- After 2 weeks of inactivity, post a message on the #pr-help channel on Discord linking to the PR.
- After 2 weeks of inactivity, add the dev-review label to the PR. This explicitly adds the PR to the agenda for the next Zephyr Dev Meeting independent of the triage process. Not all contributors have the required privileges to add labels to PRs, in this case the contributor should request help on Discord or send an email to the Zephyr devel mailing list.

Note that for new PRs, contributors should generally wait for at least one Zephyr Dev Meeting before escalating the PR themselves.

**PR Technical Escalation** In cases where a contributor objects to change requests from reviewers, Zephyr defines the following escalation process for resolving technical disagreements.

Before escalation of technical disagreements, follow the steps below:

- Resolve in the PR among assignee, maintainers and reviewer:
  - Assignee to act as moderator if applicable.
- Optionally resolve in the next Zephyr Dev Meeting meeting with more Maintainers and project stakeholders.
  - The involved parties and the Assignee to be present when the issue is discussed.
- If no progress is made, the assignee (maintainer) has the right to dismiss stale, unrelated or irrelevant change requests by reviewers giving the reviewers a minimum of 1 business day to respond and revisit their initial change requests or start the escalation process.

The assignee has the responsibility to document the reasoning for dismissing any reviews in the PR and should notify the reviewer about their review being dismissed.

To give the reviewers time to respond and escalate, the assignee is expected to block the PR from being merged either by not approving the PR or by setting the DNM label.

Escalation can be triggered by any party participating in the review process (assignee, reviewers or the original author of the change) following the steps below:

- Escalate to the Architecture Working Group by adding the Architecture Review label on the PR. Beside the weekly meeting where such escalations are processed, the Architecture Working Group shall facilitate an offline review of the escalation if requested, especially if any of the parties can’t attend the meeting.
- If all avenues of resolution and escalation have failed, assignees can escalate to the TSC and get a binding resolution in the TSC by adding the TSC label on the PR.
- The Assignee is expected to ensure the resolution of the escalation and the outcome is documented in the related pull request or issues on Github.
Reviewer Expectations

- Be respectful when commenting on PRs. Refer to the Zephyr Code of Conduct for more details.

- The Zephyr Project recognizes that reviewers and maintainers have limited bandwidth. As a reviewer, prioritize review requests in the following order:
  1. PRs related to items in the Zephyr Release Plan or those targeting the next release during the stabilization period (after RC1).
  2. PRs where the reviewer has requested blocking changes.
  3. PRs assigned to the reviewer as the area maintainer.
  4. All other PRs.

- Try to provide feedback on the entire PR in one shot. This provides the contributor an opportunity to address all comments in the next PR update.

- Partial reviews are permitted, but the reviewer must add a comment indicating what portion of the PR they reviewed. Examples of useful partial reviews include:
  - Domain specific reviews (e.g. Devicetree).
  - Code style changes that impact the readability of the PR.
  - Reviewing commits separately when the requested changes cascade into the later commits.

- Avoid increasing scope of the PR by requesting new features, especially when there is a corresponding RFC associated with the PR. Instead, reviewers should add suggestions as a comment to the RFC. This also encourages more collaboration as it is easier for multiple contributors to work on a feature once the minimum implementation has merged.

- When using the “Request Changes” option, mark trivial, non-functional, requests as “Non-blocking” in the comment. Reviewers should approve PRs once only non-blocking changes remain. The PR author has discretion as to whether they address all non-blocking comments. PR authors should acknowledge every review comment in some way, even if it's just with an emoticon.

- Reviewers shall be clear and concise what changes they are requesting when the “Request Changes” option is used. Requested changes shall be in the scope of the PR in question and following the contribution and style guidelines of the project.

Contribution Guidelines
Learn about the overall process and guidelines for contributing to the Zephyr project.

This page is a mandatory read for first-time contributors as it contains important information on how to ensure your contribution can be considered for inclusion in the project and potentially merged.

Contributor Expectations
This document is another mandatory read that describes the expected behavior of all contributors to the project.

Coding Guidelines
Code contributions are expected to follow a set of coding guidelines to ensure consistency and readability across the codebase.

This page describes these guidelines and introduces important considerations regarding the use of inclusive language.

Proposals and RFCs
Learn when and how to submit RFCs (Request for Comments) for new features and changes to the project.
8.2 Documentation

The Zephyr project thrives on good documentation. Whether it is as part of a code contribution or as a standalone effort, contributing documentation is particularly valuable to the project.

8.2.1 Documentation Guidelines

Note: For instructions on building the documentation, see Documentation Generation.

Zephyr Project content is written using the reStructuredText markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted standalone website. Developers can view this content either in its raw form as .rst markup files, or (with Sphinx installed) they can build the documentation locally to generate the documentation in HTML or PDF format. The HTML content can then be viewed using a web browser. This same .rst content is served by the Zephyr documentation website.

You can read details about reStructuredText and about Sphinx extensions from their respective websites.

This document provides a quick reference for commonly used reST and Sphinx-defined directives and roles used to create the documentation you're reading.

Headings

While reST allows use of both and overline and matching underline to indicate a heading, we only use an underline indicator for headings.

- Document title (h1) use “#” for the underline character
- First section heading level (h2) use “*”
- Second section heading level (h3) use “=”
- Third section heading level (h4) use “-”

The heading underline must be at least as long as the title it’s under.

For example:

```
This is a title heading
############################

some content goes here

First section heading
************************
```

Content Highlighting

Some common reST inline markup samples:

- one asterisk: *text* for emphasis (italics),
- two asterisks: **text** for strong emphasis (boldface), and
- two backquotes: `text` for inline code samples.

If asterisks or backquotes appear in running text and could be confused with inline markup delimiters, you can eliminate the confusion by adding a backslash (\) before it.
Lists

For bullet lists, place an asterisk (*) or hyphen (–) at the start of a paragraph and indent continuation lines with two spaces.

The first item in a list (or sublist) must have a blank line before it and should be indented at the same level as the preceding paragraph (and not indented itself).

For numbered lists start with a 1. or a. for example, and continue with autonumbering by using a # sign. Indent continuation lines with three spaces:

```
* This is a bulleted list.
* It has two items, the second
  item and has more than one line of reST text. Additional lines
  are indented to the first character of the
  text of the bullet list.

1. This is a new numbered list. If the wasn't a blank line before it,
   it would be a continuation of the previous list (or paragraph).
   #. It has two items too.

a. This is a numbered list using alphabetic list headings
#. It has three items (and uses autonumbering for the rest of the list)
#. Here's the third item

#. This is an autonumbered list (default is to use numbers starting
   with 1).
   
   #. This is a second-level list under the first item (also
      autonumbered). Notice the indenting.
   #. And a second item in the nested list.
   #. And a second item back in the containing list. No blank line
      needed, but it wouldn't hurt for readability.
```

Definition lists (with a term and its definition) are a convenient way to document a word or phrase with an explanation. For example this reST content:

```
The Makefile has targets that include:

html
   Build the HTML output for the project

clean
   Remove all generated output, restoring the folders to a
   clean state.
```

Would be rendered as:

```
The Makefile has targets that include:

   html
      Build the HTML output for the project

   clean
      Remove all generated output, restoring the folders to a clean state.
```

Multi-column lists

If you have a long bullet list of items, where each item is short, you can indicate the list items should be rendered in multiple columns with a special .. rst-class:: rst-columns directive. The directive will apply to the next non-comment element (e.g., paragraph), or to content indented under the directive. For example, this unordered list:
.. rst-class:: rst-columns

* A list of
* short items
* that should be
* displayed
* horizontally
* so it doesn’t
* use up so much
* space on
* the page

would be rendered as:

- A list of
  - short items
  - that should be
  - displayed
  - horizontally
  - so it doesn’t
  - use up so much
  - space on
  - the page

A maximum of three columns will be displayed, and change based on the available width of the display window, reducing to one column on narrow (phone) screens if necessary. We’ve deprecated use of the hlist directive because it misbehaves on smaller screens.

## Tables

There are a few ways to create tables, each with their limitations or quirks. Grid tables offer the most capability for defining merged rows and columns, but are hard to maintain:

<table>
<thead>
<tr>
<th>Header row, column 1</th>
<th>Header 2</th>
<th>Header 3</th>
<th>Header 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>(header rows optional)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| +------------------------+------------+----------+----------+
| body row 1, column 1 | | | |
| column 2 | column 3 | column 4 |
| +------------------------+------------+----------+----------+
| body row 2 | | | |
| | | | you can |
| +------------------------+------------+----------+----------+
| body row 3 with a two column span | | | |
| | | | span |
| +------------------------+------------+----------+----------+
| body row 4 | | | |
| | | | too |

This example would render as:

<table>
<thead>
<tr>
<th>Header row, column 1 (header rows optional)</th>
<th>Header 2</th>
<th>Header 3</th>
<th>Header 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>body row 1, column 1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>column 2</td>
<td>column 3</td>
<td>column 4</td>
<td></td>
</tr>
</tbody>
</table>
| +------------------------+------------+----------+----------+
| body row 2 | | | |
| ... | ... | you can easily span rows |
| +------------------------+------------+----------+----------+
| body row 3 with a two column span | | | |
| ... | ... | too |
| +------------------------+------------+----------+----------+
| body row 4 | | | |
| ... | ... | |

---

8.2. Documentation
List tables are much easier to maintain, but don’t support row or column spans:

```
.. list-table:: Table title
   :widths: 15 20 40
   :header-rows: 1

   *- Heading 1
   |- Heading 2
   |- Heading 3
   *- body row 1, column 1
   |- body row 1, column 2
   |- body row 1, column 3
   *- body row 2, column 1
   |- body row 2, column 2
   |- body row 2, column 3
```

This example would render as:

<table>
<thead>
<tr>
<th>Heading 1</th>
<th>Heading 2</th>
<th>Heading 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>body row 1, column 1</td>
<td>body row 1, column 2</td>
<td>body row 1, column 3</td>
</tr>
<tr>
<td>body row 2, column 1</td>
<td>body row 2, column 2</td>
<td>body row 2, column 3</td>
</tr>
</tbody>
</table>

The :widths: parameter lets you define relative column widths. The default is equal column widths. If you have a three-column table and you want the first column to be half as wide as the other two equal-width columns, you can specify :widths: 1 2 2. If you’d like the browser to set the column widths automatically based on the column contents, you can use :widths: auto.

**File names and Commands**

Sphinx extends reST by supporting additional inline markup elements (called “roles”) used to tag text with special meanings and allow style output formatting. (You can refer to the Sphinx Inline Markup documentation for the full list).

For example, there are roles for marking filenames (:file:`name`) and command names such as make (:command:`make`). You can also use the “inline code” markup (double backticks) to indicate a filename.

For references to files that are in the Zephyr GitHub tree, a special role can be used that creates a hyperlink to that file. For example a reference to the reST file used to create this document can be generated using :zephyr_file:`doc/contribute/documentation/index.rst` that will show up as [doc/contribute/documentation/index.rst](https://github.com/zephyrproject docs), a link to the “blob” file in the github repo. There's also a :zephyr_raw:`doc/guides/documentation/index.rst` role that will link to the “raw” content, [doc/contribute/documentation/index.rst](https://github.com/zephyrproject docs). (You can click on these links to see the difference.)

**Internal Cross-Reference Linking**

Traditional ReST links are only supported within the current file using the notation:

Refer to the `internal-linking` page

which renders as,

Refer to the internal-linking page
External Cross-Reference Linking

With Sphinx's help, we can create link-references to any tagged text within the Zephyr Project documentation.

Target locations in a document are defined with a label directive:

```
.. _my label name:

Heading
=======
```

Note the leading underscore indicating an inbound link. The content immediately following this label must be a heading, and is the target for a `:ref:`my label name` reference from anywhere within the Zephyr documentation. The heading text is shown when referencing this label. You can also change the text that's displayed for this link, such as:

```
:ref:`some other text <my label name>`
```

To enable easy cross-page linking within the site, each file should have a reference label before its title so it can be referenced from another file. These reference labels must be unique across the whole site, so generic names such as “samples” should be avoided. For example the top of this document's .rst file is:

```
.. _doc_guidelines:

Documentation Guidelines for the Zephyr Project
###################################################
```

Other .rst documents can link to this document using the `:ref:`doc_guidelines` tag and it will show up as Documentation Guidelines. This type of internal cross reference works across multiple files, and the link text is obtained from the document source so if the title changes, the link text will update as well.

You can also define links to any URL and then reference it in your document. For example, with this label definition in the document:

```
.. _Zephyr Wikipedia Page:
    https://en.wikipedia.org/wiki/Zephyr_(operating_system)
```

you can reference it with:

```
Read the `Zephyr Wikipedia Page`_ for more information about the project.
```

'any' links

Within the Zephyr project, we've defined the default role to be “any”, meaning if you just write a phrase in back-ticks, e.g., `doc_guidelines`, Sphinx will search through all domains looking for something called doc_guidelines to link to. In this case it will find the label at the top of this
document, and link to `doc_guidelines`. This can be useful for linking to doxygen-generated links for function names and such, but will cause a warning such as:

```
WARNING: 'any' reference target not found: doc_guidelines
```

if you misspelled `doc_guidelines` as `doc_giudelines`.

Non-ASCII Characters

You can insert non-ASCII characters such as a Trademark symbol (™), by using the notation `|trade|`. Available replacement names are defined in an include file used during the Sphinx processing of the reST files. The names of these replacement characters are the same as used in HTML entities used to insert characters in HTML, e.g., &trade; and are defined in the file `sphinx_build/substitutions.txt` as listed here:

```
.. |br| raw:: html .. force a line break in HTML output (blank lines needed here)
   
   <br />

.. |p| raw:: html .. force a blank line in HTML output (blank lines needed here)
   
   <p></p>

.. These are replacement strings for non-ASCII characters used within the project using the same name as the html entity names (e.g., &copy;) for that character

.. |copy| unicode:: U+000A9 .. COPYRIGHT SIGN
   :ltrim:

.. |trade| unicode:: U+02122 .. TRADEMARK SIGN
   :ltrim:

.. |reg| unicode:: U+000AE .. REGISTERED TRADEMARK SIGN
   :ltrim:

.. |deg| unicode:: U+00B0 .. DEGREE SIGN
   :ltrim:

.. |plusminus| unicode:: U+00B1 .. PLUS-MINUS SIGN
   :rtrim:

.. |micro| unicode:: U+00B5 .. MICRO SIGN
   :rtrim:

.. |sup2| unicode:: U+00B2 .. SUPERSCRIPT TWO
   :ltrim:
```

We've kept the substitutions list small but others can be added as needed by submitting a change to the `substitutions.txt` file.

Code and Command Examples

Use the reST `code-block` directive to create a highlighted block of fixed-width text, typically used for showing formatted code or console commands and output. Smart syntax highlighting is also supported (using the Pygments package). You can also directly specify the highlighting language. For example:

```
.. code-block:: c

    struct k_object {
        char *name;
        uint8_t perms[CONFIG_MAX_THREAD_BYTES];
        uint8_t type;
        uint8_t flags;
    }
```

(continues on next page)
Note the blank line between the code-block directive and the first line of the code-block body, and the body content is indented three spaces (to the first non-white space of the directive name).

This would be rendered as:

```c
struct k_object {
    char *name;
    uint8_t perms[CONFIG_MAX_THREAD_BYTES];
    uint8_t type;
    uint8_t flags;
    uint32_t data;
} __packed;
```

Other languages are of course supported (see languages supported by Pygments), and in particular, you are encouraged to make use of the following when appropriate:

- c for C code
- cpp for C++ code
- python for Python code
- console for console output, i.e. interactive shell sessions where commands are prefixed by a prompt (ex. $ for Linux, or uart:~$ for Zephyr's shell), and where the output is also shown. The commands will be highlighted, and the output will not. What's more, copying code block using the “copy” button will automatically copy just the commands, excluding the prompt and the outputs of the commands.
- shell or bash for shell commands. Both languages get highlighted the same but you may use bash for conveying that the commands are bash-specific, and shell for generic shell commands.

**Note:** Do not use bash or shell if your code block includes a prompt, use console instead.

Reciprocally, do not use console if your code block does not include a prompt and is not showcasing an interactive session with command(s) and their output.

### Table 5: When to use bash/shell vs. console

<table>
<thead>
<tr>
<th>Use case</th>
<th>code-block snippet</th>
<th>Expected output</th>
</tr>
</thead>
<tbody>
<tr>
<td>One or several commands, no output</td>
<td>.. code-block:: shell&lt;br&gt;echo &quot;Hello World!&quot;</td>
<td>echo &quot;Hello World!&quot;</td>
</tr>
</tbody>
</table>
| An interactive shell session with command(s) and their output | .. code-block:: console<br>$ echo "Hello World!"
Hello World! | $ echo "Hello World!"
Hello World! |
| An interactive Zephyr shell session, with commands and their outputs | .. code-block:: console<br>uart:~$ version<br>Zephyr version 3.5.99<br>uart:~$ kernel uptime<br>Uptime: 20970 ms | uart:~$ version<br>Zephyr version 3.5.99<br>uart:~$ kernel uptime<br>Uptime: 20970 ms |
• bat for Windows batch files
• cfg for config files with “KEY=value” entries (ex. Kconfig .conf files)
• cmake for CMake
• devicetree for Devicetree
• kconfig for Kconfig
• yaml for YAML
• rst for reStructuredText

When no language is specified, the language is set to none and the code block is not highlighted. You may also use none explicitly to achieve the same result; for example:

```.. code-block:: none
   This would be a block of text styled with a background and box, but with no syntax highlighting.
```

Would display as:

This would be a block of text styled with a background and box, but with no syntax highlighting.

There's a shorthand for writing code blocks too: end the introductory paragraph with a double colon (`::`) and indent the code block content that follows it by three spaces. On output, only one colon will be shown. The code block will have no highlighting (i.e. none). You may however use the .. highlight:: directive to customize the default language used in your document (see for example how this is done at the beginning of this very document).

**Images**

Images are included in documentation by using an image directive:

```.. image:: ../../../../images/doc-gen-flow.png
   :align: center
   :alt: alt text for the image
```

or if you'd like to add an image caption, use:

```.. figure:: ../../../../images/doc-gen-flow.png
   :alt: image description
   Caption for the figure
```

The file name specified is relative to the document source file, and we recommend putting images into an images folder where the document source is found. The usual image formats handled by a web browser are supported: JPEG, PNG, GIF, and SVG. Keep the image size only as large as needed, generally at least 500 px wide but no more than 1000 px, and no more than 250 KB unless a particularly large image is needed for clarity.

**Tabs, spaces, and indenting**

Indenting is significant in reST file content, and using spaces is preferred. Extra indenting can (unintentionally) change the way content is rendered too. For lists and directives, indent the content text to the first non-white space in the preceding line. For example:
* List item that spans multiple lines of text showing where to indent the continuation line.

1. And for numbered list items, the continuation line should align with the text of the line above.

```
code-block::

    The text within a directive block should align with the first character of the directive name.
```

Refer to the Zephyr [Coding Style](#) for additional requirements.

### zephyr-app-commands Directive

This is a Zephyr directive for generating consistent documentation of the shell commands needed to manage (build, flash, etc.) an application.

For example, to generate commands to build samples/hello_world for qemu_x86 use:

```
zephyr-app-commands:
:zephyr-app: samples/hello_world
:board: qemu_x86
:goals: build
```

**Directive options:**

- **:tool:**
  which tool to use. Valid options are currently ‘cmake’, ‘west’ and ‘all’. The default is ‘west’.

- **:app:**
  path to the application to build.

- **:zephyr-app:**
  path to the application to build, this is an app present in the upstream zephyr repository. Mutually exclusive with :app:

- **:cd-into:**
  if set, build instructions are given from within the :app: folder, instead of outside of it.

- **:generator:**
  which build system to generate. Valid options are currently ‘ninja’ and ‘make’. The default is ‘ninja’. This option is not case sensitive.

- **:host-os:**
  which host OS the instructions are for. Valid options are ‘unix’, ‘win’ and ‘all’. The default is ‘all’.

- **:board:**
  if set, the application build will target the given board.

- **:shield:**
  if set, the application build will target the given shield.

- **:conf:**
  if set, the application build will use the given configuration file. If multiple conf files are provided, enclose the space-separated list of files with quotes, e.g., “a.conf b.conf”.

- **:gen-args:**
  if set, additional arguments to the CMake invocation
:build-args:
if set, additional arguments to the build invocation

:build-dir:
if set, the application build directory will APPEND this (relative, Unix-separated) path to the standard build directory. This is mostly useful for distinguishing builds for one application within a single page.

:build-dir-fmt:
if set, assume that “west config build.dir-fmt” has been set to this path. Exclusive with ‘build-dir’ and depends on ‘tool=west’.

:goals:
a whitespace-separated list of what to do with the app (in ‘build’, ‘flash’, ‘debug’, ‘debugserver’, ‘run’). Commands to accomplish these tasks will be generated in the right order.

:maybe-skip-config:
if set, this indicates the reader may have already created a build directory and changed there, and will tweak the text to note that doing so again is not necessary.

:compact:
if set, the generated output is a single code block with no additional comment lines

:west-args:
if set, additional arguments to the west invocation (ignored for CMake)

:flash-args:
if set, additional arguments to the flash invocation

For example, the .. zephyr-app-commands listed above would render like this in the generated HTML output:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
```

**Alternative Tabbed Content**

As introduced in the *Getting Started Guide*, you can provide alternative content to the reader via a tabbed interface. When the reader clicks on a tab, the content for that tab is displayed, for example:

```
.. tabs::
   .. tab:: Apples
    Apples are green, or sometimes red.
   .. tab:: Pears
    Pears are green.
   .. tab:: Oranges
    Oranges are orange.
```

will display as:

Apples
Apples are green, or sometimes red.
Pears
Pears are green.
Oranges
Oranges are orange.

Tabs can also be grouped, so that changing the current tab in one area changes all tabs with the same name throughout the page. For example:

Linux
Linux Line 1
macOS
macOS Line 1
Windows
Windows Line 1
Linux
Linux Line 2
macOS
macOS Line 2
Windows
Windows Line 2

In this latter case, we're using .. group-tab:: instead of simply .. tab::: Under the hood, we're using the sphinx-tabs extension that's included in the Zephyr setup. Within a tab, you can have most any content other than a heading (code-blocks, ordered and unordered lists, pictures, paragraphs, and such). You can read more about sphinx-tabs from the link above.

8.2.2 Documentation Generation

These instructions will walk you through generating the Zephyr Project's documentation on your local system using the same documentation sources as we use to create the online documentation found at https://docs.zephyrproject.org

Documentation overview

Zephyr Project content is written using the reStructuredText markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted stand-alone website. Developers can view this content either in its raw form as .rst markup files, or you can generate the HTML content and view it with a web browser directly on your workstation. This same .rst content is also fed into the Zephyr Project's public website documentation area (with a different theme applied).

You can read details about reStructuredText, and Sphinx from their respective websites.

The project's documentation contains the following items:

- ReStructuredText source files used to generate documentation found at the https://docs.zephyrproject.org website. Most of the reStructuredText sources are found in the /doc directory, but others are stored within the code source tree near their specific component (such as /samples and /boards)
- Doxygen-generated material used to create all API-specific documents also found at https://docs.zephyrproject.org
• Script-generated material for kernel configuration options based on Kconfig files found in the source code tree

Fig. 1: Schematic of the documentation build process

The reStructuredText files are processed by the Sphinx documentation system, and make use of the breathe extension for including the doxygen-generated API material. Additional tools are required to generate the documentation locally, as described in the following sections.

Installing the documentation processors

Our documentation processing has been tested to run with:

• Doxygen version 1.8.13
• Graphviz 2.43
• Latexmk version 4.56
• All Python dependencies listed in the repository file doc/requirements.txt

In order to install the documentation tools, first install Zephyr as described in Getting Started Guide. Then install additional tools that are only required to generate the documentation, as described below:

Linux

Common to all Linux installations, install the Python dependencies required to build the documentation:

```
pip install -r ~/zephyrproject/zephyr/doc/requirements.txt
```

On Ubuntu Linux:

```
sudo apt-get install --no-install-recommends doxygen graphviz librsvg2-bin \ texlive-latex-base texlive-latex-extra latexmk texlive-fonts-recommended
```

On Fedora Linux:

```
sudo dnf install doxygen graphviz texlive-latex latexmk \ texlive-collection-fontsrecommended librsvg2-tools
```

On Clear Linux:
sudo swupd bundle-add texlive graphviz

On Arch Linux:
```
sudo pacman -S graphviz doxygen librsvg texlive-core texlive-bin \
texlive-latexextra texlive-fontsextra
```

macOS

Install the Python dependencies required to build the documentation:
```
pip install -r ~/zephyrproject/zephyr/doc/requirements.txt
```

Use `brew` and `tlmgr` to install the tools:
```
brew install doxygen graphviz mactex librsvg
tlmgr install latexmk
tlmgr install collection-fontsrecommended
```

Windows

Install the Python dependencies required to build the documentation:
```
pip install -r %HOMEPATH$\zephyrproject\zephyr\doc\requirements.txt
```

Open a `cmd.exe` window as `Administrator` and run the following command:
```
choco install doxygen.install graphviz strawberryperl miktex rsvg-convert
```

**Note:** On Windows, the Sphinx executable `sphinx-build.exe` is placed in the `Scripts` folder of your Python installation path. Depending on how you have installed Python, you might need to add this folder to your `PATH` environment variable. Follow the instructions in the `Windows Path` to add those if needed.

**Documentation presentation theme**

Sphinx supports easy customization of the generated documentation appearance through the use of themes. Replace the theme files and do another `make html` and the output layout and style is changed. The `read-the-docs` theme is installed as part of the `Get Zephyr and install Python dependencies` step you took in the getting started guide.

**Running the documentation processors**

The `/doc` directory in your cloned copy of the Zephyr project git repo has all the `.rst` source files, extra tools, and Makefile for generating a local copy of the Zephyr project’s technical documentation. Assuming the local Zephyr project copy is in a folder `zephyr` in your home folder, here are the commands to generate the HTML content locally:

```
# On Linux/macOS
cd ~/zephyr/doc
# On Windows
cd %userprofile%\zephyr\doc

# Use cmake to configure a Ninja-based build system:
cmake -GNinja -B build

# Enter the build directory
```

(continues on next page)
To generate HTML output, run ninja on the generated build system:

```
ninja html
```

If you modify or add .rst files, run ninja again:

```
ninja html
```

To generate PDF output, run ninja on the generated build system:

```
ninja pdf
```

**Warning:** The documentation build system creates copies in the build directory of every .rst file used to generate the documentation, along with dependencies referenced by those .rst files.

This means that Sphinx warnings and errors refer to the copies, and not the version-controlled original files in Zephyr: Be careful to make sure you don’t accidentally edit the copy of the file in an error message, as these changes will not be saved.

Depending on your development system, it will take up to 15 minutes to collect and generate the HTML content. When done, you can view the HTML output with your browser started at doc/_build/html/index.html and if generated, the PDF file is available at doc/_build/latex/zephyr.pdf.

If you want to build the documentation from scratch just delete the contents of the build folder and run cmake and then ninja again.

**Note:** If you add or remove a file from the documentation, you need to re-run CMake.

On Unix platforms a convenience `doc/Makefile` can be used to build the documentation directly from there:

```
cd ~/zephyr/doc
```

```
# To generate HTML output
make html
```

```
# To generate PDF output
make pdf
```

**Filtering expected warnings**

There are some known issues with Sphinx/Breathe that generate Sphinx warnings even though the input is valid C code. While these issues are being considered for fixing we have created a Sphinx extension that allows to filter them out based on a set of regular expressions. The extension is named `zephyr.warnings_filter` and it is located at doc/_extensions/zephyr/warnings_filter.py. The warnings to be filtered out can be added to the doc/known-warnings.txt file.

The most common warning reported by Sphinx/Breathe is related to duplicate C declarations. This warning may be caused by different Sphinx/Breathe issues:

- Multiple declarations of the same object are not supported
- Different objects (e.g. a struct and a function) can not share the same name
- Nested elements (e.g. in a struct or union) can not share the same name
Developer-mode Document Building

When making and testing major changes to the documentation, we provide an option to temporarily stub-out the auto-generated Devicetree bindings documentation so the doc build process runs faster.

To enable this mode, set the following option when invoking cmake:

```
-DDT_TURBO_MODE=1
```

or invoke make with the following target:

```
cd ~/zephyr
# To generate HTML output without detailed Kconfig
make html-fast
```

Viewing generated documentation locally

The generated HTML documentation can be hosted locally with python for viewing with a web browser:

```
$ python3 -m http.server -d _build/html
```

**Note:** WSL2 users may need to explicitly bind the address to `127.0.0.1` in order to be accessible from the host machine:

```
$ python3 -m http.server -d _build/html --bind 127.0.0.1
```

Linking external Doxygen projects against Zephyr

External projects that build upon Zephyr functionality and wish to refer to Zephyr documentation in Doxygen (through the use of @ref), can utilize the tag file exported at `zephyr.tag`

Once downloaded, the tag file can be used in a custom doxyfile.in as follows:

```
TAGFILES = "*/path/to/zephyr.tag=https://docs.zephyrproject.org/latest/doxygen/html/"
```

For additional information refer to Doxygen External Documentation.

**Documentation Guidelines**

This page provides some simple guidelines for writing documentation using the reStructuredText (reST) markup language and Sphinx documentation generator.

**Documentation Generation**

As you write documentation, it can be helpful to see how it will look when rendered. This page describes how to build the Zephyr documentation locally.

8.3 Dealing with external components
8.3.1 Contributing External Components

In some cases it is desirable to leverage existing, external source code in order to avoid re-implementing basic functionality or features that are readily available in other open source projects.

This section describes the circumstances under which external source code can be imported into Zephyr, and the process that governs the inclusion.

There are three main factors that will be considered during the inclusion process in order to determine whether it will be accepted. These will be described in the following sections.

Note that most of this page deals with external components that end up being compiled and linked into the final image, and programmed into the target hardware. For external tooling that is only used during compilation, code analysis, testing or simulation please refer to the Contributing External Tooling section at the end of the page.

Software License

**Note:** External source code licensed under the Apache-2.0 license is not subject to this section.

Integrating code into the Zephyr Project from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board, as described in the Zephyr project charter. The board will automatically reject licenses that have not been approved by the Open Source Initiative (OSI). See the Submission and review process section for more details.

By carefully reviewing potential contributions and also enforcing a Developer Certification of Origin (DCO) for contributed code, we ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

Merit

Just like with any other regular contribution, one that contains external code needs to be evaluated for merit. However, in the particular case of code that comes from an existing project, there are additional questions that must be answered in order to accept the contribution. More specifically, the following will be considered by the Technical Steering Committee and evaluated carefully before the external source code is accepted into the project:

- Is this the most optimal way to introduce the functionality to the project? Both the cost of implementing this internally and the one incurred in maintaining an externally developed codebase need to be evaluated.

- Is the external project being actively maintained? This is particularly important for source code that deals with security or cryptography.

- Have alternatives to the particular implementation proposed been considered? Are there other open source project that implement the same functionality?

Mode of integration

There are two ways of integrating external source code into the Zephyr Project, and careful consideration must be taken to choose the appropriate one for each particular case.
Integration in the main tree  The first way to integrate external source code into the project is to simply import the source code files into the main zephyr repository. This automatically implies that the imported source code becomes part of the “mainline” codebase, which in turn requires that:

- The code is formatted according to the Zephyr Coding Style
- The code adheres to the project’s Coding Guidelines
- The code is subject to the same checks and verification requirements as the rest of the code in the main tree, including static analysis
- All files contain an SPDX tag if not already present
- If the source is not Apache 2.0 licensed, an entry is added to the licensing page.

This mode of integration can be applicable to both small and large external codebases, but it is typically used more commonly with the former.

Integration as a module  The second way of integrating external source code into the project is to import the whole or parts of the third-party open source project into a separate repository, and then include it under the form of a module. With this approach the code is considered as being developed externally, and thus it is not automatically subject to the requirements of the previous section.

Integration in main manifest file (west.yaml)  Integrating external code into the main west.yaml manifest file is limited to code that is used by a Zephyr subsystem (libraries), by a platform, drivers (HAL) or tooling needed to test or build Zephyr components.

The integration of modules in this group is validated by the Zephyr project CI, and verified to be working with each Zephyr release.

Integrated modules will not be removed from the tree without a detailed migration plan.

Integration as optional modules  Standalone or loose integration of modules/projects without any incoming dependencies shall be made optional and shall be kept standalone. Optional projects that provide value to users directly and through a Zephyr subsystem or platform shall be added to an optional manifest file that is filtered by default (submanifests/optional.yml).

Such optional projects might include samples and tests in their own repositories.

There shall not be any direct dependency added in the Zephyr code tree (Git repository) and all sample or test code shall be maintained as part of the module.

Note: This is valid for all new optional modules. Existing optional modules with samples and test code in the Zephyr Git repository will be transitioned out over time.

Integration as external modules  Similar to optional modules, but added to the Zephyr project as an entry in the documentation using a pre-defined template. This type of modules exists outside the Zephyr project manifest with documentation instructing users and developers how to integrate the functionality.

Ongoing maintenance

Regardless of the mode of integration, external source code that is integrated in Zephyr requires regular ongoing maintenance. The submitter of the proposal to integrate external source code
must therefore commit to maintain the integration of such code for the foreseeable future. This may require adding an entry in the `MAINTAINERS.yml` as part of the process.

**Submission and review process**

Before external source code can be included in the project, it must be reviewed and accepted by the Technical Steering Committee (TSC) and, in some cases, by the Zephyr governing board.

A request for external source code integration must be made by creating a new issue in the Zephyr project issue tracking system on GitHub with details about the source code and how it integrates into the project.

Follow the steps below to begin the submission process:

1. Make sure to read through the [Contributing External Components](#) section in detail, so that you are informed of the criteria used by the TSC and board in order to approve or reject a request
2. Use the [New External Source Code Issue](#) to open an issue
3. Fill out all required sections, making sure you provide enough detail for the TSC to assess the merit of the request. Optionally you can also create a Pull Request that demonstrates the integration of the external source code and link to it from the issue
4. Wait for feedback from the TSC, respond to any additional questions added as GitHub issue comments

If, after consideration by the TSC, the conclusion is that integrating external source code is the best solution, and the external source code is licensed under the Apache-2.0 license, the submission process is complete and the external source code can be integrated.

If, however, the external source code uses a license other than Apache-2.0, then these additional steps must be followed:

1. The TSC chair will forward the link to the GitHub issue created during the early submission process to the Zephyr governing board for further review
2. The Zephyr governing board has two weeks to review and ask questions:
   - If there are no objections, the matter is closed. Approval can be accelerated by unanimous approval of the board before the two weeks are up
   - If a governing board member raises an objection that cannot be resolved via email, the board will meet to discuss whether to override the TSC approval or identify other approaches that can resolve the objections
3. On approval of the Zephyr TSC and governing board the submission process is complete

The flowchart below shows an overview of the process:

**Contributing External Tooling**

This section deals exclusively with the inclusion of external tooling in the Zephyr project, where tooling is defined as software that assists the compilation, testing or simulation processes but in no case ends up being part of the code compiled and linked into the final image. “Inclusion” in this context means becoming part of the Zephyr default distribution either in the main tree directly under the `scripts/` folder or indirectly as a west project in the main `west.yml` manifest.

Therefore, this section does not apply to 3rd-party tooling such as toolchains, simulators or others, which may still be referenced by the Zephyr build system or docs without being included in Zephyr.

Tooling components must be released under a license approved by the [Open Source Initiative (OSI)](#).
Fig. 2: Submission process

Just like with regular external components, tooling that is imported from another project can be integrated either in the main tree or as a west project. Note that in this case the corresponding west project will not be a module, because tooling does not make use of the Zephyr build system and does not need to be processed by it. Please see Modules vs west projects for additional information on the differences.

If the tool is integrated in the main tree it should be placed under the scripts/ folder. If the tool is integrated as a west project, then the project repository can be hosted outside the zephyrproject-rtos GitHub organization, provided that the project is made optional via the group-filter: field in the main west.yml manifest. More info on optional projects can be found in this section.

The TSC must approve every Pull Request that introduces a new external tooling component. This will be done on a case-by-case, individual analysis of the proposed addition by the TSC representatives.

Additional considerations about the main manifest

In general, any additions or removals whatsoever to the projects: section of the main manifest file requires TSC approval. This includes, but is not limited to:

- Adding and removing groups and group filters
- Adding and removing projects
- Adding and removing import statements

8.3.2 Binary Blobs

In the context of an operating system that supports multiple architectures and many different IC families, some functionality may be unavailable without the help of executable code distributed in binary form. Binary blobs (or blobs for short) are files containing proprietary machine code or data in a binary format, e.g. without corresponding source code released under an OSI approved license.
Zephyr supports downloading and using third-party binary blobs via its built-in mechanisms, with some important caveats, described in the following sections. It is important to note that all the information in this section applies only to upstream (vanilla) Zephyr.

There are no limitations whatsoever (except perhaps license compatibility) in the support for binary blobs in forks or third-party distributions of Zephyr. In fact, Zephyr’s build system supports arbitrary use cases related to blobs. This includes linking against libraries, flashing images to targets, etc. Users are therefore free to create Zephyr-based downstream software which uses binary blobs if they cannot meet the requirements described in this page.

### Software license

Most binary blobs are distributed under proprietary licenses which vary significantly in nature and conditions. It is up to the vendor to specify the license as part of the blob submission process. Blob vendors may impose a click-through or other EULA-like workflow when users fetch and install blobs.

### Hosting

Blobs must be hosted on the Internet and managed by third-party infrastructure. Two potential examples are Git repositories and web servers managed by individual hardware vendors. The Zephyr Project does not host binary blobs in its Git repositories or anywhere else.

### Fetching blobs

Blobs are fetched from official third-party sources by the `west blobs` command.

The blobs themselves must be specified in the `module.yml` files included in separate Zephyr module repositories maintained by their respective vendors. This means that in order to include a reference to a binary blob to the upstream Zephyr distribution, a module repository must exist first or be created as part of the submission process.

Each blob which may be fetched must be individually identified in the corresponding `module.yml` file. A specification for a blob must contain:

- An abstract description of the blob itself
- Version information
- A reference to vendor-provided documentation
- The blob’s `type`, which must be one of the allowed types
- A checksum for the blob, which `west blobs` checks after downloading. This is required for reproducibility and to allow bisecting issues as blobs change using Git and west
- License text applicable to the blob or a reference to such text, in SPDX format

See the corresponding section for a more formal definition of the fields.

The `west blobs` command can be used to list metadata of available blobs and to fetch blobs from user-selected modules.

The `west blobs` command only fetches and stores the binary blobs themselves. Any accompanying code, including interface header files for the blobs, must be present in the corresponding module repository.
Tainting

Inclusion of binary blobs will taint the Zephyr build. The definition of tainting originates in the Linux kernel and, in the context of Zephyr, a tainted image will be one that includes binary blobs in it.

Tainting will be communicated to the user in the following manners:

- One or more Kconfig options `TAINT_BLOBS_*` will be set to `y`
- The Zephyr build system, during its configuration phase, will issue a warning. It will be possible to disable the warning using Kconfig
- The `west spdx` command will include the tainted status in its output
- The kernel's default fatal error handler will also explicitly print out the kernel's tainted status

Allowed types

The following binary blob types are acceptable in Zephyr:

- Precompiled libraries: Hardware enablement libraries, distributed in precompiled binary form, typically for SoC peripherals. An example could be an enablement library for a wireless peripheral
- Firmware images: An image containing the executable code for a secondary processor or CPU. This can be full or partial (typically delta or patch data) and is generally copied into RAM or flash memory by the main CPU. An example could be the firmware for the core running a Bluetooth LE Controller
- Miscellaneous binary data files. An example could be pre-trained neural network model data

Hardware agnostic features provided via a proprietary library are not acceptable. For example, a proprietary and hardware agnostic TCP/IP stack distributed as a static archive would be rejected.

Note that just because a blob has an acceptable type does not imply that it will be unconditionally accepted by the project; any blob may be rejected for other reasons on a case by case basis (see library-specific requirements below). In case of disagreement, the TSC is the arbiter of whether a particular blob fits in one of the above types.

Precompiled library-specific requirements

This section contains additional requirements specific to precompiled library blobs.

Any person who wishes to submit a precompiled library must represent that it meets these requirements. The project may remove a blob from the upstream distribution if it is discovered that the blob fails to meet these requirements later on.

Interface header files   The precompiled library must be accompanied by one or more header files, distributed under a non-copyleft OSI approved license, that define the interface to the library.

Allowed dependencies   This section defines requirements related to external symbols that a library blob requires the build system to provide.
The blob must not depend on Zephyr APIs directly. In other words, it must have been possible to build the binary without any Zephyr source code present at all. This is required for loose coupling and maintainability, since Zephyr APIs may change and such blobs cannot be modified by all project maintainers.

Instead, if the code in the precompiled library requires functionality provided by Zephyr (or an RTOS in general), an implementation of an OS abstraction layer (aka porting layer) can be provided alongside the library. The implementation of this OS abstraction layer must be in source code form, released under an OSI approved license and documented using Doxygen.

**Toolchain requirements** Precompiled library blobs must be in a data format which is compatible with and can be linked by a toolchain supported by the Zephyr Project. This is required for maintainability and usability. Use of such libraries may require special compiler and/or linker flags, however. For example, a porting layer may require special flags, or a static archive may require use of specific linker flags.

**Limited scope** Allowing arbitrary library blobs carries a risk of degrading the degree to which the upstream Zephyr software distribution is open source. As an extreme example, a target with a zephyr kernel clock driver that is just a porting layer around a library blob would not be bootable with open source software.

To mitigate this risk, the scope of upstream library blobs is limited. The project maintainers define an open source test suite that an upstream target must be able to pass using only open source software included in the mainline distribution and its modules. The open source test suite currently consists of:

- samples/philosophers
- tests/kernel

The scope of this test suite may grow over time. The goal is to specify tests for a minimal feature set which must be supported via open source software for any target with upstream Zephyr support.

At the discretion of the release team, the project may remove support for a hardware target if it cannot pass this test suite.

**Support and maintenance**

The Zephyr Project is not expected to be responsible for the maintenance and support of contributed binary blobs. As a consequence, at the discretion of the Zephyr Project release team, and on a case-by-case basis:

- GitHub issues reported on the zephyr repository tracker that require use of blobs to reproduce may not be treated as bugs.
- Such issues may be closed as out of scope of the Zephyr project.

This does not imply that issues which require blobs to reproduce will be closed without investigation. For example, the issue may be exposing a bug in a Zephyr code path that is difficult or impossible to trigger without a blob. Project maintainers may accept and attempt to resolve such issues.

However, some flexibility is required because project maintainers may not be able to determine if a given issue is due to a bug in Zephyr or the blob itself, may be unable to reproduce the bug due to lack of hardware, etc.

Blobs must have designated maintainers that must be responsive to issue reports from users and provide updates to the blobs to address issues. At the discretion of the Zephyr Project release team, module revisions referencing blobs may be removed from zephyr/west.yml at any time.
due to lack of responsiveness or support from their maintainers. This is required to maintain project control over bit-rot, security issues, etc.

The submitter of the proposal to integrate a binary blob must commit to maintain the integration of such blob for the foreseeable future.

Regarding Continuous Integration, binary blobs will **not** be fetched in the project's CI infrastructure that builds and optionally executes tests and samples to prevent regressions and issues from entering the codebase. This includes both CI ran when a new GitHub Pull Request is opened as well as any other regularly scheduled execution of the CI infrastructure.

**Submission and review process**

For references to binary blobs to be included in the project, they must be reviewed and accepted by the Technical Steering Committee (TSC). This process is only required for new binary blobs, updates to binary blobs follow the *module update procedure*.

A request for integration with binary blobs must be made by creating a new issue in the Zephyr project issue tracking system on GitHub with details about the blobs and the functionality they provide to the project.

Follow the steps below to begin the submission process:

1. Make sure to read through the *Binary Blobs* section in detail, so that you are informed of the criteria used by the TSC in order to approve or reject a request
2. Use the *New Binary Blobs Issue* to open an issue
3. Fill out all required sections, making sure you provide enough detail for the TSC to assess the merit of the request. Additionally you must also create a Pull Request that demonstrates the integration of the binary blobs and then link to it from the issue
4. Wait for feedback from the TSC, respond to any additional questions added as GitHub issue comments

If, after consideration by the TSC, the submission of the binary blob(s) is approved, the submission process is complete and the binary blob(s) can be integrated.

**Contributing External Components**

Basic functionality or features that would make useful addition to Zephyr might be readily available in other open source projects, and it is recommended and encouraged to reuse such code. This page describes in more details when and how to import external source code into Zephyr.

**Contributing External Tooling**

Similarly, external tooling used during compilation, code analysis, testing or simulation, can be beneficial and is covered in this section.

**Binary Blobs**

As some functionality might only be made available with the help of executable code distributed in binary form, this page describes the process and guidelines for contributing *binary blobs* to the project.

### 8.4 Zephyr Contributor Badge

When your first contribution to the Zephyr project gets merged, you'll become eligible to claim your Zephyr Contributor Badge. This digital badge can be displayed on your website, blog, social media profile, etc. It will allow you to showcase your involvement in the Zephyr project and help raise its awareness.

You may apply for your Contributor Badge by filling out the *Zephyr Contributor Badge form*.
8.5 Need help along the way?

If you have questions related to the contribution process, the Zephyr community is here to help. You may join our Discord channel or use the Developer Mailing List.
Chapter 9

Project and Governance

9.1 TSC Project Roles

9.1.1 Main Roles

TSC projects generally will involve *Maintainers, Collaborators, and Contributors*:

**Maintainer:** lead Collaborators on an area identified by the TSC (e.g. Architecture, code sub-systems, etc.). Maintainers shall also serve as the area's representative on the TSC as needed. Maintainers may become voting members of the TSC under the guidelines stated in the project Charter.

**Collaborator:** A highly involved Contributor in one or more areas. May become a Maintainer with approval of existing TSC voting members.

**Contributor:** anyone in the community that contributes code or documentation to the project. Contributors may become Collaborators by approval of the existing Collaborators and Maintainers of the particular code base areas or subsystems.

**Contributor**

A *Contributor* is a developer who wishes to contribute to the project, at any level. Contributors are granted the following rights and responsibilities:

- Right to contribute code, documentation, translations, artwork, etc.
- Right to report defects (bugs) and suggestions for enhancement.
- Right to participate in the process of reviewing contributions by others.
- Right to initiate and participate in discussions in any communication methods.
- Right to approach any member of the community with matters they believe to be important.
- Right to participate in the feature development process.
- Responsibility to abide by decisions, once made. They are welcome to provide new, relevant information to reopen decisions.
- Responsibility for issues and bugs introduced by one's own contributions.
- Responsibility to respect the rules of the community.
- Responsibility to provide constructive advice whenever participating in discussions and in the review of contributions.
• Responsibility to follow the project’s code of conduct ([https://github.com/zephyrproject-rtos/zephyr/blob/main/CODE_OF_CONDUCT.md](https://github.com/zephyrproject-rtos/zephyr/blob/main/CODE_OF_CONDUCT.md))

Contributors are initially only given Read access to the Zephyr GitHub repository. Specifically, at the Read access level, Contributors are not allowed to assign reviewers to their own pull requests. An automated process will assign reviewers. You may also share the pull request on the Zephyr deve mailing list or on the Zephyr Discord Server.

Contributors who show dedication and skill are granted the Triage permission level to the Zephyr GitHub repository.

You may nominate yourself, or another GitHub user, for promotion to the Triage permission level by creating a GitHub issue, using the nomination template.

Contributors granted the Triage permission level are permitted to add reviewers to a pull request and can be added as a reviewer by other GitHub users. Contributor change requests or approval on pull requests are not counted with respect to accepting and merging a pull request. However, Contributors comments and requested changes should still be considered by the pull request author.

**Collaborator**

A **Collaborator** is a Contributor who is also responsible for the maintenance of Zephyr source code. Their opinions weigh more when decisions are made, in a fully meritocratic fashion.

Collaborators have the following rights and responsibilities, in addition to those listed for Contributors:

- Right to set goals for the short and medium terms for the project being maintained, alongside the Maintainer.
- Responsibility to participate in the feature development process.
- Responsibility to review relevant code changes within reasonable time.
- Responsibility to ensure the quality of the code to expected levels.
- Responsibility to participate in community discussions.
- Responsibility to mentor new contributors when appropriate
- Responsibility to participate in the quality verification and release process, when those happen.

Contributors are promoted to the Collaborator role by adding the GitHub user name to one or more collaborators sections of the **MAINTAINERS File** in the Zephyr repository.

Collaborator change requests on pull requests should be addressed by the original submitter. In cases where the changes requested do not follow the expectations and the guidelines of the project or in cases of disagreement, it is the responsibility of the assignee to advance the review process and resolve any disagreements.

Collaborator approval of pull requests are counted toward the minimum required approvals needed to merge a PR. Other criteria for merging may apply.

**Maintainer**

A **Maintainer** is a Collaborator who is also responsible for knowing, directing and anticipating the needs of a given zephyr source code area.

Maintainers have the following rights and responsibilities, in addition to those listed for Contributors and Collaborators:

- Right to set the overall architecture of the relevant subsystems or areas of involvement.
• Right to make decisions in the relevant subsystems or areas of involvement, in conjunction with the collaborators and submitters. See PR Technical Escalation.
• Responsibility to convey the direction of the relevant subsystem or areas to the TSC
• Responsibility to ensure all contributions of the project have been reviewed within reasonable time.
• Responsibility to enforce the code of conduct.
• Responsibility to triage static analysis issues in their code area. See Static Code Analysis.

Contributors or Collaborators are promoted to the Maintainer role by adding the GitHub user name to one or more maintainers sections of the MAINTAINERS File in the Zephyr repository. Maintainer approval of pull requests are counted toward the minimum required approvals needed to merge a PR. Other criteria for merging may apply.

9.1.2 Role Retirement

• Individuals elected to the following Project roles, including, Maintainer, Release Engineering Team member, Release Manager, but are no longer engaged in the project as described by the rights and responsibilities of that role, may be requested by the TSC to retire from the role they are elected.
• Such a request needs to be raised as a motion in the TSC and be approved by the TSC voting members. By approval of the TSC the individual is considered to be retired from the role they have been elected.
• The above applies to elected TSC Project roles that may be defined in addition.

9.1.3 Teams and Supporting Activities

Assignee

An Assignee is one of the maintainers of a subsystem or code being changed. Assignees are set either automatically based on the code being changed or set by the other Maintainers, the Release Engineering team can set an assignee when the latter is not possible.

• Right to dismiss stale and unrelated reviews or reviews not following expectations from reviewers and seek reviews from additional maintainers, developers and contributors
• Right to block pull requests from being merged until issues or changes requested are addressed
• Responsibility to re-assign a pull request if they are the original submitter of the code
• Responsibility to drive the pull request to a mergeable state
• Solicit approvals from maintainers of the subsystems affected
• Responsibility to drive the PR Technical Escalation process

Static Analysis Audit Team

The Static Analysis Audit team works closely with the release engineering team to ensure that static analysis defects opened during a release cycle are properly addressed. The team has the following rights and responsibilities:

• Right to revert any triage in a static analysis tool (e.g: Coverity) that does not follow the project expectations.
Responsibility to inform code owners about improper classifications.
Responsibility to alert TSC if any issues are not adequately addressed by the responsible code owners.

Joining the Static Analysis Audit team
Contributors highly involved in the project with some expertise in static analysis.

Release Engineering Team
A team of active Maintainers involved in multiple areas.
The members of the Release Engineering team are expected to fill the Release Manager role based on a defined cadence and selection process.
The cadence and selection process are defined by the Release Engineering team and are approved by the TSC.
The team reports directly into the TSC.

Release Engineering team has the following rights and responsibilities:
Right to merge code changes to the zephyr tree following the project rules.
Right to revert any changes that have broken the code base
Right to close any stale changes after <N> months of no activity
Responsibility to take directions from the TSC and follow them.
Responsibility to coordinate code merges with maintainers.
Responsibility to merge all contributions regardless of their origin and area if they have been approved by the respective maintainers and follow the merge criteria of a change.
Responsibility to keep the Zephyr code base in a working and passing state (as per CI)

Joining the Release Engineering team
Maintainers highly involved in the project may be nominated by a TSC voting member to join the Release Engineering team. Nominees may become members of the team by approval of the existing TSC voting members.

To ensure a functional Release Engineering team the TSC shall periodically review the team's followed processes, the appropriate size, and the membership composition (ensure, for example, that team members are geographically distributed across multiple locations and time-zones).

Release Manager
A Maintainer responsible for driving a specific release to completion following the milestones and the roadmap of the project for this specific release.
TSC has to approve a release manager.

A Release Manager is a member of the Release Engineering team and has the rights and responsibilities of that team in addition to the following:
Right to manage and coordinate all code merges after the code freeze milestone (M3, see program management overview.)
Responsibility to drive and coordinate the triaging process for the release
Responsibility to create the release notes of the release
- Responsibility to notify all stakeholders of the project, including the community at large about the status of the release in a timely manner.
- Responsibility to coordinate with QA and validation and verify changes either directly or through QA before major changes and major milestones.

9.1.4 MAINTAINERS File

Generic guidelines for deciding and filling in the Maintainers’ list
- The MAINTAINERS.yml file shall replace the CODEOWNERS file and will be used for both setting assignees and reviewers.
- We should keep the granularity of code maintainership at a manageable level
- We should be looking for maintainers for areas of code that are orphaned (i.e. without an explicit maintainer)
  - Un-maintained areas should be indicated clearly in the MAINTAINERS file
- All submitted pull requests should have an assignee
- We Introduce an area/subsystem hierarchy to address the above point
  - Parent-area maintainer should be acting as default substitute/fallback assignee for un-maintained sub-areas
  - Area maintainer gets precedence over parent-area maintainer
- Pull requests may be re-assigned if this is needed or more appropriate
  - Re-assigned by original assignee
- In general, updates to the MAINTAINERS file should be in a standalone commit alongside other changes introducing new files and directories to the tree.
- Major changes to the file, including the addition of new areas with new maintainers should come in as standalone pull requests and require TSC review.
- If additional review by the TSC is required, the maintainers of the file should send the requested changes to the TSC and give members of the TSC two (2) days to object to any of the changes to maintainership of areas or the addition of new maintainers or areas.
- Path, collaborator and name changes do not require a review by the TSC.
- Addition of new areas without a maintainer do not require review by the TSC.
- The MAINTAINERS file itself shall have a maintainer

9.1. TSC Project Roles
• Architectures, core components, sub-systems, samples, tests
  – Each area shall have an explicit maintainer
• Boards (incl relevant samples, tests), SoCs (incl DTS) * May have a maintainer, shall have a higher-level platform maintainer
• Drivers
  – Shall have a driver-area (and API) maintainer
  – Could have individual driver implementation maintainers but preferably collaborator/contributors
  – In the above case, platform-specific PRs may be re-assigned to respective collaborator/contributor of driver implementation

9.1.5 Release Activity

Merge Criteria

• Minimal of 2 approvals, including an approval by the designated assignee.
• Pull requests should be reviewed by at least a maintainer or collaborator of each affected area; Unless the changes to a given area are considered trivial enough, in which case approvals by other affected subsystems maintainers/collaborators would suffice.
• Four eye principle on the organisation level. We already require at least 2 approvals (basic four eye principle), however, such reviews and approvals might be unintentionally biased in the case where the submitter is from the same organisation as the approvers. To allow
for project wide review and approvals, the merge criteria is extended with the guidelines below:

- Changes or additions to common and shared code shall have approvals from different organisations (at least one approval from an organisation different than the submitters’). Common and shared code is defined as anything that does not fall under soc, boards and drivers/*/*/.

- Changes or additions to hardware support (driver, SoC, boards) shall at least have the merger be from a different organisation. This applies only to implementation of an API supporting vendor specific hardware and not the APIs.

- Release engineers may make exceptions for areas with contributions primarily coming from one organisation and where reviews from other organisations are not possible, however, merges shall be completed by a person from a different organisation. In such cases, the minimum review period of at least 2 days shall be strictly followed to allow for additional reviews.

- Release engineers shall not merge code changes originating and reviewed only by their own organisation. To be able to merge such changes, at least one review shall be from a different organisation.

  - A minimum review period of 2 business days, 4 hours for trivial changes (see Give reviewers time to review before code merge).

- Hotfixes can be merged at any time after CI has passed and are excluded from most of the conditions listed above.

- All required checks are passing:
  - Codeowners
  - Device Tree
  - Documentation
  - Gitlint
  - Identity/Emails
  - Kconfig
  - License checks
  - Checkpatch (Coding Style)
  - Pylint
  - Integration Tests (Via twister) on emulation/simulation platforms
  - Simulated Bluetooth Tests

- Planned
  - Footprint
  - Code coverage
  - Coding Guidelines
  - Static Analysis (Coverity)
  - Documentation coverage (APIs)

9.2 Release Process

The Zephyr project releases on a time-based cycle, rather than a feature-driven one. Zephyr releases represent an aggregation of the work of many contributors, companies, and individuals
from the community.

A time-based release process enables the Zephyr project to provide users with a balance of the latest technologies and features and excellent overall quality. A roughly 4-month release cycle allows the project to coordinate development of the features that have actually been implemented, allowing the project to maintain the quality of the overall release without delays because of one or two features that are not ready yet.

The Zephyr release model was loosely based on the Linux kernel model:

- **Release tagging procedure:**
  - linear mode on main branch,
  - release branches for maintenance after release tagging.
- **Each release period will consist of a development phase followed by a stabilization phase.** Release candidates will be tagged during the stabilization phase. During the stabilization phase, only stabilization changes such as bug fixes and documentation will be merged unless granted a special exemption by the Technical Steering Committee.
  - Development phase: all changes are considered and merged, subject to approval from the respective maintainers.
  - Stabilisation phase: the release manager creates a vN-rc1 tag and the tree enters the stabilization phase
  - CI sees the tag, builds and runs tests; Test teams analyse the report from the build and test run and give an ACK/NAK to the build
  - The release owner, with test teams and any other needed input, determines if the release candidate is a go for release
  - If it is a go for a release, the release owner lays a tag release vN at the same point

![Fig. 1: Release Cycle](image)

**Note:** The milestones for the current major version can be found on the [Official GitHub Wiki](https://github.com). Information on previous releases can be found here.

### 9.2.1 Development Phase

A relatively straightforward discipline is followed with regard to the merging of patches for each release. At the beginning of each development cycle, the main branch is said to be open for development. At that time, code which is deemed to be sufficiently stable (and which is accepted by the maintainers and the wide community) is merged into the mainline tree. The bulk of changes for a new development cycle (and all of the major changes) will be merged during this time.

The development phase lasts for approximately three months. At the end of this time, the release owner will declare that the development phase is over and releases the first of the release candidates. For the codebase release which is destined to be 3.1.0, for example, the release which
happens at the end of the development phase will be called 3.1.0-rc1. The -rc1 release is the signal that the time to merge new features has passed, and that the time to stabilize the next release of the code base has begun.

### 9.2.2 Stabilization Phase

Over the next weeks, only patches which fix problems should be submitted to the mainline. On occasion, a more significant change will be allowed, but such occasions are rare and require a TSC approval (Change Control Board). As a general rule, if you miss submitting your code during the development phase for a given feature, the best thing to do is to wait for the next development cycle. (An occasional exception is made for drivers for previously unsupported hardware; if they do not touch any other in-tree code, they cannot cause regressions and should be safe to add at any time).

As fixes make their way into the mainline, the patch rate will slow over time. The mainline release owner releases new -rc drops once or twice a week; a normal series will get up to somewhere between -rc4 and -rc6 before the code base is considered to be sufficiently stable and the release criteria have been achieved at which point the final 3.1.0 release is made.

At that point, the whole process starts over again.

### 9.2.3 Release Quality Criteria

The current backlog of prioritized bugs shall also be used as a quality metric to gate the final release. The following counts shall be used:

<table>
<thead>
<tr>
<th>High</th>
<th>Medium</th>
<th>Low</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&lt;20</td>
<td>&lt;50</td>
</tr>
</tbody>
</table>

**Note:** The “low” bug count target of <50 will be a phased approach starting with 150 for release 2.4.0, 100 for release 2.5.0, and 50 for release 2.6.0.

The final release must not contain any static analysis high-critical issues that can potentially compromise the functionality, security, or reliability of our software. High-critical issues represent vulnerabilities that, if left unresolved, could have severe consequences.
9.2.4 Release Milestones

Table 3: Release Milestones

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

9.2.5 Releases

The following syntax should be used for releases and tags in Git:

- Release [Major].[Minor].[Patch Level]
- Release Candidate [Major].[Minor].[Patch Level]-rc[RC Number]
- Tagging:
  - v[Major].[Minor].[Patch Level]-rc[RC Number]
  - v[Major].[Minor].[Patch Level]
  - v[Major].[Minor].99 - A tag applied to main branch to signify that work on v[Major].[Minor+1] has started. For example, v1.7.99 will be tagged at the start of v1.8 process. The tag corresponds to VERSION_MAJOR/VERSION_MINOR/PATCHLEVEL macros as defined for a work-in-progress main branch version. Presence of this tag allows generation of sensible output for “git describe” on main branch, as typically used for automated builds and CI tools.

Long Term Support (LTS)

Long-term support releases are designed to be supported and maintained for an extended period and is the recommended release for products and the auditable branch used for certification. An LTS release is defined as:

- **Product focused**
- **Extended Stabilisation period**: Allow for more testing and bug fixing
- **Stable APIs**
- **Quality Driven Process**
- **Long Term**: Maintained for an extended period of time (at least 2.5 years) overlapping previous LTS release for at least half a year.

**Product Focused**  
Zephyr LTS is the recommended release for product makers with an extended support and maintenance which includes general stability and bug fixes, security fixes. An LTS includes both mature and new features. API and feature maturity is documented and tracked. The footprint and scope of mature and stable APIs expands as we move from one LTS to the next giving users access to bleeding edge features and new hardware while keeping a stable foundation that evolves over time.

**Extended Stabilisation Period**  
Zephyr LTS development cycle differs from regular releases and has an extended stabilization period. Feature freeze of regular releases happens 3-4 weeks before the scheduled release date. The stabilization period for LTS is extended by 3 weeks with the feature freeze occurring 6-7 weeks before the anticipated release date. The time between code freeze and release date is extended in this case.

**Stable APIs**  
Zephyr LTS provides a stable and long-lived foundation for developing products. To guarantee stability of the APIs and the implementation of such APIs it is required that any release software that makes the core of the OS went through the Zephyr API lifecycle and stabilized over at least 2 releases. This guarantees that we release many of the highlighted and core features with mature and well-established implementations with stable APIs that are supported during the lifetime of the release LTS.

- **API Freeze (LTS - 2)**
  - All stable APIs need to be frozen 2 releases before an LTS. APIs can be extended with additional features, but the core implementation is not modified. This is valid for the following subsystems for example:
    - Device Drivers (i2c.h, spi.h)...
    - Kernel (k_*):
    - OS services (logging, debugging, ..)
    - DTS: API and bindings stability
    - Kconfig
– New APIs for experimental features can be added at any time as long as they are standalone and documented as experimental or unstable features/APIs.

• Feature Freeze (LTS - 1) - No new features or overhaul/restructuring of code covering major LTS features.
  – Kernel + Base OS
  – Additional advertised LTS features
  – Auxiliary features on top of and/or extending the base OS and advertised LTS features can be added at any time and should be marked as experimental if applicable

Quality Driven Process  The Zephyr project follows industry standards and processes with the goal of providing a quality oriented releases. This is achieved by providing the following products to track progress, integrity and quality of the software components provided by the project:

• Compliance with published coding guidelines, style guides and naming conventions and documentation of deviations.

• Static analysis reports
  – Regular static analysis on the complete tree using available commercial and open-source tools, and documentation of deviations and false positives.

• Documented components and APIs
• Requirements Catalog
• Verification Plans
• Verification Reports
• Coverage Reports
• Requirements Traceability Matrix (RTM)
• SPDX License Reports

Each release is created with the above products to document the quality and the state of the software when it was released.

Long Term Support and Maintenance  A Zephyr LTS release is published every 2 years and is branched and maintained independently from the main tree for at least 2.5 years after it was released. Support and maintenance for an LTS release stops at least half a year after the following LTS release is published.

Changes and fixes flow in both directions. However, changes from main branch to an LTS branch will be limited to fixes that apply to both branches and for existing features only.

All fixes for an LTS branch that apply to the mainline tree shall be submitted to mainline tree as well.
**Auditable Code Base**

An auditable code base is to be established from a defined subset of Zephyr OS features and will be limited in scope. The LTS, development tree, and the auditable code bases shall be kept in sync after the audit branch is created, but with a more rigorous process in place for adding new features into the audit branch used for certification.

This process will be applied before new features move into the auditable code base.

The initial and subsequent certification targets will be decided by the Zephyr project governing board.

Processes to achieve selected certification will be determined by the Security and Safety Working Groups and coordinated with the TSC.

**9.2.6 Release Procedure**

This section documents the Release manager responsibilities so that it serves as a knowledge repository for Release managers.

**Release Checklist**

Each release has a GitHub issue associated with it that contains the full checklist. After a release is complete, a checklist for the next release is created.

**Tagging**

The final release and each release candidate shall be tagged using the following steps:

**Note:** Tagging needs to be done via explicit git commands and not via GitHub's release interface. The GitHub release interface does not generate annotated tags (it generates 'lightweight' tags regardless of release or pre-release). You should also upload your gpg public key to your GitHub account, since the instructions below involve creating signed tags. However, if you do not have a gpg public key you can opt to remove the `-s` option from the commands below.

**Release Candidate**

**Note:** This section uses tagging 1.11.0-rc1 as an example, replace with the appropriate release candidate version.

1. Update the version variables in the `VERSION` file located in the root of the Git repository to match the version for this release candidate. The `EXTRAVERSION` variable is used to identify the `rc[RC Number]` value for this candidate:

   ```
   EXTRAVERSION = rc1
   ```

2. Post a PR with the updated `VERSION` file using `release: Zephyr 1.11.0-rc1` as the commit subject. Merge the PR after successful CI.

3. Tag and push the version, using an annotated tag:

   ```
   $ git pull
   $ git tag -s -m "Zephyr 1.11.0-rc1" v1.11.0-rc1
   $ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0-rc1
   ```
4. Send an email to the mailing lists (announce and devel) with a link to the release

Final Release

**Note:** This section uses tagging 1.11.0 as an example, replace with the appropriate final release version.

When all final release criteria has been met and the final release notes have been approved and merged into the repository, the final release version will be set and repository tagged using the following procedure:

1. Update the version variables in the `VERSION` file located in the root of the Git repository. Set `EXTRAVERSION` variable to an empty string to indicate final release:

   ```
   EXTRAVERSION =
   ```

2. Post a PR with the updated `VERSION` file using release: Zephyr 1.11.0 as the commit subject. Merge the PR after successful CI.

3. Tag and push the version, using two annotated tags:

   ```
   $ git pull
   $ git tag -s -m "Zephyr 1.11.0" v1.11.0
   $ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0
   ```

4. Find the new `v1.11.0` tag at the top of the releases page and edit the release with the Edit tag button with the following:

   - Copy the overview of `docs/releases/release-notes-1.11.rst` into the release notes textbox and link to the full release notes file on docs.zephyrproject.org.

5. Send an email to the mailing lists (announce and devel) with a link to the release

9.3 Feature Tracking

For feature tracking we use Github labels to classify new features and enhancements. The following is the description of each category:

**Enhancement**
Changes to existing features that are not considered a bug and would not block a release. This is an incremental enhancement to a feature that already exists in Zephyr.

**Feature request**
A request for the implementation or inclusion of a new unit of functionality that is not part of any release plans yet, that has not been vetted, and needs further discussion and details.

**Feature**
A committed and planned unit of functionality with a detailed design and implementation proposal and an owner. Features must go through an RFC process and must be vetted and discussed in the TSC before a target milestone is set.

**Hardware Support**
A request or plan to port an existing feature or enhancement to a particular hardware platform. This ranges from porting Zephyr itself to a new architecture, SoC or board to adding an implementation of a peripheral driver API for an existing hardware platform.

**Meta**
A label to group other GitHub issues that are part of a single feature or unit of work.

The following workflow should be used to process features:
This is the formal way for asking for a new feature in Zephyr and indicating its importance to the project. Often, the requester may have a readiness and willingness to drive implementation of the feature in an upcoming release, and should assign the request to themselves. If not though, an owner will be assigned after evaluation by the TSC. A feature request can also have a companion RFC with more details on the feature and a proposed design or implementation.

- Label new features requests as feature-request
- The TSC discusses new feature-request items regularly and triages them. Items are examined for similarity with existing features, how they fit with the project goals and other timeline considerations. The priority is determined as follows:
  - High = Next milestone
  - Medium = As soon as possible
  - Low = Best effort
- After the initial discussion and triaging, the label is moved from feature-request to feature with the target milestone and an assignee.

All items marked as feature-request are non-binding and those without an assignee are open for grabs, meaning that they can be picked up and implemented by any project member or the community. You should contact an assigned owner if you'd like to discuss or contribute to that feature's implementation.

### 9.3.1 Roadmap and Release Plans

Project roadmaps and release plans are both important tools for the project, but they have very different purposes and should not be confused. A project roadmap communicates the high-level overview of a project's strategy, while a release plan is a tactical document designed to capture and track the features planned for upcoming releases.

- The project roadmap communicates the why; a release plan details the what
- A release plan spans only a few months; a product roadmap might cover a year or more

#### Project Roadmap

The project roadmap should serve as a high-level, visual summary of the project’s strategic objectives and expectations.

If built properly, the roadmap can be a valuable tool for several reasons. It can help the project present its plan in a compelling way to existing and new stakeholders, to help recruit new members and it can be a helpful resource the team and community can refer to throughout the project's development, to ensure they are still executing according to plan.

As such, the roadmap should contain only strategic-level details, major project themes, epics, and goals.

#### Release Plans

The release plan comes into play when the project roadmap's high-level strategy is translated into an actionable plan built on specific features, enhancements, and fixes that need to go into a specific release or milestone.

The release plan communicates those features and enhancements slated for your project' next release (or the next few releases). So it acts as more of a project plan, breaking the big ideas down into smaller projects the community and main stakeholders of the project can make progress on.
9.4 Code Flow and Branches

9.4.1 Introduction

The zephyr Git repository has three types of branches:

**main**
- Which contains the latest state of development

**collab-**
- Collaboration branches that are used for shared development of new features to be introduced into the main branch when ready. Creating a new collaboration branch requires a justification and TSC approval. Collaboration branches shall be based off the main branch and any changes developed in the collab branch shall target the main development branch. For released versions of Zephyr, the introduction of fixes and new features, if approved by the TSC, shall be done using backport pull requests.

**vx.y-branch**
- Branches which track maintenance releases based on a major release

Development in collaboration branches before features go to mainline allows teams to work independently on a subsystem or a feature, improves efficiency and turnaround time, and encourages collaboration and streamlines communication between developers.

Changes submitted to a collaboration branch can evolve and improve incrementally in a branch, before they are submitted to the mainline tree for final integration.

By dedicating an isolated branch to complex features, it’s possible to initiate in-depth discussions around new additions before integrating them into the official project.

Collaboration branches are ephemeral and shall be removed once the collaboration work has been completed. When a branch is requested, the proposal should include the following:

- Define exit criteria for merging the collaboration branch changes back into the main branch.
- Define a timeline for the expected life cycle of the branch. It is recommended to select a Zephyr release to set the timeline. Extensions to this timeline requires TSC approval.

9.4.2 Roles and Responsibilities

Collaboration branch owners have the following responsibilities:

- Use the infrastructure and tools provided by the project (GitHub, Git)
- All changes to collaboration branches shall come in form of github pull requests.
- Force pushing a collaboration branch is only allowed when rebasing against the main branch.
- Review changes coming from team members and request review from branch owners when submitting changes.
- Keep the branch in sync with upstream and update on a regular basis.
- Push changes frequently to upstream using the following methods:
  - GitHub pull requests: for example, when reviews have not been done in the local branch (one-man branch).
– Merge requests: When a set of changes has been done in a local branch and has been reviewed and tested in a collaboration branch.

9.5 Modifying Contributions made by other developers

9.5.1 Scenarios

Zephyr contributors and collaborators are encouraged to assist as reviewers in pull requests, so that patches may be approved and merged to Zephyr’s main branch as part of the original pull requests. The authors of the pull requests are responsible for amending their original commits following the review process.

There are occasions, however, when a contributor might need to modify patches included in pull requests that are submitted by other Zephyr contributors. For instance, this is the case when:

• a developer cherry-picks commits submitted by other contributors into their own pull requests in order to:
  – integrate useful content which is part of a stale pull request, or
  – get content merged to the project’s main branch as part of a larger patch
• a developer pushes to a branch or pull request opened by another contributor in order to:
  – assist in updating pull requests in order to get the patches merged to the project’s main branch
  – drive stale pull requests to completion so they can be merged

9.5.2 Accepted policies

A developer who intends to cherry-pick and potentially modify patches sent by another contributor shall:

• clarify in their pull request the reason for cherry-picking the patches, instead of assisting in getting the patches merged in their original pull request, and
• invite the original author of the patches to their pull request review.

A developer who intends to force-push to a branch or pull request of another Zephyr contributor shall clarify in the pull request the reason for pushing and for modifying the existing patches (e.g. stating that it is done to drive the pull request review to completion, when the pull request author is not able to do so).

Note: Developers should try to limit the above practice to pull requests identified as stale. Read about how to identify pull requests as stale in development processes and tools

If the original patches are substantially modified, the developer can either:

• (preferably) reach out to the original author and request them to acknowledge that the modified patches may be merged while having the original sign-off line and author identity, or
• submit the modified patches as their own work (i.e. with their own sign-off line and author identity). In this case, the developer shall identify in the commit message(s) the original source the submitted work is based on (mentioning, for example, the original PR number).
9.6 Development Environment and Tools

9.6.1 Code Review

GitHub is intended to provide a framework for reviewing every commit before it is accepted into the code base. Changes, in the form of Pull Requests (PR) are uploaded to GitHub but don’t actually become a part of the project until they've been reviewed, passed a series of checks (CI), and are approved by maintainers. GitHub is used to support the standard open source practice of submitting patches, which are then reviewed by the project members before being applied to the code base.

Pull requests should be appropriately labeled, and linked to any relevant bug or feature tracking issues.

The Zephyr project uses GitHub for code reviews and Git tree management. When submitting a change or an enhancement to any Zephyr component, a developer should use GitHub. GitHub Actions automatically assigns a responsible reviewer on a component basis, as defined in the MAINTAINERS.yml file stored with the code tree in the Zephyr project repository. A limited set of release managers are allowed to merge a pull request into the main branch once reviews are complete.

Give reviewers time to review before code merge

The Zephyr project is a global project that is not tied to a certain geography or timezone. We have developers and contributors from across the globe. When changes are proposed using pull request, we need to allow for a minimal review time to give developers and contributors the opportunity to review and comment on changes. There are different categories of changes and we know that some changes do require reviews by subject matter experts and owners of the subsystem being changed. Many changes fall under the “trivial” category that can be addressed with general reviews and do not need to be queued for a maintainer or code-owner review. Additionally, some changes might require further discussions and a decision by the TSC or the Security working group. To summarize the above, the diagram below proposes minimal review times for each category:

Workflow

- An author of a change can suggest in his pull-request which category a change should belong to. A project maintainers or TSC member monitoring the inflow of changes can change the label of a pull request by adding a comment justifying why a change should belong to another category.
- The project will use the label system to categorize the pull requests.
- Changes should not be merged before the minimal time has expired.

Categories/Labels
Fig. 4: Pull request classes
Hotfix. Any change that is a fix to an issue that blocks developers from doing their daily work, for example CI breakage, Test breakage, Minor documentation fixes that impact the user experience.

Such fixes can be merged at any time after they have passed CI checks. Depending on the fix, severity, and availability of someone to review them (other than the author) they can be merged with justification without review by one of the project owners.

Trivial. Trivial changes are those that appear obvious enough and do not require maintainer or code-owner involvement. Such changes should not change the logic or the design of a subsystem or component. For example a trivial change can be:

- Documentation changes
- Configuration changes
- Minor Build System tweaks
- Minor optimization to code logic without changing the logic
- Test changes and fixes
- Sample modifications to support additional configuration or boards etc.

Maintainer. Any changes that touch the logic or the original design of a subsystem or component will need to be reviewed by the code owner or the designated subsystem maintainer. If the code changes is initiated by a contributor or developer other than the owner the pull request needs to be assigned to the code owner who will have to drive the pull request to a mergeable state by giving feedback to the author and asking for more reviews from other developers.

Security. Changes that appear to have an impact to the overall security of the system need to be reviewed by a security expert from the security working group.

TSC and Working Groups. Changes that introduce new features or functionality or change the way the overall system works need to be reviewed by the TSC or the responsible Working Group. For example for breaking API changes, the proposal needs to be presented in the Architecture meeting so that the relevant stakeholders are made aware of the change.

A Pull-Request should have an Assignee

- An assignee to a pull request should not be the same as the author of the pull-request
- An assignee to a pull request is responsible for driving the pull request to a mergeable state
- An assignee is responsible for dismissing stale reviews and seeking reviews from additional developers and contributors
- Pull requests should not be merged without an approval by the assignee.

Pull Request should not be merged by author without review

All pull requests need to be reviewed and should not be merged by the author without a review. The following exceptions apply:

- Hot fixes: Fixing CI issues, reverts, and system breakage
- Release related changes: Changing version file, applying tags and release related activities without any code changes.
Developers and contributors should always seek review, however there are cases when reviewers are not available and there is a need to get a code change into the tree as soon as possible.

**Reviewers shall not ‘Request Changes’ without comments or justification**

Any change requests (-1) on a pull request have to be justified. A reviewer should avoid blocking a pull-request with no justification. If a reviewer feels that a change should not be merged without their review, then: Request change of the category: for example:

- Trivial -> Maintainer
- Assign Pull Request to yourself, this will mean that a pull request should not be merged without your approval.

**Pull Requests should have at least 2 approvals before they are merged**

A pull-request shall be merged only with two positive reviews (approval). Beside the person merging the pull-request (merging != approval), two additional approvals are required to be able to merge a pull request. The person merging the request can merge without approving or approve and merge to get to the 2 approvals required.

**Reviewers should keep track of pull requests they have provided feedback to**

If a reviewer has requested changes in a pull request, he or she should monitor the state of the pull request and/or respond to mention requests to see if his feedback has been addressed. Failing to do so, negative reviews shall be dismissed by the assignee or an owner of the repository. Reviews will be dismissed following the criteria below:

- The feedback or concerns were visibly addressed by the author
- The reviewer did not revisit the pull request after 2 week and multiple pings by the author
- The review is unrelated to the code change or asking for unjustified structural changes such as:
  - Split the PR
  - Can you fix this unrelated code that happens to appear in the diff
  - Can you fix unrelated issues
  - Etc.

**Closing Stale Issues and Pull Requests**

- The Pull requests and issues sections on Github are NOT discussion forums. They are items that we need to execute and drive to closure. Use the mailing lists for discussions.
- In case of both issues and pull-requests the original poster needs to respond to questions and provide clarifications regarding the issue or the change. After one week without a response to a request, a second attempt to elicit a response from the contributor will be made. After one more week without a response the item may be closed (draft and DNM tagged pull requests are excluded).
9.6.2 Continuous Integration

All changes submitted to GitHub are subject to tests that are run on emulated platforms and architectures to identify breakage and regressions that can be immediately identified. Testing using Twister additionally performs build tests of all boards and platforms. Documentation changes are also verified through review and build testing to verify doc generation will be successful.

Any failures found during the CI test run will result in a negative review assigned automatically by the CI system. Developers are expected to fix issues and rework their patches and submit again.

The CI infrastructure currently runs the following tests:

- Run “checkpatch” for code style issues (can vote -1 on errors; see note)
- Gitlint: Git commit style based on project requirements
- License Check: Check for conflicting licenses
- Run “twister” script
  - Run kernel tests in QEMU (can vote -1 on errors)
  - Build various samples for different boards (can vote -1 on errors)
- Verify documentation builds correctly.

**Note:** “checkpatch” is a Perl script that uses regular expressions to extract information that requires a C language parser to process accurately. As such it sometimes issues false positives. Known cases include constructs like:

```c
static uint8_t __aligned(PAGE_SIZE) page_pool[PAGE_SIZE * POOL_PAGES];
IOPCTL_Type *base = config->base;
```

Both lines produce a diagnostic regarding spaces around the * operator: the first is misidentified as a pointer type declaration that would be correct as PAGE_SIZE * POOL_PAGES while the second is misidentified as a multiplication expression that would be correct as IOPCTL_Type * base.

Maintainers can override the -1 in cases where the CI infrastructure gets the wrong answer.

9.6.3 Labeling issues and pull requests in GitHub

The project uses GitHub issues and pull requests (PRs) to track and manage daily and long-term work and contributions to the Zephyr project. We use GitHub labels to classify and organize these issues and PRs by area, type, priority, and more, making it easier to find and report on relevant items.

All GitHub issues or pull requests must be appropriately labeled. Issues and PRs often have multiple labels assigned, to help classify them in the different available categories. When reviewing a PR, if it has missing or incorrect labels, maintainers shall fix it.

This saves us all time when searching, reduces the chances of the PR or issue being forgotten, speeds up reviewing, avoids duplicate issue reports, etc.

These are the labels we currently have, grouped by applicability:

**Labels applicable to issues only**

- `priority: {high | medium | low}`
To classify the impact and importance of a bug or feature.

Note: Issue priorities are generally set or changed during the bug-triage or TSC meetings.

- **Regression**  
  Something, which was working, but does not anymore (bug subtype).

- **Enhancement**  
  Changes/Updates/Additions to existing features.

- **Feature request**  
  A request for a new feature.

- **Feature**  
  A planned feature with a milestone.

- **Hardware Support**  
  Covers porting an existing feature (including Zephyr itself) to new hardware.

- **Duplicate**  
  This issue is a duplicate of another issue (please specify).

- **Good first issue**  
  Good for a first time contributor to take.

- **Release Notes**  
  Issues that need to be mentioned in release notes as known issues with additional information.

Any issue must be classified and labeled as either Bug, Enhancement, RFC, Feature, Feature Request or Hardware Support. More information on how feature requests are handled and become features can be found in Feature Tracking.

**Labels applicable to pull requests only**

The issue or PR describes a change to a stable API.

- **Hotfix**  
  Fix for an issue blocking development.

- **Trivial**  
  - **Maintainer**
    Maintainer review required.

- **Security Review**  
  To be reviewed by a security expert.

- **DNM**  
  This PR should not be merged (Do Not Merge). For work in progress, GitHub “draft” PRs are preferred.

- **Needs review**  
  The PR needs attention from the maintainers.

- **Backport**  
  The PR is a backport or should be backported.

- **Licensing**
The PR has licensing issues which require a licensing expert to review it.

**Note:** For all labels applicable to PRs: Please note that the label, together with PR complexity, affects how long a merge should be held to ensure proper review. See *review process* for details.

### Labels applicable to both pull requests and issues

- **area:** *

  Indicates Zephyr subsystems (e.g., `area: Kernel`, `area: I2C`, `area: Memory Management`), project functions (e.g., `area: Debugging`, `area: Documentation`, `area: Process`), or other categories (e.g., `area: Coding Style`, `area: MISRA-C`) affected by the bug or the pull request.

An area maintainer should be able to filter by an area label and find all issues and PRs which relate to that area.

- **platform:** *

  An issue or PR which affects only a particular platform.

- **dev-review**

  The issue is to be discussed in the following *dev-review* if time permits.

- **TSC**

  TSC stands for Technical Steering Committee. The issue is to be discussed in the following *TSC meeting* if time permits.

- **Breaking API Change**

  The issue or PR describes a breaking change to a stable API. See additional information in *Introducing breaking API changes*.

- **Bug**

  The issue is a bug, or the PR is fixing a bug.

- **Coverity**

  A Coverity detected issue or its fix.

- **Waiting for response**

  The Zephyr developers are waiting for the submitter to respond to a question, or address an issue.

- **Blocked**

  Blocked by another PR or issue.

- **Stale**

  An issue or a PR which seems abandoned, and requires attention by the author.

- **In progress**

  For PRs: is work in progress and should not be merged yet. For issues: Is being worked on.

- **RFC**

  The author would like input from the community. For a PR it should be considered a draft.

- **LTS**

  Long term release branch related.

- **EXT**

  Related to an external component.
9.7  Bug Reporting

To maintain traceability and relation between proposals, changes, features, and issues, it is recommended to cross-reference source code commits with the relevant GitHub issues and vice versa. Any changes that originate from a tracked feature or issue should contain a reference to the feature by mentioning the corresponding issue or pull-request identifiers.

At any time it should be possible to establish the origin of a change and the reason behind it by following the references in the code.

9.7.1  Reporting a regression issue

It could happen that the issue being reported is identified as a regression, as the use case is known to be working on earlier commit or release. In this case, providing directly the guilty commit when submitting the bug gains a lot of time in the eventual bug fixing.

To identify the commit causing the regression, several methods could be used, but tree bisecting method is an efficient one that doesn't require deep code expertise and can be used by everyone.

For this, `git bisect` is the recommended tool.

Recommendations on the process:

- Run `west update` on each bisection step.
- Once the bisection is over and a culprit identified, verify manually the result.

9.8  Communication and Collaboration

The Zephyr Discord Server is the primary chat forum used by Zephyr developers, contributors, and users.

The Zephyr project mailing lists are used as an additional communication tool by project members, contributors, and the community. There are specialized mailing lists for specific interests. Several lists are public and open. Mailing lists are always available for use in situations where Discord is unavailable or an unsuitable forum.

In general, bug reports and other issues should be reported as GitHub Issues and not broadcasted to the mailing list. The same applies to code reviews.

9.9  Code Documentation

9.9.1  API Documentation

Well documented APIs enhance the experience for developers and are an essential requirement for defining an API's success. Doxygen is a general purpose documentation tool that the Zephyr project uses for documenting APIs. It generates either an on-line documentation browser (in HTML) and/or provides input for other tools that is used to generate a reference manual from documented source files. In particular, doxygen's XML output is used as an input when producing the Zephyr project's online documentation.
9.9.2 Reference to Requirements

APIs for the most part document the implementation of requirements or advertised features and can be traced back to features. We use the API documentation as the main interface to trace implementation back to documented features. This is done using custom _doxygen_ tags that reference requirements maintained somewhere else in a requirement catalogue.

9.9.3 Test Documentation

To help understand what each test does and which functionality it tests we also document all test code using the same tools and in the same context and generate documentation for all unit and integration tests maintained in the same environment. Tests are documented using references to the APIs or functionality they validate by creating a link back to the APIs and by adding a reference to the original requirements.

9.9.4 Documentation Guidelines

Test Code

The Zephyr project uses several test methodologies, the most common being the Ztest framework. Test documentation should only be done on the entry test functions (usually prefixed with test_) and those that are called directly by the Ztest framework. Those tests are going to appear in test reports and using their name and identifier is the best way to identify them and trace back to them from requirements.

Test documentation should not interfere with the actual API documentation and needs to follow a new structure to avoid confusion. Using a consistent naming scheme and following a well-defined structure we will be able to group this documentation in its own module and identify it uniquely when parsing test data for traceability reports. Here are a few guidelines to be followed:

- All test code documentation should be grouped under the all_tests doxygen group
- All test documentation should be under doxygen groups that are prefixed with tests_

The custom doxygen @verify directive signifies that a test verifies a requirement:

```c
/**
 * @brief Tests for the Semaphore kernel object
 * @defgroup kernel_semaphore_tests Semaphore
 * @ingroup all_tests
 * @
 */
...
/**
 * @brief A brief description of the tests
 * @Some details about the test
 * @ more details
 * @verify[@req{1111}]
 */
void test_sema_thread2thread(void)
{
...
}
...
/**
(continues on next page)
To get coverage of how an implementation or a piece of code satisfies a requirements, we use the `satisfy` alias in doxygen:

```c
/**
 * @brief Give a semaphore.
 * 
 * This routine gives @a sem, unless the semaphore is already at its maximum
 * permitted count.
 * 
 * @note Can be called by ISRs.
 * 
 * @param sem Address of the semaphore.
 * 
 * @satisfy{req{015}}
 */
__syscall void k_sem_give(struct k_sem *sem);
```

To generate the matrix, you will first need to build the documentation, specifically you will need to build the doxygen XML output:

```
$ make doxygen
```

Parse the generated XML data from doxygen to generate the traceability matrix.

The Zephyr project defines a development process workflow using GitHub Issues to track feature, enhancement, and bug reports together with GitHub Pull Requests (PRs) for submitting and reviewing changes. Zephyr community members work together to review these Issues and PRs, managing feature enhancements and quality improvements of Zephyr through its regular releases, as outlined in the program management overview.

We can only manage the volume of Issues and PRs, by requiring timely reviews, feedback, and responses from the community and contributors, both for initial submissions and for follow-up questions and clarifications. Read about the project's development processes and tools and specifics about review timelines to learn about the project's goals and guidelines for our active developer community.

*TSC Project Roles* describes in detail the Zephyr project roles and associated permissions with respect to the development process workflow.

## 9.10 Terminology

- **mainline**: The main tree where the core functionality and core features are being developed.
- **subsystem/feature branch**: is a branch within the same repository. In our case, we will use the term branch also when referencing branches not in the same repository, which are a copy of a repository sharing the same history.
- **upstream**: A parent branch the source code is based on. This is the branch you pull from and push to, basically your upstream.
- **LTS**: Long Term Support
Chapter 10

Security

These documents describe the requirements, processes, and developer guidelines for ensuring security is addressed within the Zephyr project.

10.1 Zephyr Security Overview

10.1.1 Introduction

This document outlines the steps of the Zephyr Security Subcommittee towards a defined security process that helps developers build more secure software while addressing security compliance requirements. It presents the key ideas of the security process and outlines which documents need to be created. After the process is implemented and all supporting documents are created, this document is a top-level overview and entry point.

Overview and Scope

We begin with an overview of the Zephyr development process, which mainly focuses on security functionality.

In subsequent sections, the individual parts of the process are treated in detail. As depicted in Figure 1, these main steps are:

1. **Secure Development**: Defines the system architecture and development process that ensures adherence to relevant coding principles and quality assurance procedures.

2. **Secure Design**: Defines security procedures and implement measures to enforce them. A security architecture of the system and relevant sub-modules is created, threats are identified, and countermeasures designed. Their correct implementation and the validity of the threat models are checked by code reviews. Finally, a process shall be defined for reporting, classifying, and mitigating security issues.

3. **Security Certification**: Defines the certifiable part of the Zephyr RTOS. This includes an evaluation target, its assets, and how these assets are protected. Certification claims shall be determined and backed with appropriate evidence.

Intended Audience

This document is a guideline for the development of a security process by the Zephyr Security Subcommittee and the Zephyr Technical Steering Committee. It provides an overview of the Zephyr security process for (security) engineers and architects.
Nomenclature

In this document, the keywords “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” are to be interpreted as described in [?]. These words are used to define absolute requirements (or prohibitions), highly recommended requirements, and truly optional requirements. As noted in RFC-2119, “These terms are frequently used to specify behavior with security implications. The effects on security of not implementing a MUST or SHOULD, or doing something the specification says MUST NOT or SHOULD NOT be done may be very subtle. Document authors should take the time to elaborate the security implications of not following recommendations or requirements as most implementors will not have had the benefit of the experience and discussion that produced the specification.”

Security Document Update

This document is a living document. As new requirements, features, and changes are identified, they will be added to this document through the following process:

1. Changes will be submitted from the interested party(ies) via pull requests to the Zephyr documentation repository.
2. The Zephyr Security Subcommittee will review these changes and provide feedback or acceptance of the changes.
3. Once accepted, these changes will become part of the document.

10.1.2 Current Security Definition

This section recapitulates the current status of secure development within the Zephyr RTOS. Currently, focus is put on functional security and code quality assurance, although additional security features are scoped.

The three major security measures currently implemented are:

- **Security Functionality** with a focus on cryptographic algorithms and protocols. Support for cryptographic hardware is scoped for future releases. The Zephyr runtime architecture
is a monolithic binary and removes the need for dynamic loaders, thereby reducing the exposed attack surface.

- **Quality Assurance** is driven by using a development process that requires all code to be reviewed before being committed to the common repository. Furthermore, the reuse of proven building blocks such as network stacks increases the overall quality level and guarantees stable APIs. Static code analyses provide additional quality checks.

- **Execution Protection** including thread separation, stack and memory protection is currently available in the upstream Zephyr RTOS starting with version 1.9.0 (stack protection). Memory protection and thread separation were added in version 1.10.0 for X86 and in version 1.11.0 for ARM and ARC.

These topics are discussed in more detail in the following subsections.

### Security Functionality

The security functionality in Zephyr hinges mainly on the inclusion of cryptographic algorithms, and on its monolithic system design.

The cryptographic features are provided through a set of cryptographic libraries. Applications can choose TinyCrypt2 or Mbed TLS based on their needs. TinyCrypt2 supports key cryptographic algorithms required by the connectivity stacks. TinyCrypt2, however, only provides a limited set of algorithms. Mbed TLS supports a wider range of algorithms, but at the cost of additional requirements such as malloc support. Applications can choose the solution that matches their individual requirements. Future work may include APIs to abstract the underlying crypto library choice.

APIs for vendor specific cryptographic IPs in both hardware and software are planned, including secure key storage in the form of secure access modules (SAMs), Trusted Platform Modules (TPMs), and Trusted Execution Environments (TEEs).

The security architecture is based on a monolithic design where the Zephyr kernel and all applications are compiled into a single static binary. System calls are implemented as function calls without requiring context switches. Static linking eliminates the potential for dynamically loading malicious code.

Additional protection features are available in later releases. Stack protection mechanisms are provided to protect against stack overruns. In addition, applications can take advantage of thread separation features to split the system into privileged and unprivileged execution environments. Memory protection features provide the capability to partition system resources (memory, peripheral address space, etc.) and assign resources to individual threads or groups of threads. Stack, thread execution level, and memory protection constraints are enforced at the time of context switch.

### Quality Assurance

The Zephyr project uses an automated quality assurance process. The goal is to have a process including mandatory code reviews, feature and issue management/tracking, and static code analyses.

Code reviews are documented and enforced using a voting system before getting checked into the repository by the responsible subsystem’s maintainer. The main goals of the code review are:

- Verifying correct functionality of the implementation
- Increasing the readability and maintainability of the contributed source code
- Ensuring appropriate usage of string and memory functions
- Validation of the user input
• Reviewing the security relevant code for potential issues

The current coding principles focus mostly on coding styles and conventions. Functional correctness is ensured by the build system and the experience of the reviewer. Especially for security relevant code, concrete and detailed guidelines need to be developed and aligned with the developers (see: Secure Coding).

Static code analyses are run on the Zephyr code tree on a regular basis, see Static Code Analysis.

Bug and issue tracking and management is performed using Github. The term “survivability” was coined to cover pro-active security tasks such as security issue categorization and management. A problem identified as vulnerability is managed within Github security advisories.

Issues determined by static analyses should have more stringent reviews before they are closed as non-issues (at least another person educated in security processes need to agree on non-issue before closing).

A security subcommittee has been formed to develop a security process in more detail; this document is part of that process.

Execution Protection

Execution protection is supported and can be categorized into the following tasks:

• **Memory separation**: Memory will be partitioned into regions and assigned attributes based on the owner of that region of memory. Threads will only have access to regions they control.

• **Stack protection**: Stack guards would provide mechanisms for detecting and trapping stack overruns. Individual threads should only have access to their own stacks.

• **Thread separation**: Individual threads should only have access to their own memory resources. As threads are scheduled, only memory resources owned by that thread will be accessible. Topics such as program flow protection and other measures for tamper resistance are currently not in scope.

System Level Security (Ecosystem, …)

System level security encompasses a wide variety of categories. Some examples of these would be:

• Secure/trusted boot

• Over the air (OTA) updates

• External Communication

• Device authentication

• Access control of onboard resources
  – Flash updating
  – Secure storage
  – Peripherals

• Root of trust

• Reduction of attack surface

Some of these categories are interconnected and rely on multiple pieces to be in place to produce a full solution for the application.
10.1.3 Secure Development Process

The development of secure code shall adhere to certain criteria. These include coding guidelines and development processes that can be roughly separated into two categories related to software quality and related to software security. Furthermore, a system architecture document shall be created and kept up-to-date with future development.

System Architecture

A high-level schematic of the Zephyr system architecture is given in Figure 2. It separates the architecture into an OS part (kernel + OS Services) and a user-specific part (Application Services). The OS part itself contains low-level, platform specific drivers and the generic implementation of I/O APIs, file systems, kernel-specific functions, and the cryptographic library.

A document describing the system architecture and design choices shall be created and kept up to date with future development. This document shall include the base architecture of the Zephyr OS and an overview of important submodules. For each of the modules, a dedicated architecture document shall be created and evaluated against the implementation. These documents shall serve as an entry point to new developers and as a basis for the security architecture. Please refer to the Zephyr subsystem documentation for detailed information.
Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. These standards are included in the Zephyr Project documentation, specifically in its Secure Coding section. In [?], the following, widely accepted principles for protection mechanisms are defined to prevent security violations and limit their impact:

- **Open design** as a design principle incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well established cryptographic libraries shall be used.

- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [?] and abstracted APIs.

- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.

- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [?].

- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [?].

- **Least privilege** describes an access model in which each user, program and thread shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.

- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [?] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.

- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure its usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth**: do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth [?] paradigm shall be used.

- **Less commonly used services off by default**: to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely used (a threshold of 80% is given in [?]). For the Zephyr project, this can be realized using the configuration management. Each functionality and module shall be represented as a configuration option and needs to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use case can be disabled. The user shall be notified if low-level options and APIs are enabled but not used by the application.

- **Change management**: to guarantee a traceability of changes to the system, each change shall follow a specified process including a change request, impact analysis, ratification, implementation, and validation phase. In each stage, appropriate documentation shall be provided. All commits shall be related to a bug report or change request in the issue tracker. Commits without a valid reference shall be denied.

Based on these design principles and commonly accepted best practices, a secure development guide shall be developed, published, and implemented into the Zephyr development process.
Further details on this are given in the *Secure Design* section.

**Quality Assurance**

The quality assurance part encompasses the following criteria:

- **Adherence to the Coding Conventions** with respect to coding style, naming schemes of modules, functions, variables, and so forth. This increases the readability of the Zephyr code base and eases the code review. These coding conventions are enforced by automated scripts prior to check-in.

- **Adherence to Deployment Guidelines** is required to ensure consistent releases with a well-documented feature set and a trackable list of security issues.

- **Code Reviews** ensure the functional correctness of the code base and shall be performed on each proposed code change prior to check-in. Code reviews shall be performed by at least one independent reviewer other than the author(s) of the code change. These reviews shall be performed by the subsystem maintainers and developers on a functional level and are to be distinguished from security reviews as laid out in the *Secure Design* section. Refer to the *Project and Governance* documentation for more information.

- **Static Code Analysis** tools efficiently detect common coding mistakes in large code bases. All code shall be analyzed using an appropriate tool prior to merges into the main repository. This is not per individual commit, but is to be run on some interval on specific branches. It is mandatory to remove all findings or waive potential false-positives before each release. Waivers shall be documented centrally and in the form of a comment inside the source code itself. The documentation shall include the employed tool and its version, the date of the analysis, the branch and parent revision number, the reason for the waiver, the author of the respective code, and the approver(s) of the waiver. This shall as a minimum run on the main release branch and on the security branch. It shall be ensured that each release has zero issues with regard to static code analysis (including waivers). Refer to the *Project and Governance* documentation for more information.

- **Complexity Analyses** shall be performed as part of the development process and metrics such as cyclomatic complexity shall be evaluated. The main goal is to keep the code as simple as possible.

- **Automation**: the review process and checks for coding rule adherence are a mandatory part of the precommit checks. To ensure consistent application, they shall be automated as part of the precommit procedure. Prior to merging large pieces of code in from subsystems, in addition to review process and coding rule adherence, all static code analysis must have been run and issues resolved.

**Release and Lifecycle Management**

Lifecycle management contains several aspects:

- **Device management** encompasses the possibility to update the operating system and/or security related sub-systems of Zephyr enabled devices in the field.

- **Lifecycle management**: system stages shall be defined and documented along with the transactions between the stages in a system state diagram. For security reasons, this shall include locking of the device in case an attack has been detected, and a termination if the end of life is reached.

- **Release management** describes the process of defining the release cycle, documenting releases, and maintaining a record of known vulnerabilities and mitigations. Especially for certification purposes the integrity of the release needs to be ensured in a way that later manipulation (e.g., inserting of backdoors, etc.) can be easily detected.
• **Rights management and NDAs:** if required by the chosen certification, the confidentiality and integrity of the system needs to be ensured by an appropriate rights management (e.g., separate source code repository) and non-disclosure agreements between the relevant parties. In case of a repository shared between several parties, measures shall be taken that no malicious code is checked in.

These points shall be evaluated with respect to their impact on the development process employed for the Zephyr project.

### 10.1.4 Secure Design

In order to obtain a certifiable system or product, the security process needs to be clearly defined and its application needs to be monitored and driven. This process includes the development of security related modules in all of its stages and the management of reported security issues. Furthermore, threat models need to be created for currently known and future attack vectors, and their impact on the system needs to be investigated and mitigated. Please refer to the *Secure Coding* outlined in the Zephyr project documentation for detailed information.

The software security process includes:

- **Adherence to the Secure Development Coding** is mandatory to avoid that individual components breach the system security and to minimize the vulnerability of individual modules. While this can be partially achieved by automated tests, it is inevitable to investigate the correct implementation of security features such as countermeasures manually in security-critical modules.

- **Security Reviews** shall be performed by a security architect in preparation of each security-targeted release and each time a security-related module of the Zephyr project is changed. This process includes the validation of the effectiveness of implemented security measures, the adherence to the global security strategy and architecture, and the preparation of audits towards a security certification if required.

- **Security Issue Management** encompasses the evaluation of potential system vulnerabilities and their mitigation as described in *Security Issue Management*.

These criteria and tasks need to be integrated into the development process for secure software and shall be automated wherever possible. On system level, and for each security related module of the secure branch of Zephyr, a directly responsible security architect shall be defined to guide the secure development process.

### Security Architecture

The general guidelines above shall be accompanied by an architectural security design on system- and module-level. The high level considerations include

- The identification of **security and compliance requirements**
- **Functional security** such as the use of cryptographic functions whenever applicable
- Design of **countermeasures** against known attack vectors
- Recording of security relevant **auditable events**
- Support for **Trusted Platform Modules (TPM)** and **Trusted Execution Environments (TEE)**
- Mechanisms to allow for **in-the-field updates** of devices using Zephyr
- Task scheduler and separation

The security architecture development is based on assets derived from the structural overview of the overall system architecture. Based on this, the individual steps include:
1. **Identification of assets** such as user data, authentication and encryption keys, key generation data (obtained from RNG), security relevant status information.

2. **Identification of threats** against the assets such as breaches of confidentiality, manipulation of user data, etc.

3. **Definition of requirements** regarding security and protection of the assets, e.g., countermeasures or memory protection schemes.

The security architecture shall be harmonized with the existing system architecture and implementation to determine potential deviations and mitigate existing weaknesses. Newly developed sub-modules that are integrated into the secure branch of the Zephyr project shall provide individual documents describing their security architecture. Additionally, their impact on the system level security shall be considered and documented.

**Security Vulnerability Reporting**

Please see [Security Vulnerability Reporting](#) for information on reporting security vulnerabilities.

**Threat Modeling and Mitigation**

The modeling of security threats against the Zephyr RTOS is required for the development of an accurate security architecture and for most certification schemes. The first step of this process is the definition of assets to be protected by the system. The next step then models how these assets are protected by the system and which threats against them are present. After a threat has been identified, a corresponding threat model is created. This model contains the asset and system vulnerabilities, as well as the description of the potential exploits of these vulnerabilities. Additionally, the impact on the asset, the module it resides in, and the overall system is to be estimated. This threat model is then considered in the module and system security architecture and appropriate countermeasures are defined to mitigate the threat or limit the impact of exploits.

In short, the threat modeling process can be separated into these steps (adapted from [?]):

1. Definition of assets
2. Application decomposition and creation of appropriate data flow diagrams (DFDs)
3. Threat identification and categorization using the [?] and [?] approaches
4. Determination of countermeasures and other mitigation approaches

This procedure shall be carried out during the design phase of modules and before major changes of the module or system architecture. Additionally, new models shall be created, or existing ones shall be updated whenever new vulnerabilities or exploits are discovered. During security reviews, the threat models and the mitigation techniques shall be evaluated by the responsible security architect.

From these threat models and mitigation techniques tests shall be derived that prove the effectiveness of the countermeasures. These tests shall be integrated into the continuous integration workflow to ensure that the security is not impaired by regressions.

**Vulnerability Analyses**

In order to find weak spots in the software implementation, vulnerability analyses (VA) shall be performed. Of special interest are investigations on cryptographic algorithms, critical OS tasks, and connectivity protocols.

On a pure software level, this encompasses

- **Penetration testing** of the RTOS on a particular hardware platform, which involves testing the respective Zephyr OS configuration and hardware as one system.
• **Side channel attacks** (timing invariance, power invariance, etc.) should be considered. For instance, ensuring **timing invariance** of the cryptographic algorithms and modules is required to reduce the attack surface. This applies to both the software implementations and when using cryptographic hardware.

• **Fuzzing tests** shall be performed on both exposed APIs and protocols.

The list given above serves primarily illustration purposes. For each module and for the complete Zephyr system (in general on a particular hardware platform), a suitable VA plan shall be created and executed. The findings of these analyses shall be considered in the security issue management process, and learnings shall be formulated as guidelines and incorporated into the secure coding guide.

If possible (as in case of fuzzing analyses), these tests shall be integrated into the continuous integration process.

### 10.1.5 Security Certification

One goal of creating a secure branch of the Zephyr RTOS is to create a certifiable system or certifiable submodules thereof. The certification scope and scheme are yet to be decided. However, many certifications such as Common Criteria require evidence that the evaluation claims are indeed fulfilled, so a general certification process is outlined in the following. Based on the final choices for the certification scheme and evaluation level, this process needs to be refined.

**Generic Certification Process**

In general, the steps towards a certification or precertification (compare [?]) are:

1. The **definition of assets** to be protected within the Zephyr RTOS. Potential candidates are confidential information such as cryptographic keys, user data such as communication logs, and potentially IP of the vendor or manufacturer.

2. Developing a **threat model** and **security architecture** to protect the assets against exploits of vulnerabilities of the system. As a complete threat model includes the overall product including the hardware platform, this might be realized by a split model containing a precertified secure branch of Zephyr which the vendor could use to certify their Zephyr-enabled product.

3. Formulating an **evaluation target** that includes the **certification claims** on the security of the assets to be evaluated and certified, as well as assumptions on the operating conditions.

4. Providing **proof** that the claims are fulfilled. This includes consistent documentation of the security development process, etc.

These steps are partially covered in previous sections as well. In contrast to these sections, the certification process only requires to consider those components that shall be covered by the certification. The security architecture, for example, considers assets on system level and might include items not relevant for the certification.

**Certification Options**

For the security certification as such, the following options can be pursued:

1. **Abstract precertification of Zephyr as a pure software system**: this option requires assumptions on the underlying hardware platform and the final application running on top of Zephyr. If these assumptions are met by the hardware and the application, a full certification can be more easily achieved. This option is the most flexible approach but puts the largest burden on the product vendor.
2. **Certification of Zephyr on specific hardware platform without a specific application in mind**: this scenario describes the enablement of a secure platform running the Zephyr RTOS. The hardware manufacturer certifies the platform under defined assumptions on the application. If these are met, the final product can be certified with little effort.

3. **Certification of an actual product**: in this case, a full product including a specific hardware, the Zephyr RTOS, and an application is certified.

In all three cases, the certification scheme (e.g., FIPS 140-2 or Common Criteria), the scope of the certification (main-stream Zephyr, security branch, or certain modules), and the certification/assurance level need to be determined.

In case of partial certifications (options 1 and 2), assumptions on hardware and/or software are required for certifications. These can include:

- **Appropriate physical security** of the hardware platform and its environment.
- **Sufficient protection of storage and timing channels** on the hardware platform itself and all connected devices. (No mentioning of remote connections.)
- Only **trusted/assured applications** running on the device
- The device and its software stack is configured and operated by **properly trained and trusted individuals** with no malicious intent.

These assumptions shall be part of the security claim and evaluation target documents.

### 10.2 Security Vulnerability Reporting

#### 10.2.1 Introduction

Vulnerabilities to the Zephyr project may be reported via email to the vulnerabilities@zephyrproject.org mailing list. These reports will be acknowledged and analyzed by the security response team within 1 week. Each vulnerability will be entered into the Zephyr Project security advisory GitHub. The original submitter will be granted permission to view the issues that they have reported.

#### 10.2.2 Security Issue Management

Issues within this bug tracking system will transition through a number of states according to this diagram:
- **New**: This state represents new reports that have been entered directly by a reporter. When entered by the response team in response to an email, the issue shall be transitioned directly to Triage.

- **Triage**: This issue is awaiting Triage by the response team. The response team will analyze the issue, determine a responsible entity, assign it to that individual, and move the issue to the Assigned state. Part of triage will be to set the issue's priority.

- **Assigned**: The issue has been assigned, and is awaiting a fix by the assignee.

- **Review**: Once there is a Zephyr pull request for the issue, the PR link will be added to a comment in the issue, and the issue moved to the Review state.

- **Accepted**: Indicates that this issue has been merged into the appropriate branch within Zephyr.

- **Public**: The embargo period has ended. The issue will be made publicly visible, the associ-
ated CVE updated, and the vulnerabilities page in the docs updated to include the detailed information.

The security advisories created are kept private, due to the sensitive nature of security reports. The issues are only visible to certain parties:

- Members of the PSIRT mailing list
- the reporter
- others, as proposed and ratified by the Zephyr Security Subcommittee. In the general case, this will include:
  - The code owner responsible for the fix.
  - The Zephyr release owners for the relevant releases affected by this vulnerability.

The Zephyr Security Subcommittee shall review the reported vulnerabilities during any meeting with more than three people in attendance. During this review, they shall determine if new issues need to be embargoed.

The guideline for embargo will be based on: 1. Severity of the issue, and 2. Exploitability of the issue. Issues that the subcommittee decides do not need an embargo will be reproduced in the regular Zephyr project bug tracking system.

Security sensitive vulnerabilities shall be made public after an embargo period of at most 90 days. The intent is to allow 30 days within the Zephyr project to fix the issues, and 60 days for external parties building products using Zephyr to be able to apply and distribute these fixes.

Fixes to the code shall be made through pull requests PR in the Zephyr project github. Developers shall make an attempt to not reveal the sensitive nature of what is being fixed, and shall not refer to CVE numbers that have been assigned to the issue. The developer instead should merely describe what has been fixed.

The security subcommittee will maintain information mapping embargoed CVEs to these PRs (this information is within the Github security advisories), and produce regular reports of the state of security issues.

Each issue that is considered a security vulnerability shall be assigned a CVE number. As fixes are created, it may be necessary to allocate additional CVE numbers, or to retire numbers that were assigned.

10.2.3 Vulnerability Notification

Each Zephyr release shall contain a report of CVEs that were fixed in that release. Because of the sensitive nature of these vulnerabilities, the release shall merely include a list of CVEs that have been fixed. After the embargo period, the vulnerabilities page shall be updated to include additional details of these vulnerabilities. The vulnerability page shall give credit to the reporter(s) unless a reporter specifically requests anonymity.

The Zephyr project shall maintain a vulnerability-alerts mailing list. This list will be seeded initially with a contact from each project member. Additional parties can request to join this list by filling out the form at the Vulnerability Registry. These parties will be vetted by the project director to determine that they have a legitimate interest in knowing about security vulnerabilities during the embargo period.

Periodically, the security subcommittee will send information to this mailing list describing known embargoed issues, and their backport status within the project. This information is intended to allow them to determine if they need to backport these changes to any internal trees.

When issues have been triaged, this list will be informed of:

- The Zephyr Project security advisory link (GitHub).
- The CVE number assigned.
• The subsystem involved.
• The severity of the issue.

After acceptance of a PR fixing the issue (merged), in addition to the above, the list will be informed of:

• The association between the CVE number and the PR fixing it.
• Backport plans within the Zephyr project.

10.2.4 Backporting of Security Vulnerabilities

Each security issue fixed within zephyr shall be backported to the following releases:

• The current Long Term Stable (LTS) release.
• The most recent two releases.

The developer of the fix shall be responsible for any necessary backports, and apply them to any of the above listed release branches, unless the fix does not apply (the vulnerability was introduced after this release was made). All recommendations for vulnerability fixes apply for backport pull requests (and associated issues). Additionally, it is recommended that the developer privately informs the responsible release manager that the backport pull request and issue are addressing a vulnerability.

Backports will be tracked on the security advisory.

10.2.5 Need to Know

Due to the sensitive nature of security vulnerabilities, it is important to share details and fixes only with those parties that have a need to know. The following parties will need to know details about security vulnerabilities before the embargo period ends:

• Maintainers will have access to all information within their domain area only.
• The current release manager, and the release manager for historical releases affected by the vulnerability (see backporting above).
• The Project Security Incident Response (PSIRT) team will have full access to information. The PSIRT is made up of representatives from platinum members, and volunteers who do work on triage from other members.
• As needed, release managers and maintainers may be invited to attend additional security meetings to discuss vulnerabilities.

10.3 Secure Coding

Traditionally, microcontroller-based systems have not placed much emphasis on security. They have usually been thought of as isolated, disconnected from the world, and not very vulnerable, just because of the difficulty in accessing them. The Internet of Things has changed this. Now, code running on small microcontrollers often has access to the internet, or at least to other devices (that may themselves have vulnerabilities). Given the volume they are often deployed at, uncontrolled access can be devastating.

This document describes the requirements and process for ensuring security is addressed within the Zephyr project. All code submitted should comply with these principles.

Much of this document comes from [?].

---

1 An attack resulted in a significant portion of DNS infrastructure being taken down.
10.3.1 Introduction and Scope

This document covers guidelines for the Zephyr Project, from a security perspective. Many of the ideas contained herein are captured from other open source efforts.

We begin with an overview of secure design as it relates to Zephyr. This is followed by a section on Secure development knowledge, which gives basic requirements that a developer working on the project will need to have. This section gives references to other security documents, and full details of how to write secure software are beyond the scope of this document. This section also describes vulnerability knowledge that at least one of the primary developers should have. This knowledge will be necessary for the review process described below this.

Following this is a description of the review process used to incorporate changes into the Zephyr codebase. This is followed by documentation about how security-sensitive issues are handled by the project.

Finally, the document covers how changes are to be made to this document.

10.3.2 Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. In [?], the following, widely accepted principles for protection mechanisms are defined to help prevent security violations and limit their impact:

- **Open design** as a design guideline incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well-established cryptographic libraries shall be used.

- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [?] and abstracted APIs.

- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.

- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [?).

- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [?].

- **Least privilege** describes an access model in which each user, program, and thread, shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.

- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [?] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.

- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure their usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth**: do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are
performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth paradigm shall be used.

- **Less commonly used services off by default:** to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely used (a threshold of 80% is given in []). For the Zephyr project, this can be realized using the configuration management. Each functionality and module shall be represented as a configuration option and needs to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use case can be disabled. The user shall be notified if low-level options and APIs are enabled but not used by the application.

- **Change management:** to guarantee a traceability of changes to the system, each change shall follow a specified process including a change request, impact analysis, ratification, implementation, and validation phase. In each stage, appropriate documentation shall be provided. All commits shall be related to a bug report or change request in the issue tracker. Commits without a valid reference shall be denied.

### 10.3.3 Secure development knowledge

#### Secure designer

The Zephyr project must have at least one primary developer who knows how to design secure software.

This requires understanding the following design principles, including the 8 principles from []:

- economy of mechanism (keep the design as simple and small as practical, e.g., by adopting sweeping simplifications)
- fail-safe defaults (access decisions shall deny by default, and projects’ installation shall be secure by default)
- complete mediation (every access that might be limited must be checked for authority and be non-bypassable)
- open design (security mechanisms should not depend on attacker ignorance of its design, but instead on more easily protected and changed information like keys and passwords)
- separation of privilege (ideally, access to important objects should depend on more than one condition, so that defeating one protection system won’t enable complete access. For example, multi-factor authentication, such as requiring both a password and a hardware token, is stronger than single-factor authentication)
- least privilege (processes should operate with the least privilege necessary)
- least common mechanism (the design should minimize the mechanisms common to more than one user and depended on by all users, e.g., directories for temporary files)
- psychological acceptability (the human interface must be designed for ease of use - designing for “least astonishment” can help)
- limited attack surface (the set of the different points where an attacker can try to enter or extract data)
- input validation with whitelists (inputs should typically be checked to determine if they are valid before they are accepted; this validation should use whitelists (which only accept known-good values), not blacklists (which attempt to list known-bad values)).

#### Vulnerability Knowledge

A “primary developer” in a project is anyone who is familiar with the project’s code base, is comfortable making changes to it, and is acknowledged as such by most other participants in the

---

**Zephyr Project Documentation, Release 3.5.99**

3590 Chapter 10. Security
A primary developer would typically make a number of contributions over the past year (via code, documentation, or answering questions). Developers would typically be considered primary developers if they initiated the project (and have not left the project more than three years ago), have the option of receiving information on a private vulnerability reporting channel (if there is one), can accept commits on behalf of the project, or perform final releases of the project software. If there is only one developer, that individual is the primary developer.

At least one of the primary developers must know of common kinds of errors that lead to vulnerabilities in this kind of software, as well as at least one method to counter or mitigate each of them.

Examples (depending on the type of software) include SQL injection, OS injection, classic buffer overflow, cross-site scripting, missing authentication, and missing authorization. See the CWE/SANS top 25 or OWASP Top 10 for commonly used lists.

**Zephyr Security Subcommittee**

There shall be a “Zephyr Security Subcommittee”, responsible for enforcing this guideline, monitoring reviews, and improving these guidelines.

This team will be established according to the Zephyr Project charter.

**10.3.4 Code Review**

The Zephyr project shall use a code review system that all changes are required to go through. Each change shall be reviewed by at least one primary developer that is not the author of the change. This developer shall determine if this change affects the security of the system (based on their general understanding of security), and if so, shall request the developer with vulnerability knowledge, or the secure designer to also review the code. Any of these individuals shall have the ability to block the change from being merged into the mainline code until the security issues have been addressed.

**10.3.5 Issues and Bug Tracking**

The Zephyr project shall have an issue tracking system (such as GitHub) that can be used to record and track defects that are found in the system.

Because security issues are often sensitive, this issue tracking system shall have a field to indicate a security issue. Setting this field shall result in the issue only being visible to the Zephyr Security Subcommittee. In addition, there shall be a field to allow the Zephyr Security Subcommittee to add additional users that will have visibility to a given issue.

This embargo, or limited visibility, shall only be for a fixed duration, with a default being a project-decided value. However, because security considerations are often external to the Zephyr project itself, it may be necessary to increase this embargo time. The time necessary shall be clearly annotated in the issue itself.

The list of issues shall be reviewed at least once a month by the Zephyr Security Subcommittee. This review should focus on tracking the fixes, determining if any external parties need to be notified or involved, and determining when to lift the embargo on the issue. The embargo should not be lifted via an automated means, but the review team should avoid unnecessary delay in lifting issues that have been resolved.
10.3.6 Modifications to This Document

Changes to this document shall be reviewed by the Zephyr Security Subcommittee, and approved by consensus.

10.4 Sensor Device Threat Model

This document describes a threat model for an IoT sensor device. Spelling out a threat model helps direct development effort, and can be used to help prioritize these efforts as well.

This device contains a sensor of some type (for example temperature, or a pressure in a pipe), which sends this data to an SoC running a microcontroller. This microcontroller connects to a cloud service, and relays this sensor data to this service. The cloud service is also able to send configuration data to the device, as well as software update images. A general diagram can be seen in Figure 1:

![General Diagram of Sensor Device](https://www.example.com/diagram.png)

In this sensor device, the sensor connects with the SoC via an SPI bus, and the SoC has a network interface that it uses to communicate with the cloud service. The particulars of these interfaces can impact the threat model in unexpected ways, and variants on this will need to be considered (for example, using a separate network interface SoC connected via some type of bus).

This model also focuses on communicating via the MQTT-over-TLS protocol, as this seems to be in wide use.\(^1\)

10.4.1 Assets

One aspect of the threat model to consider are assets involved in the operation of the device. The following list enumerates the assets included in this model:

1. **The bootloader.** This is a small code/data image contained in on-device flash that is the first code to run. In order to establish a root of trust, this image must be immutable. This

---

\(^1\) See [https://www.slideshare.net/kartben/iot-developer-survey-2018](https://www.slideshare.net/kartben/iot-developer-survey-2018). As of this writing, the three major cloud IoT service providers, AWS IoT, Google Cloud IoT, and Microsoft Azure IoT all provide MQTT over TLS. Some feedback has suggested that some find difficulty with UDP protocols and routing issues on various networks.
model assumes that the SoC provides a mechanism to protect a region of the flash from future writes, and that this will be done after this image is programmed into the device, early in production [th-imboot].

2. **The application firmware image.** This asset consists of the remainder of the firmware run by the microcontroller. The distinction is made because this part of the image will need to be updated periodically as security vulnerabilities are discovered. Requirements for updates to this image are:
   a. The image shall only be replaced with an authorized image [th-authrepl].
   b. When an authorized replacement image is available, the update shall be done in a timely manner [th-timely-update].
   c. The image update shall be seen as atomic, meaning that when the image is run, the flash shall contain either the update image in its entirety, or the old image in its entirety [th-atomic-update].

3. **Root certificate list.** In order to authenticate the cloud service (server), the IoT device must have a list of root certificates that are allowed to sign the certificate on the server. For cloud-provider based services, this list will generally be provided by the service provider. Because the root certificates can expire, and possibly be revoked, this list will need to be periodically updated [th-root-certs], [th-root-check].

4. **Client secrets.** To authenticate the client to the service, the client must possess some kind of secret. This is generally a private key, usually either an RSA key or an EC private key. When establishing communication with the server, the device will use this secret either as part of the TLS establishment, or to sign a message used in the communication.

   This secret is generally generated by the service provider, or by software running elsewhere, and must be securely installed on the device. Policy may dictate that this secret be replaced periodically, which will require a way to update the client secret. Typically, the service will allow two or three active keys to allow this update to proceed while the old key is used.

   These secrets must be protected from read, and the smallest amount of code necessary shall have access to them. [th-secret-storage]

5. **Current date/time.** TLS certificate verification requires knowledge of the current date and time in order to determine if the current time falls within the certificate's current validity time. Also, token based client authentication will generally require the client to sign a message containing a time window that the token is valid. Certificate validation requires the device's notion of date and time to be accurate within a day or so. Token generation generally requires the time to be accurate within 5-10 minutes.

   It may be possible to approximate secure time by querying an external time server. Secure NTP is possibly beyond the capabilities of an IoT device. The main risks of having incorrect time are denial of service (the device rejects valid certificates), and the generation of tokens with invalid times. It could be possible to trick the device into generating tokens that are valid in the future, but the attacker would also have to spoof the server's certificate to be able to intercept this. [th-time]

6. **Sensor data.** The data received from the sensor itself, and delivered to the service shall be delivered without modification or tampering.

7. **Device configuration.** Various configuration data, such as the hostname of the service to connect to, the address of a time server, frequency and parameters of when sensor data is sent to the service, and other need to be kept by the device. This configuration data will need to be updated periodically as the configuration changes. Updates should be allowed only from authorized parties. [th-conf]

8. **Logs.** In order to assist with analysis of security issues, the device shall log information about security-pertinent events. IoT devices generally have limited storage, and as such, these logs need to be carefully selected. It may also be possible to send these log events
to the cloud service where they can be stored in a more resource-available environment. Types of events that should be logged include:

- **Firmware image updates.** The system should log the download of new images, and when an image is successfully updated.
- **Client secret changes.** Changes and new client secrets should be logged.
- **Changes to the device configuration.**

[th-logs]

### 10.4.2 Communication

In addition to assets, the threat model also considers the locations where data or assets are communicated between entities of the system.

1. **Flash contents.** The flash device contains several regions. The contents of flash can be modified programmatically by the SoC's CPU.

   - **The bootloader.** As described in the Assets section, the bootloader is a small section of the flash device containing the code initially run. This section shall be written early in the lifecycle of the device, and the flash device then configured to permanently disallow modification of this section. This configuration should also prevent modification via external interfaces, such as JTAG or SWD debuggers.

     The bootloader is responsible for verifying the signature of the application image as well as updating the application image from the update image when an update is needed.

     The bootloader shall verify the signature of the update image before installing it.

     The bootloader shall only accept an update image with a newer version number than the current image.

   - **The application image.** The application image contains the code executed during normal operation of the device. Before running this image, the bootloader shall verify a digital signature of the image, to avoid running an image that has been tampered with. The flash/system shall be configured such that after the bootloader has completed, the CPU will be unable to write to the application image.

   - **The update image.** This is an area of flash that holds a new version of the application image. This image will be downloaded and stored by the application during normal operation. When this has completed, the application can trigger a reboot, and the bootloader can install the new image.

   - **Secret storage.** An area of the flash will be used to store client secrets. This area is written and read by a subset of the application image. The application shall be configured to protect this area from both reads and writes by code that does not need to have access to it, giving consideration to possible exploits found within a majority of the application code. Revealing the contents of the secrets would allow the attacker to spoof this device.

     Initial secrets shall be placed in the device during a provisioning activity, distinct from normal operation of the device. Later updates can be made under the direction of communication received over a secured channel to the service.

   - **Configuration storage.** There shall be an area to store other configuration information. On resource-constrained devices, it is allowed for this to be stored in the same region as the secret storage, however, this adds additional code that has access to the secret storage area, and as such, more code that must be scrutinized.

   - **Log storage.** The device may have an area of flash where log events can be written.
2. **Sensor/Actuator interface.** In this design, the sensor or actuator communicates with the SoC via a bus, such as SPI. The hardware design shall be made to make intercepting this bus difficult for an attack. Required techniques depend on the sensitivity and use of the sensor data, and can range from having the sensor mounted on the same PCB as the MCU to epoxy potting the entire device.

3. **Communication with cloud service.** Communication between the device, and the cloud service will be done over the general internet. As such, it shall be assumed that an attacker can arbitrarily intercept this channel and, for example, return spoofed DNS results or attempt man-in-the-middle attacks against communication with cloud services.

The device shall use TLS for all communication with the cloud service [th-all-tls]. The TLS stack shall be configured to use only cipher suites that are generally considered secure\(^2\), including forward secrecy. The communication shall be secured by the following:

a. **Cipher suite selection.** The device shall only allow communication with generally agreed secure cipher suites [th-tls-ciphers].

b. **Server certificate verification.** The server presented by the server shall be verified [th-root-check].

i. **Naming.** The certificate shall name the host and service the cloud service server is providing. RFC6125 describes best practices for this. It is permissible for the device to require the certificate to be more restrictive than as described in this RFC, provided the service can use a certificate that can comply.

ii. **Path validation.** The device shall verify that the certificate chain has a valid signature path from a root certificate contained within the device, to the certificate presented by the service. RFC4158 describes this is general. The device is permitted to require a more restricted path, provided the server certificate used complies with this restriction.

iii. **Validity period.** The validity period of all presented certificates shall be checked against the device's best notion of the current time.

c. **Client authentication.** The client shall authenticate itself to the service using a secret known only to that particular device. There are several options, and the technique used is generally mandated by the particular service provider being used [th-tls-client-auth].

i. **TLS client certificates.** The TLS protocol allows the client to present a certificate, and assert its knowledge of the secret described by that certificate. Generally, these certificates will be stored within the service provider. These certificates can be self-signed, or signed by a CA. Since the service provider maintains a list of valid certificates (mapping them to a device identity), having these certificates signed by a CA does not add any additional security, but may be useful in the management of these certificates.

ii. **Token-based authentication.** It is also possible for the client to authenticate itself using the **password** field of the MQTT CONNECT packet. However, the secret itself must not be transmitted in this packet. Instead, a token-based protocol, such as RFC7519’s JSON Web Token (JWT) can be used. These tokens will generally have a small validity period (e.g. 1 hour), to prevent them from being reused if they are intercepted. The token shall not be sent until the device has verified the identity of the server.

d. **Random/Entropy source.** Cryptographic communication requires the generation of secure pseudorandom numbers. The device shall use a modern, accepted cryptographic random-bit generator to generate these random numbers. It shall use either a Non-Deterministic Random Bit Generator (True RBG) implemented in hardware within the SoC, or a Deterministic Random Bit Generator (Pseudo RBG) seeded by

\(^2\) As new exploits are discovered, what is considered secure can change. Organizations such as [https://www.ssllabs.com/](https://www.ssllabs.com/) provide information on current ideas of how TLS must be configured to be secure.
an entropy source within the SoC. Please see NIST SP 800-90A for information on approved RBGs and NIST SP 800-90B for information on testing a device's entropy source [th-entropy].

4. **Communication with the time service.** Ideally, the device shall contain hardware that maintains a secure time. However, most SoCs in use do not have support for this, and it will be necessary to consult an external time service. RFC4330 and referenced RFCs describe the Simple Network Time Protocol that can be used to query the current time from a network time server.

5. **Device lifecycle.** An IoT device will have a lifecycle from production to destruction and disposal of the device. Aspects of this lifecycle that impact security include initial provisioning, normal operation, re-provisioning, and destruction.
   a. **Initial provisioning.** During the initial provisioning stage, it is necessary to program the bootloader, an initial application image, a device secret, and initial configuration data [th-initial-provision]. In addition, the bootloader flash protection shall be installed. Of this information, only the device secret needs to differ per device. This secret shall be securely maintained, and destroyed in all locations outside of the device once it has been programmed [th-initial-secret].
   b. **Normal operation.** Normal operation includes the behavior described by the rest of this document.
   c. **Re-provisioning.** Sometimes it is necessary to re-provision a device, such as for a different application. One way to do this is to keep the same device secret, and replace the configuration data, as well as the cloud service data associated with the device. It is also possible to program a new device secret, but if this is done it shall be done securely, and the new secret destroyed externally once programmed into the device [th-reprovision].
   d. **Destruction.** To prevent the device secret from being used to spoof the device, upon decommissioning, the secret for a particular device shall be rendered ineffective [th-destruction]. Possibilities include:
      i. Hardware destruction of the device.
      ii. Securely wiping the flash area containing the secret\(^3\).
      iii. Removing the device identity and certificate from the service.

### 10.4.3 Other Considerations

In addition to the above, network connected devices generally will need a way to configure them to connect to the network environment they are placed in. There are numerous ways of doing this, and it is important for these configuration methods to not circumvent the security requirements described above.

### 10.4.4 Threats

### 10.4.5 Notes

### 10.5 Hardening Tool

Before launching a product, it’s crucial to ensure that your software is as secure as possible. This process, known as “hardening”, involves strengthening the security of a system to protect it from potential threats and vulnerabilities.

\(^3\) Note that merely erasing this flash area is unlikely to be sufficient.
At a high-level, hardening a Zephyr application can be seen as a two-fold process:

1. Disabling features and compilation flags that might lead to security vulnerabilities (ex. making sure that no “experimental” features are being used, disabling features typically used for debugging purposes such as assertions, shell, etc.).

2. Enabling optional features that can lead to improve security (ex. stack sentinel, hardware stack protection, etc.). Some of these features might be hardware-dependent.

To simplify this process, Zephyr offers a hardening tool designed to analyze an application’s configuration against a set of hardening preferences defined by the Security Working Group. The tool looks at the KConfig options in the build target and provides tailored suggestions and recommendations to adjust security-related options.

### 10.5.1 Usage

Using west:

```bash
west build -b reel_board samples/hello_world
west build -t hardenconfig
```

Using CMake and ninja:

```bash
# Use cmake to configure a Ninja-based build system:
cmake -B build -GNinja -DBOARD=reel_board samples/hello_world
# Now run the build tool on the generated build system:
ninja -C build hardenconfig
```

The output should be similar to the table below. For each configuration option set to a value that could lead to a security vulnerability, the table will propose a recommended value that should be used instead.

<table>
<thead>
<tr>
<th>name</th>
<th>current</th>
<th>recommended</th>
<th>check result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONFIG_BOOT_BANNER</td>
<td>y</td>
<td>n</td>
<td>FAIL</td>
</tr>
<tr>
<td>CONFIG_BUILD_OUTPUT_STRIPED</td>
<td>n</td>

</table>

### 10.6 Vulnerabilities

This page collects all of the vulnerabilities that are discovered and fixed in each release. It will also often have more details than is available in the releases. Some vulnerabilities are deemed to be sensitive, and will not be publicly discussed until there is sufficient time to fix them. Because the release notes are locked to a version, the information here can be updated after the embargo is lifted.

#### 10.6.1 CVE-2017
CVE-2017-14199

Buffer overflow in getaddrinfo().

- CVE-2017-14199
- Zephyr project bug tracker ZEPSEC-12
- PR6158 fix for 1.11.0

CVE-2017-14201

The shell DNS command can cause unpredictable results due to misuse of stack variables.

Use After Free vulnerability in the Zephyr shell allows a serial or telnet connected user to cause denial of service, and possibly remote code execution.

This has been fixed in release v1.14.0.

- CVE-2017-14201
- Zephyr project bug tracker ZEPSEC-17
- PR13260 fix for v1.14.0

CVE-2017-14202

The shell implementation does not protect against buffer overruns resulting in unpredictable behavior.

Improper Restriction of Operations within the Bounds of a Memory Buffer vulnerability in the shell component of Zephyr allows a serial or telnet connected user to cause a crash, possibly with arbitrary code execution.

This has been fixed in release v1.14.0.

- CVE-2017-14202
- Zephyr project bug tracker ZEPSEC-18
- PR13048 fix for v1.14.0

10.6.2  CVE-2019

CVE-2019-9506

The Bluetooth BR/EDR specification up to and including version 5.1 permits sufficiently low encryption key length and does not prevent an attacker from influencing the key length negotiation. This allows practical brute-force attacks (aka “KNOB”) that can decrypt traffic and inject arbitrary ciphertext without the victim noticing.

- CVE-2019-9506
- Zephyr project bug tracker ZEPSEC-20
- PR18702 fix for v1.14.0
- PR18659 fix for v2.0.0
10.6.3 CVE-2020

CVE-2020-10019

Buffer Overflow vulnerability in USB DFU of zephyr allows a USB connected host to cause possible remote code execution.

This has been fixed in releases v1.14.2, v2.2.0, and v2.1.1.
  - CVE-2020-10019
  - Zephyr project bug tracker ZEPSEC-25
  - PR23460 fix for 1.14.x
  - PR23457 fix for 2.1.x
  - PR23190 fix in 2.2.0

CVE-2020-10021

Out-of-bounds write in USB Mass Storage with unaligned sizes

Out-of-bounds Write in the USB Mass Storage memoryWrite handler with unaligned Sizes.

See NCC-ZEP-024, NCC-ZEP-025, NCC-ZEP-026

This has been fixed in releases v1.14.2, and v2.2.0.
  - CVE-2020-10021
  - Zephyr project bug tracker ZEPSEC-26
  - PR23455 fix for v1.14.2
  - PR23456 fix for the v2.1 branch
  - PR23240 fix for v2.2.0

CVE-2020-10022

UpdateHub Module Copies a Variable-Size Hash String Into a Fixed-Size Array

A malformed JSON payload that is received from an UpdateHub server may trigger memory corruption in the Zephyr OS. This could result in a denial of service in the best case, or code execution in the worst case.

See NCC-ZEP-016

This has been fixed in the below pull requests for main, branch from v2.1.0, and branch from v2.2.0.
  - CVE-2020-10022
  - Zephyr project bug tracker ZEPSEC-28
  - PR24154 fix for main
  - PR24065 fix for branch from v2.1.0
  - PR24066 fix for branch from v2.2.0
CVE-2020-10023

Shell Subsystem Contains a Buffer Overflow Vulnerability In shell_spaces_trim

The shell subsystem contains a buffer overflow, whereby an adversary with physical access to the device is able to cause a memory corruption, resulting in denial of service or possibly code execution within the Zephyr kernel.

See NCC-ZEP-019

This has been fixed in releases v1.14.2, v2.2.0, and in a branch from v2.1.0,

- CVE-2020-10023
- Zephyr project bug tracker ZEPSEC-29
- PR23646 fix for v1.14.2
- PR23649 fix for branch from v2.1.0
- PR23304 fix for v2.2.0

CVE-2020-10024

ARM Platform Uses Signed Integer Comparison When Validating Syscall Numbers

The arm platform-specific code uses a signed integer comparison when validating system call numbers. An attacker who has obtained code execution within a user thread is able to elevate privileges to that of the kernel.

See NCC-ZEP-001

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0,

- CVE-2020-10024
- Zephyr project bug tracker ZEPSEC-30
- PR23535 fix for v1.14.2
- PR23498 fix for branch from v2.1.0
- PR23323 fix for v2.2.0

CVE-2020-10027

ARC Platform Uses Signed Integer Comparison When Validating Syscall Numbers

An attacker who has obtained code execution within a user thread is able to elevate privileges to that of the kernel.

See NCC-ZEP-001

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0,

- CVE-2020-10027
- Zephyr project bug tracker ZEPSEC-35
- PR23500 fix for v1.14.2
- PR23499 fix for branch from v2.1.0
- PR23328 fix for v2.2.0
CVE-2020-10028

Multiple Syscalls In GPIO Subsystem Performs No Argument Validation

Multiple syscalls with insufficient argument validation

See NCC-ZEP-006

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0.

- CVE-2020-10028
- Zephyr project bug tracker ZEPSEC-32
- PR23733 fix for v1.14.2
- PR23737 fix for branch from v2.1.0
- PR23308 fix for v2.2.0 (gpio patch)

CVE-2020-10058

Multiple Syscalls In kscan Subsystem Performs No Argument Validation

Multiple syscalls in the Kscan subsystem perform insufficient argument validation, allowing code executing in userspace to potentially gain elevated privileges.

See NCC-ZEP-006

This has been fixed in a branch from v2.1.0, and release v2.2.0.

- CVE-2020-10058
- Zephyr project bug tracker ZEPSEC-34
- PR23748 fix for branch from v2.1.0
- PR23308 fix for v2.2.0 (kscan patch)

CVE-2020-10059

UpdateHub Module Explicitly Disables TLS Verification

The UpdateHub module disables DTLS peer checking, which allows for a man in the middle attack. This is mitigated by firmware images requiring valid signatures. However, there is no benefit to using DTLS without the peer checking.

See NCC-ZEP-018

This has been fixed in a PR against Zephyr main.

- CVE-2020-10059
- Zephyr project bug tracker ZEPSEC-36
- PR24954 fix on main (to be fixed in v2.3.0)
- PR24954 fix v2.1.0
- PR24954 fix v2.2.0
CVE-2020-10060

UpdateHub Might Dereference An Uninitialized Pointer

In updatehub_probe, right after JSON parsing is complete, objects[1] is accessed from the output structure in two different places. If the JSON contained less than two elements, this access would reference uninitialized stack memory. This could result in a crash, denial of service, or possibly an information leak.

Recommend disabling updatehub until such a time as a fix can be made available.

See NCC-ZEP-030

This has been fixed in a PR against Zephyr main.

- CVE-2020-10060
- Zephyr project bug tracker ZEPSEC-37
- PR27865 fix on main (to be fixed in v2.4.0)
- PR27865 fix for v2.3.0
- PR27865 fix for v2.2.0
- PR27865 fix for v2.1.0

CVE-2020-10061

Error handling invalid packet sequence

Improper handling of the full-buffer case in the Zephyr Bluetooth implementation can result in memory corruption.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- CVE-2020-10061
- Zephyr project bug tracker ZEPSEC-75
- PR23516 fix for v2.3 (split driver)
- PR23517 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23547 fix for branch from v2.2.0

CVE-2020-10062

Packet length decoding error in MQTT

CVE: An off-by-one error in the Zephyr project MQTT packet length decoder can result in memory corruption and possible remote code execution. NCC-ZEP-031

The MQTT packet header length can be 1 to 4 bytes. An off-by-one error in the code can result in this being interpreted as 5 bytes, which can cause an integer overflow, resulting in memory corruption.

This has been fixed in main for v2.3.

- CVE-2020-10062
- Zephyr project bug tracker ZEPSEC-84
- commit 11b7a37d for v2.3
- NCC-ZEP report (NCC-ZEP-031)
**CVE-2020-10063**

Remote Denial of Service in CoAP Option Parsing Due To Integer Overflow

A remote adversary with the ability to send arbitrary CoAP packets to be parsed by Zephyr is able to cause a denial of service.

This has been fixed in main for v2.3.

- CVE-2020-10063
- Zephyr project bug tracker ZEPSEC-55
- PR24435 fix in main for v2.3
- PR24531 fix for branch from v2.2
- PR24535 fix for branch from v2.1
- PR24530 fix for branch from v1.14
- NCC-ZEP report (NCC-ZEP-032)

**CVE-2020-10064**

Improper Input Frame Validation in ieee802154 Processing

- CVE-2020-10064
- Zephyr project bug tracker ZEPSEC-65
- PR24971 fix for v2.4
- PR33451 fix for v1.4

**CVE-2020-10065**

OOB Write after not validating user-supplied length (<= 0xffff) and copying to fixed-size buffer (default: 77 bytes) for HCI_ACL packets in bluetooth HCI over SPI driver.

- CVE-2020-10065
- Zephyr project bug tracker ZEPSEC-66
- This issue has not been fixed.

**CVE-2020-10066**

Incorrect Error Handling in Bluetooth HCI core

In hci_cmd_done, the buf argument being passed as null causes nullpointer dereference.

- CVE-2020-10066
- Zephyr project bug tracker ZEPSEC-67
- PR24902 fix for v2.4
- PR25089 fix for v1.4
 Integer Overflow In is_in_region Allows User Thread To Access Kernel Memory
A malicious userspace application can cause an integer overflow and bypass security checks performed by system call handlers. The impact would depend on the underlying system call and can range from denial of service to information leak to memory corruption resulting in code execution within the kernel.
See NCC-ZEP-005
This has been fixed in releases v1.14.2, and v2.2.0.
  • CVE-2020-10067
  • Zephyr project bug tracker ZEPSEC-27
  • PR23653 fix for v1.14.2
  • PR23654 fix for the v2.1 branch
  • PR23239 fix for v2.2.0

 Zephyr Bluetooth DLE duplicate requests vulnerability
In the Zephyr project Bluetooth subsystem, certain duplicate and back-to-back packets can cause incorrect behavior, resulting in a denial of service.
This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.
  • CVE-2020-10068
  • Zephyr project bug tracker ZEPSEC-78
  • PR23707 fix for v2.3 (split driver)
  • PR23708 fix for v2.3 (legacy driver)
  • PR23091 fix for branch from v1.14.0
  • PR23964 fix for v2.2.0

 Zephyr Bluetooth unchecked packet data results in denial of service
An unchecked parameter in bluetooth data can result in an assertion failure, or division by zero, resulting in a denial of service attack.
This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.
  • CVE-2020-10069
  • Zephyr project bug tracker ZEPSEC-81
  • PR23705 fix for v2.3 (split driver)
  • PR23706 fix for v2.3 (legacy driver)
  • PR23091 fix for branch from v1.14.0
  • PR23963 fix for branch from v2.2.0
CVE-2020-10070

MQTT buffer overflow on receive buffer

In the Zephyr Project MQTT code, improper bounds checking can result in memory corruption and possibly remote code execution. NCC-ZEP-031

When calculating the packet length, arithmetic overflow can result in accepting a receive buffer larger than the available buffer space, resulting in user data being written beyond this buffer.

This has been fixed in main for v2.3.

- CVE-2020-10070
- Zephyr project bug tracker ZEPSEC-85
- commit 0b39cbf3 for v2.3
- NCC-ZEP report (NCC-ZEP-031)

CVE-2020-10071

Insufficient publish message length validation in MQTT

The Zephyr MQTT parsing code performs insufficient checking of the length field on publish messages, allowing a buffer overflow and potentially remote code execution. NCC-ZEP-031

This has been fixed in main for v2.3.

- CVE-2020-10071
- Zephyr project bug tracker ZEPSEC-86
- commit 989c4713 fix for v2.3
- NCC-ZEP report (NCC-ZEP-031)

CVE-2020-10072

All threads can access all socket file descriptors

There is no management of permissions to network socket API file descriptors. Any thread running on the system may read/write a socket file descriptor knowing only the numerical value of the file descriptor.

- CVE-2020-10072
- Zephyr project bug tracker ZEPSEC-87
- PR25804 fix for v2.4
- PR27176 fix for v1.4

CVE-2020-10136

IP-in-IP protocol routes arbitrary traffic by default zephyrproject

- CVE-2020-10136
- Zephyr project bug tracker ZEPSEC-64
CVE-2020-13598

FS: Buffer Overflow when enabling Long File Names in FAT_FS and calling fs_stat
Performing fs_stat on a file with a filename longer than 12 characters long will cause a buffer overflow.

- CVE-2020-13598
- Zephyr project bug tracker ZEPSEC-88
- PR25852 fix for v2.4
- PR28782 fix for v2.3
- PR33577 fix for v1.4

CVE-2020-13599

Security problem with settings and littlefs
When settings is used in combination with littlefs all security related information can be extracted from the device using MCUmgr and this could be used e.g in bt-mesh to get the device key, network key, app keys from the device.

- CVE-2020-13599
- Zephyr project bug tracker ZEPSEC-57
- PR26083 fix for v2.4

CVE-2020-13600

Malformed SPI in response for eswifi can corrupt kernel memory

- CVE-2020-13600
- Zephyr project bug tracker ZEPSEC-91
- PR26712 fix for v2.4

CVE-2020-13601

Possible read out of bounds in dns read

- CVE-2020-13601
- Zephyr project bug tracker ZEPSEC-92
- PR27774 fix for v2.4
- PR30503 fix for v1.4

CVE-2020-13602

Remote Denial of Service in LwM2M do_write_op_tlv
In the Zephyr LwM2M implementation, malformed input can result in an infinite loop, resulting in a denial of service attack.

- CVE-2020-13602
- Zephyr project bug tracker ZEPSEC-56
• PR26571 fix for v2.4
• PR33578 fix for v1.4

CVE-2020-13603

Possible overflow in mempool

• Zephyr offers pre-built ‘malloc’ wrapper function instead.
  • The ‘malloc’ function is wrapper for the ‘sys_mem_pool_alloc’ function
  • sys_mem_pool_alloc allocates ‘size + WB_UP(sizeof(struct sys_mem_pool_block))’ in an unsafe manner.
• Asking for very large size values leads to internal integer wrap-around.
• Integer wrap-around leads to successful allocation of very small memory.
• For example: calling malloc(0xffffffff) leads to successful allocation of 7 bytes.
• That leads to heap overflow.
• CVE-2020-13603
  • Zephyr project bug tracker ZEPSEC-111
  • PR31796 fix for v2.4
  • PR32808 fix for v1.4

10.6.4 CVE-2021

CVE-2021-3319

DOS: Incorrect 802154 Frame Validation for Omitted Source / Dest Addresses
Improper processing of omitted source and destination addresses in ieee802154 frame validation (ieee802154_validate_frame)
This has been fixed in main for v2.5.0

• CVE-2020-3319
  • Zephyr project bug tracker GHSA-94jg-2p6q-5364
  • PR31908 fix for main

CVE-2021-3320

Mismatch between validation and handling of 802154 ACK frames, where ACK frames are considered during validation, but not during actual processing, leading to a type confusion.

• CVE-2020-3320
  • PR31908 fix for main

CVE-2021-3321

Incomplete check of minimum IEEE 802154 fragment size leading to an integer underflow.

• CVE-2020-3321
  • Zephyr project bug tracker ZEPSEC-114
• PR33453 fix for v2.4

**CVE-2021-3323**

Integer Underflow in 6LoWPAN IPHC Header Uncompression
This has been fixed in main for v2.5.0
  • CVE-2020-3323
  • Zephyr project bug tracker GHSA-89j6-qpxf-pfpc
  • PR 31971 fix for main

**CVE-2021-3430**

Assertion reachable with repeated LL_CONNECTION_PARAM_REQ.
This has been fixed in main for v2.6.0
  • CVE-2021-3430
  • Zephyr project bug tracker GHSA-46h3-hjcq-2jjr
  • PR 33272 fix for main
  • PR 33369 fix for 2.5
  • PR 33759 fix for 1.14.2

**CVE-2021-3431**

BT: Assertion failure on repeated LL_FEATURE_REQ
This has been fixed in main for v2.6.0
  • CVE-2021-3431
  • Zephyr project bug tracker GHSA-7548-5m6f-mqv9
  • PR 33340 fix for main
  • PR 33369 fix for 2.5

**CVE-2021-3432**

Invalid interval in CONNECT_IND leads to Division by Zero
This has been fixed in main for v2.6.0
  • CVE-2021-3432
  • Zephyr project bug tracker GHSA-7364-p4wc-8mj4
  • PR 33278 fix for main
  • PR 33369 fix for 2.5
CVE-2021-3433

BT: Invalid channel map in CONNECT_IND results to Deadlock
This has been fixed in main for v2.6.0
- CVE-2021-3433
- Zephyr project bug tracker GHSA-3c2f-w4v6-qxrp
- PR 33278 fix for main
- PR 33369 fix for 2.5

CVE-2021-3434

L2CAP: Stack based buffer overflow in le_ecred_conn_req()
This has been fixed in main for v2.6.0
- CVE-2021-3434
- Zephyr project bug tracker GHSA-8w87-6rfp-cfrm
- PR 33305 fix for main
- PR 33419 fix for 2.5
- PR 33418 fix for 1.14.2

CVE-2021-3435

L2CAP: Information leakage in le_ecred_conn_req()
This has been fixed in main for v2.6.0
- CVE-2021-3435
- Zephyr project bug tracker GHSA-xhg3-gvj6-4rqh
- PR 33305 fix for main
- PR 33419 fix for 2.5
- PR 33418 fix for 1.14.2

CVE-2021-3436

Bluetooth: Possible to overwrite an existing bond during keys distribution phase when the identity address of the bond is known
During the distribution of the identity address information we don't check for an existing bond with the same identity address. This means that a duplicate entry will be created in RAM while the newest entry will overwrite the existing one in persistent storage.
This has been fixed in main for v2.6.0
- CVE-2021-3436
- Zephyr project bug tracker GHSA-j76f-35mc-4h63
- PR 33266 fix for main
- PR 33432 fix for 2.5
- PR 33433 fix for 2.4
• PR 33718 fix for 1.14.2

**CVE-2021-3454**

Truncated L2CAP K-frame causes assertion failure
For example, sending L2CAP K-frame where SDU length field is truncated to only one byte, causes assertion failure in previous releases of Zephyr. This has been fixed in master by commit 0ba9437 but has not yet been backported to older release branches.
This has been fixed in main for v2.6.0
  • CVE-2021-3454
  • Zephyr project bug tracker GHSA-fx88-6c29-vrp3
  • PR 32588 fix for main
  • PR 33513 fix for 2.5
  • PR 33514 fix for 2.4

**CVE-2021-3455**

Disconnecting L2CAP channel right after invalid ATT request leads freeze
When Central device connects to peripheral and creates L2CAP connection for Enhanced ATT, sending some invalid ATT request and disconnecting immediately causes freeze.
This has been fixed in main for v2.6.0
  • CVE-2021-3455
  • Zephyr project bug tracker GHSA-7g38-3x9v-v7vp
  • PR 35597 fix for main
  • PR 36104 fix for 2.5
  • PR 36105 fix for 2.4

**CVE-2021-3510**

Zephyr JSON decoder incorrectly decodes array of array
When using JSON_OBJ_DESCR_ARRAY_ARRAY, the subarray is has the token type JSON_TOK_LIST_START, but then assigns to the object part of the union. arr_parse then takes the offset of the array-object (which has nothing todo with the list) treats it as relative to the parent object, and stores the length of the subarray in there.
This has been fixed in main for v2.7.0
  • CVE-2021-3510
  • Zephyr project bug tracker GHSA-289f-7mw3-2qf4
  • PR 36340 fix for main
  • PR 37816 fix for 2.6
CVE-2021-3581

HCI data not properly checked leads to memory overflow in the Bluetooth stack

In the process of setting SCAN_RSP through the HCI command, the Zephyr Bluetooth protocol stack did not effectively check the length of the incoming HCI data. Causes memory overflow, and then the data in the memory is overwritten, and may even cause arbitrary code execution.

This has been fixed in main for v2.6.0

- CVE-2021-3581

Chapter 11

Safety

These documents describe the processes, developer guidelines and requirements for ensuring safety is addressed within the Zephyr project.

11.1 Zephyr Safety Overview

11.1.1 Introduction

This document is the safety documentation providing an overview over the safety-relevant activities and what the Zephyr Project and the Zephyr Safety Working Group / Committee try to achieve.

This overview is provided for people who are interested in the functional safety development part of the Zephyr RTOS and project members who want to contribute to the safety aspects of the project.

11.1.2 Overview

In this section we give the reader an overview of what the general goal of the safety certification is, what standard we aim to achieve and what quality standards and processes need to be implemented to reach such a safety certification.

11.1.3 Safety Document update

This document is a living document and may evolve over time as new requirements, guidelines, or processes are introduced.

1. Changes will be submitted from the interested party(ies) via pull requests to the Zephyr documentation repository.

2. The Zephyr Safety Committee will review these changes and provide feedback or acceptance of the changes.

3. Once accepted, these changes will become part of the document.
11.1.4 General safety scope

The general scope of the Safety Committee is to achieve a certification for the IEC 61508 standard and the Safety Integrity Level (SIL) 3 / Systematic Capability (SC) 3 for a limited source scope (see certification scope TBD). Since the code base is pre-existing, we use the route 3s/1s approach defined by the IEC 61508 standard.

Route 3s
Assessment of non-compliant development. Which is basically the route 1s with existing sources.

Route 1s
Compliant development. Compliance with the requirements of this standard for the avoidance and control of systematic faults in software.

Summarization IEC 61508 standard

The IEC 61508 standard is a widely recognized international standard for functional safety of electrical, electronic, and programmable electronic safety-related systems. Here's an overview of some of the key safety aspects of the standard:

1. **Hazard and Risk Analysis**: The IEC 61508 standard requires a thorough analysis of potential hazards and risks associated with a system in order to determine the appropriate level of safety measures needed to reduce those risks to acceptable levels.

2. **Safety Integrity Level (SIL)**: The standard introduces the concept of Safety Integrity Level (SIL) to classify the level of risk reduction required for each safety function. The higher the SIL, the greater the level of risk reduction required.

3. **System Design**: The IEC 61508 standard requires a systematic approach to system design that includes the identification of safety requirements, the development of a safety plan, and the use of appropriate safety techniques and measures to ensure that the system meets the required SIL.

4. **Verification and Validation**: The standard requires rigorous testing and evaluation of the safety-related system to ensure that it meets the specified SIL and other safety requirements. This includes verification of the system design, validation of the system's functionality, and ongoing monitoring and maintenance of the system.

5. **Documentation and Traceability**: The IEC 61508 standard requires a comprehensive documentation process to ensure that all aspects of the safety-related system are fully documented and that there is full traceability from the safety requirements to the final system design and implementation.

Overall, the IEC 61508 standard provides a framework for the design, development, and implementation of safety-related systems that aims to reduce the risk of accidents and improve overall safety. By following the standard, organizations can ensure that their safety-related systems are designed and implemented to the highest level of safety integrity.

11.1.5 Quality

Quality is a mandatory expectation for software across the industry. The code base of the project must achieve various software quality goals in order to be considered an auditable code base from a safety perspective and to be usable for certification purposes. But software quality is not an additional requirement caused by functional safety standards. Functional safety considers quality as an existing pre-condition and therefore the “quality managed” status should be pursued for any project regardless of the functional safety goals. The following list describes the quality goals which need to be reached to achieve an auditable code base:

1. Basic software quality standards
a. **Coding Guidelines** (including: static code analysis, coding style, etc.)
b. Requirements and requirements tracing
c. Test coverage

2. Software architecture design principles
   a. Layered architecture model
   b. Encapsulated components
   c. Encapsulated single functionality (if not fitable and manageable in safety)

**Basic software quality standards - Safety view**

In this chapter the Safety Committee describes why they need the above listed quality goals as pre-condition and what needs to be done to achieve an auditable code base from the safety perspective. Generally speaking, it can be said that all of these quality measures regarding safety are used to minimize the error rate during code development.

**Coding Guidelines**  The coding guidelines are the basis to a common understanding and a unified ruleset and development style for industrial software products. For safety the coding guidelines are essential and have another purpose beside the fact of a unified ruleset. It is also necessary to prove that the developers follow a unified development style to prevent systematic errors in the process of developing software and thus to minimize the overall error rate of the complete software system.

Also the IEC 61508 standard sets a pre-condition and recommendation towards the use of coding standards / guidelines to reduce likelihood of errors.

**Requirements and requirements tracing**  Requirements and requirement management are not only important for software development, but also very important in terms of safety. On the one hand, this specifies and describes in detail and on a technical level what the software should do, and on the other hand, it is an important and necessary tool to verify whether the described functionality is implemented as expected. For this purpose, tracing the requirements down to the code level is used. With the requirements management and tracing in hand, it can now be verified whether the functionality has been tested and implemented correctly, thus minimizing the systematic error rate.

Also the IEC 61508 standard highly recommends (which is like a must-have for the certification) requirements and requirements tracing.

**Test coverage**  A high test coverage, in turn, is evidence of safety that the code conforms precisely to what it was developed for and does not execute any unforeseen instructions. If the entire code is tested and has a high (ideally 100%) test coverage, it has the additional advantage of quickly detecting faulty changes and further minimizing the error rate. However, it must be noted that different requirements apply to safety for test coverage, and various metrics must be considered, which are prescribed by the IEC 61508 standard for the SIL 3 / SC3 target. The following must be fulfilled, among other things:

- Structural test coverage (entry points) 100%
- Structural test coverage (statements) 100%
- Structural test coverage (branches) 100%

If the 100% cannot be reached (e.g. statement coverage of defensive code) that part needs to be described and justified in the documentation.
Software architecture design principles

To create and maintain a structured software product it is also necessary to consider individual software architecture designs and implement them in accordance with safety standards because some designs and implementations are not reasonable in safety, so that the overall software and code base can be used as auditable code. However, most of these software architecture designs have already been implemented in the Zephyr project and need to be verified by the Safety Committee / Safety Working Group and the safety architect.

Layered architecture model  The IEC 61508 standard strongly recommends a modular approach to software architecture. This approach has been pursued in the Zephyr project from the beginning with its layered architecture. The idea behind this architecture is to organize modules or components with similar functionality into layers. As a result, each layer can be assigned a specific role in the system. This model has the advantage in safety that interfaces between different components and layers can be shown at a very high level, and thus it can be determined which functionalities are safety-relevant and can be limited. Furthermore, various analyses and documentations can be built on top of this architecture, which are important for certification and the responsible certification body.

Encapsulated components  Encapsulated components are an essential part of the architecture design for safety at this point. The most important aspect is the separation of safety-relevant components from non-safety-relevant components, including their associated interfaces. This ensures that the components have no repercussions on other components.

Encapsulated single functionality (if not reasonable and manageable in safety)  Another requirement for the overall system and software environment is that individual functionalities can be disabled within components. This is because if a function is absolutely unacceptable for safety (e.g. complete dynamic memory management), then these individual functionalities should be able to be turned off. The Zephyr Project already offers such a possibility through the use of Kconfig and its flexible configurability.

11.1.6 Processes and workflow

The diagram describes the rough process defined by the Safety Committee to ensure safety in the development of the Zephyr project. To ensure understanding, a few points need to be highlighted and some details explained regarding the role of the safety architect and the role of the safety committee in the whole process. The diagram only describes the paths that are possible when a change is related to safety.

1. On the main branch, the safety scope of the project should be identified, which typically represents a small subset of the entire code base. This subset should then be made auditable during normal development on “main”, which means that special attention is paid to quality goals (Quality) and safety processes within this scope. The Safety Architect works alongside the Technical Steering Committee (TSC) in this area, monitoring the development process to ensure that the architecture meets the safety requirements.

2. At this point, the safety architect plays an increasingly important role. For PRs/issues that fall within the safety scope, the safety architect should ideally be involved in the discussions and decisions of minor changes in the safety scope to be able to react to safety-relevant changes that are not conformant. If a pull request or issue introduces a significant and influential change or improvement that requires extended discussion or decision-making, the safety architect should bring it to the attention of the Safety Committee or the Technical Steering Committee (TSC) as appropriate, so that they can make a decision on the best course of action.
Fig. 1: Safety process and workflow overview
3. This section describes the certification side. At this point, the code base has to be in an “auditable” state, and ideally no further changes should be necessary or made to the code base. There is still a path from the main branch to this area. This is needed in case a serious bug or important change is found or implemented on the main branch in the safety scope, after the LTS and the auditable branch were created. In this case, the Safety Committee, together with the safety architect, must decide whether this bug fix or change should be integrated into the LTS so that the bug fix or change could also be integrated into the auditable branch. This integration can take three forms: First either as only a code change or second as only an update to the safety documentation or third as both.

4. This describes the necessary safety process required for certification itself. Here, the final analyses, tests, and documents are created and conducted which must be created and conducted during the certification, and which are prescribed by the certifying authority and the standard being certified. If the certification body approves everything at this stage and the safety process is completed, a safety release can be created and published.

5. This transition from the auditable branch to the main branch should only occur in exceptional circumstances, specifically when something has been identified during the certification process that needs to be quickly adapted on the “auditable” branch in order to obtain certification. In order to prevent this issue from arising again during the next certification, there needs to be a path to merge these changes back into the main branch so that they are not lost, and to have them ready for the next certification if necessary.

**Important:** Safety should not block the project and minimize the room to grow in any way.

**Important: TODO:** Find and define ways, guidelines and processes which minimally impact the daily work of the maintainers, reviewers and contributors and also the safety architect itself. But which are also suitable for safety.
Chapter 12

Glossary of Terms

API
(Application Program Interface) A defined set of routines and protocols for building application software.

application
The set of user-supplied files that the Zephyr build system uses to build an application image for a specified board configuration. It can contain application-specific code, kernel configuration settings, and at least one CMakeLists.txt file. The application's kernel configuration settings direct the build system to create a custom kernel that makes efficient use of the board's resources. An application can sometimes be built for more than one type of board configuration (including boards with different CPU architectures), if it does not require any board-specific capabilities.

application image
A binary file that is loaded and executed by the board for which it was built. Each application image contains both the application's code and the Zephyr kernel code needed to support it. They are compiled as a single, fully-linked binary. Once an application image is loaded onto a board, the image takes control of the system, initializes it, and runs as the system's sole application. Both application code and kernel code execute as privileged code within a single shared address space.

board
A target system with a defined set of devices and capabilities, which can load and execute an application image. It may be an actual hardware system or a simulated system running under QEMU. The Zephyr kernel supports a variety of boards.

board configuration
A set of kernel configuration options that specify how the devices present on a board are used by the kernel. The Zephyr build system defines one or more board configurations for each board it supports. The kernel configuration settings that are specified by the build system can be over-ridden by the application, if desired.

device runtime power management
Device Runtime Power Management (PM) refers the capability of devices to save energy independently of the system power state. Devices will keep reference of their usage and will automatically be suspended or resumed. This feature is enabled via the CONFIG_PM_DEVICE_RUNTIME Kconfig option.

idle thread
A system thread that runs when there are no other threads ready to run.

IDT
(Interrupt Descriptor Table) a data structure used by the x86 architecture to implement an interrupt vector table. The IDT is used to determine the correct response to interrupts and exceptions.
ISR
(Interrupt Service Routine) Also known as an interrupt handler, an ISR is a callback function whose execution is triggered by a hardware interrupt (or software interrupt instructions) and is used to handle high-priority conditions that require interrupting the current code executing on the processor.

kernel
The set of Zephyr-supplied files that implement the Zephyr kernel, including its core services, device drivers, network stack, and so on.

power domain
A power domain is a collection of devices for which power is applied and removed collectively in a single action. Power domains are represented by \texttt{device}.

power gating
Power gating reduces power consumption by shutting off areas of an integrated circuit that are not in use.

SoC
System on a chip

system power state
System power states describe the power consumption of the system as a whole. System power states are represented by \texttt{pm.state}.

west
A multi-repo meta-tool developed for the Zephyr project. See \textit{West (Zephyr’s meta-tool)}.

west installation
An obsolete term for a \textit{west workspace} used prior to west 0.7.

west manifest
A YAML file, usually named \texttt{west.yml}, which describes projects, or the Git repositories which make up a \textit{west workspace}, along with additional metadata. See Basics for general information and West Manifests for details.

west manifest repository
The Git repository in a \textit{west workspace} which contains the \textit{west manifest}. Its location is given by the \texttt{manifest.path} configuration option. See Basics.

west workspace
A directory on your system with a .west subdirectory and a \textit{west manifest repository}. You clone the Zephyr source code onto your system by creating a \textit{west workspace} using the \texttt{west init} command. See Basics.

XIP
(eXecute In Place) a method of executing programs directly from long term storage rather than copying it into RAM, saving writable memory for dynamic data and not the static program code.

[th-imboot] Must boot with an immutable bootloader.
[th-authrepl] Application image shall only be replaced with an authorized image.
[th-timely-update] Application updates shall be done in a timely manner.
[th-atomic-update] Application updates shall be atomic.
[th-root-certs] TLS must have a list of trusted root certificates.
[th-root-check] TLS must verify root certificate from server is valid.
[th-secret-storage] There must be a mechanism to securely store client secrets. The least amount of code necessary shall have access to these secrets.
[th-time] System must have moderately accurate notion of the current date/time.
[th-conf] The system must receive, and keep configuration data.
[th-logs] The system must log security-related events, and either store them locally, or send to a service.
[th-all-tls] All communications with the cloud service shall use TLS.
[th-tls-ciphers] TLS shall be configured to allow only generally agreed cipher suites (including forward secrecy).
[th-tls-client-auth] The device shall authenticate itself with the cloud provider using one of the methods described.
[th-entropy] The TLS layer shall use a modern, accepted cryptographic random-bit generator seeded by an entropy source within the SoC.
The device shall have a per-device secret loaded before deployment.
The initial secret shall be securely maintained, and destroyed in any external location as soon as the device is provisioned.
Reprovisioning a device shall be done securely.
Upon decommissioning, the device secret shall be rendered ineffective.
